Abstract

Guide to developing Web services using Apache CXF.
# Table of Contents

## PART I. WRITING WSDL CONTRACTS

### CHAPTER 1. INTRODUCING WSDL CONTRACTS

1.1. STRUCTURE OF A WSDL DOCUMENT
   - Overview
   - The logical part
   - The concrete part

1.2. WSDL ELEMENTS

1.3. DESIGNING A CONTRACT

### CHAPTER 2. DEFINING LOGICAL DATA UNITS

2.1. INTRODUCTION TO LOGICAL DATA UNITS

2.2. MAPPING DATA INTO LOGICAL DATA UNITS
   - Overview
   - Available type systems for defining service data units
   - XML Schema as a type system
   - Considerations for creating your data units

2.3. ADDING DATA UNITS TO A CONTRACT
   - Overview
   - Procedure

2.4. XML SCHEMA SIMPLE TYPES
   - Overview
   - Entering simple types
   - Supported XSD simple types

2.5. DEFINING COMPLEX DATA TYPES
   - 2.5.1. Defining data structures
     - Overview
     - Complex type varieties
     - Defining the parts of a structure
     - Defining attributes
   - 2.5.2. Defining arrays
     - Overview
     - Complex type arrays
     - SOAP arrays
   - 2.5.3. Defining types by extension
   - 2.5.4. Defining types by restriction
     - Overview
     - Specifying the base type
     - Defining the restrictions
     - Example
   - 2.5.5. Defining enumerated types
     - Overview
     - Defining an enumeration in XML Schema
     - Example

2.6. DEFINING ELEMENTS

### CHAPTER 3. DEFINING LOGICAL MESSAGES USED BY A SERVICE

OVERVIEW

MESSAGES AND PARAMETER LISTS

MESSAGE DESIGN FOR INTEGRATING WITH LEGACY SYSTEMS

MESSAGE DESIGN FOR SOAP SERVICES

MESSAGE NAMING
### MESSAGE PARTS
- Example

### CHAPTER 4. DEFINING YOUR LOGICAL INTERFACES
- Overview
- Process
- Port Types
- Operations
- Operation Messages
- Return Values
- Example

### PART II. WEB SERVICES BINDINGS

### CHAPTER 5. UNDERSTANDING BINDINGS IN WSDL
- Overview
- Port Types and Bindings
- The WSDL Elements
- Adding to a Contract
- Supported Bindings

### CHAPTER 6. USING SOAP 1.1 MESSAGES
- 6.1. Adding a SOAP 1.1 Binding
  - Using wsdl2soap
  - Example
- 6.2. Adding SOAP Headers to a SOAP 1.1 Binding
  - Overview
  - Syntax
  - Splitting messages between body and header
  - Example

### CHAPTER 7. USING SOAP 1.2 MESSAGES
- 7.1. Adding a SOAP 1.2 Binding to a WSDL Document
  - Using wsdl2soap
  - Example
- 7.2. Adding Headers to a SOAP 1.2 Message
  - Overview
  - Syntax
  - Splitting messages between body and header
  - Example

### CHAPTER 8. SENDING BINARY DATA USING SOAP WITH ATTACHMENTS
- Overview
- Namespace
- Changing the Message Binding
- Describing a MIME Multipart Message
- Example

### CHAPTER 9. SENDING BINARY DATA WITH SOAP MTOM
- 9.1. Overview of MTOM
- 9.2. Annotating Data Types to Use MTOM
  - Overview
  - WSDL first
  - Java first
- 9.3. Enabling MTOM
9.3.1. Using JAX-WS APIs
- Overview
- Service provider
- Consumer
9.3.2. Using configuration
- Overview
- Procedure
- Example

CHAPTER 10. USING XML DOCUMENTS
- XML BINDING NAMESPACE
- HAND EDITING
- XML MESSAGES ON THE WIRE
- OVER RIDING THE BINDING’S ROOTNODE ATTRIBUTE SETTING

PART III. WEB SERVICES TRANSPORTS

CHAPTER 11. UNDERSTANDING HOW ENDPOINTS ARE DEFINED IN WSDL
- OVERVIEW
- ENDPOINTS AND SERVICES
- THE WSDL ELEMENTS
- ADDING ENDPOINTS TO A CONTRACT
- SUPPORTED TRANSPORTS

CHAPTER 12. USING HTTP
- 12.1. ADDING A BASIC HTTP ENDPOINT
  - Alternative HTTP runtimes
  - Netty HTTP URL
  - Payload types
  - SOAP 1.1
  - SOAP 1.2
  - Other messages types
- 12.2. CONFIGURING A CONSUMER
  - 12.2.1. Mechanisms for HTTP Consumer Endpoints
  - 12.2.2. Using Configuration
    - Namespace
    - Undertow runtime or Netty runtime
    - The conduit element
    - The client element
    - Example
    - More information
  - 12.2.3. Using WSDL
    - Namespace
    - Undertow runtime or Netty runtime
    - The client element
    - Example
  - 12.2.4. Consumer Cache Control Directives
- 12.3. CONFIGURING A SERVICE PROVIDER
  - 12.3.1. Mechanisms for a HTTP Service Provider
  - 12.3.2. Using Configuration
    - Namespace
    - Undertow runtime or Netty runtime
    - The destination element
    - The server element

Table of Contents
14.1. APPROACHES TO CONFIGURING JMS
14.2. USING THE JMS CONFIGURATION BEAN
Overview
Configuration namespace
Specifying the configuration
Applying the configuration to an endpoint
Applying the configuration to the transport
14.3. OPTIMIZING CLIENT-SIDE JMS PERFORMANCE
Overview
Pooling
Avoiding synchronous receives
14.4. CONFIGURING JMS TRANSACTIONS
Overview
Local transactions
JTA transactions
14.5. USING WSDL TO CONFIGURE JMS
14.5.1. JMS WSDL Extension Namespace
14.5.2. Basic JMS configuration
Overview
Specifying the JMS address
Specifying JNDI properties
Example
14.5.3. JMS client configuration
Overview
Specifying the message type
Example
14.5.4. JMS provider configuration
Overview
Specifying the configuration
Example
14.6. USING A NAMED REPLY DESTINATION
Overview
Setting the reply destination name
Example

CHAPTER 15. INTEGRATING WITH APACHE ACTIVEMQ
................................................................. 143
OVERVIEW
THE INITIAL CONTEXT FACTORY
LOOKING UP THE CONNECTION FACTORY
SYNTAX FOR DYNAMIC DESTINATIONS

CHAPTER 16. CONDUITS
................................................................. 145
OVERVIEW
CONDUIT LIFE-CYCLE
CONDUIT WEIGHT

PART IV. CONFIGURING WEB SERVICE ENDPOINTS
................................................................. 146
CHAPTER 17. CONFIGURING JAX-WS ENDPOINTS
................................................................. 147
17.1. CONFIGURING SERVICE PROVIDERS
17.1.1. Elements for Configuring Service Providers
17.1.2. Using the jaxws:endpoint Element
Overview
Identifying the endpoint being configured
How to attach a model schema to an endpoint
Configuration of model schema referencing a class
Configuration of model schema referencing an interface
Model Schema Reference

CHAPTER 19. APACHE CXF LOGGING ................................................................. 183
19.1. OVERVIEW OF APACHE CXF LOGGING ................................................. 183
  Overview ................................................................................................. 183
  Default properties file ........................................................................... 183
  Logging feature ....................................................................................... 183
  Where to begin? ...................................................................................... 183
  More information on java.util.logging ................................................... 183
19.2. SIMPLE EXAMPLE OF USING LOGGING ............................................... 184
  Changing the log levels and output destination ....................................... 184
19.3. DEFAULT LOGGING CONFIGURATION FILE .......................................... 185
  19.3.1. Overview of Logging Configuration .............................................. 185
  19.3.2. Configuring Logging Output .......................................................... 185
    Overview ............................................................................................... 185
    Configuring the console handler .......................................................... 186
    Configuring the file handler .................................................................. 186
    Configuring both the console handler and the file handler ................... 187
  19.3.3. Configuring Logging Levels ............................................................ 187
    Logging levels ....................................................................................... 187
    Configuring the global logging level ....................................................... 188
    Configuring logging at an individual package ....................................... 188
19.4. ENABLING LOGGING AT THE COMMAND LINE ................................. 188
  Overview ................................................................................................. 188
  Specifying the log configuration file on application ................................ 188
19.5. LOGGING FOR SUBSYSTEMS AND SERVICES ...................................... 188
  Overview ................................................................................................. 188
  Apache CXF logging subsystems ............................................................ 189
  Example .................................................................................................. 190
19.6. LOGGING MESSAGE CONTENT ............................................................. 190
  Overview ................................................................................................. 190
  Configuring message content logging ..................................................... 190
  Adding the logging feature to an endpoint .............................................. 191
  Adding the logging feature to a consumer .............................................. 191
  Set logging to log INFO level messages ................................................ 191
  Logging SOAP messages ....................................................................... 191

CHAPTER 20. DEPLOYING WS-ADDRESSING ................................................. 194
20.1. INTRODUCTION TO WS-ADDRESSING ............................................... 194
  Overview ................................................................................................. 194
  Supported specifications .......................................................................... 194
  Further information ................................................................................ 194
20.2. WS-ADDRESSING INTERCEPTORS ....................................................... 194
  Overview ................................................................................................. 194
  WS-Addressing Interceptors .................................................................. 194
20.3. ENABLING WS-ADDRESSING ............................................................... 195
  Overview ................................................................................................. 195
  Adding WS-Addressing as a Feature ....................................................... 195
20.4. CONFIGURING WS-ADDRESSING ATTRIBUTES .................................. 196
  Overview ................................................................................................. 196

Table of Contents
CHAPTER 21. ENABLING RELIABLE MESSAGING

21.1. INTRODUCTION TO WS-RM

Overview
How WS-RM works
WS-RM delivery assurances
Supported specifications
Selecting the WS-RM version

21.2. WS-RM INTERCEPTORS

Overview
Apache CXF WS-RM Interceptors
Enabling WS-RM
Configuring WS-RM Attributes

21.3. ENABLING WS-RM

Overview
Spring beans: explicitly adding interceptors
WS-Policy framework: implicitly adding interceptors

21.4. RUNTIME CONTROL

Overview
Runtime control options
Controlling WS-RM through JMX
Example of JMX control

21.5. CONFIGURING WS-RM

21.5.1. Configuring Apache CXF-Specific WS-RM Attributes

Overview
Children of the rmManager Spring bean
Example

21.5.2. Configuring Standard WS-RM Policy Attributes

Overview
WS-Policy RMAssertion Children
More detailed reference information
RMAssertion in rmManager Spring bean
Policy within a feature
WSDL file
External attachment

21.5.3. WS-RM Configuration Use Cases

Overview
Base retransmission interval
Exponential backoff for retransmission
Acknowledgement interval
Maximum unacknowledged messages threshold
Maximum length of an RM sequence
Message delivery assurance policies

21.6. CONFIGURING WS-RM PERSISTENCE

Overview
How it works
Enabling WS-persistence
Configuring WS-persistence

CHAPTER 22. ENABLING HIGH AVAILABILITY

22.1. INTRODUCTION TO HIGH AVAILABILITY
Overview
HA with static failover

22.2. ENABLING HA WITH STATIC FAILOVER
Overview
Encode replica details in your service WSDL file
Add the clustering feature to your client configuration

22.3. CONFIGURING HA WITH STATIC FAILOVER
Overview
Configuring a random strategy

CHAPTER 23. APACHE CXF BINDING IDS

APPENDIX A. USING THE MAVEN OSGI TOOLING

PART V. DEVELOPING APPLICATIONS USING JAX-WS
Document bare style parameters
Document wrapped parameters
Example
Overview
The @WebMethod annotation
The @RequestWrapper annotation
The @ResponseWrapper annotation
The @WebFault annotation
The @Oneway annotation
Example
Overview
The @WebParam annotation
The @WebResult annotation
Example
24.3.4. Apache CXF Annotations
24.3.4.1. WSDL Documentation
@WSDLDocumentation annotation
24.3.4.2. @WSDLDocumentation properties
@WSDLDocumentationCollection annotation
Placement in the WSDL contract
Example of @WSDLDocumentation
24.3.4.3. Using @WSDLDocumentation
24.3.4.4. WSDL generated with documentation
Example of @WSDLDocumentationCollection
24.3.4.5. Using @WSDLDocumentationCollection
24.3.4.6. Schema Validation of Messages
@SchemaValidation annotation
Schema validation type
24.3.4.7. Schema Validation Type Values
Example
24.3.4.8. Specifying the Data Binding
@DataBinding annotation
Supported data bindings
Example
24.3.4.9. Setting the data binding
24.3.4.10. Compressing Messages
@GZIP annotation
24.3.4.11. @GZIP Properties
@FastInfoset
24.3.4.12. @FastInfoset Properties
Example of @GZIP
24.3.4.13. Enabling GZIP
Example of @FastInfoset
24.3.4.14. Enabling FastInfoset
24.3.4.15. Enable Logging on an Endpoint
@Logging annotation
24.3.4.16. @Logging Properties
Example
24.3.4.17. Logging configuration using annotations
24.3.4.18. Adding Properties and Policies to an Endpoint
24.3.4.19. Adding properties
@EndpointProperty annotation
24.3.4.20. Configuring WS-Security Using @EndpointProperty Annotations
CHAPTER 29. FINDING WSDL AT RUNTIME .................................................. 275
  29.1. MECHANISMS FOR LOCATING THE WSDL DOCUMENT .................. 275
  29.2. INSTANTIATING A PROXY BY INJECTION ........................................ 275
    Overview ......................................................................................... 275
    Procedure ...................................................................................... 275
    Configuring the proxy ................................................................. 276
    Coding the provider implementation ........................................... 277
  29.3. USING A JAX-WS CATALOG .......................................................... 277
    Overview ......................................................................................... 277
    Writing the catalog ......................................................................... 277
    Packaging the catalog ................................................................. 278
  29.4. USING A CONTRACT RESOLVER .................................................... 278
    Overview ......................................................................................... 278
    Implementing the contract resolver .............................................. 278
    Registering the contract resolver programatically ....................... 279
    Registering a contract resolver using configuration ..................... 279
    Contract resolution order ............................................................ 281

CHAPTER 30. GENERIC FAULT HANDLING ............................................... 282
  30.1. RUNTIME FAULTS .......................................................................... 282
    Overview ......................................................................................... 282
    APIs that throw WebServiceException ......................................... 282
  30.2. PROTOCOL FAULTS ....................................................................... 283
    Overview ......................................................................................... 283
    Types of protocol exceptions ..................................................... 283
    Using the SOAP protocol exception ............................................ 283

CHAPTER 31. PUBLISHING A SERVICE .................................................... 285
  31.1. WHEN TO PUBLISH A SERVICE ................................................... 285
  31.2. APIS USED TO PUBLISH A SERVICE .......................................... 285
    Overview ......................................................................................... 285
    Instantiating an service provider ............................................... 285
    Publishing a service provider ..................................................... 286
    Stopping a published service provider ....................................... 286
  31.3. PUBLISHING A SERVICE IN A PLAIN JAVA APPLICATION ............ 286
    Overview ......................................................................................... 286
    Generating a Server Mainline ...................................................... 287
    Writing a Server Mainline ............................................................ 287
  31.4. PUBLISHING A SERVICE IN AN OSGI CONTAINER ....................... 289
    Overview ......................................................................................... 289
    The bundle activator interface .................................................... 289
    Implementing the start method .................................................... 289
    Implementing the stop method ..................................................... 290
    Informing the container .............................................................. 291

CHAPTER 32. BASIC DATA BINDING CONCEPTS ...................................... 292
  32.1. INCLUDING AND IMPORTING SCHEMA DEFINITIONS .................... 292
    Overview ......................................................................................... 292
    xsd:include syntax ...................................................................... 292

Marshalling
Unmarshalling
36.2. USING THE XML SCHEMA ANYTYPE TYPE
   Overview
   Using in XML Schema
   Mapping to Java
   Marshalling
   Unmarshalling
36.3. USING UNBOUND ATTRIBUTES
   Overview
   Defining in XML Schema
   Mapping to Java
   Working with undeclared attributes

CHAPTER 37. ELEMENT SUBSTITUTION ......................................................... 349
37.1. SUBSTITUTION GROUPS IN XML SCHEMA
   Overview
   Syntax
   Type restrictions
   Abstract head elements
37.2. SUBSTITUTION GROUPS IN JAVA
   Overview
   Generated object factory methods
   Substitution groups in interfaces
   Substitution groups in complex types
   Setting a substitution group property
   Getting the value of a substitution group property
37.3. WIDGET VENDOR EXAMPLE
   37.3.1. Widget Ordering Interface
   37.3.2. The checkWidgets Operation
      Overview
      Consumer implementation
      Service implementation
   37.3.3. The placeWidgetOrder Operation
      Overview
      Consumer implementation
      Service implementation

CHAPTER 38. CUSTOMIZING HOW TYPES ARE GENERATED ............................. 364
38.1. BASICS OF CUSTOMIZING TYPE MAPPINGS
   Overview
   Namespace
   Version declaration
   Using in-line customization
   Using an external binding declaration
38.2. SPECIFYING THE JAVA CLASS OF AN XML SCHEMA PRIMITIVE
   Overview
   Syntax
   Specifying the converters
   What is generated
   Implementing converters
   Default primitive type converters
38.3. GENERATING JAVA CLASSES FOR SIMPLE TYPES
Overview
Adding the customization
Generated classes
38.4. CUSTOMIZING ENUMERATION MAPPING
Overview
Member name customizer
Class customizer
Member customizer
Examples
38.5. CUSTOMIZING FIXED VALUE ATTRIBUTE MAPPING
Overview
Global customization
Local mapping
Java mapping
38.6. SPECIFYING THE BASE TYPE OF AN ELEMENT OR AN ATTRIBUTE
Overview
Customization usage
Specializing or generalizing the default mapping
Usage with javaType

CHAPTER 39. USING A JAXBCONTEXT OBJECT
OVERVIEW
BEST PRACTICES
GETTING A JAXBCONTEXT OBJECT USING AN OBJECT FACTORY
GETTING A JAXBCONTEXT OBJECT USING PACKAGE NAMES

CHAPTER 40. DEVELOPING ASYNCHRONOUS APPLICATIONS
40.1. TYPES OF ASYNCHRONOUS INVOCATION
40.2. WSDL FOR ASYNCHRONOUS EXAMPLES
40.3. GENERATING THE STUB CODE
Overview
Using an external binding declaration
Using an embedded binding declaration
Generated interface
40.4. IMPLEMENTING AN ASYNCHRONOUS CLIENT WITH THE POLLING APPROACH
Overview
Using the non-blocking pattern
Using the blocking pattern
40.5. IMPLEMENTING AN ASYNCHRONOUS CLIENT WITH THE CALLBACK APPROACH
Overview
Implementing the callback
Implementing the consumer
40.6. CATCHING EXCEPTIONS RETURNED FROM A REMOTE SERVICE
Overview
Catching the exception
Getting the exception details
Example

CHAPTER 41. USING RAW XML MESSAGES
41.1. USING XML IN A CONSUMER
41.1.1. Usage Modes
Overview
Message mode
Payload mode
41.1.2. Data Types
   Overview
   Using Source objects
   Using SOAPMessage objects
   Using DataSource objects
   Using JAXB objects
41.1.3. Working with Dispatch Objects
   Procedure
   Creating a Dispatch object
   Constructing request messages
   Synchronous invocation
   Asynchronous invocation
   Oneway invocation
41.2. USING XML IN A SERVICE PROVIDER
41.2.1. Messaging Modes
   Overview
   Message mode
   Payload mode
41.2.2. Data Types
   Overview
   Using Source objects
   Using SOAPMessage objects
   Using DataSource objects
41.2.3. Implementing a Provider Object
   Overview
   Working with messages
   The @WebServiceProvider annotation
   Implementing the invoke() method
   Examples

CHAPTER 42. WORKING WITH CONTEXTS ................................................................. 411
42.1. UNDERSTANDING CONTEXTS
   Overview
   How properties are stored in a context
   Property scopes
   Overview of contexts in handlers
   Overview of contexts in service implementations
   Overview of contexts in consumer implementations
42.2. WORKING WITH CONTEXTS IN A SERVICE IMPLEMENTATION
   Overview
   Obtaining a context
   Reading a property from a context
   Setting properties in a context
   Supported contexts
42.3. WORKING WITH CONTEXTS IN A CONSUMER IMPLEMENTATION
   Overview
   Obtaining a context
   Reading a property from a context
   Setting properties in a context
   Supported contexts
42.4. WORKING WITH JMS MESSAGE PROPERTIES
   Overview
   Getting the JMS Message Headers in a Service
Getting JMS Message Header Properties in a Consumer

42.4.2. Inspecting the Message Header Properties

Standard JMS Header Properties
Optional Header Properties
Example

42.4.3. Setting JMS Properties

JMS Header Properties
Optional JMS Header Properties
Client Receive Timeout
Example

CHAPTER 43. WRITING HANDLERS

43.1. HANDLERS: AN INTRODUCTION

Overview
Handler types
Implementation of handlers
Adding handlers to an application

43.2. IMPLEMENTING A LOGICAL HANDLER

Overview
Procedure

43.3. HANDLING MESSAGES IN A LOGICAL HANDLER

Overview
Getting the message data
Working with the message body as an XML object
Working with the message body as a JAXB object
Working with context properties
Determining the direction of the message
Determining the return value
Example

43.4. IMPLEMENTING A PROTOCOL HANDLER

Overview
Procedure
Implementing the getHeaders() method

43.5. HANDLING MESSAGES IN A SOAP HANDLER

Overview
Working with the message body
Getting the SOAP headers
Working with context properties
Determining the direction of the message
Determining the return value
Example

43.6. INITIALIZING A HANDLER

Overview
Order of initialization

43.7. HANDLING FAULT MESSAGES

Overview
Getting the message payload
Determining the return value
Example

43.8. CLOSING A HANDLER

43.9. RELEASING A HANDLER

Overview
Order of release
### CHAPTER 43. CONFIGURING ENDPOINTS TO USE HANDLERS

43.10. CONFIGURING ENDPOINTS TO USE HANDLERS

43.10.1. Programmatic Configuration

43.10.1.1. Adding a Handler Chain to a Consumer

- **Overview**
- **Procedure**
- **Example**

43.10.1.2. Adding a Handler Chain to a Service Provider

- **Overview**
- **Procedure**
  - The @HandlerChain annotation
  - Handler configuration file

43.10.2. Spring Configuration

- **Overview**
- **Procedure**
- **The handlers element**
- **Example**

### CHAPTER 44. MAVEN TOOLING REFERENCE

44.1. PLUG-IN SETUP

- **Dependencies**

44.2. CXF-CODEGEN-PLUGIN

- **Overview**
- **Basic example**
- **Basic configuration settings**
- **Description**
- **WSDL options**
- **Default options**
- **Specifying code generation options**
- **Specifying binding files**
- **Generating code for a specific WSDL service**
- **Generating code for multiple WSDL files**
- **Downloading WSDL from a Maven repository**
- **Encoding**
- **Forking a separate process**
- **Options reference**

44.3. JAVA2WS

- **Synopsis**
- **Description**
- **Required configuration**
- **Optional configuration**

### PART VI. DEVELOPING RESTFUL WEB SERVICES

### CHAPTER 45. INTRODUCTION TO RESTFUL WEB SERVICES

- **OVERVIEW**
- **BASIC REST PRINCIPLES**
- **RESOURCES**
- **REST BEST PRACTICES**
- **DESIGNING A RESTFUL WEB SERVICE**
- **IMPLEMENTING REST WITH APACHE CXF**
- **DATA BINDINGS**

### CHAPTER 46. CREATING RESOURCES

- **INTRODUCTION**
Dealing with lists and sets

Example

47.2.6. Injecting Parameters into a Java Bean

Overview

Injection target

Example without BeanParam annotation

Example with BeanParam annotation

47.3. PARAMETER CONVERTERS

Overview

Automatic conversions

Parameter converters

Factory pattern

ParamConverter interface

ParamConverterProvider interface

Binding the parameter converter provider

Example

Using the parameter converter

Lazy conversion of default value

47.4. USING APACHE CXF EXTENSIONS

Overview

Supported injection annotations

Syntax

Example

CHAPTER 48. RETURNING INFORMATION TO THE CONSUMER

48.1. RETURN TYPES

48.2. RETURNING PLAIN JAVA CONSTRUCTS

Overview

Returnable types

MIME types

Response codes

48.3. FINE TUNING AN APPLICATION’S RESPONSES

48.3.1. Basics of building responses

Overview

Relationship between a response and a response builder

Getting a response builder

More information

48.3.2. Creating responses for common use cases

Overview

Creating responses for successful requests

Creating responses for redirection

Creating responses to signal errors

48.3.3. Handling more advanced responses

Overview

Adding custom headers

Adding a cookie

Setting the response status

Setting cache control directives

48.4. RETURNING ENTITIES WITH GENERIC TYPE INFORMATION

Overview

Using a GenericEntity<T> object

Creating a GenericEntity<T> object
48.5. ASYNCHRONOUS RESPONSE

48.5.1. Asynchronous Processing on the Server

Overview
- Basic model for asynchronous processing
- Thread pool implementation with Java executor
- Defining an asynchronous resource method
- AsyncResponse class
- Encapsulating a suspended request as a Runnable
- Example of asynchronous processing

48.5.2. Timeouts and Timeout Handlers

Overview
- Example of setting a timeout without a handler
- Default timeout behaviour
- TimeoutHandler interface
- Example of setting a timeout with a handler
- Using a timeout handler to cancel the response
- Dealing with a cancelled response in the Runnable instance

48.5.3. Handling Dropped Connections

Overview
- ConnectionCallback interface
- Registering a connection callback
- Typical scenario for connection callback

48.5.4. Registering Callbacks

Overview
- CompletionCallback interface
- Registering a completion callback

CHAPTER 49. JAX-RS 2.0 CLIENT API

49.1. INTRODUCTION TO THE JAX-RS 2.0 CLIENT API

Overview
- Dependencies
- Client API package
- Example of a simple client request
- Fluent API
- Steps to make a REST invocation
- Bootstrap the client
- Configure the target
- Build and make the invocation
- Parse the response

49.2. BUILDING THE CLIENT TARGET

Overview
- WebTarget builder class
- Create the client target
- Base path and path segments
- URI template parameters
- Define query parameters
- Define matrix parameters

49.3. BUILDING THE CLIENT INVOCATION

Overview
- Invocation.Builder class
- Create the invocation builder
- Define HTTP headers
- Define cookies
Define properties
Define accepted media types, languages, or encodings
Invoke HTTP method
Typed responses
Specifying the outgoing message in post or put
Delayed invocation
Asynchronous invocation

49.4. PARSING REQUESTS AND RESPONSES
Overview
Entities
Variants
Entity providers
Standard entity providers
Response object
Accessing the response status
Accessing the returned headers
Accessing the returned cookies
Accessing the returned message content
Collection return value

49.5. CONFIGURING THE CLIENT ENDPOINT
Overview
Example
Configurable API for registering objects
What can you configure on the client?
Features
Providers
Filters
Interceptors
Properties
Other configurable types

49.6. ASYNCHRONOUS PROCESSING ON THE CLIENT
Overview
Asynchronous invocation with Future<V> return value
Asynchronous invocation with invocation callback

CHAPTER 50. HANDLING EXCEPTIONS

50.1. OVERVIEW OF JAX-RS EXCEPTION CLASSES
Overview
JAX-RS runtime level exceptions
JAX-RS application level exceptions

50.2. USING WEBAPPLICATIONEXCEPTION EXCEPTIONS TO REPORT
Overview
Creating a simple exception
Setting the status code returned to the client
Providing an entity body
Extending the generic exception

50.3. JAX-RS 2.0 EXCEPTION TYPES
Overview
Exception hierarchy
WebApplicationException class
ClientErrorException class
ServerErrorException class
RedirectionException class

PART I. WRITING WSDL CONTRACTS
This part describes how to define a Web service interface using WSDL.
CHAPTER 1. INTRODUCING WSDL CONTRACTS

Abstract

WSDL documents define services using Web Service Description Language and a number of possible extensions. The documents have a logical part and a concrete part. The abstract part of the contract defines the service in terms of implementation neutral data types and messages. The concrete part of the document defines how an endpoint implementing a service will interact with the outside world.

The recommended approach to design services is to define your services in WSDL and XML Schema before writing any code. When hand-editing WSDL documents you must make sure that the document is valid, as well as correct. To do this you must have some familiarity with WSDL. You can find the standard on the W3C web site, www.w3.org.

1.1. STRUCTURE OF A WSDL DOCUMENT

Overview

A WSDL document is, at its simplest, a collection of elements contained within a root definition element. These elements describe a service and how an endpoint implementing that service is accessed.

A WSDL document has two distinct parts:

- A logical part that defines the service in implementation neutral terms
- A concrete part that defines how an endpoint implementing the service is exposed on a network

The logical part

The logical part of a WSDL document contains the types, the message, and the portType elements. It describes the service’s interface and the messages exchanged by the service. Within the types element, XML Schema is used to define the structure of the data that makes up the messages. A number of message elements are used to define the structure of the messages used by the service. The portType element contains one or more operation elements that define the messages sent by the operations exposed by the service.

The concrete part

The concrete part of a WSDL document contains the binding and the service elements. It describes how an endpoint that implements the service connects to the outside world. The binding elements describe how the data units described by the message elements are mapped into a concrete, on-the-wire data format, such as SOAP. The service elements contain one or more port elements which define the endpoints implementing the service.

1.2. WSDL ELEMENTS

A WSDL document is made up of the following elements:

- definitions – The root element of a WSDL document. The attributes of this element specify the name of the WSDL document, the document’s target namespace, and the shorthand definitions for the namespaces referenced in the WSDL document.
- **types** – The XML Schema definitions for the data units that form the building blocks of the messages used by a service. For information about defining data types see Chapter 2, *Defining Logical Data Units*.

- **message** – The description of the messages exchanged during invocation of a services operations. These elements define the arguments of the operations making up your service. For information on defining messages see Chapter 3, *Defining Logical Messages Used by a Service*.

- **portType** – A collection of operation elements describing the logical interface of a service. For information about defining port types see Chapter 4, *Defining Your Logical Interfaces*.

- **operation** – The description of an action performed by a service. Operations are defined by the messages passed between two endpoints when the operation is invoked. For information on defining operations see the section called “Operations”.

- **binding** – The concrete data format specification for an endpoint. A binding element defines how the abstract messages are mapped into the concrete data format used by an endpoint. This element is where specifics such as parameter order and return values are specified.

- **service** – A collection of related port elements. These elements are repositories for organizing endpoint definitions.

- **port** – The endpoint defined by a binding and a physical address. These elements bring all of the abstract definitions together, combined with the definition of transport details, and they define the physical endpoint on which a service is exposed.

### 1.3. DESIGNING A CONTRACT

To design a WSDL contract for your services you must perform the following steps:

1. Define the data types used by your services.
2. Define the messages used by your services.
3. Define the interfaces for your services.
4. Define the bindings between the messages used by each interface and the concrete representation of the data on the wire.
5. Define the transport details for each of the services.
CHAPTER 2. DEFINING LOGICAL DATA UNITS

Abstract

When describing a service in a WSDL contract complex data types are defined as logical units using XML Schema.

2.1. INTRODUCTION TO LOGICAL DATA UNITS

When defining a service, the first thing you must consider is how the data used as parameters for the exposed operations is going to be represented. Unlike applications that are written in a programming language that uses fixed data structures, services must define their data in logical units that can be consumed by any number of applications. This involves two steps:

1. Breaking the data into logical units that can be mapped into the data types used by the physical implementations of the service
2. Combining the logical units into messages that are passed between endpoints to carry out the operations

This chapter discusses the first step. Chapter 3, Defining Logical Messages Used by a Service discusses the second step.

2.2. MAPPING DATA INTO LOGICAL DATA UNITS

Overview

The interfaces used to implement a service define the data representing operation parameters as XML documents. If you are defining an interface for a service that is already implemented, you must translate the data types of the implemented operations into discreet XML elements that can be assembled into messages. If you are starting from scratch, you must determine the building blocks from which your messages are built, so that they make sense from an implementation standpoint.

Available type systems for defining service data units

According to the WSDL specification, you can use any type system you choose to define data types in a WSDL contract. However, the W3C specification states that XML Schema is the preferred canonical type system for a WSDL document. Therefore, XML Schema is the intrinsic type system in Apache CXF.

XML Schema as a type system

XML Schema is used to define how an XML document is structured. This is done by defining the elements that make up the document. These elements can use native XML Schema types, like \texttt{xsd:int}, or they can use types that are defined by the user. User defined types are either built up using combinations of XML elements or they are defined by restricting existing types. By combining type definitions and element definitions you can create intricate XML documents that can contain complex data.

When used in WSDL XML Schema defines the structure of the XML document that holds the data used to interact with a service. When defining the data units used by your service, you can define them as types that specify the structure of the message parts. You can also define your data units as elements that make up the message parts.
Considerations for creating your data units

You might consider simply creating logical data units that map directly to the types you envision using when implementing the service. While this approach works, and closely follows the model of building RPC-style applications, it is not necessarily ideal for building a piece of a service-oriented architecture.

The Web Services Interoperability Organization’s WS-I basic profile provides a number of guidelines for defining data units and can be accessed at http://www.ws-i.org/Profiles/BasicProfile-1.1-2004-08-24.html#WSDLTYPES. In addition, the W3C also provides the following guidelines for using XML Schema to represent data types in WSDL documents:

- Use elements, not attributes.
- Do not use protocol-specific types as base types.

2.3. ADDING DATA UNITS TO A CONTRACT

Overview

Depending on how you choose to create your WSDL contract, creating new data definitions requires varying amounts of knowledge. The Apache CXF GUI tools provide a number of aids for describing data types using XML Schema. Other XML editors offer different levels of assistance. Regardless of the editor you choose, it is a good idea to have some knowledge about what the resulting contract should look like.

Procedure

Defining the data used in a WSDL contract involves the following steps:

1. Determine all the data units used in the interface described by the contract.
2. Create a **types** element in your contract.
3. Create a **schema** element, shown in Example 2.1, “Schema entry for a WSDL contract”, as a child of the **type** element.
   The **targetNamespace** attribute specifies the namespace under which new data types are defined. Best practice is to also define the namespace that provides access to the target namespace. The remaining entries should not be changed.

   **Example 2.1. Schema entry for a WSDL contract**

   ```xml
   <schema targetNamespace="http://schemas.iona.com/bank.idl"
           xmlns="http://www.w3.org/2001/XMLSchema"
           xmlns:xsd1="http://schemas.iona.com/bank.idl"
           xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/">
   ...
   </schema>
   ```

4. For each complex type that is a collection of elements, define the data type using a **complexType** element. See Section 2.5.1, “Defining data structures”.
5. For each array, define the data type using a **complexType** element. See Section 2.5.2, “Defining arrays”.

6. For each complex type that is derived from a simple type, define the data type using a `simpleType` element. See Section 2.5.4, “Defining types by restriction”.

7. For each enumerated type, define the data type using a `simpleType` element. See Section 2.5.5, “Defining enumerated types”.

8. For each element, define it using an `element` element. See Section 2.6, “Defining elements”.

2.4. XML SCHEMA SIMPLE TYPES

Overview

If a message part is going to be of a simple type it is not necessary to create a type definition for it. However, the complex types used by the interfaces defined in the contract are defined using simple types.

Entering simple types

XML Schema simple types are mainly placed in the `element` elements used in the types section of your contract. They are also used in the `base` attribute of `restriction` elements and `extension` elements.

Simple types are always entered using the `xsd` prefix. For example, to specify that an element is of type `int`, you would enter `xsd:int` in its `type` attribute as shown in Example 2.2, “Defining an element with a simple type”.

Example 2.2. Defining an element with a simple type

```
<element name="simpleInt" type="xsd:int" />
```

Supported XSD simple types

Apache CXF supports the following XML Schema simple types:

- `xsd:string`
- `xsd:normalizedString`
- `xsd:int`
- `xsd:unsignedInt`
- `xsd:long`
- `xsd:unsignedLong`
- `xsd:short`
- `xsd:unsignedShort`
- `xsd:float`
- `xsd:double`
2.5. DEFINING COMPLEX DATA TYPES
Abstract

XML Schema provides a flexible and powerful mechanism for building complex data structures from its simple data types. You can create data structures by creating a sequence of elements and attributes. You can also extend your defined types to create even more complex types.

In addition to building complex data structures, you can also describe specialized types such as enumerated types, data types that have a specific range of values, or data types that need to follow certain patterns by either extending or restricting the primitive types.

2.5.1. Defining data structures

Overview

In XML Schema, data units that are a collection of data fields are defined using `<complexType>` elements. Specifying a complex type requires three pieces of information:

1. The name of the defined type is specified in the `name` attribute of the `<complexType>` element.
2. The first child element of the `<complexType>` describes the behavior of the structure's fields when it is put on the wire. See the section called “Complex type varieties”.
3. Each of the fields of the defined structure are defined in `<element>` elements that are grandchildren of the `<complexType>` element. See the section called “Defining the parts of a structure”.

For example, the structure shown in Example 2.3, “Simple Structure" is defined in XML Schema as a complex type with two elements.

```
Example 2.3. Simple Structure

struct personalInfo
{
    string name;
    int age;
};
```

Example 2.4, “A complex type” shows one possible XML Schema mapping for the structure shown in Example 2.3, “Simple Structure". The structure defined in Example 2.4, “A complex type” generates a message containing two elements: `name` and `age`.

```
Example 2.4. A complex type

<complexType name="personalInfo">
    <sequence>
        <element name="name" type="xsd:string" />
        <element name="age" type="xsd:int" />
    </sequence>
</complexType>
```
Complex type varieties

XML Schema has three ways of describing how the fields of a complex type are organized when represented as an XML document and passed on the wire. The first child element of the complexType element determines which variety of complex type is being used. Table 2.1, “Complex type descriptor elements” shows the elements used to define complex type behavior.

Table 2.1. Complex type descriptor elements

<table>
<thead>
<tr>
<th>Element</th>
<th>Complex Type Behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td>sequence</td>
<td>All of a complex type’s fields can be present and they must be in the order in which they are specified in the type definition.</td>
</tr>
<tr>
<td>all</td>
<td>All of the complex type’s fields can be present but they can be in any order.</td>
</tr>
<tr>
<td>choice</td>
<td>Only one of the elements in the structure can be placed in the message.</td>
</tr>
</tbody>
</table>

If the structure is defined using a choice element, as shown in Example 2.5, “Simple complex choice type”, it generates a message with either a name element or an age element.

Example 2.5. Simple complex choice type

```xml
<complexType name="personalInfo">
  <choice>
    <element name="name" type="xsd:string"/>
    <element name="age" type="xsd:int"/>
  </choice>
</complexType>
```

Defining the parts of a structure

You define the data fields that make up a structure using element elements. Every complexType element should contain at least one element element. Each element element in the complexType element represents a field in the defined data structure.

To fully describe a field in a data structure, element elements have two required attributes:

- The name attribute specifies the name of the data field and it must be unique within the defined complex type.
- The type attribute specifies the type of the data stored in the field. The type can be either one of the XML Schema simple types, or any named complex type that is defined in the contract.

In addition to name and type, element elements have two other commonly used optional attributes: minOccurs and maxOccurs. These attributes place bounds on the number of times the field occurs in the structure. By default, each field occurs only once in a complex type. Using these attributes, you can
change how many times a field must or can appear in a structure. For example, you can define a field, **previousJobs**, that must occur at least three times, and no more than seven times, as shown in Example 2.6, “Simple complex type with occurrence constraints”.

### Example 2.6. Simple complex type with occurrence constraints

```xml
<complexType name="personalInfo">
  <all>
    <element name="name" type="xsd:string"/>
    <element name="age" type="xsd:int"/>
    <element name="previousJobs" type="xsd:string:
      minOccurs="3" maxOccurs="7"/>
  </all>
</complexType>
```

You can also use the **minOccurs** to make the **age** field optional by setting the **minOccurs** to zero as shown in Example 2.7, “Simple complex type with minOccurs set to zero”. In this case **age** can be omitted and the data will still be valid.

### Example 2.7. Simple complex type with minOccurs set to zero

```xml
<complexType name="personalInfo">
  <choice>
    <element name="name" type="xsd:string"/>
    <element name="age" type="xsd:int" minOccurs="0"/>
  </choice>
</complexType>
```

### Defining attributes

In XML documents, attributes are contained in the element’s tag. For example, in the **complexType** element in the code below, **name** is an attribute. To specify an attribute for a complex type, you define an **attribute** element in the **complexType** element definition. An **attribute** element can appear only after the **all**, **sequence**, or **choice** element. Specify one **attribute** element for each of the complex type’s attributes. Any **attribute** elements must be direct children of the **complexType** element.

### Example 2.8. Complex type with an attribute

```xml
<complexType name="personalInfo">
  <all>
    <element name="name" type="xsd:string"/>
    <element name="previousJobs" type="xsd:string:
      minOccurs="3" maxOccurs="7"/>
  </all>
  <attribute name="age" type="xsd:int" use="required"/>
</complexType>
```

In the previous code, the **attribute** element specifies that the **personalInfo** complex type has an **age** attribute. The **attribute** element has these attributes:
name – A required attribute that specifies the string that identifies the attribute.

type – Specifies the type of the data stored in the field. The type can be one of the XML Schema simple types.

use – An optional attribute that specifies whether the complex type is required to have this attribute. Valid values are required or optional. The default is that the attribute is optional.

In an attribute element, you can specify the optional default attribute, which lets you specify a default value for the attribute.

2.5.2. Defining arrays

Overview

Apache CXF supports two methods for defining arrays in a contract. The first is define a complex type with a single element whose maxOccurs attribute has a value greater than one. The second is to use SOAP arrays. SOAP arrays provide added functionality such as the ability to easily define multi-dimensional arrays and to transmit sparsely populated arrays.

Complex type arrays

Complex type arrays are a special case of a sequence complex type. You simply define a complex type with a single element and specify a value for the maxOccurs attribute. For example, to define an array of twenty floating point numbers you use a complex type similar to the one shown in Example 2.9, “Complex type array”.

Example 2.9. Complex type array

```
<complexType name="personalInfo">
  <element name="averages" type="xsd:float" maxOccurs="20"/>
</complexType>
```

You can also specify a value for the minOccurs attribute.

SOAP arrays

SOAP arrays are defined by deriving from the SOAP-ENC:Array base type using the wsdl:arrayType element. The syntax for this is shown in Example 2.10, “Syntax for a SOAP array derived using wsdl:arrayType”. Ensure that the definitions element declares xmlns:SOAP-ENC="http://schemas.xmlsoap.org/soap/encoding/".

Example 2.10. Syntax for a SOAP array derived using wsdl:arrayType

```
<complexType name="TypeName">
  <complexContent>
    <restriction base="SOAP-ENC:Array">
      <attribute ref="SOAP-ENC:arrayType" wsdl:arrayType="ElementType<ArrayBounds>"/>
    </restriction>
  </complexContent>
</complexType>
```
Using this syntax, **TypeName** specifies the name of the newly-defined array type. **ElementType** specifies the type of the elements in the array. **ArrayBounds** specifies the number of dimensions in the array. To specify a single dimension array use [ ]; to specify a two-dimensional array use either [ ][ ] or [ , ].

For example, the SOAP Array, SOAPStrings, shown in Example 2.11, “Definition of a SOAP array”, defines a one-dimensional array of strings. The **wsdl:arrayType** attribute specifies the type of the array elements, **xsd:string**, and the number of dimensions, with [] implying one dimension.

### Example 2.11. Definition of a SOAP array

```xml
<complexType name="SOAPStrings">
  <complexContent>
    <restriction base="SOAP-ENC:Array">
      <attribute ref="SOAP-ENC:arrayType" wsdl:arrayType="xsd:string[]"/>
    </restriction>
  </complexContent>
</complexType>
```

You can also describe a SOAP Array using a simple element as described in the SOAP 1.1 specification. The syntax for this is shown in Example 2.12, “Syntax for a SOAP array derived using an element”.

### Example 2.12. Syntax for a SOAP array derived using an element

```xml
<complexType name="TypeName">
  <complexContent>
    <restriction base="SOAP-ENC:Array">
      <sequence>
        <element name="ElementName" type="ElementType" maxOccurs="unbounded"/>
      </sequence>
    </restriction>
  </complexContent>
</complexType>
```

When using this syntax, the element’s **maxOccurs** attribute must always be set to **unbounded**.

### 2.5.3. Defining types by extension

Like most major coding languages, XML Schema allows you to create data types that inherit some of their elements from other data types. This is called defining a type by extension. For example, you could create a new type called **alienInfo**, that extends the **personalInfo** structure defined in Example 2.4, “A complex type” by adding a new element called **planet**.

Types defined by extension have four parts:

1. The name of the type is defined by the **name** attribute of the **complexType** element.
2. The **complexContent** element specifies that the new type will have more than one element.
NOTE

If you are only adding new attributes to the complex type, you can use a simpleContent element.

3. The type from which the new type is derived, called the base type, is specified in the base attribute of the extension element.

4. The new type’s elements and attributes are defined in the extension element, the same as they are for a regular complex type.

For example, alienInfo is defined as shown in Example 2.13, “Type defined by extension”.

Example 2.13. Type defined by extension

```xml
<complexType name="alienInfo">
  <complexContent>
    <extension base="xsd1:personalInfo">
      <sequence>
        <element name="planet" type="xsd:string"/>
      </sequence>
    </extension>
  </complexContent>
</complexType>
```

2.5.4. Defining types by restriction

Overview

XML Schema allows you to create new types by restricting the possible values of an XML Schema simple type. For example, you can define a simple type, SSN, which is a string of exactly nine characters. New types defined by restricting simple types are defined using a simpleType element.

The definition of a type by restriction requires three things:

1. The name of the new type is specified by the name attribute of the simpleType element.

2. The simple type from which the new type is derived, called the base type, is specified in the restriction element. See the section called “Specifying the base type”.

3. The rules, called facets, defining the restrictions placed on the base type are defined as children of the restriction element. See the section called “Defining the restrictions”.

Specifying the base type

The base type is the type that is being restricted to define the new type. It is specified using a restriction element. The restriction element is the only child of a simpleType element and has one attribute, base, that specifies the base type. The base type can be any of the XML Schema simple types.

For example, to define a new type by restricting the values of an xsd:int you use a definition like the one shown in Example 2.14, “Using int as the base type”.
Example 2.14. Using int as the base type

```xml
<simpleType name="restrictedInt">
    <restriction base="xsd:int">
        ...
    </restriction>
</simpleType>
```

Defining the restrictions

The rules defining the restrictions placed on the base type are called facets. Facets are elements with one attribute, value, that defines how the facet is enforced. The available facets and their valid value settings depend on the base type. For example, xsd:string supports six facets, including:

- length
- minLength
- maxLength
- pattern
- whitespace
- enumeration

Each facet element is a child of the restriction element.

Example

Example 2.15, “SSN simple type description” shows an example of a simple type, SSN, which represents a social security number. The resulting type is a string of the form xxx-xx-xxxx. <SSN>032-43-9876</SSN> is a valid value for an element of this type, but <SSN>032439876</SSN> is not.

```xml
<simpleType name="SSN">
    <restriction base="xsd:string">
        <pattern value="\d{3}-\d{2}-\d{4}"/>
    </restriction>
</simpleType>
```

2.5.5. Defining enumerated types

Overview

Enumerated types in XML Schema are a special case of definition by restriction. They are described by using the enumeration facet which is supported by all XML Schema primitive types. As with enumerated types in most modern programming languages, a variable of this type can only have one of the specified values.
Defining an enumeration in XML Schema

The syntax for defining an enumeration is shown in Example 2.16, “Syntax for an enumeration”.

Example 2.16. Syntax for an enumeration

```xml
<simpleType name="EnumName">
  <restriction base="EnumType">
    <enumeration value="Case1Value"/>
    <enumeration value="Case2Value"/>
    ...
    <enumeration value="CaseNValue"/>
  </restriction>
</simpleType>
```

*EnumName* specifies the name of the enumeration type. *EnumType* specifies the type of the case values. *CaseNValue*, where *N* is any number one or greater, specifies the value for each specific case of the enumeration. An enumerated type can have any number of case values, but because it is derived from a simple type, only one of the case values is valid at a time.

Example

For example, an XML document with an element defined by the enumeration *widgetSize*, shown in Example 2.17, “widgetSize enumeration”, would be valid if it contained `<widgetSize>big</widgetSize>`, but it would not be valid if it contained `<widgetSize>big,mungo</widgetSize>`.

Example 2.17. widgetSize enumeration

```xml
<simpleType name="widgetSize">
  <restriction base="xsd:string">
    <enumeration value="big"/>
    <enumeration value="large"/>
    <enumeration value="mungo"/>
  </restriction>
</simpleType>
```

2.6. DEFINING ELEMENTS

Elements in XML Schema represent an instance of an element in an XML document generated from the schema. The most basic element consists of a single `element` element. Like the `element` element used to define the members of a complex type, they have three attributes:

- **name** – A required attribute that specifies the name of the element as it appears in an XML document.
- **type** – Specifies the type of the element. The type can be any XML Schema primitive type or any named complex type defined in the contract. This attribute can be omitted if the type has an in-line definition.
- **nillable** – Specifies whether an element can be omitted from a document entirely. If **nillable** is set to **true**, the element can be omitted from any document generated using the schema.
An element can also have an in-line type definition. In-line types are specified using either a `complexType` element or a `simpleType` element. Once you specify if the type of data is complex or simple, you can define any type of data needed using the tools available for each type of data. In-line type definitions are discouraged because they are not reusable.
CHAPTER 3. DEFINING LOGICAL MESSAGES USED BY A SERVICE

Abstract

A service is defined by the messages exchanged when its operations are invoked. In a WSDL contract these messages are defined using `message` element. The messages are made up of one or more parts that are defined using `part` elements.

OVERVIEW

A service’s operations are defined by specifying the logical messages that are exchanged when an operation is invoked. These logical messages define the data that is passed over a network as an XML document. They contain all of the parameters that are a part of a method invocation. Logical messages are defined using the `message` element in your contracts. Each logical message consists of one or more parts, defined in `part` elements.

While your messages can list each parameter as a separate part, the recommended practice is to use only a single part that encapsulates the data needed for the operation.

MESSAGES AND PARAMETER LISTS

Each operation exposed by a service can have only one input message and one output message. The input message defines all of the information the service receives when the operation is invoked. The output message defines all of the data that the service returns when the operation is completed. Fault messages define the data that the service returns when an error occurs.

In addition, each operation can have any number of fault messages. The fault messages define the data that is returned when the service encounters an error. These messages usually have only one part that provides enough information for the consumer to understand the error.

MESSAGE DESIGN FOR INTEGRATING WITH LEGACY SYSTEMS

If you are defining an existing application as a service, you must ensure that each parameter used by the method implementing the operation is represented in a message. You must also ensure that the return value is included in the operation’s output message.

One approach to defining your messages is RPC style. When using RPC style, you define the messages using one part for each parameter in the method’s parameter list. Each message part is based on a type defined in the `types` element of the contract. Your input message contains one part for each input parameter in the method. Your output message contains one part for each output parameter, plus a part to represent the return value, if needed. If a parameter is both an input and an output parameter, it is listed as a part for both the input message and the output message.

RPC style message definition is useful when service enabling legacy systems that use transports such as Tibco or CORBA. These systems are designed around procedures and methods. As such, they are easiest to model using messages that resemble the parameter lists for the operation being invoked. RPC style also makes a cleaner mapping between the service and the application it is exposing.

MESSAGE DESIGN FOR SOAP SERVICES

While RPC style is useful for modeling existing systems, the service’s community strongly favors the wrapped document style. In wrapped document style, each message has a single part. The message’s
part references a wrapper element defined in the types element of the contract. The wrapper element has the following characteristics:

- It is a complex type containing a sequence of elements. For more information see Section 2.5, “Defining complex data types”.
- If it is a wrapper for an input message:
  - It has one element for each of the method’s input parameters.
  - Its name is the same as the name of the operation with which it is associated.
- If it is a wrapper for an output message:
  - It has one element for each of the method’s output parameters and one element for each of the method’s inout parameters.
  - Its first element represents the method’s return parameter.
  - Its name would be generated by appending Response to the name of the operation with which the wrapper is associated.

MESSAGE NAMING

Each message in a contract must have a unique name within its namespace. It is recommended that you use the following naming conventions:

- Messages should only be used by a single operation.
- Input message names are formed by appending Request to the name of the operation.
- Output message names are formed by appending Response to the name of the operation.
- Fault message names should represent the reason for the fault.

MESSAGE PARTS

Message parts are the formal data units of the logical message. Each part is defined using a part element, and is identified by a name attribute and either a type attribute or an element attribute that specifies its data type. The data type attributes are listed in Table 3.1, “Part data type attributes”.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>element=&quot;elem_name&quot;</td>
<td>The data type of the part is defined by an element called elem_name.</td>
</tr>
<tr>
<td>type=&quot;type_name&quot;</td>
<td>The data type of the part is defined by a type called type_name.</td>
</tr>
</tbody>
</table>

Messages are allowed to reuse part names. For instance, if a method has a parameter, foo, that is passed by reference or is an in/out, it can be a part in both the request message and the response message, as shown in Example 3.1, “Reused part”.
Example 3.1. Reused part

```xml
<message name="fooRequest">
  <part name="foo" type="xsd:int"/>
<message>
<message name="fooReply">
  <part name="foo" type="xsd:int"/>
<message>
```

EXAMPLE

For example, imagine you had a server that stored personal information and provided a method that returned an employee's data based on the employee's ID number. The method signature for looking up the data is similar to Example 3.2, "personalInfo lookup method".

Example 3.2. personalInfo lookup method

```java
personalInfo lookup(long empId)
```

This method signature can be mapped to the RPC style WSDL fragment shown in Example 3.3, "RPC WSDL message definitions".

Example 3.3. RPC WSDL message definitions

```xml
<message name="personalLookupRequest">
  <part name="empId" type="xsd:int"/>
<message/>
<message name="personalLookupResponse">
  <part name="return" element="xsd1:personalInfo"/>
<message/>
```

It can also be mapped to the wrapped document style WSDL fragment shown in Example 3.4, "Wrapped document WSDL message definitions".

Example 3.4. Wrapped document WSDL message definitions

```xml
<wsdl:types>
  <xsd:schema ... >
    ...
    <element name="personalLookup">
      <complexType>
        <sequence>
          <element name="empId" type="xsd:int"/>
        </sequence>
      </complexType>
    </element>
    <element name="personalLookupResponse">
      <complexType>
        <sequence>
          ...
        </sequence>
      </complexType>
    </element>
  </xsd:schema>
</wsdl:types>
```
CHAPTER 3. DEFINING LOGICAL MESSAGES USED BY A SERVICE

```xml
<element name="return" type="personalInfo" />
</sequence>
</complexType>
</element>
</schema>
</types>
<wSDL:message name="personalLookupRequest">
<wSDL:part name="emplId" element="xsd1:personalLookup"/>
<message/>
<wSDL:message name="personalLookupResponse">
<wSDL:part name="return" element="xsd1:personalLookupResponse"/>
<message/>
```
CHAPTER 4. DEFINING YOUR LOGICAL INTERFACES

Abstract
Logical service interfaces are defined using the **portType** element.

OVERVIEW
Logical service interfaces are defined using the WSDL **portType** element. The **portType** element is a collection of abstract operation definitions. Each operation is defined by the input, output, and fault messages used to complete the transaction the operation represents. When code is generated to implement the service interface defined by a **portType** element, each operation is converted into a method containing the parameters defined by the input, output, and fault messages specified in the contract.

PROCESS
To define a logical interface in a **WSDL** contract you must do the following:

1. Create a **portType** element to contain the interface definition and give it a unique name. See the section called “Port types”.
2. Create an **operation** element for each operation defined in the interface. See the section called “Operations”.
3. For each operation, specify the messages used to represent the operation’s parameter list, return type, and exceptions. See the section called “Operation messages”.

PORT TYPES
A WSDL **portType** element is the root element in a logical interface definition. While many Web service implementations map **portType** elements directly to generated implementation objects, a logical interface definition does not specify the exact functionality provided by the the implemented service. For example, a logical interface named ticketSystem can result in an implementation that either sells concert tickets or issues parking tickets.

The **portType** element is the unit of a WSDL document that is mapped into a binding to define the physical data used by an endpoint exposing the defined service.

Each **portType** element in a WSDL document must have a unique name, which is specified using the **name** attribute, and is made up of a collection of operations, which are described in **operation** elements. A WSDL document can describe any number of port types.

OPERATIONS
Logical operations, defined using WSDL **operation** elements, define the interaction between two endpoints. For example, a request for a checking account balance and an order for a gross of widgets can both be defined as operations.

Each operation defined within a **portType** element must have a unique name, specified using the **name** attribute. The **name** attribute is required to define an operation.

OPERATION MESSAGES
Logical operations are made up of a set of elements representing the logical messages communicated between the endpoints to execute the operation. The elements that can describe an operation are listed in Table 4.1, “Operation message elements”.

Table 4.1. Operation message elements

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>input</td>
<td>Specifies the message the client endpoint sends to the service provider when a request is made. The parts of this message correspond to the input parameters of the operation.</td>
</tr>
<tr>
<td>output</td>
<td>Specifies the message that the service provider sends to the client endpoint in response to a request. The parts of this message correspond to any operation parameters that can be changed by the service provider, such as values passed by reference. This includes the return value of the operation.</td>
</tr>
<tr>
<td>fault</td>
<td>Specifies a message used to communicate an error condition between the endpoints.</td>
</tr>
</tbody>
</table>

An operation is required to have at least one input or one output element. An operation can have both input and output elements, but it can only have one of each. Operations are not required to have any fault elements, but can, if required, have any number of fault elements.

The elements have the two attributes listed in Table 4.2, “Attributes of the input and output elements”.

Table 4.2. Attributes of the input and output elements

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Identifies the message so it can be referenced when mapping the operation to a concrete data format. The name must be unique within the enclosing port type.</td>
</tr>
<tr>
<td>message</td>
<td>Specifies the abstract message that describes the data being sent or received. The value of the message attribute must correspond to the name attribute of one of the abstract messages defined in the WSDL document.</td>
</tr>
</tbody>
</table>

It is not necessary to specify the name attribute for all input and output elements; WSDL provides a default naming scheme based on the enclosing operation’s name. If only one element is used in the operation, the element name defaults to the name of the operation. If both an input and an output element are used, the element name defaults to the name of the operation with either Request or Response respectively appended to the name.

RETURN VALUES
Because the operation element is an abstract definition of the data passed during an operation, WSDL does not provide for return values to be specified for an operation. If a method returns a value it will be mapped into the output element as the last part of that message.

EXAMPLE

For example, you might have an interface similar to the one shown in Example 4.1, “personalInfo lookup interface”.

Example 4.1. personalInfo lookup interface

```java
interface personalInfoLookup
{
    personalInfo lookup(in int empID)
    raises(idNotFound);
}
```

This interface can be mapped to the port type in Example 4.2, “personalInfo lookup port type”.

Example 4.2. personalInfo lookup port type

```xml
<message name="personalLookupRequest">
    <part name="empId" element="xsd1:personalLookup"/>
<message/>
<message name="personalLookupResponse">
    <part name="return" element="xsd1:personalLookupResponse"/>
<message/>
<message name="idNotFoundException">
    <part name="exception" element="xsd1:idNotFound"/>
<message/>
<portType name="personalInfoLookup">
    <operation name="lookup">
        <input name="empID" message="tns:personalLookupRequest"/>
        <output name="return" message="tns:personalLookupResponse"/>
        <fault name="exception" message="tns:idNotFoundException"/>
    </operation>
</portType>
```
PART II. WEB SERVICES BINDINGS

This part describes how to add Apache CXF bindings to a WSDL document.
CHAPTER 5. UNDERSTANDING BINDINGS IN WSDL

Abstract

Bindings map the logical messages used to define a service into a concrete payload format that can be transmitted and received by an endpoint.

OVERVIEW

Bindings provide a bridge between the logical messages used by a service to a concrete data format that an endpoint uses in the physical world. They describe how the logical messages are mapped into a payload format that is used on the wire by an endpoint. It is within the bindings that details such as parameter order, concrete data types, and return values are specified. For example, the parts of a message can be reordered in a binding to reflect the order required by an RPC call. Depending on the binding type, you can also identify which of the message parts, if any, represent the return type of a method.

PORT TYPES AND BINDINGS

Port types and bindings are directly related. A port type is an abstract definition of a set of interactions between two logical services. A binding is a concrete definition of how the messages used to implement the logical services will be instantiated in the physical world. Each binding is then associated with a set of network details that finish the definition of one endpoint that exposes the logical service defined by the port type.

To ensure that an endpoint defines only a single service, WSDL requires that a binding can only represent a single port type. For example, if you had a contract with two port types, you could not write a single binding that mapped both of them into a concrete data format. You would need two bindings.

However, WSDL allows for a port type to be mapped to several bindings. For example, if your contract had a single port type, you could map it into two or more bindings. Each binding could alter how the parts of the message are mapped or they could specify entirely different payload formats for the message.

THE WSDL ELEMENTS

Bindings are defined in a contract using the WSDL binding element. The binding element consists of attributes like, name, that specifies a unique name for the binding and type that provides reference to PortType. The value of this attribute is used to associate the binding with an endpoint as discussed in Chapter 4, Defining Your Logical Interfaces.

The actual mappings are defined in the children of the binding element. These elements vary depending on the type of payload format you decide to use. The different payload formats and the elements used to specify their mappings are discussed in the following chapters.

ADDING TO A CONTRACT

Apache CXF provides command line tools that can generate bindings for predefined service interfaces.

The tools will add the proper elements to your contract for you. However, it is recommended that you have some knowledge of how the different types of bindings work.

You can also add a binding to a contract using any text editor. When hand editing a contract, you are responsible for ensuring that the contract is valid.
SUPPORTED BINDINGS

Apache CXF supports the following bindings:

- SOAP 1.1
- SOAP 1.2
- CORBA
- Pure XML
CHAPTER 6. USING SOAP 1.1 MESSAGES

Abstract

Apache CXF provides a tool to generate a SOAP 1.1 binding which does not use any SOAP headers. However, you can add SOAP headers to your binding using any text or XML editor.

6.1. ADDING A SOAP 1.1 BINDING

Using wsdl2soap

To generate a SOAP 1.1 binding using wsdl2soap use the following command:

```
wsdl2soap -i port-type-name -b binding-name -d output-directory -o output-file -n soap-body-namespace -s (document/rpc) -u (literal/encoded) -v -w
```

**NOTE**

To use wsdl2soap you will need to download the Apache CXF distribution.

The command has the following options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Interpretation</th>
</tr>
</thead>
<tbody>
<tr>
<td>-i port-type-name</td>
<td>Specifies the <strong>portType</strong> element for which a binding is generated.</td>
</tr>
<tr>
<td>wsdlurl</td>
<td>The path and name of the WSDL file containing the <strong>portType</strong> element definition.</td>
</tr>
</tbody>
</table>

The tool has the following optional arguments:

<table>
<thead>
<tr>
<th>Option</th>
<th>Interpretation</th>
</tr>
</thead>
<tbody>
<tr>
<td>-b binding-name</td>
<td>Specifies the name of the generated SOAP binding.</td>
</tr>
<tr>
<td>-d output-directory</td>
<td>Specifies the directory to place the generated WSDL file.</td>
</tr>
<tr>
<td>-o output-file</td>
<td>Specifies the name of the generated WSDL file.</td>
</tr>
<tr>
<td>-n soap-body-namespace</td>
<td>Specifies the SOAP body namespace when the style is RPC.</td>
</tr>
<tr>
<td>-s (document/rpc)</td>
<td>Specifies the encoding style (document or RPC) to use in the SOAP binding. The default is document.</td>
</tr>
<tr>
<td>-u (literal/encoded)</td>
<td>Specifies the binding use (encoded or literal) to use in the SOAP binding. The default is literal.</td>
</tr>
<tr>
<td>Option</td>
<td>Interpretation</td>
</tr>
<tr>
<td>---------</td>
<td>----------------</td>
</tr>
<tr>
<td><code>-v</code></td>
<td>Displays the version number for the tool.</td>
</tr>
<tr>
<td><code>-verbose</code></td>
<td>Displays comments during the code generation process.</td>
</tr>
<tr>
<td><code>-quiet</code></td>
<td>Suppresses comments during the code generation process.</td>
</tr>
</tbody>
</table>

The `-port-type-name` and `wsdlurl` arguments are required. If the `-style rpc` argument is specified, the `-soap-body-namespace` argument is also required. All other arguments are optional and may be listed in any order.

**IMPORTANT**

`wsdl2soap` does not support the generation of `document/encoded` SOAP bindings.

**Example**

If your system has an interface that takes orders and offers a single operation to process the orders it is defined in a WSDL fragment similar to the one shown in Example 6.1, "Ordering System Interface".

**Example 6.1. Ordering System Interface**

```xml
<?xml version="1.0" encoding="UTF-8"?>
<definitions name="widgetOrderForm.wsdl"
    targetNamespace="http://widgetVendor.com/widgetOrderForm"
    xmlns="http://schemas.xmlsoap.org/wsdl/
    xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap/
    xmlns:tns="http://widgetVendor.com/widgetOrderForm"
    xmlns:xsd="http://www.w3.org/2001/XMLSchema"
    xmlns:xsd1="http://widgetVendor.com/types/widgetTypes"
    xmlns:SOAP-ENC="http://schemas.xmlsoap.org/soap/encoding/">

<message name="widgetOrder">
    <part name="numOrdered" type="xsd:int"/>
</message>

<message name="widgetOrderBill">
    <part name="price" type="xsd:float"/>
</message>

<message name="badSize">
    <part name="numInventory" type="xsd:int"/>
</message>

<portType name="orderWidgets">
    <operation name="placeWidgetOrder">
        <input message="tns:widgetOrder" name="order"/>
        <output message="tns:widgetOrderBill" name="bill"/>
        <fault message="tns:badSize" name="sizeFault"/>
    </operation>
</portType>
</definitions>
```
The SOAP binding generated for orderWidgets is shown in Example 6.2, “SOAP 1.1 Binding for orderWidgets”.

Example 6.2. SOAP 1.1 Binding for orderWidgets

```xml
<binding name="orderWidgetsBinding" type="tns:orderWidgets">
  <soap:binding style="document" transport="http://schemas.xmlsoap.org/soap/http"/>
  <operation name="placeWidgetOrder">
    <soap:operation soapAction="" style="document"/>
    <input name="order">
      <soap:body use="literal"/>
    </input>
    <output name="bill">
      <soap:body use="literal"/>
    </output>
    <fault name="sizeFault">
      <soap:body use="literal"/>
    </fault>
  </operation>
</binding>
```

This binding specifies that messages are sent using the document/literal message style.

### 6.2. ADDING SOAP HEADERS TO A SOAP 1.1 BINDING

**Overview**

SOAP headers are defined by adding soap:header elements to your default SOAP 1.1 binding. The soap:header element is an optional child of the input, output, and fault elements of the binding. The SOAP header becomes part of the parent message. A SOAP header is defined by specifying a message and a message part. Each SOAP header can only contain one message part, but you can insert as many SOAP headers as needed.

**Syntax**

The syntax for defining a SOAP header is shown in Example 6.3, “SOAP Header Syntax”. The message attribute of soap:header is the qualified name of the message from which the part being inserted into the header is taken. The part attribute is the name of the message part inserted into the SOAP header. Because SOAP headers are always document style, the WSDL message part inserted into the SOAP header must be defined using an element. Together the message and the part attributes fully describe the data to insert into the SOAP header.

Example 6.3. SOAP Header Syntax

```xml
<binding name="headwig">
  <soap:binding style="document" transport="http://schemas.xmlsoap.org/soap/http"/>
```

Red Hat Fuse 7.8 Apache CXF Development Guide
As well as the mandatory message and part attributes, soap:header also supports the namespace, the use, and the encodingStyle attributes. These attributes function the same for soap:header as they do for soap:body.

Splitting messages between body and header

The message part inserted into the SOAP header can be any valid message part from the contract. It can even be a part from the parent message which is being used as the SOAP body. Because it is unlikely that you would want to send information twice in the same message, the SOAP binding provides a means for specifying the message parts that are inserted into the SOAP body.

The soap:body element has an optional attribute, parts, that takes a space delimited list of part names. When parts is defined, only the message parts listed are inserted into the SOAP body. You can then insert the remaining parts into the SOAP header.

NOTE
When you define a SOAP header using parts of the parent message, Apache CXF automatically fills in the SOAP headers for you.

Example

Example 6.4, “SOAP 1.1 Binding with a SOAP Header” shows a modified version of the orderWidgets service shown in Example 6.1, “Ordering System Interface”. This version has been modified so that each order has an xsd:base64binary value placed in the SOAP header of the request and response. The SOAP header is defined as being the keyVal part from the widgetKey message. In this case you are responsible for adding the SOAP header to your application logic because it is not part of the input or output message.

Example 6.4. SOAP 1.1 Binding with a SOAP Header

```xml
<?xml version="1.0" encoding="UTF-8"?>
<definitions name="widgetOrderForm.wsdl" targetNamespace="http://widgetVendor.com/widgetOrderForm"
xmlns="http://schemas.xmlsoap.org/wsdl/
xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap/
xmlns:tns="http://widgetVendor.com/widgetOrderForm"
xmlns:xsd="http://www.w3.org/2001/XMLSchema"
xmlns:xsd1="http://widgetVendor.com/types/widgetTypes"
xmlns:SOAP-ENC="http://schemas.xmlsoap.org/soap/encoding/">

<types>
<schema targetNamespace="http://widgetVendor.com/types/widgetTypes"
xmlns="http://www.w3.org/2001/XMLSchema"
```
You can also modify Example 6.4, “SOAP 1.1 Binding with a SOAP Header” so that the header value is a part of the input and output messages.
CHAPTER 7. USING SOAP 1.2 MESSAGES

Abstract

Apache CXF provides tools to generate a SOAP 1.2 binding which does not use any SOAP headers. You can add SOAP headers to your binding using any text or XML editor.

7.1. ADDING A SOAP 1.2 BINDING TO A WSDL DOCUMENT

Using wsdl2soap

NOTE

To use wsdl2soap you will need to download the Apache CXF distribution.

To generate a SOAP 1.2 binding using `wsdl2soap` use the following command:

```
wsdl2soap -i port-type-name -b binding-name -soap12 -d output-directory -o output-file -n soap-body-namespace -s (document/rpc) -u (literal/encoded) -v -quiet
```

The tool has the following required arguments:

<table>
<thead>
<tr>
<th>Option</th>
<th>Interpretation</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-i port-type-name</code></td>
<td>Specifies the <code>portType</code> element for which a binding is generated.</td>
</tr>
<tr>
<td><code>-soap12</code></td>
<td>Specifies that the generated binding uses SOAP 1.2.</td>
</tr>
<tr>
<td><code>wsdlurl</code></td>
<td>The path and name of the WSDL file containing the <code>portType</code> element definition.</td>
</tr>
</tbody>
</table>

The tool has the following optional arguments:

<table>
<thead>
<tr>
<th>Option</th>
<th>Interpretation</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-b binding-name</code></td>
<td>Specifies the name of the generated SOAP binding.</td>
</tr>
<tr>
<td><code>-soap12</code></td>
<td>Specifies that the generated binding will use SOAP 1.2.</td>
</tr>
<tr>
<td><code>-d output-directory</code></td>
<td>Specifies the directory to place the generated WSDL file.</td>
</tr>
<tr>
<td><code>-o output-file</code></td>
<td>Specifies the name of the generated WSDL file.</td>
</tr>
<tr>
<td><code>-n soap-body-namespace</code></td>
<td>Specifies the SOAP body namespace when the style is RPC.</td>
</tr>
<tr>
<td>Option</td>
<td>Interpretation</td>
</tr>
<tr>
<td>------------------</td>
<td>--------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>-style</strong> (document/rpc)</td>
<td>Specifies the encoding style (document or RPC) to use in the SOAP binding. The default is document.</td>
</tr>
<tr>
<td><strong>-use</strong> (literal/encoded)</td>
<td>Specifies the binding use (encoded or literal) to use in the SOAP binding. The default is literal.</td>
</tr>
<tr>
<td><strong>-v</strong></td>
<td>Displays the version number for the tool.</td>
</tr>
<tr>
<td><strong>-verbose</strong></td>
<td>Displays comments during the code generation process.</td>
</tr>
<tr>
<td><strong>-quiet</strong></td>
<td>Suppresses comments during the code generation process.</td>
</tr>
</tbody>
</table>

The **-i** **port-type-name** and **wsdlurl** arguments are required. If the **-style rpc** argument is specified, the **-n** **soap-body-namspace** argument is also required. All other arguments are optional and can be listed in any order.

**IMPORTANT**

**wsdl2soap** does not support the generation of **document/encoded** SOAP 1.2 bindings.

**Example**

If your system has an interface that takes orders and offers a single operation to process the orders it is defined in a **WSDL** fragment similar to the one shown in **Example 7.1, "Ordering System Interface"**.

**Example 7.1. Ordering System Interface**

```xml
<?xml version="1.0" encoding="UTF-8"?>
<definitions name="widgetOrderForm.wsdl"
    targetNamespace="http://widgetVendor.com/widgetOrderForm"
    xmlns="http://schemas.xmlsoap.org/wsdl/"
    xmlns:soap12="http://schemas.xmlsoap.org/wsdl/soap12/"
    xmlns:tns="http://widgetVendor.com/widgetOrderForm"
    xmlns:xsd="http://www.w3.org/2001/XMLSchema"
    xmlns:xsd1="http://widgetVendor.com/types/widgetTypes"
    xmlns:SOAP-ENC="http://schemas.xmlsoap.org/soap/encoding/">

<message name="widgetOrder">
    <part name="numOrdered" type="xsd:int"/>
</message>
<message name="widgetOrderBill">
    <part name="price" type="xsd:float"/>
</message>
<message name="badSize">
    <part name="numInventory" type="xsd:int"/>
</message>

<portType name="orderWidgets">
    <message name="widgetOrder">
    ...
    </message>
    <message name="widgetOrderBill">
    ...
    </message>
    <message name="badSize">
    ...
    </message>
</portType>
</definitions>
```
The SOAP binding generated for orderWidgets is shown in Example 7.2, “SOAP 1.2 Binding for orderWidgets”.

Example 7.2. SOAP 1.2 Binding for orderWidgets

```xml
<binding name="orderWidgetsBinding" type="tns:orderWidgets">
  <soap12:binding style="document" transport="http://schemas.xmlsoap.org/soap/http"/>
  <operation name="placeWidgetOrder">
    <soap12:operation soapAction="" style="document"/>
    <input name="order">
      <soap12:body use="literal"/>
    </input>
    <output name="bill">
      <wsoap12:body use="literal"/>
    </output>
    <fault name="sizeFault">
      <soap12:body use="literal"/>
    </fault>
  </operation>
</binding>
```

This binding specifies that messages are sent using the document/literal message style.

### 7.2. ADDING HEADERS TO A SOAP 1.2 MESSAGE

**Overview**

SOAP message headers are defined by adding soap12:header elements to your SOAP 1.2 message. The soap12:header element is an optional child of the input, output, and fault elements of the binding. The SOAP header becomes part of the parent message. A SOAP header is defined by specifying a message and a message part. Each SOAP header can only contain one message part, but you can insert as many headers as needed.

**Syntax**

The syntax for defining a SOAP header is shown in Example 7.3, “SOAP Header Syntax”.

Example 7.3. SOAP Header Syntax

```xml
<binding name="headwig">
  <soap12:binding style="document" transport="http://schemas.xmlsoap.org/soap/http"/>
  <operation name="weave">
```
The soap12:header element’s attributes are described in Table 7.1, “soap12:header Attributes”.

### Table 7.1. soap12:header Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>message</td>
<td>A required attribute specifying the qualified name of the message from which the part being inserted into the header is taken.</td>
</tr>
<tr>
<td>part</td>
<td>A required attribute specifying the name of the message part inserted into the SOAP header.</td>
</tr>
<tr>
<td>use</td>
<td>Specifies if the message parts are to be encoded using encoding rules. If set to encoded the message parts are encoded using the encoding rules specified by the value of the encodingStyle attribute. If set to literal, the message parts are defined by the schema types referenced.</td>
</tr>
<tr>
<td>encodingStyle</td>
<td>Specifies the encoding rules used to construct the message.</td>
</tr>
<tr>
<td>namespace</td>
<td>Defines the namespace to be assigned to the header element serialized with use=&quot;encoded&quot;.</td>
</tr>
</tbody>
</table>

**Splitting messages between body and header**

The message part inserted into the SOAP header can be any valid message part from the contract. It can even be a part from the parent message which is being used as the SOAP body. Because it is unlikely that you would send information twice in the same message, the SOAP 1.2 binding provides a means for specifying the message parts that are inserted into the SOAP body.

The soap12:body element has an optional attribute, parts, that takes a space delimited list of part names. When parts is defined, only the message parts listed are inserted into the body of the SOAP 1.2 message. You can then insert the remaining parts into the message’s header.
NOTE

When you define a SOAP header using parts of the parent message, Apache CXF automatically fills in the SOAP headers for you.

Example

Example 7.4, "SOAP 1.2 Binding with a SOAP Header" shows a modified version of the orderWidgets service shown in Example 7.1, "Ordering System Interface". This version is modified so that each order has an xsd:base64binary value placed in the header of the request and the response. The header is defined as being the keyVal part from the widgetKey message. In this case you are responsible for adding the application logic to create the header because it is not part of the input or output message.

Example 7.4. SOAP 1.2 Binding with a SOAP Header

```xml
<?xml version="1.0" encoding="UTF-8"?>
<definitions name="widgetOrderForm.wsdl"
    targetNamespace="http://widgetVendor.com/widgetOrderForm"
    xmlns="http://schemas.xmlsoap.org/wsdl/
    xmlns:soap12="http://schemas.xmlsoap.org/wsdl/soap12/"
    xmlns:tns="http://widgetVendor.com/widgetOrderForm"
    xmlns:xsd="http://www.w3.org/2001/XMLSchema"
    xmlns:xsd1="http://widgetVendor.com/types/widgetTypes"
    xmlns:SOAP-ENC="http://schemas.xmlsoap.org/soap/encoding"/>

<types>
    <schema targetNamespace="http://widgetVendor.com/types/widgetTypes"
        xmlns="http://www.w3.org/2001/XMLSchema"
        xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/">
        <element name="keyElem" type="xsd:base64Binary/>
    </schema>
</types>

<message name="widgetOrder">
    <part name="numOrdered" type="xsd:int"/>
</message>

<message name="widgetOrderBill">
    <part name="price" type="xsd:float"/>
</message>

<message name="badSize">
    <part name="numInventory" type="xsd:int"/>
</message>

<message name="widgetKey">
    <part name="keyVal" element="xsd1:keyElem"/>
</message>

<portType name="orderWidgets">
    <operation name="placeWidgetOrder">
        <input message="tns:widgetOrder" name="order"/>
        <output message="tns:widgetOrderBill" name="bill"/>
        <fault message="tns:badSize" name="sizeFault"/>
    </operation>
</portType>

<binding name="orderWidgetsBinding" type="tns:orderWidgets"/>
```
You can modify Example 7.4, “SOAP 1.2 Binding with a SOAP Header” so that the header value is a part of the input and output messages, as shown in Example 7.5, “SOAP 1.2 Binding for orderWidgets with a SOAP Header”. In this case keyVal is a part of the input and output messages. In the soap12:body elements the parts attribute specifies that keyVal should not be inserted into the body. However, it is inserted into the header.

Example 7.5. SOAP 1.2 Binding for orderWidgets with a SOAP Header

```xml
<?xml version="1.0" encoding="UTF-8"?>
<definitions name="widgetOrderForm.wsdl"
    targetNamespace="http://widgetVendor.com/widgetOrderForm"
    xmlns="http://schemas.xmlsoap.org/wsdl/"
    xmlns:soap12="http://schemas.xmlsoap.org/wsdl/soap12/
    xmlns:tns="http://widgetVendor.com/widgetOrderForm"
    xmlns:xsd="http://www.w3.org/2001/XMLSchema"
    xmlns:xsd1="http://widgetVendor.com/types/widgetTypes"
    xmlns:SOAP-ENC="http://schemas.xmlsoap.org/soap/encoding/>
</definitions>

<types>
    <schema targetNamespace="http://widgetVendor.com/types/widgetTypes"
        xmlns="http://www.w3.org/2001/XMLSchema"
        xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/">
        <element name="keyElem" type="xsd:base64Binary"/>
    </schema>
</types>

<message name="widgetOrder">
    <part name="numOrdered" type="xsd:int"/>
    <part name="keyVal" element="xsd1:keyElem"/>
</message>

<message name="widgetOrderBill">
    <part name="price" type="xsd:float"/>
    <part name="keyVal" element="xsd1:keyElem"/>
</message>

<message name="badSize">
</message>
```
<portType name="orderWidgets">
  <operation name="placeWidgetOrder">
    <input message="tns:widgetOrder" name="order"/>
    <output message="tns:widgetOrderBill" name="bill"/>
    <fault message="tns:badSize" name="sizeFault"/>
  </operation>
</portType>

<binding name="orderWidgetsBinding" type="tns:orderWidgets">
  <soap12:binding style="document" transport="http://schemas.xmlsoap.org/soap/http"/>
  <soap12:operation soapAction="" style="document"/>
  <input name="order">
    <soap12:body use="literal" parts="numOrdered"/>
    <soap12:header message="tns:widgetOrder" part="keyVal"/>
  </input>
  <output name="bill">
    <soap12:body use="literal" parts="bill"/>
    <soap12:header message="tns:widgetOrderBill" part="keyVal"/>
  </output>
  <fault name="sizeFault">
    <soap12:body use="literal"/>
  </fault>
</operation>
</binding>
...
CHAPTER 8. SENDING BINARY DATA USING SOAP WITH ATTACHMENTS

Abstract

SOAP attachments provide a mechanism for sending binary data as part of a SOAP message. Using SOAP with attachments requires that you define your SOAP messages as MIME multipart messages.

OVERVIEW

SOAP messages generally do not carry binary data. However, the W3C SOAP 1.1 specification allows for using MIME multipart/related messages to send binary data in SOAP messages. This technique is called using SOAP with attachments. SOAP attachments are defined in the W3C’s SOAP Messages with Attachments Note.

NAMESPACE

The WSDL extensions used to define the MIME multipart/related messages are defined in the namespace http://schemas.xmlsoap.org/wsdl/mime/.

In the discussion that follows, it is assumed that this namespace is prefixed with mime. The entry in the WSDL definitions element to set this up is shown in Example 8.1, “MIME Namespace Specification in a Contract”.

Example 8.1. MIME Namespace Specification in a Contract

```xml
xmlns:mime="http://schemas.xmlsoap.org/wsdl/mime/"
```

CHANGING THE MESSAGE BINDING

In a default SOAP binding, the first child element of the input, output, and fault elements is a soap:body element describing the body of the SOAP message representing the data. When using SOAP with attachments, the soap:body element is replaced with a mime:multipartRelated element.

NOTE

WSDL does not support using mime:multipartRelated for fault messages.

The mime:multipartRelated element tells Apache CXF that the message body is a multipart message that potentially contains binary data. The contents of the element define the parts of the message and their contents. mime:multipartRelated elements contain one or more mime:part elements that describe the individual parts of the message.

The first mime:part element must contain the soap:body element that would normally appear in a default SOAP binding. The remaining mime:part elements define the attachments that are being sent in the message.

DESCRIBING A MIME MULTIPART MESSAGE
MIME multipart messages are described using a `mime:multipartRelated` element that contains a number of `mime:part` elements. To fully describe a MIME multipart message you must do the following:

1. Inside the input or output message you are sending as a MIME multipart message, add a `mime:multipartRelated` element as the first child element of the enclosing message.

2. Add a `mime:part` child element to the `mime:multipartRelated` element and set its `name` attribute to a unique string.

3. Add a `soap:body` element as the child of the `mime:part` element and set its attributes appropriately.

   **NOTE**
   If the contract had a default SOAP binding, you can copy the `soap:body` element from the corresponding message from the default binding into the MIME multipart message.

4. Add another `mime:part` child element to the `mime:multipartRelated` element and set its `name` attribute to a unique string.

5. Add a `mime:content` child element to the `mime:part` element to describe the contents of this part of the message.
   To fully describe the contents of a MIME message part the `mime:content` element has the following attributes:

   **Table 8.1. mime:content Attributes**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description +</th>
</tr>
</thead>
<tbody>
<tr>
<td>part</td>
<td>Specifies the name of the WSDL message part, from the parent message definition, that is used as the content of this part of the MIME multipart message being placed on the wire. +</td>
</tr>
<tr>
<td>type</td>
<td>The MIME type of the data in this message part. MIME types are defined as a type and a subtype using the syntax type/subtype. +</td>
</tr>
<tr>
<td></td>
<td>There are a number of predefined MIME types such as <code>image/jpeg</code> and <code>text/plain</code>. The MIME types are maintained by the Internet Assigned Numbers Authority (IANA) and described in detail in <em>Multipurpose Internet Mail Extensions (MIME) Part One: Format of Internet Message Bodies</em> and <em>Multipurpose Internet Mail Extensions (MIME) Part Two: Media Types</em>. +</td>
</tr>
</tbody>
</table>

6. For each additional MIME part, repeat steps [i303819] and [i303821].
Example 8.2, “Contract using SOAP with Attachments” shows a WSDL fragment defining a service that stores X-rays in JPEG format. The image data, xRay, is stored as an xsd:base64binary and is packed into the MIME multipart message’s second part, imageData. The remaining two parts of the input message, patientName and patientNumber, are sent in the first part of the MIME multipart image as part of the SOAP body.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<definitions name="XrayStorage"
    targetNamespace="http://mediStor.org/x-rays"
    xmlns="http://schemas.xmlsoap.org/wsdl/
    xmlns:tns="http://mediStor.org/x-rays"
    xmlns:mime="http://schemas.xmlsoap.org/wsdl/mime/
    xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap/
    xmlns:xsd="http://www.w3.org/2001/XMLSchema">
    <message name="storRequest">
        <part name="patientName" type="xsd:string"/>
        <part name="patientNumber" type="xsd:int"/>
        <part name="xRay" type="xsd:base64Binary"/>
    </message>
    <message name="storResponse">
        <part name="success" type="xsd:boolean"/>
    </message>

    <portType name="xRayStorage">
        <operation name="store">
            <input message="tns:storRequest" name="storRequest"/>
            <output message="tns:storResponse" name="storResponse"/>
        </operation>
    </portType>

    <binding name="xRayStorageBinding" type="tns:xRayStorage">
        <soap:binding style="document" transport="http://schemas.xmlsoap.org/soap/http"/>
        <operation name="store">
            <soap:operation soapAction="" style="document"/>
            <input name="storRequest">
                <mime:multipartRelated>
                    <mime:part name="bodyPart">
                        <soap:body use="literal"/>
                    </mime:part>
                    <mime:part name="imageData">
                        <mime:content part="xRay" type="image/jpeg"/>
                    </mime:part>
                </mime:multipartRelated>
            </input>
            <output name="storResponse">
                <soap:body use="literal"/>
            </output>
        </operation>
    </binding>

    <service name="xRayStorageService">
```

Red Hat Fuse 7.8 Apache CXF Development Guide
<port binding="tns:xRayStorageBinding" name="xRayStoragePort">
  <soap:address location="http://localhost:9000"/>
</port>
</service>
</definitions>
CHAPTER 9. SENDING BINARY DATA WITH SOAP MTOM

Abstract

SOAP Message Transmission Optimization Mechanism (MTOM) replaces SOAP with attachments as a mechanism for sending binary data as part of an XML message. Using MTOM with Apache CXF requires adding the correct schema types to a service's contract and enabling the MTOM optimizations.

9.1. OVERVIEW OF MTOM

SOAP Message Transmission Optimization Mechanism (MTOM) specifies an optimized method for sending binary data as part of a SOAP message. Unlike SOAP with Attachments, MTOM requires the use of XML-binary Optimized Packaging (XOP) packages for transmitting binary data. Using MTOM to send binary data does not require you to fully define the MIME Multipart/Related message as part of the SOAP binding. It does, however, require that you do the following:

1. **Annotate** the data that you are going to send as an attachment. You can annotate either your WSDL or the Java class that implements your data.

2. **Enable** the runtime's MTOM support. This can be done either programmatically or through configuration.

3. Develop a **DataHandler** for the data being passed as an attachment.

**NOTE**

Developing **DataHandler**s is beyond the scope of this book.

9.2. ANNOTATING DATA TYPES TO USE MTOM

Overview

In WSDL, when defining a data type for passing along a block of binary data, such as an image file or a sound file, you define the element for the data to be of type `xsd:base64Binary`. By default, any element of type `xsd:base64Binary` results in the generation of a `byte[]` which can be serialized using MTOM. However, the default behavior of the code generators does not take full advantage of the serialization.

In order to fully take advantage of MTOM you must add annotations to either your service’s WSDL document or the JAXB class that implements the binary data structure. Adding the annotations to the WSDL document forces the code generators to generate streaming data handlers for the binary data. Annotating the JAXB class involves specifying the proper content types and might also involve changing the type specification of the field containing the binary data.

WSDL first

Example 9.1, "Message for MTOM" shows a WSDL document for a Web service that uses a message which contains one string field, one integer field, and a binary field. The binary field is intended to carry a large image file, so it is not appropriate to send it as part of a normal SOAP message.

```xml
<?xml version="1.0" encoding="UTF-8"?>
```
If you want to use MTOM to send the binary part of the message as an optimized attachment you must add the `xmime:expectedContentTypes` attribute to the element containing the binary data. This attribute is defined in the `http://www.w3.org/2005/05/xmime` namespace and specifies the MIME types that the element is expected to contain. You can specify a comma separated list of MIME types.
The setting of this attribute changes how the code generators create the JAXB class for the data. For most MIME types, the code generator creates a DataHandler. Some MIME types, such as those for images, have defined mappings.

**NOTE**

The MIME types are maintained by the Internet Assigned Numbers Authority (IANA) and are described in detail in *Multipurpose Internet Mail Extensions (MIME) Part One: Format of Internet Message Bodies* and *Multipurpose Internet Mail Extensions (MIME) Part Two: Media Types*.

For most uses you specify **application/octet-stream**.

Example 9.2, "Binary Data for MTOM" shows how you can modify the `xRayType` from Example 9.1, "Message for MTOM" for using MTOM.

**Example 9.2. Binary Data for MTOM**

```xml
...<types>
    <schema targetNamespace="http://mediStor.org/types/"
        xmlns="http://www.w3.org/2001/XMLSchema"
        xmlns:xmime="http://www.w3.org/2005/05/xmlmime">
        <complexType name="xRayType">
            <sequence>
                <element name="patientName" type="xsd:string" />
                <element name="patientNumber" type="xsd:int" />
                <element name="imageData" type="xsd:base64Binary"
                    xmime:expectedContentTypes="application/octet-stream"/>
            </sequence>
        </complexType>
    </schema>
</types>
...```

The generated JAXB class generated for `xRayType` no longer contains a `byte[]`. Instead the code generator sees the `xmime:expectedContentTypes` attribute and generates a DataHandler for the `imageData` field.

**NOTE**

You do not need to change the `binding` element to use MTOM. The runtime makes the appropriate changes when the data is sent.

**Java first**

If you are doing Java first development you can make your JAXB class MTOM ready by doing the following:

1. Make sure the field holding the binary data is a DataHandler.
2. Add the `@XmlMimeType()` annotation to the field containing the data you want to stream as an MTOM attachment.

Example 9.3, “JAXB Class for MTOM” shows a JAXB class annotated for using MTOM.

```
Example 9.3. JAXB Class for MTOM

@XmlElement
public class XRayType {
    protected String patientName;
    protected int patientNumber;
    @XmlMimeType("application/octet-stream")
    protected DataHandler imageData;
    ...
}
```

9.3. ENABLING MTOM

By default the Apache CXF runtime does not enable MTOM support. It sends all binary data as either part of the normal SOAP message or as an unoptimized attachment. You can activate MTOM support either programmatically or through the use of configuration.

9.3.1. Using JAX-WS APIs

Overview

Both service providers and consumers must have the MTOM optimizations enabled. The JAX-WS APIs offer different mechanisms for each type of endpoint.

Service provider

If you published your service provider using the JAX-WS APIs you enable the runtime’s MTOM support as follows:

1. Access the `Endpoint` object for your published service.
   The easiest way to access the `Endpoint` object is when you publish the endpoint. For more information see Chapter 31, Publishing a Service.

2. Get the SOAP binding from the `Endpoint` using its `getBinding()` method, as shown in Example 9.4, “Getting the SOAP Binding from an Endpoint”.

   ```java
   // Endpoint ep is declared previously
   SOAPBinding binding = (SOAPBinding)ep.getBinding();
   ```

   You must cast the returned binding object to a `SOAPBinding` object to access the MTOM property.

3. Set the binding’s MTOM enabled property to `true` using the binding’s `setMTOMEnabled()` method, as shown in Example 9.5, “Setting a Service Provider’s MTOM Enabled Property”.
Example 9.5. Setting a Service Provider’s MTOM Enabled Property

binding.setMTOMEnabled(true);

Consumer

To MTOM enable a JAX-WS consumer you must do the following:

1. Cast the consumer’s proxy to a BindingProvider object.
   For information on getting a consumer proxy see Chapter 25, Developing a Consumer Without a WSDL Contract or Chapter 28, Developing a Consumer From a WSDL Contract.

2. Get the SOAP binding from the BindingProvider using its getBinding() method, as shown in Example 9.6, “Getting a SOAP Binding from a BindingProvider”.

Example 9.6. Getting a SOAP Binding from a BindingProvider

// BindingProvider bp declared previously
SOAPBinding binding = (SOAPBinding)bp.getBinding();

3. Set the bindings MTOM enabled property to true using the binding’s setMTOMEnabled() method, as shown in Example 9.7, “Setting a Consumer’s MTOM Enabled Property”.

Example 9.7. Setting a Consumer’s MTOM Enabled Property

binding.setMTOMEnabled(true);

9.3.2. Using configuration

Overview

If you publish your service using XML, such as when deploying to a container, you can enable your endpoint’s MTOM support in the endpoint’s configuration file. For more information on configuring endpoint’s see Part IV, “Configuring Web Service Endpoints”.

Procedure

The MTOM property is set inside the jaxws:endpoint element for your endpoint. To enable MTOM do the following:

1. Add a jaxws:property child element to the endpoint’s jaxws:endpoint element.

2. Add a entry child element to the jaxws:property element.

3. Set the entry element’s key attribute to mtom-enabled.

4. Set the entry element’s value attribute to true.

Example
Example 9.8, "Configuration for Enabling MTOM" shows an endpoint that is MTOM enabled.

Example 9.8. Configuration for Enabling MTOM

```xml
<beans xmlns="http://www.springframework.org/schema/beans"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xmlns:jaxws="http://cxf.apache.org/jaxws"
    xsi:schemaLocation="http://www.springframework.org/schema/beans
    http://www.springframework.org/schema/beans/spring-beans-2.0.xsd

    <jaxws:endpoint id="xRayStorage"
        implementor="demo.spring.xRayStorImpl"
        address="http://localhost/xRayStorage">
        <jaxws:properties>
            <entry key="mtom-enabled" value="true"/>
        </jaxws:properties>
    </jaxws:endpoint>

</beans>
```
CHAPTER 10. USING XML DOCUMENTS

Abstract

The pure XML payload format provides an alternative to the SOAP binding by allowing services to exchange data using straight XML documents without the overhead of a SOAP envelope.

XML BINDING NAMESPACE

The extensions used to describe XML format bindings are defined in the namespace http://cxf.apache.org/bindings/xformat. Apache CXF tools use the prefix xformat to represent the XML binding extensions. Add the following line to your contracts:

```xml
xmlns:xformat="http://cxf.apache.org/bindings/xformat"
```

HAND EDITING

To map an interface to a pure XML payload format do the following:

1. Add the namespace declaration to include the extensions defining the XML binding. See the section called “XML binding namespace”.

2. Add a standard WSDL binding element to your contract to hold the XML binding, give the binding a unique name, and specify the name of the WSDL portType element that represents the interface being bound.

3. Add an xformat:binding child element to the binding element to identify that the messages are being handled as pure XML documents without SOAP envelopes.

4. Optionally, set the xformat:binding element’s rootNode attribute to a valid QName. For more information on the effect of the rootNode attribute see the section called “XML messages on the wire”.

5. For each operation defined in the bound interface, add a standard WSDL operation element to hold the binding information for the operation’s messages.

6. For each operation added to the binding, add the input, output, and fault children elements to represent the messages used by the operation. These elements correspond to the messages defined in the interface definition of the logical operation.

7. Optionally add an xformat:body element with a valid rootNode attribute to the added input, output, and fault elements to override the value of rootNode set at the binding level.

NOTE

If any of your messages have no parts, for example the output message for an operation that returns void, you must set the rootNode attribute for the message to ensure that the message written on the wire is a valid, but empty, XML document.

XML MESSAGES ON THE WIRE

When you specify that an interface’s messages are to be passed as XML documents, without a SOAP
envelope, you must take care to ensure that your messages form valid XML documents when they are written on the wire. You also need to ensure that non-Apache CXF participants that receive the XML documents understand the messages generated by Apache CXF.

A simple way to solve both problems is to use the optional rootNode attribute on either the global xformat:binding element or on the individual message’s xformat:body elements. The rootNode attribute specifies the QName for the element that serves as the root node for the XML document generated by Apache CXF. When the rootNode attribute is not set, Apache CXF uses the root element of the message part as the root element when using doc style messages, or an element using the message part name as the root element when using rpc style messages.

For example, if the rootNode attribute is not set the message defined in Example 10.1, “Valid XML Binding Message” would generate an XML document with the root element lineNumber.

Example 10.1. Valid XML Binding Message

```xml
<type ...
    ...
    <element name="operatorID" type="xsd:int"/>
    ...
</types>
<message name="operator">
    <part name="lineNumber" element="ns1:operatorID"/>
</message>
```

For messages with one part, Apache CXF will always generate a valid XML document even if the rootNode attribute is not set. However, the message in Example 10.2, “Invalid XML Binding Message” would generate an invalid XML document.

Example 10.2. Invalid XML Binding Message

```xml
<types>
    ...
    <element name="pairName" type="xsd:string"/>
    <element name="entryNum" type="xsd:int"/>
    ...
</types>
<message name="matildas">
    <part name="dancing" element="ns1:pairName"/>
    <part name="number" element="ns1:entryNum"/>
</message>
```

Without the rootNode attribute specified in the XML binding, Apache CXF will generate an XML document similar to Example 10.3, "Invalid XML Document” for the message defined in Example 10.2, “Invalid XML Binding Message”. The generated XML document is invalid because it has two root elements: pairName and entryNum.

Example 10.3. Invalid XML Document

```xml
<pairName>
    Fred&Linda
</pairName>
```
If you set the `rootNode` attribute, as shown in Example 10.4, “XML Binding with rootNode set” Apache CXF will wrap the elements in the specified root element. In this example, the `rootNode` attribute is defined for the entire binding and specifies that the root element will be named `entrants`.

Example 10.4. XML Binding with rootNode set

```xml
<portType name="danceParty">
  <operation name="register">
    <input message="tns:matildas" name="contestant"/>
  </operation>
</portType>

<binding name="matildaXMLBinding" type="tns:dancingMatildas">
  <xmlformat:binding rootNode="entrants"/>
  <operation name="register">
    <input name="contestant"/>
    <output name="entered"/>
  </operation>
</binding>
```

An XML document generated from the input message would be similar to Example 10.5, “XML Document generated using the rootNode attribute”. Notice that the XML document now only has one root element.

Example 10.5. XML Document generated using the rootNode attribute

```xml
<entrants>
  <pairName>
    Fred&Linda
  </pairName>
  <entryNum>
    123
  </entryNum>
</entrants>
```

**OVERRIDING THE BINDING’S ROOTNODE ATTRIBUTE SETTING**

You can also set the `rootNode` attribute for each individual message, or override the global setting for a particular message, by using the `xformat:body` element inside of the message binding. For example, if you wanted the output message defined in Example 10.4, “XML Binding with rootNode set” to have a different root element from the input message, you could override the binding’s root element as shown in Example 10.6, “Using xformat:body”.

Example 10.6. Using xformat:body

```xml
<binding name="matildaXMLBinding" type="tns:dancingMatildas">
  <xmlformat:binding rootNode="entrants"/>
```
<operation name="register">
  <input name="contestant"/>
  <output name="entered">
    <xformat:body rootNode="entryStatus" />
  </output>
</operation>
</binding>
PART III. WEB SERVICES TRANSPORTS

This part describes how to add Apache CXF transports to a WSDL document.
CHAPTER 11. UNDERSTANDING HOW ENDPOINTS ARE DEFINED IN WSDL

Abstract

Endpoints represent an instantiated service. They are defined by combining a binding and the networking details used to expose the endpoint.

OVERVIEW

An endpoint can be thought of as a physical manifestation of a service. It combines a binding, which specifies the physical representation of the logical data used by a service, and a set of networking details that define the physical connection details used to make the service contactable by other endpoints.

NOTE

CXF providers are servers for CXF consumers, which correspond to clients. If you are using the CXF (camel-cxf) component as the starting endpoint in a route, then the endpoint is both a Camel consumer and a CXF provider. If you are using the Camel CXF component, as an ending endpoint in a route, then the endpoint is both a Camel producer and a CXF consumer.

ENDPOINTS AND SERVICES

In the same way a binding can only map a single interface, an endpoint can only map to a single service. However, a service can be manifested by any number of endpoints. For example, you could define a ticket selling service that was manifested by four different endpoints. However, you could not have a single endpoint that manifested both a ticket selling service and a widget selling service.

THE WSDL ELEMENTS

Endpoints are defined in a contract using a combination of the WSDL service element and the WSDL port element. The service element is a collection of related port elements. The port elements define the actual endpoints.

The WSDL service element has a single attribute, name, that specifies a unique name. The service element is used as the parent element of a collection of related port elements. WSDL makes no specification about how the port elements are related. You can associate the port elements in any manner you see fit.

The WSDL port element has a has a binding attribute, that specifies the binding used by the endpoint and is a reference to the wsdl:binding element. It also includes the name attribute, which is a mandatory attribute that provides a unique name among all ports. The port element is the parent element of the elements that specify the actual transport details used by the endpoint. The elements used to specify the transport details are discussed in the following sections.

ADDING ENDPOINTS TO A CONTRACT

Apache CXF provides command line tools that can generated endpoints for predefined service interface and binding combinations.
The tools will add the proper elements to your contract for you. However, it is recommended that you have some knowledge of how the different transports used in defining an endpoint work.

You can also add an endpoint to a contract using any text editor. When you hand edit a contract, you are responsible for ensuring that the contract is valid.

**SUPPORTED TRANSPORTS**

Endpoint definitions are built using extensions defined for each of the transports Apache CXF supports. This includes the following transports:

- HTTP
- CORBA
- Java Messaging Service
CHAPTER 12. USING HTTP

Abstract

HTTP is the underlying transport for the Web. It provides a standardized, robust, and flexible platform for communicating between endpoints. Because of these factors it is the assumed transport for most WS-* specifications and is integral to RESTful architectures.

12.1. ADDING A BASIC HTTP ENDPOINT

Alternative HTTP runtimes

Apache CXF supports the following alternative HTTP runtime implementations:

- **Undertow**, which is described in detail in Section 12.4, “Configuring the Undertow Runtime”.
- **Netty**, which is described in detail in Section 12.5, “Configuring the Netty Runtime”.

Netty HTTP URL

Normally, a HTTP endpoint uses whichever HTTP runtime is included on the classpath (either Undertow or Netty). If both the Undertow runtime and Netty runtime are included on the classpath, however, you need to specify explicitly when you want to use the Netty runtime, because the Undertow runtime will be used by default.

In the case where more than one HTTP runtime is available on the classpath, you can select the Undertow runtime by specifying the endpoint URL to have the following format:

```
netty://http://RestOfURL
```

Payload types

There are three ways of specifying an HTTP endpoint’s address depending on the payload format you are using.

- SOAP 1.1 uses the standardized `soap:address` element.
- SOAP 1.2 uses the `soap12:address` element.
- All other payload formats use the `http:address` element.

**NOTE**

From Camel 2.16.0 release, Apache Camel CXF Payload supports stream cache out of box.

SOAP 1.1

When you are sending SOAP 1.1 messages over HTTP you must use the SOAP 1.1 `address` element to specify the endpoint’s address. It has one attribute, `location`, that specifies the endpoint’s address as a URL. The SOAP 1.1 `address` element is defined in the namespace `http://schemas.xmlsoap.org/wsd1/soap/`. 
Example 12.1, “SOAP 1.1 Port Element” shows a port element used to send SOAP 1.1 messages over HTTP.

```xml
<definitions ...
  xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap/" ...>
...
<service name="SOAP11Service">
  <port binding="SOAP11Binding" name="SOAP11Port">
    <soap:address location="http://artie.com/index.xml">
  </port>
</service>
...
<definitions>
```

SOAP 1.2

When you are sending SOAP 1.2 messages over HTTP you must use the SOAP 1.2 address element to specify the endpoint’s address. It has one attribute, location, that specifies the endpoint’s address as a URL. The SOAP 1.2 address element is defined in the namespace http://schemas.xmlsoap.org/wsdl/soap12/.

Example 12.2, “SOAP 1.2 Port Element” shows a port element used to send SOAP 1.2 messages over HTTP.

```xml
<definitions ...
  xmlns:soap12="http://schemas.xmlsoap.org/wsdl/soap12/" ...>
<service name="SOAP12Service">
  <port binding="SOAP12Binding" name="SOAP12Port">
    <soap12:address location="http://artie.com/index.xml">
  </port>
</service>
...
</definitions>
```

Other messages types

When your messages are mapped to any payload format other than SOAP you must use the HTTP address element to specify the endpoint’s address. It has one attribute, location, that specifies the endpoint’s address as a URL. The HTTP address element is defined in the namespace http://schemas.xmlsoap.org/wsdl/http/.

Example 12.3, “HTTP Port Element” shows a port element used to send an XML message.

```xml
<definitions ...
  xmlns:http="http://schemas.xmlsoap.org/wsdl/http/" ...>
```
12.2. CONFIGURING A CONSUMER

12.2.1. Mechanisms for HTTP Consumer Endpoints

HTTP consumer endpoints can specify a number of HTTP connection attributes including whether the endpoint automatically accepts redirect responses, whether the endpoint can use chunking, whether the endpoint will request a keep-alive, and how the endpoint interacts with proxies. In addition to the HTTP connection properties, an HTTP consumer endpoint can specify how it is secured.

A consumer endpoint can be configured using two mechanisms:

- **Configuration**
- **WSDL**

12.2.2. Using Configuration

Namespace

The elements used to configure an HTTP consumer endpoint are defined in the namespace http://cxf.apache.org/transports/http/configuration. It is commonly referred to using the prefix `http-conf`. In order to use the HTTP configuration elements you must add the lines shown in Example 12.4, “HTTP Consumer Configuration Namespace” to the `beans` element of your endpoint’s configuration file. In addition, you must add the configuration elements’ namespace to the `xsi:schemaLocation` attribute.

**Example 12.4. HTTP Consumer Configuration Namespace**

```xml
<beans ... ...
    xsi:schemaLocation="...
    http://cxf.apache.org/transports/http/configuration
    http://cxf.apache.org/schemas/configuration/http-conf.xsd
    ...
">

**Undertow runtime or Netty runtime**

You can use the elements from the `http-conf` namespace to configure either the Undertow runtime or the Netty runtime.

**The conduit element**
You configure an HTTP consumer endpoint using the `http-conf:conduit` element and its children. The `http-conf:conduit` element takes a single attribute, `name`, that specifies the WSDL `port` element corresponding to the endpoint. The value for the `name` attribute takes the form `portQName` `.http-conduit`. Example 12.5, “http-conf:conduit Element” shows the `http-conf:conduit` element that would be used to add configuration for an endpoint that is specified by the WSDL fragment `<port binding="widgetSOAPBinding" name="widgetSOAPPort> when the endpoint’s target namespace is http://widgets.widgetvendor.net.

Example 12.5. http-conf:conduit Element

```xml
...<http-conf:conduit name="{http://widgets/widgetvendor.net}widgetSOAPPort.http-conduit">
  ...
</http-conf:conduit>
...```

The `http-conf:conduit` element has child elements that specify configuration information. They are described in Table 12.1, “Elements Used to Configure an HTTP Consumer Endpoint”.

Table 12.1. Elements Used to Configure an HTTP Consumer Endpoint

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>http-conf:client</code></td>
<td>Specifies the HTTP connection properties such as timeouts, keep-alive requests, content types, etc. See the section called “The client element”.</td>
</tr>
<tr>
<td><code>http-conf:authorization</code></td>
<td>Specifies the parameters for configuring the basic authentication method that the endpoint uses preemptively. The preferred approach is to supply a http-conf:basicAuthSupplier object.</td>
</tr>
<tr>
<td><code>http-conf:proxyAuthorization</code></td>
<td>Specifies the parameters for configuring basic authentication against outgoing HTTP proxy servers.</td>
</tr>
<tr>
<td><code>http-conf:tlsClientParameters</code></td>
<td>Specifies the parameters used to configure SSL/TLS.</td>
</tr>
<tr>
<td><code>http-conf:basicAuthSupplier</code></td>
<td>Specifies the bean reference or class name of the object that supplies the basic authentication information used by the endpoint, either preemptively or in response to a 401 HTTP challenge.</td>
</tr>
<tr>
<td><code>http-conf:trustDecider</code></td>
<td>Specifies the bean reference or class name of the object that checks the HTTP(S) URLConnection object to establish trust for a connection with an HTTPS service provider before any information is transmitted.</td>
</tr>
</tbody>
</table>

The client element
The `http-conf:client` element is used to configure the non-security properties of a consumer endpoint’s HTTP connection. Its attributes, described in Table 12.2, “HTTP Consumer Configuration Attributes”, specify the connection’s properties.

### Table 12.2. HTTP Consumer Configuration Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
</table>
| ConnectionTimeout | Specifies the amount of time, in milliseconds, that the consumer attempts to establish a connection before it times out. The default is **30000**.  
|                 | **0** specifies that the consumer will continue to send the request indefinitely.                                                             |
| ReceiveTimeout   | Specifies the amount of time, in milliseconds, that the consumer will wait for a response before it times out. The default is **30000**.           
|                 | **0** specifies that the consumer will wait indefinitely.                                                                                     |
| AutoRedirect     | Specifies if the consumer will automatically follow a server issued redirection. The default is **false**.                                      |
| MaxRetransmits   | Specifies the maximum number of times a consumer will retransmit a request to satisfy a redirect. The default is **-1** which specifies that unlimited retransmissions are allowed. |
| AllowChunking    | Specifies whether the consumer will send requests using chunking. The default is **true** which specifies that the consumer will use chunking when sending requests.  
|                 | Chunking cannot be used if either of the following are true:  
|                 | - `http-conf:basicAuthSupplier` is configured to provide credentials preemptively.                                                            
|                 | - `AutoRedirect` is set to **true**.                                                                                                          
<p>|                 | In both cases the value of <code>AllowChunking</code> is ignored and chunking is disallowed.                                                             |
| Accept          | Specifies what media types the consumer is prepared to handle. The value is used as the value of the HTTP <code>Accept</code> property. The value of the attribute is specified using multipurpose internet mail extensions (MIME) types. |</p>
<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
</table>
| **AcceptLanguage** | Specifies what language (for example, American English) the consumer prefers for the purpose of receiving a response. The value is used as the value of the HTTP `AcceptLanguage` property.  
Language tags are regulated by the International Organization for Standards (ISO) and are typically formed by combining a language code, determined by the ISO-639 standard, and country code, determined by the ISO-3166 standard, separated by a hyphen. For example, en-US represents American English. |
| **AcceptEncoding** | Specifies what content encodings the consumer is prepared to handle. Content encoding labels are regulated by the Internet Assigned Numbers Authority (IANA). The value is used as the value of the HTTP `AcceptEncoding` property. |
| **ContentType**  | Specifies the media type of the data being sent in the body of a message. Media types are specified using multipurpose internet mail extensions (MIME) types. The value is used as the value of the HTTP `ContentType` property. The default is `text/xml`.  
For web services, this should be set to `text/xml`. If the client is sending HTML form data to a CGI script, this should be set to `application/x-www-form-urlencoded`. If the HTTP POST request is bound to a fixed payload format (as opposed to SOAP), the content type is typically set to `application/octet-stream`. |
| **Host**         | Specifies the Internet host and port number of the resource on which the request is being invoked. The value is used as the value of the HTTP `Host` property.  
This attribute is typically not required. It is only required by certain DNS scenarios or application designs. For example, it indicates what host the client prefers for clusters (that is, for virtual servers mapping to the same Internet protocol (IP) address). |
<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connection</td>
<td>Specifies whether a particular connection is to be kept open or closed after each request/response dialog. There are two valid values:</td>
</tr>
<tr>
<td></td>
<td>- <strong>Keep-Alive</strong> — Specifies that the consumer wants the connection kept open after the initial request/response sequence. If the server honors it, the connection is kept open until the consumer closes it.</td>
</tr>
<tr>
<td></td>
<td>- <strong>close</strong> (default) — Specifies that the connection to the server is closed after each request/response sequence.</td>
</tr>
<tr>
<td>CacheControl</td>
<td>Specifies directives about the behavior that must be adhered to by caches involved in the chain comprising a request from a consumer to a service provider. See Section 12.2.4, &quot;Consumer Cache Control Directives&quot;.</td>
</tr>
<tr>
<td>Cookie</td>
<td>Specifies a static cookie to be sent with all requests.</td>
</tr>
<tr>
<td>BrowserType</td>
<td>Specifies information about the browser from which the request originates. In the HTTP specification from the World Wide Web consortium (W3C) this is also known as the <strong>user-agent</strong>. Some servers optimize based on the client that is sending the request.</td>
</tr>
<tr>
<td>Referer</td>
<td>Specifies the URL of the resource that directed the consumer to make requests on a particular service. The value is used as the value of the HTTP Referer property.</td>
</tr>
<tr>
<td></td>
<td>This HTTP property is used when a request is the result of a browser user clicking on a hyperlink rather than typing a URL. This can allow the server to optimize processing based upon previous task flow, and to generate lists of back-links to resources for the purposes of logging, optimized caching, tracing of obsolete or mistyped links, and so on. However, it is typically not used in web services applications.</td>
</tr>
<tr>
<td></td>
<td>If the <strong>AutoRedirect</strong> attribute is set to <strong>true</strong> and the request is redirected, any value specified in the <strong>Referer</strong> attribute is overridden. The value of the HTTP Referer property is set to the URL of the service that redirected the consumer’s original request.</td>
</tr>
<tr>
<td>Attribute</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>DecoupledEndpoint</td>
<td>Specifies the URL of a decoupled endpoint for the receipt of responses over a separate provider→consumer connection. For more information on using decoupled endpoints see, Section 12.6, “Using the HTTP Transport in Decoupled Mode”. You must configure both the consumer endpoint and the service provider endpoint to use WS-Addressing for the decoupled endpoint to work.</td>
</tr>
<tr>
<td>ProxyServer</td>
<td>Specifies the URL of the proxy server through which requests are routed.</td>
</tr>
<tr>
<td>ProxyServerPort</td>
<td>Specifies the port number of the proxy server through which requests are routed.</td>
</tr>
</tbody>
</table>
| ProxyServerType     | Specifies the type of proxy server used to route requests. Valid values are:  
  - HTTP (default)  
  - SOCKS                                                                                                                                   |

### Example

**Example 12.6, “HTTP Consumer Endpoint Configuration”** shows the configuration of an HTTP consumer endpoint that wants to keep its connection to the provider open between requests, that will only retransmit requests once per invocation, and that cannot use chunking streams.

#### Example 12.6. HTTP Consumer Endpoint Configuration

```xml
<beans xmlns="http://www.springframework.org/schema/beans"  
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"  
  xsi:schemaLocation="http://cxf.apache.org/transports/http/configuration  
  http://cxf.apache.org/schemas/configuration/http-conf.xsd  
  http://www.springframework.org/schema/beans  
  http://www.springframework.org/schema/beans/spring-beans.xsd">  
    <http-conf:client Connection="Keep-Alive"  
      MaxRetransmits="1"  
      AllowChunking="false" />  
  </http-conf:conduit>  
</beans>
```

More information
For more information on HTTP conduits see Chapter 16, Conduits.

12.2.3. Using WSDL

Namespace

The WSDL extension elements used to configure an HTTP consumer endpoint are defined in the namespace http://cxf.apache.org/transports/http/configuration. It is commonly referred to using the prefix http-conf. In order to use the HTTP configuration elements you must add the line shown in Example 12.7, “HTTP Consumer WSDL Element’s Namespace” to the definitions element of your endpoint’s WSDL document.

Example 12.7. HTTP Consumer WSDL Element’s Namespace

```xml
<definitions ...>
</definitions>
```

Undertow runtime or Netty runtime

You can use the elements from the http-conf namespace to configure either the Undertow runtime or the Netty runtime.

The client element

The http-conf:client element is used to specify the connection properties of an HTTP consumer in a WSDL document. The http-conf:client element is a child of the WSDL port element. It has the same attributes as the client element used in the configuration file. The attributes are described in Table 12.2, “HTTP Consumer Configuration Attributes”.

Example

Example 12.8, “WSDL to Configure an HTTP Consumer Endpoint” shows a WSDL fragment that configures an HTTP consumer endpoint to specify that it does not interact with caches.

Example 12.8. WSDL to Configure an HTTP Consumer Endpoint

```xml
<service ... />
<port ...>
    <soap:address ... />
    <http-conf:client CacheControl="no-cache"/>
</port>
</service>
```

12.2.4. Consumer Cache Control Directives

Table 12.3, “http-conf:client Cache Control Directives” lists the cache control directives supported by an HTTP consumer.

Table 12.3. http-conf:client Cache Control Directives
### Directive

<table>
<thead>
<tr>
<th>Directive</th>
<th>Behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td>no-cache</td>
<td>Caches cannot use a particular response to satisfy subsequent requests without first revalidating that response with the server. If specific response header fields are specified with this value, the restriction applies only to those header fields within the response. If no response header fields are specified, the restriction applies to the entire response.</td>
</tr>
<tr>
<td>no-store</td>
<td>Caches must not store either any part of a response or any part of the request that invoked it.</td>
</tr>
<tr>
<td>max-age</td>
<td>The consumer can accept a response whose age is no greater than the specified time in seconds.</td>
</tr>
<tr>
<td>max-stale</td>
<td>The consumer can accept a response that has exceeded its expiration time. If a value is assigned to max-stale, it represents the number of seconds beyond the expiration time of a response up to which the consumer can still accept that response. If no value is assigned, the consumer can accept a stale response of any age.</td>
</tr>
<tr>
<td>min-fresh</td>
<td>The consumer wants a response that is still fresh for at least the specified number of seconds indicated.</td>
</tr>
<tr>
<td>no-transform</td>
<td>Caches must not modify media type or location of the content in a response between a provider and a consumer.</td>
</tr>
<tr>
<td>only-if-cached</td>
<td>Caches should return only responses that are currently stored in the cache, and not responses that need to be reloaded or revalidated.</td>
</tr>
<tr>
<td>cache-extension</td>
<td>Specifies additional extensions to the other cache directives. Extensions can be informational or behavioral. An extended directive is specified in the context of a standard directive, so that applications not understanding the extended directive can adhere to the behavior mandated by the standard directive.</td>
</tr>
</tbody>
</table>

### 12.3. CONFIGURING A SERVICE PROVIDER

#### 12.3.1. Mechanisms for a HTTP Service Provider

HTTP service provider endpoints can specify a number of HTTP connection attributes including if it will honor keep alive requests, how it interacts with caches, and how tolerant it is of errors in communicating with a consumer.

A service provider endpoint can be configured using two mechanisms:
12.3.2. Using Configuration

Namespace

The elements used to configure an HTTP provider endpoint are defined in the namespace `http://cxf.apache.org/transports/http/configuration`. It is commonly referred to using the prefix `http-conf`. In order to use the HTTP configuration elements you must add the lines shown in Example 12.9, “HTTP Provider Configuration Namespace” to the `beans` element of your endpoint’s configuration file. In addition, you must add the configuration elements’ namespace to the `xsi:schemaLocation` attribute.

Example 12.9. HTTP Provider Configuration Namespace

```xml
<beans ...
    ...
    xsi:schemaLocation="...
        http://cxf.apache.org/transports/http/configuration
        http://cxf.apache.org/schemas/configuration/http-conf.xsd
        ...
">

Undertow runtime or Netty runtime

You can use the elements from the `http-conf` namespace to configure either the Undertow runtime or the Netty runtime.

The destination element

You configure an HTTP service provider endpoint using the `http-conf:destination` element and its children. The `http-conf:destination` element takes a single attribute, `name`, that specifies the WSDL port element that corresponds to the endpoint. The value for the `name` attribute takes the form `portQName`. Example 12.10, “http-conf:destination Element” shows the `http-conf:destination` element that is used to add configuration for an endpoint that is specified by the WSDL fragment `<port binding="widgetSOAPBinding" name="widgetSOAPPort">` when the endpoint’s target namespace is `http://widgets.widgetvendor.net`.

Example 12.10. http-conf:destination Element

```xml
...
    ...
</http-conf:destination>
...
```

The `http-conf:destination` element has a number of child elements that specify configuration information. They are described in Table 12.4, “Elements Used to Configure an HTTP Service Provider Endpoint”.

Table 12.4. Elements Used to Configure an HTTP Service Provider Endpoint

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>http-conf:server</td>
<td>Specifies the HTTP connection properties. See the section called “The server element”.</td>
</tr>
<tr>
<td>http-conf:contextMatchStrategy</td>
<td>Specifies the parameters that configure the context match strategy for processing HTTP requests.</td>
</tr>
<tr>
<td>http-conf:fixedParameterOrder</td>
<td>Specifies whether the parameter order of an HTTP request handled by this destination is fixed.</td>
</tr>
</tbody>
</table>

The server element

The http-conf:server element is used to configure the properties of a service provider endpoint’s HTTP connection. Its attributes, described in Table 12.5, “HTTP Service Provider Configuration Attributes”, specify the connection’s properties.

Table 12.5. HTTP Service Provider Configuration Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ReceiveTimeout</td>
<td>Sets the length of time, in milliseconds, the service provider attempts to receive a request before the connection times out. The default is 30000. 0 specifies that the provider will not timeout.</td>
</tr>
<tr>
<td>SuppressClientSendErrors</td>
<td>Specifies whether exceptions are to be thrown when an error is encountered on receiving a request. The default is false; exceptions are thrown on encountering errors.</td>
</tr>
<tr>
<td>SuppressClientReceiveErrors</td>
<td>Specifies whether exceptions are to be thrown when an error is encountered on sending a response to a consumer. The default is false; exceptions are thrown on encountering errors.</td>
</tr>
<tr>
<td>HonorKeepAlive</td>
<td>Specifies whether the service provider honors requests for a connection to remain open after a response has been sent. The default is false; keep-alive requests are ignored.</td>
</tr>
<tr>
<td>Attribute</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>RedirectURL</td>
<td>Specifies the URL to which the client request should be redirected if the URL specified in the client request is no longer appropriate for the requested resource. In this case, if a status code is not automatically set in the first line of the server response, the status code is set to 302 and the status description is set to Object Moved. The value is used as the value of the HTTP RedirectURL property.</td>
</tr>
<tr>
<td>CacheControl</td>
<td>Specifies directives about the behavior that must be adhered to by caches involved in the chain comprising a response from a service provider to a consumer. See Section 12.3.4, “Service Provider Cache Control Directives”.</td>
</tr>
<tr>
<td>ContentLocation</td>
<td>Sets the URL where the resource being sent in a response is located.</td>
</tr>
<tr>
<td>ContentType</td>
<td>Specifies the media type of the information being sent in a response. Media types are specified using multipurpose internet mail extensions (MIME) types. The value is used as the value of the HTTP ContentType location.</td>
</tr>
<tr>
<td>ContentEncoding</td>
<td>Specifies any additional content encodings that have been applied to the information being sent by the service provider. Content encoding labels are regulated by the Internet Assigned Numbers Authority (IANA). Possible content encoding values include zip, gzip, compress, deflate, and identity. This value is used as the value of the HTTP ContentEncoding property. The primary use of content encodings is to allow documents to be compressed using some encoding mechanism, such as zip or gzip. Apache CXF performs no validation on content codings. It is the user’s responsibility to ensure that a specified content coding is supported at application level.</td>
</tr>
<tr>
<td>ServerType</td>
<td>Specifies what type of server is sending the response. Values take the form program-name/version, for example, Apache/1.2.5.</td>
</tr>
</tbody>
</table>

Example
Example 12.11, “HTTP Service Provider Endpoint Configuration” shows the configuration for an HTTP service provider endpoint that honors keep-alive requests and suppresses all communication errors.

Example 12.11. HTTP Service Provider Endpoint Configuration

```xml
<beans xmlns="http://www.springframework.org/schema/beans"
      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xsi:schemaLocation="http://cxf.apache.org/transports/http/configuration
http://cxf.apache.org/schemas/configuration/http-conf.xsd
http://www.springframework.org/schema/beans
http://www.springframework.org/schema/beans/spring-beans.xsd">
  <http-conf:destination name="{http://apache.org/hello_world_soap_http}SoapPort.http-destination">
    <http-conf:server SuppressClientSendErrors="true"
                      SuppressClientReceiveErrors="true"
                      HonorKeepAlive="true" />
  </http-conf:destination>
</beans>
```

12.3.3. Using WSDL

Namespace

The WSDL extension elements used to configure an HTTP provider endpoint are defined in the namespace http://cxf.apache.org/transports/http/configuration. It is commonly referred to using the prefix http-conf. To use the HTTP configuration elements you must add the line shown in Example 12.12, “HTTP Provider WSDL Element’s Namespace” to the definitions element of your endpoint’s WSDL document.

Example 12.12. HTTP Provider WSDL Element’s Namespace

```xml
<definitions ...
</definitions>
```

Undertow runtime or Netty runtime

You can use the elements from the http-conf namespace to configure either the Undertow runtime or the Netty runtime.

The server element

The http-conf:server element is used to specify the connection properties of an HTTP service provider in a WSDL document. The http-conf:server element is a child of the WSDL port element. It has the same attributes as the server element used in the configuration file. The attributes are described in Table 12.5, “HTTP Service Provider Configuration Attributes”.

Example
Example 12.13, “WSDL to Configure an HTTP Service Provider Endpoint” shows a WSDL fragment that configures an HTTP service provider endpoint specifying that it will not interact with caches.

Example 12.13. WSDL to Configure an HTTP Service Provider Endpoint

```
<service ... >
  <port ... >
    <soap:address .../>
    <http-conf:server CacheControl="no-cache"/>
  </port>
</service>
```

12.3.4. Service Provider Cache Control Directives

Table 12.6, “http-conf:server Cache Control Directives” lists the cache control directives supported by an HTTP service provider.

Table 12.6. http-conf:server Cache Control Directives

<table>
<thead>
<tr>
<th>Directive</th>
<th>Behavior</th>
</tr>
</thead>
<tbody>
<tr>
<td>no-cache</td>
<td>Caches cannot use a particular response to satisfy subsequent requests without first revalidating that response with the server. If specific response header fields are specified with this value, the restriction applies only to those header fields within the response. If no response header fields are specified, the restriction applies to the entire response.</td>
</tr>
<tr>
<td>public</td>
<td>Any cache can store the response.</td>
</tr>
<tr>
<td>private</td>
<td>Public (shared) caches cannot store the response because the response is intended for a single user. If specific response header fields are specified with this value, the restriction applies only to those header fields within the response. If no response header fields are specified, the restriction applies to the entire response.</td>
</tr>
<tr>
<td>no-store</td>
<td>Caches must not store any part of the response or any part of the request that invoked it.</td>
</tr>
<tr>
<td>no-transform</td>
<td>Caches must not modify the media type or location of the content in a response between a server and a client.</td>
</tr>
<tr>
<td>must-revalidate</td>
<td>Caches must revalidate expired entries that relate to a response before that entry can be used in a subsequent response.</td>
</tr>
</tbody>
</table>
### Directive | Behavior
--- | ---
proxy-revalidate | Does the same as must-revalidate, except that it can only be enforced on shared caches and is ignored by private unshared caches. When using this directive, the public cache directive must also be used.

max-age | Clients can accept a response whose age is no greater that the specified number of seconds.

s-max-age | Does the same as max-age, except that it can only be enforced on shared caches and is ignored by private unshared caches. The age specified by s-max-age overrides the age specified by max-age. When using this directive, the proxy-revalidate directive must also be used.

cache-extension | Specifies additional extensions to the other cache directives. Extensions can be informational or behavioral. An extended directive is specified in the context of a standard directive, so that applications not understanding the extended directive can adhere to the behavior mandated by the standard directive.

---

### 12.4. CONFIGURING THE UNDERTOW RUNTIME

#### Overview

The Undertow runtime is used by HTTP service providers and HTTP consumers using a decoupled endpoint. The runtime’s thread pool can be configured, and you can also set a number of the security settings for an HTTP service provider through the Undertow runtime.

#### Maven dependency

If you use Apache Maven as your build system, you can add the Undertow runtime to your project by including the following dependency in your project’s pom.xml file:

```xml
<dependency>
  <groupId>org.apache.cxf</groupId>
  <artifactId>cxf-rt-transports-http-undertow</artifactId>
  <version>${cxf-version}</version>
</dependency>
```

#### Namespace

The elements used to configure the Undertow runtime are defined in the namespace http://cxf.apache.org/transports/http-undertow/configuration. In order to use the Undertow configuration elements you must add the lines shown in Example 12.14, “Undertow Runtime
Configuration Namespace" to the beans element of your endpoint’s configuration file. In this example, the namespace is assigned the prefix httpu. In addition, you must add the configuration element’s namespace to the xsi:schemaLocation attribute.

```
<beans ... 
    xmlns:httpu="http://cxf.apache.org/transports/http-undertow/configuration"
    ... 
    xsi:schemaLocation="...
    http://cxf.apache.org/transports/http-undertow/configuration
    http://cxf.apache.org/schemas/configuration/http-undertow.xsd
    ..."> 
```

The engine-factory element

The httpu:engine-factory element is the root element used to configure the Undertow runtime used by an application. It has a single required attribute, bus, whose value is the name of the Bus that manages the Undertow instances being configured.

NOTE

The value is typically cxf which is the name of the default Bus instance.

The httpu:engine-factory element has three children that contain the information used to configure the HTTP ports instantiated by the Undertow runtime factory. The children are described in Table 12.7, “Elements for Configuring a Undertow Runtime Factory”.

Table 12.7. Elements for Configuring a Undertow Runtime Factory

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>httpu:engine</td>
<td>Specifies the configuration for a particular Undertow runtime instance. See the section called “The engine element”.</td>
</tr>
<tr>
<td>httpu:identifiedTLSServerParameters</td>
<td>Specifies a reusable set of properties for securing an HTTP service provider. It has a single attribute, id, that specifies a unique identifier by which the property set can be referred.</td>
</tr>
<tr>
<td>httpu:identifiedThreadingParameters</td>
<td>Specifies a reusable set of properties for controlling a Undertow instance’s thread pool. It has a single attribute, id, that specifies a unique identifier by which the property set can be referred.</td>
</tr>
</tbody>
</table>

See the section called “Configuring the thread pool”.

The engine element
The `httpu:engine` element is used to configure specific instances of the Undertow runtime. It has a single attribute, `port`, that specifies the number of the port being managed by the Undertow instance.

**NOTE**

You can specify a value of 0 for the `port` attribute. Any threading properties specified in an `httpu:engine` element with its `port` attribute set to 0 are used as the configuration for all Undertow listeners that are not explicitly configured.

Each `httpu:engine` element can have two children: one for configuring security properties and one for configuring the Undertow instance’s thread pool. For each type of configuration you can either directly provide the configuration information or you can provide a reference to a set of configuration properties defined in the parent `httpu:engine-factory` element.

The child elements used to provide the configuration properties are described in Table 12.8, “Elements for Configuring an Undertow Runtime Instance”.

**Table 12.8. Elements for Configuring an Undertow Runtime Instance**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>httpu:tlsServerParameters</code></td>
<td>Specifies a set of properties for configuring the security used for the specific Undertow instance.</td>
</tr>
<tr>
<td><code>httpu:tlsServerParametersRef</code></td>
<td>Refers to a set of security properties defined by a <code>identifiedTLSServerParameters</code> element. The <code>id</code> attribute provides the id of the referred <code>identifiedTLSServerParameters</code> element.</td>
</tr>
<tr>
<td><code>httpu:threadingParameters</code></td>
<td>Specifies the size of the thread pool used by the specific Undertow instance. See the section called “Configuring the thread pool”.</td>
</tr>
<tr>
<td><code>httpu:threadingParametersRef</code></td>
<td>Refers to a set of properties defined by a <code>identifiedThreadingParameters</code> element. The <code>id</code> attribute provides the id of the referred <code>identifiedThreadingParameters</code> element.</td>
</tr>
</tbody>
</table>

**Configuring the thread pool**

You can configure the size of an Undertow instance’s thread pool by either:

- Specifying the size of the thread pool using a `identifiedThreadingParameters` element in the `engine-factory` element. You then refer to the element using a `threadingParametersRef` element.

- Specifying the size of the thread pool directly using a `threadingParameters` element.

The `threadingParameters` has two attributes to specify the size of a thread pool. The attributes are described in Table 12.9, “Attributes for Configuring an Undertow Thread Pool”.

Red Hat Fuse 7.8 Apache CXF Development Guide
NOTE

The `http://identifiedThreadingParameters` element has a single child `threadingParameters` element.

Table 12.9. Attributes for Configuring an Undertow Thread Pool

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>workerIOThreads</code></td>
<td>Specifies the number of I/O threads to be created for the worker. If not specified, the default value will be chosen. The default value is one I/O thread per CPU core.</td>
</tr>
<tr>
<td><code>minThreads</code></td>
<td>Specifies the minimum number of threads available to the Undertow instance for processing requests.</td>
</tr>
<tr>
<td><code>maxThreads</code></td>
<td>Specifies the maximum number of threads available to the Undertow instance for processing requests.</td>
</tr>
</tbody>
</table>

Example

Example 12.15, "Configuring an Undertow Instance" shows a configuration fragment that configures an Undertow instance on port number 9001.

Example 12.15. Configuring an Undertow Instance

```xml
<beans xmlns="http://www.springframework.org/schema/beans"
       xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
       xmlns:sec="http://cxf.apache.org/configuration/security"
       xmlns:http="http://cxf.apache.org/transports/http/configuration"
       xmlns:httpu="http://cxf.apache.org/transports/http-undertow/configuration"
       xmlns:jaxws="http://java.sun.com/xml/ns/jaxws"
       xsi:schemaLocation="http://cxf.apache.org/configuration/security
       http://cxf.apache.org/schemas/configuration/security.xsd
       http://cxf.apache.org/transports/http/configuration
       http://cxf.apache.org/schemas/configuration/http-conf.xsd
       http://cxf.apache.org/transports/http-undertow/configuration
       http://cxf.apache.org/schemas/configuration/http-undertow.xsd
       http://www.springframework.org/schema/beans
       http://www.springframework.org/schema/beans/spring-beans-2.0.xsd">
  ...
  <httpu:engine-factory bus="cxf">
    <httpu:identifiedTLSServerParameters id="secure">
      <sec:keyManagers keyPassword="password">
        <sec:keyStore type="JKS" password="password"
            file="certs/cherry.jks"/>
      </sec:keyManagers>
    </httpu:identifiedTLSServerParameters>
  </httpu:engine-factory>
  <httpu:engine port="9001"/>
</beans>
```
12.5. CONFIGURING THE NETTY RUNTIME

Overview

The Netty runtime is used by HTTP service providers and HTTP consumers using a decoupled endpoint. The runtime's thread pool can be configured, and you can also set a number of the security settings for an HTTP service provider through the Netty runtime.

Maven dependencies

If you use Apache Maven as your build system, you can add the server-side implementation of the Netty runtime (for defining Web service endpoints) to your project by including the following dependency in your project’s pom.xml file:

```xml
<dependency>
  <groupId>org.apache.cxf</groupId>
  <artifactId>cxf-rt-transports-http-netty-server</artifactId>
  <version>${cxf-version}</version>
</dependency>
```

You can add the client-side implementation of the Netty runtime (for defining Web service clients) to your project by including the following dependency in your project’s pom.xml file:

```xml
<dependency>
  <groupId>org.apache.cxf</groupId>
  <artifactId>cxf-rt-transports-http-netty-client</artifactId>
  <version>${cxf-version}</version>
</dependency>
```

Namespace

The elements used to configure the Netty runtime are defined in the namespace http://cxf.apache.org/transports/http-netty-server/configuration. It is commonly referred to using the prefix httpn. In order to use the Netty configuration elements you must add the lines shown in Example 12.16, “Netty Runtime Configuration Namespace” to the beans element of your endpoint’s configuration file. In addition, you must add the configuration elements’ namespace to the xsi:schemaLocation attribute.

Example 12.16. Netty Runtime Configuration Namespace

```xml
<beans ...>
  xsi:schemaLocation="..."
...</beans>
```
The engine-factory element

The httpn:engine-factory element is the root element used to configure the Netty runtime used by an application. It has a single required attribute, `bus`, whose value is the name of the Bus that manages the Netty instances being configured.

NOTE

The value is typically `cxf`, which is the name of the default Bus instance.

The httpn:engine-factory element has three children that contain the information used to configure the HTTP ports instantiated by the Netty runtime factory. The children are described in Table 12.10, “Elements for Configuring a Netty Runtime Factory”.

Table 12.10. Elements for Configuring a Netty Runtime Factory

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>httpn:engine</td>
<td>Specifies the configuration for a particular Netty runtime instance. See the section called “The engine element”.</td>
</tr>
<tr>
<td>httpn:identifiedTLSServerParameters</td>
<td>Specifies a reusable set of properties for securing an HTTP service provider. It has a single attribute, <code>id</code>, that specifies a unique identifier by which the property set can be referred.</td>
</tr>
<tr>
<td>httpn:identifiedThreadingParameters</td>
<td>Specifies a reusable set of properties for controlling a Netty instance’s thread pool. It has a single attribute, <code>id</code>, that specifies a unique identifier by which the property set can be referred. See the section called “Configuring the thread pool.”</td>
</tr>
</tbody>
</table>

The engine element

The httpn:engine element is used to configure specific instances of the Netty runtime. Table 12.11, “Attributes for Configuring a Netty Runtime Instance” shows the attributes supported by the httpn:engine element.

Table 12.11. Attributes for Configuring a Netty Runtime Instance

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
</table>

**Attribute** | **Description**
---|---
**port** | Specifies the port used by the Netty HTTP server instance. You can specify a value of 0 for the port attribute. Any threading properties specified in an engine element with its port attribute set to 0 are used as the configuration for all Netty listeners that are not explicitly configured.

**host** | Specifies the listen address used by the Netty HTTP server instance. The value can be a hostname or an IP address. If not specified, Netty HTTP server will listen on all local addresses.

**readIdleTime** | Specifies the maximum read idle time for a Netty connection. The timer is reset whenever there are any read actions on the underlying stream.

**writeIdleTime** | Specifies the maximum write idle time for a Netty connection. The timer is reset whenever there are any write actions on the underlying stream.

**maxChunkContentSize** | Specifies the maximum aggregated content size for a Netty connection. The default value is 10MB.

A **httpn:engine** element has one child element for configuring security properties and one child element for configuring the Netty instance’s thread pool. For each type of configuration you can either directly provide the configuration information or you can provide a reference to a set of configuration properties defined in the parent **httpn:engine-factory** element.

The supported child elements of **httpn:engine** are shown in Table 12.12, “Elements for Configuring a Netty Runtime Instance”.

**Table 12.12. Elements for Configuring a Netty Runtime Instance**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>httpn:tlsServerParameters</strong></td>
<td>Specifies a set of properties for configuring the security used for the specific Netty instance.</td>
</tr>
<tr>
<td><strong>httpn:tlsServerParametersRef</strong></td>
<td>Refers to a set of security properties defined by a <strong>identifiedTLSServerParameters</strong> element. The <strong>id</strong> attribute provides the id of the referred <strong>identifiedTLSServerParameters</strong> element.</td>
</tr>
<tr>
<td><strong>httpn:threadingParameters</strong></td>
<td>Specifies the size of the thread pool used by the specific Netty instance. See the section called “Configuring the thread pool”.</td>
</tr>
</tbody>
</table>
### Element Description

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>httpn:threadingParametersRef</code></td>
<td>Refers to a set of properties defined by a <code>identifiedThreadingParameters</code> element. The <code>id</code> attribute provides the id of the referred <code>identifiedThreadingParameters</code> element.</td>
</tr>
<tr>
<td><code>httpn:sessionSupport</code></td>
<td>When <code>true</code>, enables support for HTTP sessions. Default is <code>false</code>.</td>
</tr>
<tr>
<td><code>httpn:reuseAddress</code></td>
<td>Specifies a boolean value to set the <code>ReuseAddress</code> TCP socket option. Default is <code>false</code>.</td>
</tr>
</tbody>
</table>

### Configuring the thread pool

You can configure the size of a Netty instance’s thread pool by either:

- Specifying the size of the thread pool using a `identifiedThreadingParameters` element in the `engine-factory` element. You then refer to the element using a `threadingParametersRef` element.

- Specifying the size of the thread pool directly using a `threadingParameters` element.

The `threadingParameters` element has one attribute to specify the size of a thread pool, as described in Table 12.13, “Attributes for Configuring a Netty Thread Pool”.

#### NOTE

The `httpn:identifiedThreadingParameters` element has a single child `threadingParameters` element.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>threadPoolSize</code></td>
<td>Specifies the number of threads available to the Netty instance for processing requests.</td>
</tr>
</tbody>
</table>

### Example

Example 12.17, “Configuring a Netty Instance” shows a configuration fragment that configures a variety of Netty ports.

```
<?xml version="1.0" encoding="UTF-8"?>
<beans xmlns="http://www.springframework.org/schema/beans"
       xmlns:bean="http://www.springframework.org/schema/beans"
>
```
12.6. USING THE HTTP TRANSPORT IN DECOUPLED MODE
Overview

In normal HTTP request/response scenarios, the request and the response are sent using the same HTTP connection. The service provider processes the request and responds with a response containing the appropriate HTTP status code and the contents of the response. In the case of a successful request, the HTTP status code is set to 200.

In some instances, such as when using WS-RM or when requests take an extended period of time to execute, it makes sense to decouple the request and response message. In this case the service providers sends the consumer a 202 Accepted response to the consumer over the back-channel of the HTTP connection on which the request was received. It then processes the request and sends the response back to the consumer using a new decoupled server→client HTTP connection. The consumer runtime receives the incoming response and correlates it with the appropriate request before returning to the application code.

Configuring decoupled interactions

Using the HTTP transport in decoupled mode requires that you do the following:

1. Configure the consumer to use WS-Addressing.
   See the section called “Configuring an endpoint to use WS-Addressing”.

2. Configure the consumer to use a decoupled endpoint.
   See the section called “Configuring the consumer”.

3. Configure any service providers that the consumer interacts with to use WS-Addressing.
   See the section called “Configuring an endpoint to use WS-Addressing”.

Configuring an endpoint to use WS-Addressing

Specify that the consumer and any service provider with which the consumer interacts use WS-Addressing.

You can specify that an endpoint uses WS-Addressing in one of two ways:

- Adding the `wswa:UsingAddressing` element to the endpoint’s WSDL `port` element as shown in Example 12.18, “Activating WS-Addressing using WSDL”.

  Example 12.18. Activating WS-Addressing using WSDL

  ```xml
  ...<service name="WidgetSOAPService">
  <port name="WidgetSOAPPort" binding="tns:WidgetSOAPBinding">
    <soap:address="http://widgetvendor.net/widgetSeller" />
    <wswa:UsingAddressing xmlns:wswa="http://www.w3.org/2005/02/addressing/wsdl"/>
  </port>
  </service>
  ...
  ```

- Adding the WS-Addressing policy to the endpoint’s WSDL `port` element as shown in Example 12.19, “Activating WS-Addressing using a Policy”.

  Example 12.19. Activating WS-Addressing using a Policy

  ```xml
  ...
<service name="WidgetSOAPService">
  <port name="WidgetSOAPPort" binding="tns:WidgetSOAPBinding">
    <soap:address="http://widgetvendor.net/widgetSeller" />
      <wsam:Addressing />
    </wsp:Policy>
  </port>
</service>

NOTE
The WS-Addressing policy supersedes the wswa:UsingAddressing WSDL element.

Configuring the consumer

Configure the consumer endpoint to use a decoupled endpoint using the DecoupledEndpoint attribute of the http-conf:conduit element.

Example 12.20, "Configuring a Consumer to Use a Decoupled HTTP Endpoint" shows the configuration for setting up the endpoint defined in Example 12.18, "Activating WS-Addressing using WSDL" to use a decoupled endpoint. The consumer now receives all responses at http://widgetvendor.net/widgetSellerInbox.

```xml
<beans xmlns="http://www.springframework.org/schema/beans"
       xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
       xmlns:http="http://cxf.apache.org/transports/http/configuration"
       xsi:schemaLocation="http://cxf.apache.org/transports/http/configuration
                          http://cxf.apache.org/schemas/configuration/http-conf.xsd
                          http://www.springframework.org/schema/beans
                          http://www.springframework.org/schema/beans/spring-beans.xsd">
  <http:conduit name="{http://widgetvendor.net/services}WidgetSOAPPort.http-conduit">
  </http:conduit>
</beans>
```

How messages are processed

Using the HTTP transport in decoupled mode adds extra layers of complexity to the processing of HTTP messages. While the added complexity is transparent to the implementation level code in an application, it might be important to understand what happens for debugging reasons.

Figure 12.1, "Message Flow in for a Decoupled HTTP Transport" shows the flow of messages when using HTTP in decoupled mode.
Figure 12.1. Message Flow in for a Decoupled HTTP Transport

A request starts the following process:

1. The consumer implementation invokes an operation and a request message is generated.

2. The WS-Addressing layer adds the WS-A headers to the message. When a decoupled endpoint is specified in the consumer’s configuration, the address of the decoupled endpoint is placed in the WS-A ReplyTo header.

3. The message is sent to the service provider.

4. The service provider receives the message.

5. The request message from the consumer is dispatched to the provider’s WS-A layer.

6. Because the WS-A ReplyTo header is not set to anonymous, the provider sends back a message with the HTTP status code set to 202, acknowledging that the request has been received.

7. The HTTP layer sends a 202 Accepted message back to the consumer using the original connection’s back-channel.

8. The consumer receives the 202 Accepted reply on the back-channel of the HTTP connection used to send the original message. When the consumer receives the 202 Accepted reply, the HTTP connection closes.

9. The request is passed to the service provider’s implementation where the request is processed.
10. When the response is ready, it is dispatched to the WS-A layer.

11. The WS-A layer adds the WS-Addressing headers to the response message.

12. The HTTP transport sends the response to the consumer’s decoupled endpoint.

13. The consumer’s decoupled endpoint receives the response from the service provider.

14. The response is dispatched to the consumer’s WS-A layer where it is correlated to the proper request using the WS-A RelatesTo header.

15. The correlated response is returned to the client implementation and the invoking call is unblocked.
CHAPTER 13. USING SOAP OVER JMS

Abstract

Apache CXF implements the W3C standard SOAP/JMS transport. This standard is intended to provide a more robust alternative to SOAP/HTTP services. Apache CXF applications using this transport should be able to interoperate with applications that also implement the SOAP/JMS standard. The transport is configured directly in an endpoint’s WSDL.

NOTE: Support for the JMS 1.0.2 APIs has been removed in CXF 3.0. If you are using Red Hat JBoss Fuse 6.2 or higher (includes CXF 3.0), your JMS provider must support the JMS 1.1 APIs.

13.1. BASIC CONFIGURATION

Overview

The SOAP over JMS protocol is defined by the World Wide Web Consortium (W3C) as a way of providing a more reliable transport layer to the customary SOAP/HTTP protocol used by most services. The Apache CXF implementation is fully compliant with the specification and should be compatible with any framework that is also compliant.

This transport uses JNDI to find the JMS destinations. When an operation is invoked, the request is packaged as a SOAP message and sent in the body of a JMS message to the specified destination.

To use the SOAP/JMS transport:

1. Specify that the transport type is SOAP/JMS.
2. Specify the target destination using a JMS URI.
3. Optionally, configure the JNDI connection.
4. Optionally, add additional JMS configuration.

Specifying the JMS transport type

You configure a SOAP binding to use the JMS transport when specifying the WSDL binding. You set the soap:binding element’s transport attribute to http://www.w3.org/2010/soapjms/. Example 13.1, “SOAP over JMS binding specification” shows a WSDL binding that uses SOAP/JMS.

Example 13.1. SOAP over JMS binding specification

```xml
<wSDL:binding ... >
 <soap:binding style="document"
      transport="http://www.w3.org/2010/soapjms/" />
 ... 
</wSDL:binding>
```

Specifying the target destination

You specify the address of the JMS target destination when specifying the WSDL port for the endpoint. The address specification for a SOAP/JMS endpoint uses the same soap:address element and
attribute as a SOAP/HTTP endpoint. The difference is the address specification. JMS endpoints use a JMS URI as defined in the URI Scheme for JMS 1.0. Example 13.2, “JMS URI syntax” shows the syntax for a JMS URI.

Example 13.2. JMS URI syntax

```
jms:variant:destination?options
```

Table 13.1, “JMS URI variants” describes the available variants for the JMS URI.

Table 13.1. JMS URI variants

<table>
<thead>
<tr>
<th>Variant</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>jndi</td>
<td>Specifies that the destination name is a JNDI queue name. When using this variant, you must provide the configuration for accessing the JNDI provider.</td>
</tr>
<tr>
<td>jndi-topic</td>
<td>Specifies that the destination name is a JNDI topic name. When using this variant, you must provide the configuration for accessing the JNDI provider.</td>
</tr>
<tr>
<td>queue</td>
<td>Specifies that the destination is a queue name resolved using JMS. The string provided is passed into <code>Session.createQueue()</code> to create a representation of the destination.</td>
</tr>
<tr>
<td>topic</td>
<td>Specifies that the destination is a topic name resolved using JMS. The string provided is passed into <code>Session.createTopic()</code> to create a representation of the destination.</td>
</tr>
</tbody>
</table>

The `options` portion of a JMS URI are used to configure the transport and are discussed in Section 13.2, “JMS URIs”.

Example 13.3, “SOAP/JMS endpoint address” shows the WSDL port entry for a SOAP/JMS endpoint whose target destination is looked up using JNDI.

Example 13.3. SOAP/JMS endpoint address

```
<wSDL:port ...>
...
<soap:address location="jms:jndi:dynamicQueues/test.cxf.jmstransport.queue"/>
</wsdl:port>
```

Configuring JNDI and the JMS transport

The SOAP/JMS provides several ways to configure the JNDI connection and the JMS transport:
13.2. JMS URIs

Overview

When using SOAP/JMS, a JMS URI is used to specify the endpoint’s target destination. The JMS URI can also be used to configure JMS connection by appending one or more options to the URI. These options are detailed in the IETF standard, *URI Scheme for Java Message Service 1.0*. They can be used to configure the JNDI system, the reply destination, the delivery mode to use, and other JMS properties.

Syntax

As shown in Example 13.4, “Syntax for JMS URI options”, you can append one or more options to the end of a JMS URI by separating them from the destination’s address with a question mark (?). Multiple options are separated by an ampersand (&). Example 13.4, “Syntax for JMS URI options” shows the syntax for using multiple options in a JMS URI.

Example 13.4. Syntax for JMS URI options

```
jms:variant:jmsAddress?option1=value1&option2=value2&_optionN_=valueN
```

JMS properties

Table 13.2, “JMS properties settable as URI options” shows the URI options that affect the JMS transport layer.

Table 13.2. JMS properties settable as URI options

<table>
<thead>
<tr>
<th>Property</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>conduitIdSelectorPrefix</td>
<td></td>
<td>[Optional] A string value that is prefixed to all correlation IDs that the conduit creates. The selector can use it to listen for replies.</td>
</tr>
<tr>
<td>deliveryMode</td>
<td>PERSISTENT</td>
<td>Specifies whether to use JMS PERSISTENT or NON_PERSISTENT message semantics. In the case of PERSISTENT delivery mode, the JMS broker stores messages in persistent storage before acknowledging them; whereas NON_PERSISTENT messages are kept in memory only.</td>
</tr>
<tr>
<td>Property</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>---------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>durableSubscriptionClientID</td>
<td></td>
<td>[Optional] Specifies the client identifier for the connection. This property is used to associate a connection with a state that the provider maintains on behalf of the client. This enables subsequent subscribers with the same identity to resume the subscription in the state that the preceding subscriber left it.</td>
</tr>
<tr>
<td>durableSubscriptionName</td>
<td></td>
<td>[Optional] Specifies the name of the subscription.</td>
</tr>
<tr>
<td>messageType</td>
<td>byte</td>
<td>Specifies the JMS message type used by CXF. Valid values are:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- byte</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- text</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- binary</td>
</tr>
<tr>
<td>password</td>
<td></td>
<td>[Optional] Specifies the password for creating the connection. Appending this property to the URI is discouraged.</td>
</tr>
<tr>
<td>priority</td>
<td>4</td>
<td>Specifies the JMS message priority, which ranges from 0 (lowest) to 9 (highest).</td>
</tr>
<tr>
<td>receiveTimeout</td>
<td>60000</td>
<td>Specifies the time, in milliseconds, the client will wait for a reply when request/reply exchanges are used.</td>
</tr>
<tr>
<td>reconnectOnException</td>
<td>true</td>
<td>[Deprecated in CXF 3.0] Specifies whether the transport should reconnect when exceptions occur.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>As of 3.0, the transport will always reconnect when an exception occurs.</td>
</tr>
<tr>
<td>Property</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>---------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| replyToName           |         | [Optional] Specifies the reply destination for queue messages. The reply destination appears in the JMSReplyTo header. Setting this property is recommended for applications that have request-reply semantics because the JMS provider will assign a temporary reply queue if one is not specified. The value of this property is interpreted according to the variant specified in the JMS URI:  
  - jndi variant—the name of the destination queue resolved by JNDI  
  - queue variant—the name of the destination queue resolved using JMS |
| sessionTransacted     | false   | Specifies the transaction type. Valid values are:  
  - true—resource local transactions  
  - false—JTA transactions                                                                 |
| timeToLive            | 0       | Specifies the time, in milliseconds, after which the JMS provider will discard the message. A value of 0 indicates an infinite lifetime.       |
| topicReplyToName      |         | [Optional] Specifies the reply destination for topic messages. The value of this property is interpreted according to the variant specified in the JMS URI:  
  - jndi-topic—the name of the destination topic resolved by JNDI  
  - topic—the name of the destination topic resolved by JMS |
### useConduitIdSelector

Specifies whether the conduit’s UUID will be used as the prefix for all correlation IDs.

As all conduits are assigned a unique UUID, setting this property to true enables multiple endpoints to share a JMS queue or topic.

### username

[Optional] Specifies the username to use to create the connection.

---

### JNDI properties

Table 13.3, “JNDI properties settable as URI options” shows the URI options that can be used to configure JNDI for this endpoint.

#### Table 13.3. JNDI properties settable as URI options

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>jndiConnectionFactoryName</td>
<td>Specifies the JNDI name of the JMS connection factory.</td>
</tr>
<tr>
<td>jndiInitialContextFactory</td>
<td>Specifies the fully qualified Java class name of the JNDI provider (which must be of javax.jms.InitialContextFactory type). Equivalent to setting the java.naming.factory.initial Java system property.</td>
</tr>
<tr>
<td>jndiTransactionManagerName</td>
<td>Specifies the name of the JTA transaction manager that will be searched for in Spring, Blueprint, or JNDI. If a transaction manager is found, JTA transactions will be enabled. See the sessionTransacted JMS property.</td>
</tr>
<tr>
<td>jndiURL</td>
<td>Specifies the URL that initializes the JNDI provider. Equivalent to setting the java.naming.provider.url Java system property.</td>
</tr>
</tbody>
</table>

### Additional JNDI properties

The properties, java.naming.factory.initial and java.naming.provider.url, are standard properties, which are required to initialize any JNDI provider. Sometimes, however, a JNDI provider might support custom properties in addition to the standard ones. In this case, you can set an arbitrary JNDI property by setting a URI option of the form jndi-PropertyName.
For example, if you were using SUN’s LDAP implementation of JNDI, you could set the JNDI property, `java.naming.factory.control`, in a JMS URI as shown in Example 13.5, “Setting a JNDI property in a JMS URI”.

Example 13.5. Setting a JNDI property in a JMS URI

Example

If the JMS provider is not already configured, it is possible to provide the requisite JNDI configuration details in the URI using options (see Table 13.3, “JNDI properties settable as URI options”). For example, to configure an endpoint to use the Apache ActiveMQ JMS provider and connect to the queue called `test.cxf.jmstransport.queue`, use the URI shown in Example 13.6, “JMS URI that configures a JNDI connection”.

Example 13.6. JMS URI that configures a JNDI connection

ejms:jndi:dynamicQueues/test.cxf.jmstransport.queue
&jndiConnectionFactoryName=ConnectionFactory
&jndiURL=tcp://localhost:61616

Publishing a service

The JAX-WS standard `publish()` method cannot be used to publish a SOAP/JMS service. Instead, you must use the Apache CXF’s `JaxWsServerFactoryBean` class as shown in Example 13.7, “Publishing a SOAP/JMS service”.

Example 13.7. Publishing a SOAP/JMS service

```java
String address = "jms:jndi:dynamicQueues/test.cxf.jmstransport.queue3"
   + "?jndiInitialContextFactory="
   + "org.apache.activemq.jndi.ActiveMQInitialContextFactory"
   + "&jndiConnectionFactoryName=ConnectionFactory"
   + "&jndiURL=tcp://localhost:61500";
Hello implementor = new HelloImpl();
JaxWsServerFactoryBean vrFactory = new JaxWsServerFactoryBean();
vrFactory.setServiceClass(Hello.class);
vrFactory.setAddress(address);
vrFactory.setTransportId(JMSSpecConstants.SOAP_JMS_SPECIFICIATION_TRANSPORTID);
vrFactory.setServiceBean(implementor);
vrFactory.create();
```

The code in Example 13.7, “Publishing a SOAP/JMS service” does the following:

Creates the JMS URI representing the endpoint’s address.

Instantiates a `JaxWsServerFactoryBean` to publish the service.
Sets the `address` field of the factory bean with the JMS URI of the service.

Specifies that the service created by the factory will use the SOAP/JMS transport.

### Consuming a service

The standard JAX-WS APIs cannot be used to consume a SOAP/JMS service. Instead, you must use the Apache CXF’s `JaxWsProxyFactoryBean` class as shown in Example 13.8, “Consuming a SOAP/JMS service”.

```
public void invoke() throws Exception {
    String address = "jms:jndi:dynamicQueues/test.cxf.jmstransport.queue3"
     + "？jndiInitialContextFactory"
     + "=org.apache.activemq.jndi.ActiveMQInitialContextFactory"
     + "&jndiConnectionFactoryName=ConnectionFactory&jndiURL=tcp://localhost:61500";
    JaxWsProxyFactoryBean factory = new JaxWsProxyFactoryBean();
    factory.setAddress(address);
    factory.setTransportId(JMSSpecConstants.SOAP_JMS_SPECIFICIATION_TRANSPORTID);
    factory.setServiceClass(Hello.class);
    Hello client = (Hello)factory.create();
    String reply = client.sayHi("HI");
    System.out.println(reply);
}
```

The code in Example 13.8, “Consuming a SOAP/JMS service” does the following:

- Creates the JMS URI representing the endpoint’s address.
- Instantiates a `JaxWsProxyFactoryBean` to create the proxy.
- Sets the `address` field of the factory bean with the JMS URI of the service.
- Specifies that the proxy created by the factory will use the SOAP/JMS transport.

### 13.3. WSDL EXTENSIONS

#### Overview

You can specify the basic configuration of the JMS transport by inserting WSDL extension elements into the contract, either at binding scope, service scope, or port scope. The WSDL extensions enable you to specify the properties for bootstrapping a JNDI `InitialContext`, which can then be used to look up JMS destinations. You can also set some properties that affect the behavior of the JMS transport layer.

#### SOAP/JMS namespace

The SOAP/JMS WSDL extensions are defined in the `http://www.w3.org/2010/soapjms/` namespace. To use them in your WSDL contracts add the following setting to the `wsdl:definitions` element:
WSDL extension elements

Table 13.4, “SOAP/JMS WSDL extension elements” shows all of the WSDL extension elements you can use to configure the JMS transport.

Table 13.4. SOAP/JMS WSDL extension elements

<table>
<thead>
<tr>
<th>Element</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>soapjms:jndiInitialContextFactory</td>
<td></td>
<td>Specifies the fully qualified Java class name of the JNDI provider. Equivalent to setting the java.naming.factory.initial Java system property.</td>
</tr>
<tr>
<td>soapjms:jndiURL</td>
<td></td>
<td>Specifies the URL that initializes the JNDI provider. Equivalent to setting the java.naming.provider.url Java system property.</td>
</tr>
<tr>
<td>soapjms:jndiContextParameter</td>
<td></td>
<td>Specifies an additional property for creating the JNDI InitialContext. Use the name and value attributes to specify the property.</td>
</tr>
<tr>
<td>soapjms:jndiConnectionFactory</td>
<td></td>
<td>Specifies the JNDI name of the JMS connection factory.</td>
</tr>
<tr>
<td>soapjms:deliveryMode</td>
<td>PERSISTENT</td>
<td>Specifies whether to use JMS PERSISTENT or NON_PERSISTENT message semantics. In the case of PERSISTENT delivery mode, the JMS broker stores messages in persistent storage before acknowledging them; whereas NON_PERSISTENT messages are kept in memory only.</td>
</tr>
</tbody>
</table>
soapjms:replyToName

[Optional] Specifies the reply destination for queue messages. The reply destination appears in the JMSReplyTo header. Setting this property is recommended for applications that have request-reply semantics because the JMS provider will assign a temporary reply queue if one is not specified.

The value of this property is interpreted according to the variant specified in the JMS URI:

- jndi variant—the name of the destination queue resolved by JNDI
- queue variant—the name of the destination queue resolved using JMS

soapjms:priority

4

Specifies the JMS message priority, which ranges from 0 (lowest) to 9 (highest).

soapjms:timeToLive

0

Time, in milliseconds, after which the JMS provider will discard the message. A value of 0 represents an infinite lifetime.

Configuration scopes

The WSDL elements placement in the WSDL contract effect the scope of the configuration changes on the endpoints defined in the contract. The SOAP/JMS WSDL elements can be placed as children of either the wsdl:binding element, the wsdl:service element, or the wsdl:port element. The parent of the SOAP/JMS elements determine which of the following scopes the configuration is placed into.

Binding scope

You can configure the JMS transport at the binding scope by placing extension elements inside the wsdl:binding element. Elements in this scope define the default configuration for all endpoints that use this binding. Any settings in the binding scope can be overridden at the service scope or the port scope.

Service scope

You can configure the JMS transport at the service scope by placing extension elements inside a wsdl:service element. Elements in this scope define the default configuration for all endpoints in this service. Any settings in the service scope can be overridden at the port scope.
Port scope

You can configure the JMS transport at the **port scope** by placing extension elements inside a **wsdl:port** element. Elements in the port scope define the configuration for this port. They override the defaults of the same extension elements defined at the service scope or at the binding scope.

Example

**Example 13.9, “WSDL contract with SOAP/JMS configuration”** shows a WSDL contract for a SOAP/JMS service. It configures the JNDI layer in the binding scope, the message delivery details in the service scope, and the reply destination in the port scope.

```xml
<wsdl:definitions ... xmlns:soapjms="http://www.w3.org/2010/soapjms/" ...

<wsdl:binding name="JMSGreeterPortBinding" type="tns:JMSGreeterPortType">
  ...
  <soapjms:jndiInitialContextFactory>
    org.apache.activemq.jndi.ActiveMQInitialContextFactory
  </soapjms:jndiInitialContextFactory>
  <soapjms:jndiURL>tcp://localhost:61616</soapjms:jndiURL>
  <soapjms:jndiConnectionFactoryName>ConnectionFactory</soapjms:jndiConnectionFactoryName>
  ...
</wsdl:binding>

<wsdl:service name="JMSGreeterService">
  ...
  <soapjms:deliveryMode>NON_PERSISTENT</soapjms:deliveryMode>
  <soapjms:timeToLive>60000</soapjms:timeToLive>
  ...
  <wsdl:port binding="tns:JMSGreeterPortBinding" name="GreeterPort">
    <soap:address location="jms:jndi:dynamicQueues/test.cxf.jmstransport.queue" />
    <soapjms:replyToName>
      dynamicQueues/greeterReply.queue
    </soapjms:replyToName>
    ...
  </wsdl:port>
  ...
</wsdl:service>
...
</wsdl:definitions>
```

The WSDL in **Example 13.9, “WSDL contract with SOAP/JMS configuration”** does the following:

- Declares the namespace for the SOAP/JMS extensions.
- Configures the JNDI connections in the binding scope.
- Sets the JMS delivery style to non-persistent and each message to live for one minute.
Specifies the target destination.

Configures the JMS transport so that reply messages are delivered on the greeterReply.queue queue.
CHAPTER 14. USING GENERIC JMS

Abstract

Apache CXF provides a generic implementation of a JMS transport. The generic JMS transport is not restricted to using SOAP messages and allows for connecting to any application that uses JMS.

NOTE: Support for the JMS 1.0.2 APIs has been removed in CXF 3.0. If you are using Red Hat JBoss Fuse 6.2 or higher (includes CXF 3.0), your JMS provider must support the JMS 1.1 APIs.

14.1. APPROACHES TO CONFIGURING JMS

The Apache CXF generic JMS transport can connect to any JMS provider and work with applications that exchange JMS messages with bodies of either TextMessage or ByteMessage.

There are two ways to enable and configure the JMS transport:

- Section 14.2, “Using the JMS configuration bean”
- Section 14.5, “Using WSDL to configure JMS”

14.2. USING THE JMS CONFIGURATION BEAN

Overview

To simplify JMS configuration and make it more powerful, Apache CXF uses a single JMS configuration bean to configure JMS endpoints. The bean is implemented by the org.apache.cxf.transport.jms.JMSConfiguration class. It can be used to either configure endpoint’s directly or to configure the JMS conduits and destinations.

Configuration namespace

The JMS configuration bean uses the Spring p-namespace to make the configuration as simple as possible. To use this namespace you need to declare it in the configuration’s root element as shown in Example 14.1, “Declaring the Spring p-namespace”.

Example 14.1. Declaring the Spring p-namespace

```xml
<beans ... xmlns:p="http://www.springframework.org/schema/p"
    ...>
    ...
</beans>
```

Specifying the configuration

You specify the JMS configuration by defining a bean of class org.apache.cxf.transport.jms.JMSConfiguration. The properties of the bean provide the configuration settings for the transport.
IMPORTANT
In CXF 3.0, the JMS transport no longer has a dependency on Spring JMS, so some Spring JMS-related options have been removed.

Table 14.1, “General JMS Configuration Properties” lists properties that are common to both providers and consumers.

Table 14.1. General JMS Configuration Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>connectionFactory</td>
<td></td>
<td>[Required] Specifies a reference to a bean that defines a JMS ConnectionFactory.</td>
</tr>
</tbody>
</table>
| wrapInSingleConnectionFactory     | true [pre v3.0] | Removed in CXF 3.0  
pre CXF 3.0 Specifies whether to wrap the ConnectionFactory with a Spring SingleConnectionFactory.  
Enable this property when using a ConnectionFactory that does not pool connections, as it will improve the performance of the JMS transport. This is so because the JMS transport creates a new connection for each message, and the SingleConnectionFactory is needed to cache the connection, so it can be reused. |
<table>
<thead>
<tr>
<th>Property</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>reconnectOnException</td>
<td>false</td>
<td>Deprecated in CXF 3.0 CXF always reconnects when an exception occurs.</td>
</tr>
<tr>
<td></td>
<td></td>
<td><strong>pre CXF 3.0</strong> Specifies whether to create a new connection when an exception occurs.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>When wrapping the ConnectionFactory with a Spring SingleConnectionFactory:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- <strong>true</strong> – on an exception, create a new connection Do not enable this option when using a PooledConnectionFactory, as this option only returns the pooled connection, but does not reconnect.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- <strong>false</strong> – on an exception, do not try to reconnect</td>
</tr>
<tr>
<td>targetDestination</td>
<td></td>
<td>Specifies the JNDI name or provider-specific name of a destination.</td>
</tr>
<tr>
<td>replyDestination</td>
<td></td>
<td>Specifies the JMS name of the JMS destination where replies are sent. This property allows the use of a user-defined destination for replies. For more details see Section 14.6, “Using a Named Reply Destination”</td>
</tr>
<tr>
<td>Property</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>----------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| destinationResolver | DynamicDestinationResolver | Specifies a reference to a Spring DestinationResolver.  
This property allows you to define how destination names are resolved to JMS destinations. Valid values are:  
- **DynamicDestinationResolver** – resolve destination names using the features of the JMS provider.  
- **JndiDestinationResolver** – resolve destination names using JNDI. |
| transactionManager |                       | Specifies a reference to a Spring transaction manager. This enables the service to participate in JTA transactions. |
| taskExecutor      | SimpleAsyncTaskExecutor | Removed in CXF 3.0  
pre CXF 3.0 Specifies a reference to a Spring TaskExecutor. This is used in listeners to decide how to handle incoming messages. |
| useJms11          | false                | Removed in CXF 3.0  
CXF 3.0 supports JMS 1.1 features only.  
pre CXF 3.0 Specifies whether JMS 1.1 features are used. Valid values are:  
- **true** – JMS 1.1 features  
- **false** – JMS 1.0.2 features |
<table>
<thead>
<tr>
<th>Property</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>messageIdEnabled</td>
<td>true</td>
<td>Removed in CXF 3.0&lt;br&gt;&lt;br&gt;&lt;strong&gt;pre CXF 3.0&lt;/strong&gt; Specifies whether the JMS transport wants the JMS broker to provide message IDs. Valid values are:&lt;br&gt;- <strong>true</strong> – broker needs to provide message IDs&lt;br&gt;- <strong>false</strong> – broker need not provide message IDs&lt;br&gt;In this case, the endpoint calls its message producer’s <code>setDisableMessageID()</code> method with a value of <strong>true</strong>. The broker is then given a hint that it need not generate message IDs or add them to the endpoint’s messages. The broker either accepts the hint or ignores it.</td>
</tr>
<tr>
<td>messageTimestampEnabled</td>
<td>true</td>
<td>Removed in CXF 3.0&lt;br&gt;&lt;br&gt;&lt;strong&gt;pre CXF 3.0&lt;/strong&gt; Specifies whether the JMS transport wants the JMS broker to provide message time stamps. </tr>
</tbody>
</table>

As shown in Example 14.2, “JMS configuration bean”, the bean’s properties are specified as attributes to the bean element. They are all declared in the Spring p namespace.

**Example 14.2. JMS configuration bean**

```
<bean id="jmsConfig" class="org.apache.cxf.transport.jms.JMSConfiguration"
     p:connectionFactory="jmsConnectionFactory"
     p:targetDestination="dynamicQueues/greeter.request.queue"
     p:pubSubDomain="false" />
```

**Applying the configuration to an endpoint**

The JMSConfiguration bean can be applied directly to both server and client endpoints using the Apache CXF features mechanism. To do so:

1. Set the endpoint’s address attribute to jms://.
2. Add a jaxws:feature element to the endpoint’s configuration.
3. Add a bean of type org.apache.cxf.transport.jms.JMSConfigFeature to the feature.
4. Set the bean element’s p:jmsConfig-ref attribute to the ID of the JMSConfiguration bean.

Example 14.3, “Adding JMS configuration to a JAX-WS client” shows a JAX-WS client that uses the JMS configuration from Example 14.2, “JMS configuration bean”.

**Example 14.3. Adding JMS configuration to a JAX-WS client**

```
<jaxws:client id="CustomerService"
    xmlns:customer="http://customerservice.example.com/"
    serviceName="customer:CustomerServiceService"
    endpointName="customer:CustomerServiceEndpoint"
    address="jms://" serviceClass="com.example.customerservice.CustomerService">
```
Applying the configuration to the transport

The **JMSConfiguration** bean can be applied to JMS conduits and JMS destinations using the **jms:jmsConfig-ref** element. The **jms:jmsConfig-ref** element’s value is the ID of the **JMSConfiguration** bean.

Example 14.4, ”Adding JMS configuration to a JMS conduit” shows a JMS conduit that uses the JMS configuration from Example 14.2, ”JMS configuration bean”.

**Example 14.4. Adding JMS configuration to a JMS conduit**

```xml
<jms:conduit name="{http://cxf.apache.org/jms_conf_test}HelloWorldQueueBinMsgPort.jms-conduit">
  ...
  <jms:jmsConfig-ref>jmsConf</jms:jmsConfig-ref>
</jms:conduit>
```

14.3. OPTIMIZING CLIENT-SIDE JMS PERFORMANCE

**Overview**

Two major settings affect the JMS performance of clients: pooling and synchronous receives.

**Pooling**

On the client side, CXF creates a new JMS session and JMS producer for each message. This is so because neither session nor producer objects are thread safe. Creating a producer is especially time intensive because it requires communicating with the server.

Pooling connection factories improves performance by caching the connection, session, and producer.

For ActiveMQ, configuring pooling is simple; for example:

```java
import org.apache.activemq.ActiveMQConnectionFactory;
import org.apache.activemq.pool.PooledConnectionFactory;

ConnectionFactory cf = new ActiveMQConnectionFactory("tcp://localhost:61616");
PooledConnectionFactory pcf = new PooledConnectionFactory();

//Set expiry timeout because the default (0) prevents reconnection on failure
pcf.setExpireTimeout(5000);
pcf.setConnectionFactory(cf);
```
JMSConfiguration jmsConfig = new JMSConfiguration();
jmsConfig.setConnectionFactory(pdf);

For more information on pooling, see “Appendix A Optimizing Performance of JMS Single- and Multiple-Resource Transactions” in the Red Hat JBoss Fuse Transaction Guide

Avoiding synchronous receives

For request/reply exchanges, the JMS transport sends a request and then waits for a reply. Whenever possible, request/reply messaging is implemented asynchronously using a JMS MessageListener.

However, CXF must use a synchronous Consumer.receive() method when it needs to share queues between endpoints. This scenario requires the MessageListener to use a message selector to filter the messages. The message selector must be known in advance, so the MessageListener is opened only once.

Two cases in which the message selector cannot be known in advance should be avoided:

- When JMSMessageID is used as the JMSCorrelationID
  If the JMS properties useConduitSelector and conduitSelectorPrefix are not set on the JMS transport, the client does not set a JMSCorrelationId. This causes the server to use the JMSmessageid of the request message as the JMSCorrelationId. As JMSmessageid cannot be known in advance, the client has to use a synchronous Consumer.receive() method.

  Note that you must use the Consumer.receive() method with IBM JMS endpoints (their default).

- The user sets the JMStype in the request message and then sets a custom JMSCorrelationID. Again, as the custom JMSCorrelationID cannot be known in advance, the client has to use a synchronous Consumer.receive() method.

So the general rule is to avoid using settings that require using a synchronous receive.

14.4. CONFIGURING JMS TRANSACTIONS

Overview

CXF 3.0 supports both local JMS transactions and JTA transactions on CXF endpoints, when using one-way messaging.

Local transactions

Transactions using local resources roll back the JMS message only when an exception occurs. They do not directly coordinate other resources, such as database transactions.

To set up a local transaction, configure the endpoint as you normally would, and set the property sessionTrasnsacted to true.

NOTE

For more information on transactions and pooling, see the Red Hat JBoss Fuse Transaction Guide.
JTA transactions

Using JTA transactions, you can coordinate any number of XA resources. If a CXF endpoint is configured for JTA transactions, it starts a transaction before calling the service implementation. The transaction will be committed if no exception occurs. Otherwise, it will be rolled back.

In JTA transactions, a JMS message is consumed and the data written to a database. When an exception occurs, both resources are rolled back, so either the message is consumed and the data is written to the database, or the message is rolled back and the data is not written to the database.

Configuring JTA transactions requires two steps:

1. Defining a transaction manager
   - bean method
     - Define a transaction manager
       ```xml
       <bean id="transactionManager" class="org.apache.geronimo.transaction.manager.GeronimoTransactionManager"/>
       ```
     - Set the name of the transaction manager in the JMS URI
       ```xml
       jms:queue:myqueue?jndiTransactionManager=TransactionManager
       ```
       This example finds a bean with the ID `TransactionManager`.
   - OSGi reference method
     - Look up the transaction manager as an OSGi service using Blueprint
       ```xml
       <reference id="TransactionManager" interface="javax.transaction.TransactionManager"/>
       ```
     - Set the name of the transaction manager in the JMS URI
       ```xml
       jms:jndi:myqueue?jndiTransactionManager=java:comp/env/TransactionManager
       ```
       This example looks up the transaction manager in JNDI.

2. Configuring a JCA pooled connection factory
   Using Spring to define the JCA pooled connection factory:
   ```xml
   <bean id="xacf" class="org.apache.activemq.ActiveMQXAConnectionFactory">
     <property name="brokerURL" value="tcp://localhost:61616" />
   </bean>
   
   <bean id="ConnectionFactory" class="org.apache.activemq.jms.pool.JcaPooledConnectionFactory">
     <property name="transactionManager" ref="transactionManager" />
     <property name="connectionFactory" ref="xacf" />
   </bean>
   ```
   In this example, the first bean defines an ActiveMQ XA connection factory, which is given to a...
In this example, the first bean defines an ActiveMQ XA connection factory, which is given to a `JcaPooledConnectionFactory`. The `JcaPooledConnectionFactory` is then provided as the default bean with id `ConnectionFactory`.

Note that the `JcaPooledConnectionFactory` looks like a normal ConnectionFactory. But when a new connection and session are opened, it checks for an XA transaction and, if found, automatically registers the JMS session as an XA resource. This allows the JMS session to participate in the JMS transaction.

IMPORTANT

Directly setting an XA ConnectionFactory on the JMS transport will not work!

### 14.5. USING WSDL TO CONFIGURE JMS

#### 14.5.1. JMS WSDL Extension Namespace

The WSDL extensions for defining a JMS endpoint are defined in the namespace `http://cxf.apache.org/transports/jms`. In order to use the JMS extensions you will need to add the line shown in Example 14.5, “JMS WSDL extension namespace” to the definitions element of your contract.

Example 14.5. JMS WSDL extension namespace

```xml
xmlns:jms="http://cxf.apache.org/transports/jms"
```

#### 14.5.2. Basic JMS configuration

**Overview**

The JMS address information is provided using the `jms:address` element and its child, the `jms:JMSNamingProperties` element. The `jms:address` element’s attributes specify the information needed to identify the JMS broker and the destination. The `jms:JMSNamingProperties` element specifies the Java properties used to connect to the JNDI service.

IMPORTANT

Information specified using the JMS feature will override the information in the endpoint’s WSDL file.

**Specifying the JMS address**

The basic configuration for a JMS endpoint is done by using a `jms:address` element as the child of your service’s `port` element. The `jms:address` element used in WSDL is identical to the one used in the configuration file. Its attributes are listed in Table 14.2, “JMS endpoint attributes”.

Table 14.2. JMS endpoint attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>destinationStyle</td>
<td>Specifies if the JMS destination is a JMS queue or a JMS topic.</td>
</tr>
<tr>
<td>jndiConnectionFactoryName</td>
<td>Specifies the JNDI name bound to the JMS connection factory to use when connecting to the JMS destination.</td>
</tr>
<tr>
<td>jmsDestinationName</td>
<td>Specifies the JMS name of the JMS destination to which requests are sent.</td>
</tr>
<tr>
<td>jmsReplyDestinationName</td>
<td>Specifies the JMS name of the JMS destinations where replies are sent. This attribute allows you to use a user defined destination for replies. For more details see Section 14.6, “Using a Named Reply Destination”.</td>
</tr>
<tr>
<td>jndiDestinationName</td>
<td>Specifies the JNDI name bound to the JMS destination to which requests are sent.</td>
</tr>
<tr>
<td>jndiReplyDestinationName</td>
<td>Specifies the JNDI name bound to the JMS destinations where replies are sent. This attribute allows you to use a user defined destination for replies. For more details see Section 14.6, “Using a Named Reply Destination”.</td>
</tr>
<tr>
<td>connectionUserName</td>
<td>Specifies the user name to use when connecting to a JMS broker.</td>
</tr>
<tr>
<td>connectionPassword</td>
<td>Specifies the password to use when connecting to a JMS broker.</td>
</tr>
</tbody>
</table>

The **jms:address** WSDL element uses a **jms:JMSNamingProperties** child element to specify additional information needed to connect to a JNDI provider.

**Specifying JNDI properties**

To increase interoperability with JMS and JNDI providers, the **jms:address** element has a child element, **jms:JMSNamingProperties**, that allows you to specify the values used to populate the properties used when connecting to the JNDI provider. The **jms:JMSNamingProperties** element has two attributes: **name** and **value**. *name* specifies the name of the property to set. *value* attribute specifies the value for the specified property. **jms:JMSNamingProperties** element can also be used for specification of provider specific properties.

The following is a list of common JNDI properties that can be set:

1. **java.naming.factory.initial**
2. **java.naming.provider.url**
3. **java.naming.factory.object**
4. java.naming.factory.state
5. java.naming.factory.url.pkgs
6. java.naming.dns.url
7. java.naming.authoritative
8. java.naming.batchsize
9. java.naming.referral
10. java.naming.security.protocol
11. java.naming.security.authentication
12. java.naming.security.principal
13. java.naming.security.credentials
14. java.naming.language
15. java.naming.applet

For more details on what information to use in these attributes, check your JNDI provider’s documentation and consult the Java API reference material.

Example

Example 14.6, “JMS WSDL port specification” shows an example of a JMS WSDL port specification.

Example 14.6. JMS WSDL port specification

```
<service name="JMSService">
  <port binding="tns:Greeter_SOAPBinding" name="SoapPort">
    <jms:address jndiConnectionFactoryName="ConnectionFactory"
    jndiDestinationName="dynamicQueues/test.Celtix.jmstransport">
      <jms:JMSNamingProperty name="java.naming.factory.initial"
      value="org.activemq.jndi.ActiveMQInitialContextFactory" />
      <jms:JMSNamingProperty name="java.naming.provider.url"
      value="tcp://localhost:61616" />
    </jms:address>
  </port>
</service>
```

14.5.3. JMS client configuration

Overview

JMS consumer endpoints specify the type of messages they use. JMS consumer endpoint can use either a JMS ByteMessage or a JMS TextMessage.

When using an ByteMessage the consumer endpoint uses a byte[] as the method for storing data into and retrieving data from the JMS message body. When messages are sent, the message data, including
any formatting information, is packaged into a `byte[]` and placed into the message body before it is placed on the wire. When messages are received, the consumer endpoint will attempt to unmarshall the data stored in the message body as if it were packed in a `byte[]`

When using a `TextMessage`, the consumer endpoint uses a string as the method for storing and retrieving data from the message body. When messages are sent, the message information, including any format-specific information, is converted into a string and placed into the JMS message body. When messages are received the consumer endpoint will attempt to unmarshall the data stored in the JMS message body as if it were packed into a string.

When native JMS applications interact with Apache CXF consumers, the JMS application is responsible for interpreting the message and the formatting information. For example, if the Apache CXF contract specifies that the binding used for a JMS endpoint is SOAP, and the messages are packaged as `TextMessage`, the receiving JMS application will get a text message containing all of the SOAP envelope information.

**Specifying the message type**

The type of messages accepted by a JMS consumer endpoint is configured using the optional `jms:client` element. The `jms:client` element is a child of the WSDL `port` element and has one attribute:

<table>
<thead>
<tr>
<th>Table 14.3. JMS Client WSDL Extensions</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>messageType</strong></td>
</tr>
<tr>
<td>Specifies how the message data will be packaged as a JMS message. <strong>text</strong> specifies that the data will be packaged as a <code>TextMessage</code>. <strong>binary</strong> specifies that the data will be packaged as a <code>ByteMessage</code>.</td>
</tr>
</tbody>
</table>

**Example**

Example 14.7, “WSDL for a JMS consumer endpoint” shows the WSDL for configuring a JMS consumer endpoint.

```xml
<service name="JMSService">
    <port binding="tns:Greeter_SOAPBinding" name="SoapPort">
        <jms:address jndiConnectionFactoryName="ConnectionFactory"
                     jndiDestinationName="dynamicQueues/test.Celtix.jmstransport">
            <jms:JMSNamingProperty name="java.naming.factory.initial" value="org.activemq.jndi.ActiveMQInitialContextFactory" />
            <jms:JMSNamingProperty name="java.naming.provider.url" value="tcp://localhost:61616" />
        </jms:address>
        <jms:client messageType="binary" />
    </port>
</service>
```

14.5.4. JMS provider configuration

**Overview**
JMS provider endpoints have a number of behaviors that are configurable. These include:

- how messages are correlated
- the use of durable subscriptions
- if the service uses local JMS transactions
- the message selectors used by the endpoint

**Specifying the configuration**

Provider endpoint behaviors are configured using the optional `jms:server` element. The `jms:server` element is a child of the WSDL `wsdl:port` element and has the following attributes:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>useMessageIDAsCorrelationID</code></td>
<td>Specifies whether JMS will use the message ID to correlate messages. The default is <code>false</code>.</td>
</tr>
<tr>
<td><code>durableSubscriberName</code></td>
<td>Specifies the name used to register a durable subscription.</td>
</tr>
<tr>
<td><code>messageSelector</code></td>
<td>Specifies the string value of a message selector to use. For more information on the syntax used to specify message selectors, see the JMS 1.1 specification.</td>
</tr>
<tr>
<td><code>transactional</code></td>
<td>Specifies whether the local JMS broker will create transactions around message processing. The default is <code>false</code>. [a]</td>
</tr>
</tbody>
</table>

[a] Currently, setting the `transactional` attribute to `true` is not supported by the runtime.

**Example**

Example 14.8, "WSDL for a JMS provider endpoint" shows the WSDL for configuring a JMS provider endpoint.

```xml
<service name="JMSService">
    <port binding="tns:Greeter_SOAPBinding" name="SoapPort">
        <jms:address jndiConnectionFactoryName="ConnectionFactory"
                     jndiDestinationName="dynamicQueues/test.Celtix.jmstransport">
            <jms:JMSNamingProperty name="java.naming.factory.initial" value="org.activemq.jndi.ActiveMQInitialContextFactory" />
            <jms:JMSNamingProperty name="java.naming.provider.url" value="tcp://localhost:61616" />
        </jms:address>
    </port>
</service>
```
14.6. USING A NAMED REPLY DESTINATION

Overview

By default, Apache CXF endpoints using JMS create a temporary queue for sending replies back and forth. If you prefer to use named queues, you can configure the queue used to send replies as part of an endpoint’s JMS configuration.

Setting the reply destination name

You specify the reply destination using either the `jmsReplyDestinationName` attribute or the `jndiReplyDestinationName` attribute in the endpoint’s JMS configuration. A client endpoint will listen for replies on the specified destination and it will specify the value of the attribute in the `ReplyTo` field of all outgoing requests. A service endpoint will use the value of the `jndiReplyDestinationName` attribute as the location for placing replies if there is no destination specified in the request’s `ReplyTo` field.

Example

Example 14.9, “JMS Consumer Specification Using a Named Reply Queue” shows the configuration for a JMS client endpoint.

Example 14.9. JMS Consumer Specification Using a Named Reply Queue

```xml
<jms:conduit name="{http://cxf.apache.org/jms_endpt}HelloWorldJMSPort.jms-conduit">
  <jms:address destinationStyle="queue"
    jndiConnectionFactoryName="myConnectionFactory"
    jndiDestinationName="myDestination"
    jndiReplyDestinationName="myReplyDestination">
    <jms:JMSNamingProperty name="java.naming.factory.initial" value="org.apache.cxf.transport.jms.MyInitialContextFactory"/>
    <jms:JMSNamingProperty name="java.naming.provider.url" value="tcp://localhost:61616"/>
  </jms:address>
</jms:conduit>
```
CHAPTER 15. INTEGRATING WITH APACHE ACTIVEMQ

OVERVIEW

If you are using Apache ActiveMQ as your JMS provider, the JNDI name of your destinations can be specified in a special format that dynamically creates JNDI bindings for queues or topics. This means that it is not necessary to configure the JMS provider in advance with the JNDI bindings for your queues or topics.

THE INITIAL CONTEXT FACTORY

The key to integrating Apache ActiveMQ with JNDI is the ActiveMQInitialContextFactory class. This class is used to create a JNDI InitialContext instance, which you can then use to access JMS destinations in the JMS broker.

Example 15.1, “SOAP/JMS WSDL to connect to Apache ActiveMQ” shows SOAP/JMS WSDL extensions to create a JNDI InitialContext that is integrated with Apache ActiveMQ.

Example 15.1. SOAP/JMS WSDL to connect to Apache ActiveMQ

```xml
<soapjms:jndiInitialContextFactory>
  org.apache.activemq.jndi.ActiveMQInitialContextFactory
</soapjms:jndiInitialContextFactory>
<soapjms:jndiURL>tcp://localhost:61616</soapjms:jndiURL>
```

In Example 15.1, “SOAP/JMS WSDL to connect to Apache ActiveMQ” , the Apache ActiveMQ client connects to the broker port located at tcp://localhost:61616.

LOOKING UP THE CONNECTION FACTORY

As well as creating a JNDI InitialContext instance, you must specify the JNDI name that is bound to a javax.jms.ConnectionFactory instance. In the case of Apache ActiveMQ, there is a predefined binding in the InitialContext instance, which maps the JNDI name ConnectionFactory to an ActiveMQConnectionFactory instance. Example 15.2, “SOAP/JMS WSDL for specifying the Apache ActiveMQ connection factory” shows the SOAP/JMS extension element for specifying the Apache ActiveMQ connection factory.

Example 15.2. SOAP/JMS WSDL for specifying the Apache ActiveMQ connection factory

```xml
<soapjms:jndiConnectionFactoryName>
  ConnectionFactory
</soapjms:jndiConnectionFactoryName>
```

SYNTAX FOR DYNAMIC DESTINATIONS

To access queues or topics dynamically, specify the destination’s JNDI name as a JNDI composite name in either of the following formats:
QueueName and TopicName are the names that the Apache ActiveMQ broker uses. They are not abstract JNDI names.

Example 15.3, “WSDL port specification with a dynamically created queue” shows a WSDL port that uses a dynamically created queue.

Example 15.3. WSDL port specification with a dynamically created queue

```xml
<service name="JMSService">
  <port binding="tns:GreeterBinding" name="JMSPort">
    <jms:address jndiConnectionFactoryName="ConnectionFactory"
                 jndiDestinationName="dynamicQueues/greeter.request.queue">
      <jms:JMSNamingProperty name="java.naming.factory.initial"
                              value="org.activemq.jndi.ActiveMQInitialContextFactory" />
      <jms:JMSNamingProperty name="java.naming.provider.url"
                              value="tcp://localhost:61616" />
    </jms:address>
  </port>
</service>
```

When the application attempts to open the JMS connection, Apache ActiveMQ will check to see if a queue with the JNDI name greeter.request.queue exists. If it does not exist, it will create a new queue and bind it to the JNDI name greeter.request.queue.
Abstract

Conduits are a low-level piece of the transport architecture that are used to implement outbound connections. Their behavior and life-cycle can effect system performance and processing load.

OVERVIEW

Conduits manage the client-side, or outbound, transport details in the Apache CXF runtime. They are responsible for opening ports, establishing outbound connections, sending messages, and listening for any responses between an application and a single external endpoint. If an application connects to multiple endpoints, it will have one conduit instance for each endpoint.

Each transport type implements its own conduit using the Conduit interface. This allows for a standardized interface between the application level functionality and the transports.

In general, you only need to worry about the conduits being used by your application when configuring the client-side transport details. The underlying semantics of how the runtime handles conduits is, generally, not something a developer needs to worry about.

However, there are cases when an understanding of conduit’s can prove helpful:

- Implementing a custom transport
- Advanced application tuning to manage limited resources

CONDUIT LIFE-CYCLE

Conduits are managed by the client implementation object. Once created, a conduit lives for the duration of the client implementation object. The conduit’s life-cycle is:

1. When the client implementation object is created, it is given a reference to a ConduitSelector object.

2. When the client needs to send a message is request’s a reference to a conduit from the conduit selector.
   If the message is for a new endpoint, the conduit selector creates a new conduit and passes it to the client implementation. Otherwise, it passes the client a reference to the conduit for the target endpoint.

3. The conduit sends messages when needed.

4. When the client implementation object is destroyed, all of the conduits associated with it are destroyed.

CONDUIT WEIGHT

The weight of a conduit object depends on the transport implementation. HTTP conduits are extremely light weight. JMS conduits are heavy because they are associated with the JMS Session object and one or more JMSListenerContainer objects.
PART IV. CONFIGURING WEB SERVICE ENDPOINTS

This guide describes how to create Apache CXF endpoints in Red Hat Fuse.
CHAPTER 17. CONFIGURING JAX-WS ENDPOINTS

Abstract

JAX-WS endpoints are configured using one of three Spring configuration elements. The correct element depends on what type of endpoint you are configuring and which features you wish to use. For consumers you use the `jaxws:client` element. For service providers you can use either the `jaxws:endpoint` element or the `jaxws:server` element.

The information used to define an endpoint is typically defined in the endpoint’s contract. You can use the configuration element’s to override the information in the contract. You can also use the configuration elements to provide information that is not provided in the contract.

You must use the configuration elements to activate advanced features such as WS-RM. This is done by providing child elements to the endpoint’s configuration element. Note that when dealing with endpoints developed using a Java-first approach it is likely that the SEI serving as the endpoint’s contract is lacking information about the type of binding and transport to use.

17.1. CONFIGURING SERVICE PROVIDERS

17.1.1. Elements for Configuring Service Providers

Apache CXF has two elements that can be used to configure a service provider:

- Section 17.1.2, “Using the jaxws:endpoint Element”
- Section 17.1.3, “Using the jaxws:server Element”

The differences between the two elements are largely internal to the runtime. The `jaxws:endpoint` element injects properties into the `org.apache.cxf.jaxws.EndpointImpl` object created to support a service endpoint. The `jaxws:server` element injects properties into the `org.apache.cxf.jaxws.support.JaxWsServerFactoryBean` object created to support the endpoint. The `EndpointImpl` object passes the configuration data to the `JaxWsServerFactoryBean` object. The `JaxWsServerFactoryBean` object is used to create the actual service object. Because either configuration element will configure a service endpoint, you can choose based on the syntax you prefer.

17.1.2. Using the jaxws:endpoint Element

Overview

The `jaxws:endpoint` element is the default element for configuring JAX-WS service providers. Its attributes and children specify all of the information needed to instantiate a service provider. Many of the attributes map to information in the service’s contract. The children are used to configure interceptors and other advanced features.

Identifying the endpoint being configured

For the runtime to apply the configuration to the proper service provider, it must be able to identify it. The basic means for identifying a service provider is to specify the class that implements the endpoint. This is done using the `jaxws:endpoint` element’s `implementor` attribute.
For instances where different endpoint’s share a common implementation, it is possible to provide different configuration for each endpoint. There are two approaches for distinguishing a specific endpoint in configuration:

- a combination of the `serviceName` attribute and the `endpointName` attribute
  The `serviceName` attribute specifies the `wsdl:service` element defining the service’s endpoint. The `endpointName` attribute specifies the specific `wsdl:port` element defining the service’s endpoint. Both attributes are specified as QNames using the format `ns:name`. `ns` is the namespace of the element and `name` is the value of the element’s `name` attribute.

  **NOTE**
  If the `wsdl:service` element only has one `wsdl:port` element, the `endpointName` attribute can be omitted.

- the `name` attribute
  The `name` attribute specifies the QName of the specific `wsdl:port` element defining the service’s endpoint. The QName is provided in the format `{ns}localPart`. `ns` is the namespace of the `wsdl:port` element and `localPart` is the value of the `wsdl:port` element’s `name` attribute.

**Attributes**

The attributes of the `jaxws:endpoint` element configure the basic properties of the endpoint. These properties include the address of the endpoint, the class that implements the endpoint, and the `bus` that hosts the endpoint.

Table 17.1, “Attributes for Configuring a JAX-WS Service Provider Using the jaxws:endpoint Element” describes the attribute of the `jaxws:endpoint` element.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>Specifies a unique identifier that other configuration elements can use to refer to the endpoint.</td>
</tr>
<tr>
<td>implementor</td>
<td>Specifies the class implementing the service. You can specify the implementation class using either the class name or an ID reference to a Spring bean configuring the implementation class. This class must be on the classpath.</td>
</tr>
<tr>
<td>implementorClass</td>
<td>Specifies the class implementing the service. This attribute is useful when the value provided to the <code>implementor</code> attribute is a reference to a bean that is wrapped using Spring AOP.</td>
</tr>
<tr>
<td>address</td>
<td>Specifies the address of an HTTP endpoint. This value overrides the value specified in the services contract.</td>
</tr>
<tr>
<td>Attribute</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>wsdlLocation</td>
<td>Specifies the location of the endpoint’s WSDL contract. The WSDL contract’s location is relative to the folder from which the service is deployed.</td>
</tr>
<tr>
<td>endpointName</td>
<td>Specifies the value of the service’s <code>wsdl:port</code> element’s <code>name</code> attribute. It is specified as a QName using the format <code>ns:name</code> where <code>ns</code> is the namespace of the <code>wsdl:port</code> element.</td>
</tr>
<tr>
<td>serviceName</td>
<td>Specifies the value of the service’s <code>wsdl:service</code> element’s <code>name</code> attribute. It is specified as a QName using the format <code>ns:name</code> where <code>ns</code> is the namespace of the <code>wsdl:service</code> element.</td>
</tr>
<tr>
<td>publish</td>
<td>Specifies if the service should be automatically published. If this is set to <code>false</code>, the developer must explicitly publish the endpoint as described in Chapter 31, Publishing a Service.</td>
</tr>
<tr>
<td>bus</td>
<td>Specifies the ID of the Spring bean configuring the bus used to manage the service endpoint. This is useful when configuring several endpoints to use a common set of features.</td>
</tr>
<tr>
<td>bindingUri</td>
<td>Specifies the ID of the message binding the service uses. A list of valid binding IDs is provided in Chapter 23, Apache CXF Binding IDs.</td>
</tr>
<tr>
<td>name</td>
<td>Specifies the stringified QName of the service’s <code>wsdl:port</code> element. It is specified as a QName using the format <code>{ns}localPart</code> where <code>ns</code> is the namespace of the <code>wsdl:port</code> element and <code>localPart</code> is the value of the <code>wsdl:port</code> element’s <code>name</code> attribute.</td>
</tr>
<tr>
<td>abstract</td>
<td>Specifies if the bean is an abstract bean. Abstract beans act as parents for concrete bean definitions and are not instantiated. The default is <code>false</code>. Setting this to <code>true</code> instructs the bean factory not to instantiate the bean.</td>
</tr>
<tr>
<td>depends-on</td>
<td>Specifies a list of beans that the endpoint depends on being instantiated before it can be instantiated.</td>
</tr>
</tbody>
</table>
### Attribute Table

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>createdFromAPI</code></td>
<td>Specifies that the user created that bean using Apache CXF APIs, such as <code>Endpoint.publish()</code> or <code>Service.getPort()</code>. The default is <code>false</code>. Setting this to <code>true</code> does the following:</td>
</tr>
<tr>
<td></td>
<td>- Changes the internal name of the bean by appending <code>.jaxws-endpoint</code> to its id</td>
</tr>
<tr>
<td></td>
<td>- Makes the bean abstract</td>
</tr>
<tr>
<td><code>publishedEndpointUrl</code></td>
<td>The URL that is placed in the <code>address</code> element of the generated WSDL. If this value is not specified, the value of the <code>address</code> attribute is used. This attribute is useful when the &quot;public&quot; URL is not the same as the URL on which the service is deployed.</td>
</tr>
</tbody>
</table>

In addition to the attributes listed in Table 17.1, “Attributes for Configuring a JAX-WS Service Provider Using the jaxws:endpoint Element”, you might need to use multiple `xmlns:shortName` attributes to declare the namespaces used by the `endpointName` and `serviceName` attributes.

### Example

**Example 17.1, “Simple JAX-WS Endpoint Configuration”** shows the configuration for a JAX-WS endpoint that specifies the address where the endpoint is published. The example assumes that you want to use the defaults for all other values or that the implementation has specified values in the annotations.

**Example 17.1. Simple JAX-WS Endpoint Configuration**

```
<beans ...
  xmlns:jaxws="http://cxf.apache.org/jaxws"
  ...
  schemaLocation="..." http://cxf.apache.org/jaxws http://cxf.apache.org/schemas/jaxws.xsd ...
  >
  <jaxws:endpoint id="example"
    implementor="org.apache.cxf.example.DemoImpl"
    address="http://localhost:8080/demo" />
</beans>
```

**Example 17.2, “JAX-WS Endpoint Configuration with a Service Name”** shows the configuration for a JAX-WS endpoint whose contract contains two service definitions. In this case, you must specify which service definition to instantiate using the `serviceName` attribute.

**Example 17.2. JAX-WS Endpoint Configuration with a Service Name**
The `xmlns:samp` attribute specifies the namespace in which the WSDL `service` element is defined.

Example 17.3, “JAX-WS Endpoint Configuration with with HTTP/2 enabled” shows the configuration for a JAX-WS endpoint that specifies the address with HTTP/2 enabled.

**Configuring HTTP/2 for Apache CXF**

HTTP/2 is supported when using the standalone Apache CXF Undertow transport (`http-undertow`) on Apache Karaf. To enable the HTTP/2 protocol you must set the `jaxws:endpoint` element’s `address` attribute as an absolute URL and set the `org.apache.cxf.transports.http_undertow.EnableHttp2` property as `true`.

**NOTE**

This HTTP/2 implementation only supports server side HTTP/2 transport with plain HTTP or HTTPS.

Example 17.3. JAX-WS Endpoint Configuration with with HTTP/2 enabled

```xml
<beans ...
xmlns:jaxws="http://cxf.apache.org/jaxws"
...
schemaLocation="...

<jaxws:endpoint id="example2"
    implementor="org.apache.cxf.example.DemoImpl"
    serviceName="samp:demoService2"
    xmlns:samp="http://org.apache.cxf/wsdl/example" />

</beans>
```
NOTE
For improved performance, Red Hat recommends using the servlet transport on Apache Karaf (pax-web-undertow) which enables centralized configuration and tuning of the web container, however, pax-web-undertow does not support the HTTP/2 transport protocol.

17.1.3. Using the jaxws:server Element

Overview

The jaxws:server element is an element for configuring JAX-WS service providers. It injects the configuration information into the org.apache.cxf.jaxws.support.JaxWsServerFactoryBean. This is a Apache CXF specific object. If you are using a pure Spring approach to building your services, you will not be forced to use Apache CXF specific APIs to interact with the service.

The attributes and children of the jaxws:server element specify all of the information needed to instantiate a service provider. The attributes specify the information that is required to instantiate an endpoint. The children are used to configure interceptors and other advanced features.

Identifying the endpoint being configured

In order for the runtime to apply the configuration to the proper service provider, it must be able to identify it. The basic means for identifying a service provider is to specify the class that implements the endpoint. This is done using the jaxws:server element’s serviceBean attribute.

For instances where different endpoint’s share a common implementation, it is possible to provide different configuration for each endpoint. There are two approaches for distinguishing a specific endpoint in configuration:

- a combination of the serviceName attribute and the endpointName attribute
  The serviceName attribute specifies the wsdl:service element defining the service’s endpoint. The endpointName attribute specifies the specific wsdl:port element defining the service’s endpoint. Both attributes are specified as QNames using the format ns:name. ns is the namespace of the element and name is the value of the element’s name attribute.

NOTE
If the wsdl:service element only has one wsdl:port element, the endpointName attribute can be omitted.

- the name attribute
  The name attribute specifies the QName of the specific wsdl:port element defining the service’s endpoint. The QName is provided in the format {ns}localPart. ns is the namespace of the wsdl:port element and localPart is the value of the wsdl:port element’s name attribute.

Attributes

The attributes of the jaxws:server element configure the basic properties of the endpoint. These properties include the address of the endpoint, the class that implements the endpoint, and the bus that hosts the endpoint.

Table 17.2, “Attributes for Configuring a JAX-WS Service Provider Using the jaxws:server Element” describes the attribute of the jaxws:server element.
Table 17.2. Attributes for Configuring a JAX-WS Service Provider Using the jaxws:server Element

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>Specifies a unique identifier that other configuration elements can use to refer to the endpoint.</td>
</tr>
<tr>
<td>serviceBean</td>
<td>Specifies the class implementing the service. You can specify the implementation class using either the class name or an ID reference to a Spring bean configuring the implementation class. This class must be on the classpath.</td>
</tr>
<tr>
<td>serviceClass</td>
<td>Specifies the class implementing the service. This attribute is useful when the value provided to the implementor attribute is a reference to a bean that is wrapped using Spring AOP.</td>
</tr>
<tr>
<td>address</td>
<td>Specifies the address of an HTTP endpoint. This value will override the value specified in the services contract.</td>
</tr>
<tr>
<td>wsdlLocation</td>
<td>Specifies the location of the endpoint’s WSDL contract. The WSDL contract’s location is relative to the folder from which the service is deployed.</td>
</tr>
<tr>
<td>endpointName</td>
<td>Specifies the value of the service’s wsdl:port element’s name attribute. It is specified as a QName using the format ns:name, where ns is the namespace of the wsdl:port element.</td>
</tr>
<tr>
<td>serviceName</td>
<td>Specifies the value of the service’s wsdl:service element’s name attribute. It is specified as a QName using the format ns:name, where ns is the namespace of the wsdl:service element.</td>
</tr>
<tr>
<td>publish</td>
<td>Specifies if the service should be automatically published. If this is set to false, the developer must explicitly publish the endpoints described in Chapter 31, Publishing a Service.</td>
</tr>
<tr>
<td>bus</td>
<td>Specifies the ID of the Spring bean configuring the bus used to manage the service endpoint. This is useful when configuring several endpoints to use a common set of features.</td>
</tr>
<tr>
<td>bindingId</td>
<td>Specifies the ID of the message binding the service uses. A list of valid binding IDs is provided in Chapter 23, Apache CXF Binding IDs.</td>
</tr>
<tr>
<td>Attribute</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>name</td>
<td>Specifies the stringified QName of the service’s <code>wsdl:port</code> element. It is specified as a QName using the format <code>{ns}localPart</code>, where <code>ns</code> is the namespace of the <code>wsdl:port</code> element and <code>localPart</code> is the value of the <code>wsdl:port</code> element’s <code>name</code> attribute.</td>
</tr>
<tr>
<td>abstract</td>
<td>Specifies if the bean is an abstract bean. Abstract beans act as parents for concrete bean definitions and are not instantiated. The default is <code>false</code>. Setting this to <code>true</code> instructs the bean factory not to instantiate the bean.</td>
</tr>
<tr>
<td>depends-on</td>
<td>Specifies a list of beans that the endpoint depends on being instantiated before the endpoint can be instantiated.</td>
</tr>
<tr>
<td>createdFromAPI</td>
<td>Specifies that the user created that bean using Apache CXF APIs, such as <code>Endpoint.publish()</code> or <code>Service.getPort()</code>. The default is <code>false</code>. Setting this to <code>true</code> does the following:</td>
</tr>
<tr>
<td></td>
<td>- Changes the internal name of the bean by appending <code>.jaxws-endpoint</code> to its id</td>
</tr>
<tr>
<td></td>
<td>- Makes the bean abstract</td>
</tr>
</tbody>
</table>

In addition to the attributes listed in Table 17.2, “Attributes for Configuring a JAX-WS Service Provider Using the jaxws:server Element”, you might need to use multiple `xmlns:shortName` attributes to declare the namespaces used by the `endpointName` and `serviceName` attributes.

**Example**

Example 17.4, “Simple JAX-WS Server Configuration” shows the configuration for a JAX-WS endpoint that specifies the address where the endpoint is published.

**Example 17.4. Simple JAX-WS Server Configuration**

```xml
<beans ...>
  <jaxws:server id="exampleServer"
    xmlns:jaxws="http://cxf.apache.org/jaxws"
</beans>
```
serviceBean="org.apache.cxf.example.DemoImpl"
address="http://localhost:8080/demo" />

17.1.4. Adding Functionality to Service Providers

Overview

The jaxws:endpoint and the jaxws:server elements provide the basic configuration information needed to instantiate a service provider. To add functionality to your service provider or to perform advanced configuration you must add child elements to the configuration.

Child elements allow you to do the following:

- Chapter 19, Apache CXF Logging
- Chapter 59, Configuring Endpoints to Use Interceptors
- Chapter 20, Deploying WS-Addressing
- Chapter 21, Enabling Reliable Messaging
- Section 17.1.5, “Enable Schema Validation on a JAX-WS Endpoint”

Elements

Table 17.3, “Elements Used to Configure JAX-WS Service Providers” describes the child elements that jaxws:endpoint supports.

Table 17.3. Elements Used to Configure JAX-WS Service Providers

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>jaxws:handlers</td>
<td>Specifies a list of JAX-WS Handler implementations for processing messages. For more information on JAX-WS Handler implementations see Chapter 43, Writing Handlers.</td>
</tr>
<tr>
<td>jaxws:inInterceptors</td>
<td>Specifies a list of interceptors that process inbound requests. For more information see Part VII, “Developing Apache CXF Interceptors”.</td>
</tr>
<tr>
<td>jaxws:inFaultInterceptors</td>
<td>Specifies a list of interceptors that process inbound fault messages. For more information see Part VII, “Developing Apache CXF Interceptors”.</td>
</tr>
<tr>
<td>jaxws:outInterceptors</td>
<td>Specifies a list of interceptors that process outbound replies. For more information see Part VII, “Developing Apache CXF Interceptors”.</td>
</tr>
<tr>
<td>Element</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>jaxws:outFaultInterceptors</td>
<td>Specifies a list of interceptors that process outbound fault messages. For more information see Part VII, “Developing Apache CXF Interceptors”.</td>
</tr>
<tr>
<td>jaxws:binding</td>
<td>Specifies a bean configuring the message binding used by the endpoint. Message bindings are configured using implementations of the org.apache.cxf.binding.BindingFactory interface.[a]</td>
</tr>
<tr>
<td>jaxws:converter[b]</td>
<td>Specifies the class implementing the data binding used by the endpoint. This is specified using an embedded bean definition.</td>
</tr>
<tr>
<td>jaxws:executor</td>
<td>Specifies a Java executor that is used for the service. This is specified using an embedded bean definition.</td>
</tr>
<tr>
<td>jaxws:features</td>
<td>Specifies a list of beans that configure advanced features of Apache CXF. You can provide either a list of bean references or a list of embedded beans.</td>
</tr>
<tr>
<td>jaxws:invoker</td>
<td>Specifies an implementation of the org.apache.cxf.service.Invoker interface used by the service. [c]</td>
</tr>
<tr>
<td>jaxws:properties</td>
<td>Specifies a Spring map of properties that are passed along to the endpoint. These properties can be used to control features like enabling MTOM support.</td>
</tr>
<tr>
<td>jaxws:serviceFactory</td>
<td>Specifies a bean configuring the JaxWsServiceFactoryBean object used to instantiate the service.</td>
</tr>
</tbody>
</table>

[a] The SOAP binding is configured using the soap:soapBinding bean.
[b] The jaxws:endpoint element does not support the jaxws:converter element.
[c] The Invoker implementation controls how a service is invoked. For example, it controls whether each request is handled by a new instance of the service implementation or if state is preserved across invocations.

17.1.5. Enable Schema Validation on a JAX-WS Endpoint

Overview

You can set the schema-validation-enabled property to enable schema validation on a jaxws:endpoint element or on a jaxws:server element. When schema validation is enabled, the messages sent between client and server are checked for conformity to the schema. By default, schema validation is turned off, because it has a significant impact on performance.
Example

To enable schema validation on a JAX-WS endpoint, set the `schema-validation-enabled` property in the `jaxws:properties` child element of the `jaxws:endpoint` element or of the `jaxws:server` element. For example, to enable schema validation on a `jaxws:endpoint` element:

```xml
<jaxws:endpoint name="{http://apache.org/hello_world_soap_http}SoapPort"
    wsdlLocation="wsdl/hello_world.wsdl"
    createdFromAPI="true">
    <jaxws:properties>
        <entry key="schema-validation-enabled" value="BOTH"/>
    </jaxws:properties>
</jaxws:endpoint>
```

For the list of allowed values of the `schema-validation-enabled` property, see Section 24.3.4.7, “Schema Validation Type Values”.

17.2. CONFIGURING CONSUMER ENDPOINTS

Overview

JAX-WS consumer endpoints are configured using the `jaxws:client` element. The element’s attributes provide the basic information necessary to create a consumer.

To add other functionality, like WS-RM, to the consumer you add children to the `jaxws:client` element. Child elements are also used to configure the endpoint’s logging behavior and to inject other properties into the endpoint’s implementation.

Basic Configuration Properties

The attributes described in Table 17.4, “Attributes Used to Configure a JAX-WS Consumer” provide the basic information necessary to configure a JAX-WS consumer. You only need to provide values for the specific properties you want to configure. Most of the properties have sensible defaults, or they rely on information provided by the endpoint’s contract.

**Table 17.4. Attributes Used to Configure a JAX-WS Consumer**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>address</td>
<td>Specifies the HTTP address of the endpoint where the consumer will make requests. This value overrides the value set in the contract.</td>
</tr>
<tr>
<td>bindingId</td>
<td>Specifies the ID of the message binding the consumer uses. A list of valid binding IDs is provided in Chapter 23, Apache CXF Binding IDs.</td>
</tr>
<tr>
<td>bus</td>
<td>Specifies the ID of the Spring bean configuring the bus managing the endpoint.</td>
</tr>
<tr>
<td>Attribute</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>endpointName</td>
<td>Specifies the value of the <code>wsdl:port</code> element’s <code>name</code> attribute for the service on which the consumer is making requests. It is specified as a QName using the format <code>ns:name</code>, where <code>ns</code> is the namespace of the <code>wsdl:port</code> element.</td>
</tr>
<tr>
<td>serviceName</td>
<td>Specifies the value of the <code>wsdl:service</code> element’s <code>name</code> attribute for the service on which the consumer is making requests. It is specified as a QName using the format <code>ns:name</code> where <code>ns</code> is the namespace of the <code>wsdl:service</code> element.</td>
</tr>
<tr>
<td>username</td>
<td>Specifies the username used for simple username/password authentication.</td>
</tr>
<tr>
<td>password</td>
<td>Specifies the password used for simple username/password authentication.</td>
</tr>
<tr>
<td>serviceClass</td>
<td>Specifies the name of the service endpoint interface(SEI).</td>
</tr>
<tr>
<td>wsdlLocation</td>
<td>Specifies the location of the endpoint’s WSDL contract. The WSDL contract’s location is relative to the folder from which the client is deployed.</td>
</tr>
<tr>
<td>name</td>
<td>Specifies the stringified QName of the <code>wsdl:port</code> element for the service on which the consumer is making requests. It is specified as a QName using the format <code>{ns}localPart</code>, where <code>ns</code> is the namespace of the <code>wsdl:port</code> element and <code>localPart</code> is the value of the <code>wsdl:port</code> element’s <code>name</code> attribute.</td>
</tr>
<tr>
<td>abstract</td>
<td>Specifies if the bean is an abstract bean. Abstract beans act as parents for concrete bean definitions and are not instantiated. The default is false. Setting this to true instructs the bean factory not to instantiate the bean.</td>
</tr>
<tr>
<td>depends-on</td>
<td>Specifies a list of beans that the endpoint depends on being instantiated before it can be instantiated.</td>
</tr>
</tbody>
</table>
**Attribute** | **Description**
--- | ---
createdFromAPI | Specifies that the user created that bean using Apache CXF APIs like `Service.getPort()`. The default is `false`. Setting this to `true` does the following:
- Changes the internal name of the bean by appending `.jaxws-client` to its id
- Makes the bean abstract

In addition to the attributes listed in Table 17.4, “Attributes Used to Configure a JAX-WS Consumer”, it might be necessary to use multiple `xmlns:shortName` attributes to declare the namespaces used by the `endpointName` and the `serviceName` attributes.

### Adding functionality

To add functionality to your consumer or to perform advanced configuration, you must add child elements to the configuration.

Child elements allow you to do the following:

- Chapter 19, Apache CXF Logging
- Chapter 59, Configuring Endpoints to Use Interceptors
- Chapter 20, Deploying WS-Addressing
- Chapter 21, Enabling Reliable Messaging
- the section called “Enable schema validation on a JAX-WS consumer”

Table 17.5, “Elements For Configuring a Consumer Endpoint” describes the child element’s you can use to configure a JAX-WS consumer.

### Table 17.5. Elements For Configuring a Consumer Endpoint

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>jaxws:binding</td>
<td>Specifies a bean configuring the message binding used by the endpoint. Message bindings are configured using implementations of the <code>org.apache.cxf.binding.BindingFactory</code> interface.[a]</td>
</tr>
<tr>
<td>jaxws:dataBinding</td>
<td>Specifies the class implementing the data binding used by the endpoint. You specify this using an embedded bean definition. The class implementing the JAXB data binding is <code>org.apache.cxf.jaxb.JAXBDataBinding</code>.</td>
</tr>
<tr>
<td>Element</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>jaxws:features</td>
<td>Specifies a list of beans that configure advanced features of Apache CXF. You can provide either a list of bean references or a list of embedded beans.</td>
</tr>
<tr>
<td>jaxws:handlers</td>
<td>Specifies a list of JAX-WS Handler implementations for processing messages. For more information in JAX-WS Handler implementations see Chapter 43, Writing Handlers.</td>
</tr>
<tr>
<td>jaxws:inInterceptors</td>
<td>Specifies a list of interceptors that process inbound responses. For more information see Part VII, “Developing Apache CXF Interceptors”.</td>
</tr>
<tr>
<td>jaxws:inFaultInterceptors</td>
<td>Specifies a list of interceptors that process inbound fault messages. For more information see Part VII, “Developing Apache CXF Interceptors”.</td>
</tr>
<tr>
<td>jaxws:outInterceptors</td>
<td>Specifies a list of interceptors that process outbound requests. For more information see Part VII, “Developing Apache CXF Interceptors”.</td>
</tr>
<tr>
<td>jaxws:outFaultInterceptors</td>
<td>Specifies a list of interceptors that process outbound fault messages. For more information see Part VII, “Developing Apache CXF Interceptors”.</td>
</tr>
<tr>
<td>jaxws:properties</td>
<td>Specifies a map of properties that are passed to the endpoint.</td>
</tr>
<tr>
<td>jaxws:conduitSelector</td>
<td>Specifies an org.apache.cxf.endpoint.ConduitSelector implementation for the client to use. A ConduitSelector implementation will override the default process used to select the Conduit object that is used to process outbound requests.</td>
</tr>
</tbody>
</table>

[a] The SOAP binding is configured using the soap:soapBinding bean.

Example

Example 17.5, “Simple Consumer Configuration” shows a simple consumer configuration.

Example 17.5. Simple Consumer Configuration

```xml
<beans ...
  xmlns:jaxws="http://cxf.apache.org/jaxws"
  ...>
</beans>
```
Enable schema validation on a JAX-WS consumer

To enable schema validation on a JAX-WS consumer, set the `schema-validation-enabled` property in the `jaxws:properties` child element of the `jaxws:client` element—for example:

```xml
<jaxws:client name="{http://apache.org/hello_world_soap_http}SoapPort"
  createdFromAPI="true">
  <jaxws:properties>
    <entry key="schema-validation-enabled" value="BOTH" />
  </jaxws:properties>
</jaxws:client>
```

For the list of allowed values of the `schema-validation-enabled` property, see Section 24.3.4.7, “Schema Validation Type Values”. 
CHAPTER 18. CONFIGURING JAX-RS ENDPOINTS

Abstract

This chapter explains how to instantiate and configure JAX-RS server endpoints in Blueprint XML and in Spring XML, and also how to instantiate and configure JAX-RS client endpoints (client proxy beans) in XML.

18.1. CONFIGURING JAX-RS SERVER ENDPOINTS

18.1.1. Defining a JAX-RS Server Endpoint

Basic server endpoint definition

To define a JAX-RS server endpoint in XML, you need to specify at least the following:

1. A jaxrs:server element, which is used to define the endpoint in XML. Note that the jaxrs: namespace prefix maps to different namespaces in Blueprint and in Spring respectively.

2. The base URL of the JAX-RS service, using the address attribute of the jaxrs:server element. Note that there are two different ways of specifying the address URL, which affects how the endpoint gets deployed:

   • As a relative URL—for example, /customers. In this case, the endpoint is deployed into the default HTTP container, and the endpoint’s base URL is implicitly obtained by combining the CXF servlet base URL with the specified relative URL. For example, if you deploy a JAX-RS endpoint to the Fuse container, the specified /customers URL would get resolved to the URL, http://Hostname:8181/cxf/customers (assuming that the container is using the default 8181 port).

   • As an absolute URL—for example, http://0.0.0.0:8200/cxf/customers. In this case, a new HTTP listener port is opened for the JAX-RS endpoint (if it is not already open). For example, in the context of Fuse, a new Undertow container would implicitly be created to host the JAX-RS endpoint. The special IP address, 0.0.0.0, acts as a wildcard, matching any of the hostnames assigned to the current host (which can be useful on multi-homed host machines).

3. One or more JAX-RS root resource classes, which provide the implementation of the JAX-RS service. The simplest way to specify the resource classes is to list them inside a jaxrs:serviceBeans element.

Blueprint example

The following Blueprint XML example shows how to define a JAX-RS endpoint, which specifies the relative address, /customers (so that it deploys into the default HTTP container) and is implemented by the service.CustomerService resource class:

```xml
<blueprint xmlns="http://www.osgi.org/xmlns/blueprint/v1.0.0"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xmlns:jaxrs="http://cxf.apache.org/blueprint/jaxrs"
    xmlns:cxf="http://cxf.apache.org/blueprint/core"
    xsi:schemaLocation="http://www.osgi.org/xmlns/blueprint/v1.0.0 https://www.osgi.org/xmlns/blueprint/v1.0.0/blueprint.xsd
```
To define a JAX-RS endpoint in Blueprint, you typically require at least the following XML namespaces:

<table>
<thead>
<tr>
<th>Prefix</th>
<th>Namespace</th>
</tr>
</thead>
<tbody>
<tr>
<td>(default)</td>
<td><a href="http://www.osgi.org/xmlns/blueprint/v1.0.0">http://www.osgi.org/xmlns/blueprint/v1.0.0</a></td>
</tr>
<tr>
<td>cxf</td>
<td><a href="http://cxf.apache.org/blueprint/core">http://cxf.apache.org/blueprint/core</a></td>
</tr>
<tr>
<td>jaxrs</td>
<td><a href="http://cxf.apache.org/blueprint/jaxrs">http://cxf.apache.org/blueprint/jaxrs</a></td>
</tr>
</tbody>
</table>

**Spring example**

The following Spring XML example shows how to define a JAX-RS endpoint, which specifies the relative address, `/customers` (so that it deploys into the default HTTP container) and is implemented by the `service.CustomerService` resource class:

```xml
<beans xmlns="http://www.springframework.org/schema/beans"
       xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
       xmlns:jaxrs="http://cxf.apache.org/jaxrs"
  <jaxrs:server id="customerService" address="/customers">
    <jaxrs:serviceBeans>
      <ref bean="serviceBean"/>
    </jaxrs:serviceBeans>
  </jaxrs:server>
  <bean id="serviceBean" class="service.CustomerService"/>
</beans>
```
Spring XML namespaces

To define a JAX-RS endpoint in Spring, you typically require at least the following XML namespaces:

<table>
<thead>
<tr>
<th>Prefix</th>
<th>Namespace</th>
</tr>
</thead>
<tbody>
<tr>
<td>(default)</td>
<td><a href="http://www.springframework.org/schema/beans">http://www.springframework.org/schema/beans</a></td>
</tr>
<tr>
<td>cxf</td>
<td><a href="http://cxf.apache.org/core">http://cxf.apache.org/core</a></td>
</tr>
<tr>
<td>jaxrs</td>
<td><a href="http://cxf.apache.org/jaxrs">http://cxf.apache.org/jaxrs</a></td>
</tr>
</tbody>
</table>

Auto-discovery in Spring XML

*(Spring only)* Instead of specifying the JAX-RS root resource classes explicitly, Spring XML enables you to configure auto-discovery, so that specific Java packages are searched for resource classes (classes annotated by @Path) and all of the discovered resource classes are automatically attached to the endpoint. In this case, you need to specify just the **address** attribute and the **basePackages** attribute in the **jaxrs:server** element.

For example, to define a JAX-RS endpoint which uses all of the JAX-RS resource classes under the **a.b.c** Java package, you can define the endpoint in Spring XML, as follows:

```xml
<jaxrs:server address="/customers" basePackages="a.b.c"/>
```

The auto-discovery mechanism also discovers and installs into the endpoint any JAX-RS provider classes that it finds under the specified Java packages.

Lifecycle management in Spring XML

*(Spring only)* Spring XML enables you to control the lifecycle of beans by setting the **scope** attribute on a **bean** element. The following scope values are supported by Spring:

- **singleton**  
  *(Default)* Creates a single bean instance, which is used everywhere and lasts for the entire lifetime of the Spring container.

- **prototype**  
  Creates a new bean instance every time the bean is injected into another bean or when a bean is obtained by invoking **getBean()** on the bean registry.

- **request**  
  *(Only available in a Web-aware container)* Creates a new bean instance for every request invoked on the bean.

- **session**  
  *(Only available in a Web-aware container)* Creates a new bean for the lifetime of a single HTTP session.

- **globalSession**  
  *(Only available in a Web-aware container)* Creates a new bean for the lifetime of a single HTTP session that is shared between portlets.
For more details about Spring scopes, please consult the Spring framework documentation on Bean scopes.

Note that Spring scopes do not work properly, if you specify JAX-RS resource beans through the jaxrs:serviceBeans element. If you specify the scope attribute on the resource beans in this case, the scope attribute is effectively ignored.

In order to make bean scopes work properly within a JAX-RS server endpoint, you require a level of indirection that is provided by a service factory. The simplest way to configure bean scopes is to specify resource beans using the beanNames attribute on the jaxrs:server element, as follows:

```xml
<beans ...>
   <jaxrs:server id="customerService" address="/service1"
      beanNames="customerBean1 customerBean2"/>

   <bean id="customerBean1" class="demo.jaxrs.server.CustomerRootResource1"
      scope="prototype"/>
   <bean id="customerBean2" class="demo.jaxrs.server.CustomerRootResource2"
      scope="prototype"/>
</beans>
```

Where the preceding example configures two resource beans, customerBean1 and customerBean2. The beanNames attribute is specified as a space-separated list of resource bean IDs.

For the ultimate degree of flexibility, you have the option of defining service factory objects explicitly, when you configure the JAX-RS server endpoint, using the jaxrs:serviceFactories element. This more verbose approach has the advantage that you can replace the default service factory implementation with your custom implementation, thus giving you ultimate control over the bean lifecycle. The following example shows how to configure the two resource beans, customerBean1 and customerBean2, using this approach:

```xml
<beans ...>
   <jaxrs:server id="customerService" address="/service1">
      <jaxrs:serviceFactories>
         <ref bean="sfactory1" />
         <ref bean="sfactory2" />
      </jaxrs:serviceFactories>
   </jaxrs:server>

   <bean id="sfactory1" class="org.apache.cxf.jaxrs.spring.SpringResourceFactory">
      <property name="beanId" value="customerBean1"/>
   </bean>
   <bean id="sfactory2" class="org.apache.cxf.jaxrs.spring.SpringResourceFactory">
      <property name="beanId" value="customerBean2"/>
   </bean>

   <bean id="customerBean1" class="demo.jaxrs.server.CustomerRootResource1"
      scope="prototype"/>
   <bean id="customerBean2" class="demo.jaxrs.server.CustomerRootResource2"
      scope="prototype"/>
</beans>
```
NOTE

If you specify a non-singleton lifecycle, it is often a good idea to implement and register an org.apache.cxf.service.Invoker bean (where the instance can be registered by referencing it from a jaxrs:server/jaxrs:invoker element).

Attaching a WADL document

You can optionally associate a WADL document with the JAX-RS server endpoint using the docLocation attribute on the jaxrs:server element. For example:

```xml
<jaxrs:server address="/rest" docLocation="wadl/bookStore.wadl">
  <jaxrs:serviceBeans>
    <bean class="org.bar.generated.BookStore"/>
  </jaxrs:serviceBeans>
</jaxrs:server>
```

Schema validation

If you have some external XML schemas, for describing message content in JAX-B format, you can associate these external schemas with the JAX-RS server endpoint through the jaxrs:schemaLocations element.

For example, if you have associated the server endpoint with a WADL document and you also want to enable schema validation on incoming messages, you can specify associated XML schema files as follows:

```xml
<jaxrs:server address="/rest" docLocation="wadl/bookStore.wadl">
  <jaxrs:serviceBeans>
    <bean class="org.bar.generated.BookStore"/>
  </jaxrs:serviceBeans>
  <jaxrs:schemaLocations>
    <jaxrs:schemaLocation>classpath:/schemas/a.xsd</jaxrs:schemaLocation>
    <jaxrs:schemaLocation>classpath:/schemas/b.xsd</jaxrs:schemaLocation>
  </jaxrs:schemaLocations>
</jaxrs:server>
```

Alternatively, if you want to include all of the schema files, *.xsd, in a given directory, you can just specify the directory name, as follows:

```xml
<jaxrs:server address="/rest" docLocation="wadl/bookStore.wadl">
  <jaxrs:serviceBeans>
    <bean class="org.bar.generated.BookStore"/>
  </jaxrs:serviceBeans>
  <jaxrs:schemaLocations>
    <jaxrs:schemaLocation>classpath:/schemas/</jaxrs:schemaLocation>
  </jaxrs:schemaLocations>
</jaxrs:server>
```

Specifying schemas in this way is generally useful for any kind of functionality that requires access to the JAX-B schemas.
Specifying the data binding

You can use the `jaxrs:dataBinding` element to specify the data binding that encodes the message body in request and reply messages. For example, to specify the JAX-B data binding, you could configure a JAX-RS endpoint as follows:

```xml
<jaxrs:server id="jaxbbook" address="/jaxb">
  <jaxrs:serviceBeans>
    <ref bean="serviceBean" />
  </jaxrs:serviceBeans>
  <jaxrs:dataBinding>
    <bean class="org.apache.cxf.jaxb.JAXBDataBinding"/>
  </jaxrs:dataBinding>
</jaxrs:server>
```

Or to specify the Aegis data binding, you could configure a JAX-RS endpoint as follows:

```xml
<jaxrs:server id="aegisbook" address="/aegis">
  <jaxrs:serviceBeans>
    <ref bean="serviceBean" />
  </jaxrs:serviceBeans>
  <jaxrs:dataBinding>
    <bean class="org.apache.cxf.aegis.databinding.AegisDatabinding">
      <property name="aegisContext">
        <bean class="org.apache.cxf.aegis.AegisContext">
          <property name="writeXsiTypes" value="true"/>
        </bean>
      </property>
    </bean>
  </jaxrs:dataBinding>
</jaxrs:server>
```

Using the JMS transport

It is possible to configure JAX-RS to use a JMS messaging library as a transport protocol, instead of HTTP. Because JMS itself is not a transport protocol, the actual messaging protocol depends on the particular JMS implementation that you configure.

For example, the following Spring XML example shows how to configure a JAX-RS server endpoint to use the JMS transport protocol:

```xml
<beans xmlns="http://www.springframework.org/schema/beans"
      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xmlns:jms="http://cxf.apache.org/transports/jms"
      xmlns:jaxrs="http://cxf.apache.org/jaxrs"
      xsi:schemaLocation="
  <bean class="org.springframework.beans.factory.config.PropertyPlaceholderConfigurer"/>
  <bean id="ConnectionFactory" class="org.apache.activemq.ActiveMQConnectionFactory">
    <property name="brokerURL" value="amq://localhost:5672"/>
  </bean>
</beans>
```
Note the following points about the preceding example:

- **JMS implementation**—the JMS implementation is provided by the `ConnectionFactory` bean, which instantiates an Apache ActiveMQ connection factory object. After you instantiate the connection factory, it is automatically installed as the default JMS implementation layer.

- **JMS conduit or destination object**—Apache CXF implicitly instantiates a JMS conduit object (to represent a JMS consumer) or a JMS destination object (to represent a JMS provider). This object must be uniquely identified by a QName, which is defined through the attribute settings `xmlns:s="http://books.com"` (defining the namespace prefix) and `serviceName="s:BookService"` (defining the QName).

- **Transport ID**—to select the JMS transport, the `transportId` attribute must be set to `http://cxf.apache.org/transports/jms`.

- **JMS address**—the `jaxrs:server/@address` attribute uses a standardized syntax to specify the JMS queue or JMS topic to send to. For details of this syntax, see [https://tools.ietf.org/id/draft-merrick-jms-uri-06.txt](https://tools.ietf.org/id/draft-merrick-jms-uri-06.txt).

### Extension mappings and language mappings

A JAX-RS server endpoint can be configured so that it automatically maps a file suffix (appearing in the URL) to a MIME content type header, and maps a language suffix to a language type header. For example, consider a HTTP request of the following form:

```
GET /resource.xml
```

You can configure the JAX-RS server endpoint to map the `.xml` suffix automatically, as follows:

```
<jaxrs:server id="customerService" address="/">
  <jaxrs:serviceBeans>
    <bean class="org.apache.cxf.jaxrs.systests.CustomerService" />
  </jaxrs:serviceBeans>
  <jaxrs:extensionMappings>
    <entry key="json" value="application/json"/>
    <entry key="xml" value="application/xml"/>
  </jaxrs:extensionMappings>
</jaxrs:server>
```

When the preceding server endpoint receives the HTTP request, it automatically creates a new content type header of type, `application/xml`, and strips the `.xml` suffix from the resource URL.
For the language mapping, consider a HTTP request of the following form:

```
GET /resource.en
```

You can configure the JAX-RS server endpoint to map the `.en` suffix automatically, as follows:

```xml
<jaxrs:server id="customerService" address="/"

<jaxrs:serviceBeans>
    <bean class="org.apache.cxf.jaxrs.systests.CustomerService" />
</jaxrs:serviceBeans>

<jaxrs:languageMappings>
    <entry key="en" value="en-gb"/>
</jaxrs:languageMappings>
</jaxrs:server>
```

When the preceding server endpoint receives the HTTP request, it automatically creates a new accept language header with the value, `en-gb`, and strips the `.en` suffix from the resource URL.

### 18.1.2. jaxrs:server Attributes

#### Attributes

Table 18.1, ”JAX-RS Server Endpoint Attributes” describes the attributes available on the `jaxrs:server` element.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>id</code></td>
<td>Specifies a unique identifier that other configuration elements can use to refer to the endpoint.</td>
</tr>
<tr>
<td><code>address</code></td>
<td>Specifies the address of an HTTP endpoint. This value will override the value specified in the services contract.</td>
</tr>
<tr>
<td><code>basePackages</code></td>
<td><em>(Spring only)</em> Enables auto-discovery, by specifying a comma-separated list of Java packages, which are searched to discover JAX-RS root resource classes and/or JAX-RS provider classes.</td>
</tr>
<tr>
<td><code>beanNames</code></td>
<td>Specifies a space-separated list of bean IDs of JAX-RS root resource beans. In the context of Spring XML, it is possible to define a root resource beans’ lifecycle by setting the <code>scope</code> attribute on the root resource <code>bean</code> element.</td>
</tr>
<tr>
<td><code>bindingId</code></td>
<td>Specifies the ID of the message binding the service uses. A list of valid binding IDs is provided in Chapter 23, Apache CXF Binding IDs.</td>
</tr>
<tr>
<td>Attribute</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>bus</strong></td>
<td>Specifies the ID of the Spring bean configuring the bus used to manage the service endpoint. This is useful when configuring several endpoints to use a common set of features.</td>
</tr>
<tr>
<td><strong>docLocation</strong></td>
<td>Specifies the location of an external WADL document.</td>
</tr>
<tr>
<td><strong>modelRef</strong></td>
<td>Specifies a model schema as a classpath resource (for example, a URL of the form <code>classpath:/path/to/model.xml</code>). For details of how to define a JAX-RS model schema, see Section 18.3, “Defining REST Services with the Model Schema”.</td>
</tr>
<tr>
<td><strong>publish</strong></td>
<td>Specifies if the service should be automatically published. If set to <code>false</code>, the developer must explicitly publish the endpoint.</td>
</tr>
<tr>
<td><strong>publishedEndpointUrl</strong></td>
<td>Specifies the URL base address, which gets inserted into the <code>wadl:resources/@base</code> attribute of the auto-generated WADL interface.</td>
</tr>
<tr>
<td><strong>serviceAnnotation</strong></td>
<td><em>(Spring only)</em> Specifies the service annotation class name for auto-discovery in Spring. When used in combination with the <code>basePackages</code> property, this option restricts the collection of auto-discovered classes to include only the classes that are annotated by this annotation type. guess!! Is this correct?</td>
</tr>
<tr>
<td><strong>serviceClass</strong></td>
<td>Specifies the name of a JAX-RS root resource class (which implements a JAX-RS service). In this case, the class is instantiated by Apache CXF, not by Blueprint or Spring. If you want to instantiate the class in Blueprint or Spring, use the <code>jaxrs:serviceBeans</code> child element instead.</td>
</tr>
<tr>
<td><strong>serviceName</strong></td>
<td>Specifies the service QName (using the format <code>ns:name</code>) for the JAX-RS endpoint in the special case where a JMS transport is used. For details, see the section called “Using the JMS transport”.</td>
</tr>
<tr>
<td><strong>staticSubresourceResolution</strong></td>
<td>If true, disables dynamic resolution of static sub-resources. Default is false.</td>
</tr>
</tbody>
</table>
18.1.3. jaxrs:server Child Elements

**Child elements**

Table 18.2, “JAX-RS Server Endpoint Child Elements” describes the child elements of the `jaxrs:server` element.

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>jaxrs:executor</td>
<td>Specifies a Java Executor (thread pool implementation) that is used for the service. This is specified using an embedded bean definition.</td>
</tr>
<tr>
<td>jaxrs:features</td>
<td>Specifies a list of beans that configure advanced features of Apache CXF. You can provide either a list of bean references or a list of embedded beans.</td>
</tr>
<tr>
<td>jaxrs:binding</td>
<td>Not used.</td>
</tr>
<tr>
<td>jaxrs:dataBinding</td>
<td>Specifies the class implementing the data binding used by the endpoint. This is specified using an embedded bean definition. For more details, see the section called “Specifying the data binding”.</td>
</tr>
<tr>
<td>Element</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>jaxrs:inInterceptors</td>
<td>Specifies a list of interceptors that process inbound requests. For more information see Part VII, “Developing Apache CXF Interceptors”.</td>
</tr>
<tr>
<td>jaxrs:inFaultInterceptors</td>
<td>Specifies a list of interceptors that process inbound fault messages. For more information see Part VII, “Developing Apache CXF Interceptors”.</td>
</tr>
<tr>
<td>jaxrs:outInterceptors</td>
<td>Specifies a list of interceptors that process outbound replies. For more information see Part VII, “Developing Apache CXF Interceptors”.</td>
</tr>
<tr>
<td>jaxrs:outFaultInterceptors</td>
<td>Specifies a list of interceptors that process outbound fault messages. For more information see Part VII, “Developing Apache CXF Interceptors”.</td>
</tr>
<tr>
<td>jaxrs:invoker</td>
<td>Specifies an implementation of the org.apache.cxf.service.Invoker interface used by the service.</td>
</tr>
<tr>
<td>jaxrs:serviceFactories</td>
<td>Provides you with the maximum degree of control over the lifecycle of the JAX-RS root resources associated with this endpoint. The children of this element (which must be instances of org.apache.cxf.jaxrs.lifecycle.ResourceProvider type) are used to create JAX-RS root resource instances.</td>
</tr>
<tr>
<td>jaxrs:properties</td>
<td>Specifies a Spring map of properties that are passed along to the endpoint. These properties can be used to control features like enabling MTOM support.</td>
</tr>
<tr>
<td>jaxrs:serviceBeans</td>
<td>The children of this element are instances of (bean element) or references to (ref element) JAX-RS root resources. Note that in this case the scope attribute (Spring only), if present in the bean element, is ignored.</td>
</tr>
<tr>
<td>jaxrs:modelBeans</td>
<td>Consists of a list of references to one or more org.apache.cxf.jaxrs.model.UserResource beans, which are the basic elements of a resource model (corresponding to jaxrs:resource elements). For details, see Section 18.3, “Defining REST Services with the Model Schema”.</td>
</tr>
<tr>
<td>Element</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>jaxrs:model</td>
<td>Defines a resource model directly in this endpoint (that is, this jaxrs:model element can contain one or more jaxrs:resource elements). For details, see Section 18.3, “Defining REST Services with the Model Schema”.</td>
</tr>
<tr>
<td>jaxrs:providers</td>
<td>Enables you to register one or more custom JAX-RS providers with this endpoint. The children of this element are instances of (bean element) or references to (ref element) JAX-RS providers.</td>
</tr>
<tr>
<td>jaxrs:extensionMappings</td>
<td>When the URL of a REST invocation ends in a file extension, you can use this element to associate it automatically with a particular content type. For example, the .xml file extension could be associated with the application/xml content type. For details, see the section called “Extension mappings and language mappings”.</td>
</tr>
<tr>
<td>jaxrs:languageMappings</td>
<td>When the URL of a REST invocation ends in a language suffix, you can use this element to map this to a particular language. For example, the .en language suffix could be associated with the en-GB language. For details, see the section called “Extension mappings and language mappings”.</td>
</tr>
<tr>
<td>jaxrs:schemaLocations</td>
<td>Specifies one or more XML schemas used for validating XML message content. This element can contain one or more jaxrs:schemaLocation elements, each specifying the location of an XML schema file (usually as a classpath URL). For details, see the section called “Schema validation”.</td>
</tr>
<tr>
<td>jaxrs:resourceComparator</td>
<td>Enables you to register a custom resource comparator, which implements the algorithm used to match an incoming URL path to a particular resource class or method.</td>
</tr>
<tr>
<td>jaxrs:resourceClasses</td>
<td>(Blueprint only) Can be used instead of the jaxrs:server/@serviceClass attribute, if you want to create multiple resources from class names. The children of jaxrs:resourceClasses must be class elements with aname attribute set to the name of the resource class. In this case, the classes are instantiated by Apache CXF, not by Blueprint or Spring.</td>
</tr>
</tbody>
</table>

[a] The Invoker implementation controls how a service is invoked. For example, it controls whether each request is handled by a new instance of the service implementation or if state is preserved across invocations.
18.2. CONFIGURING JAX-RS CLIENT ENDPOINTS

18.2.1. Defining a JAX-RS Client Endpoint

Injecting client proxies

The main point of instantiating a client proxy bean in an XML language (Blueprint XML or Spring XML) is in order to inject it into another bean, which can then use the client proxy to invoke the REST service. To create a client proxy bean in XML, use the `jaxrs:client` element.

Namespaces

The JAX-RS client endpoint is defined using a different XML namespace from the server endpoint. The following table shows which namespace to use for which XML language:

<table>
<thead>
<tr>
<th>XML Language</th>
<th>Namespace for client endpoint</th>
</tr>
</thead>
<tbody>
<tr>
<td>Blueprint</td>
<td><a href="http://cxf.apache.org/blueprint/jaxrs-client">http://cxf.apache.org/blueprint/jaxrs-client</a></td>
</tr>
<tr>
<td>Spring</td>
<td><a href="http://cxf.apache.org/jaxrs-client">http://cxf.apache.org/jaxrs-client</a></td>
</tr>
</tbody>
</table>

Basic client endpoint definition

The following example shows how to create a client proxy bean in Blueprint XML or Spring XML:

```xml
<jaxrs:client id="restClient"
              address="http://localhost:8080/test/services/rest"
              serviceClass="org.apache.cxf.systest.jaxrs.BookStoreJaxrsJaxws"/>
```

Where you must set the following attributes to define the basic client endpoint:

**id**

The bean ID of the client proxy can be used to inject the client proxy into other beans in your XML configuration.

**address**

The address attribute specifies the base URL of the REST invocations.

**serviceClass**

The `serviceClass` attribute provides a description of the REST service by specifying a root resource class (annotated by `@Path`). In fact, this is a server class, but it is not used directly by the client. The specified class is used only for its metadata (through Java reflection and JAX-RS annotations), which is used to construct the client proxy dynamically.

Specifying headers

You can add HTTP headers to the client proxy’s invocations using the `jaxrs:headers` child elements, as follows:

```xml
<jaxrs:client id="restClient"
              address="http://localhost:8080/test/services/rest"
              serviceClass="org.apache.cxf.systest.jaxrs.BookStoreJaxrsJaxws"/>
```
18.2.2. jaxrs:client Attributes

Attributes

Table 18.3, “JAX-RS Client Endpoint Attributes” describes the attributes available on the jaxrs:client element.

Table 18.3. JAX-RS Client Endpoint Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>address</td>
<td>Specifies the HTTP address of the endpoint where the consumer will make requests. This value overrides the value set in the contract.</td>
</tr>
<tr>
<td>bindingId</td>
<td>Specifies the ID of the message binding the consumer uses. A list of valid binding IDs is provided in Chapter 23, Apache CXF Binding IDs.</td>
</tr>
<tr>
<td>bus</td>
<td>Specifies the ID of the Spring bean configuring the bus managing the endpoint.</td>
</tr>
<tr>
<td>inheritHeaders</td>
<td>Specifies whether the headers set for this proxy will be inherited, if a subresource proxy is created from this proxy. Default is false.</td>
</tr>
<tr>
<td>username</td>
<td>Specifies the username used for simple username/password authentication.</td>
</tr>
<tr>
<td>password</td>
<td>Specifies the password used for simple username/password authentication.</td>
</tr>
<tr>
<td>modelRef</td>
<td>Specifies a model schema as a classpath resource (for example, a URL of the form classpath:/path/to/model.xml). For details of how to define a JAX-RS model schema, see Section 18.3, “Defining REST Services with the Model Schema”.</td>
</tr>
</tbody>
</table>
### Attribute Description

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>serviceClass</td>
<td>Specifies the name of a service interface or a resource class (that is annotated with <code>@PATH</code>), re-using it from the JAX-RS server implementation. In this case, the specified class is <strong>not</strong> invoked directly (it is actually a server class). The specified class is used only for its metadata (through Java reflection and JAX-RS annotations), which is used to construct the client proxy dynamically.</td>
</tr>
<tr>
<td>serviceName</td>
<td>Specifies the service QName (using the format <code>ns:name</code>) for the JAX-RS endpoint in the special case where a JMS transport is used. For details, see the section called “Using the JMS transport.”</td>
</tr>
<tr>
<td>threadSafe</td>
<td>Specifies whether or not the client proxy is thread-safe. Default is <code>false</code>.</td>
</tr>
<tr>
<td>transportId</td>
<td>For selecting a non-standard transport layer (in place of HTTP). In particular, you can select the JMS transport by setting this property to <code>http://cxf.apache.org/transports/jms</code>. For details, see the section called “Using the JMS transport”.</td>
</tr>
<tr>
<td>abstract</td>
<td><em>(Spring only)</em> Specifies if the bean is an abstract bean. Abstract beans act as parents for concrete bean definitions and are not instantiated. The default is <code>false</code>. Setting this to <code>true</code> instructs the bean factory not to instantiate the bean.</td>
</tr>
<tr>
<td>depends-on</td>
<td><em>(Spring only)</em> Specifies a list of beans that the endpoint depends on being instantiated before it can be instantiated.</td>
</tr>
</tbody>
</table>

#### 18.2.3. jaxrs:client Child Elements

**Child elements**

Table 18.4, “JAX-RS Client Endpoint Child Elements” describes the child elements of the `jaxrs:client` element.

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>jaxrs:executor</td>
<td></td>
</tr>
<tr>
<td>Element</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>jaxrs:features</td>
<td>Specifies a list of beans that configure advanced features of Apache CXF. You can provide either a list of bean references or a list of embedded beans.</td>
</tr>
<tr>
<td>jaxrs:binding</td>
<td>Not used.</td>
</tr>
<tr>
<td>jaxrs:dataBinding</td>
<td>Specifies the class implementing the data binding used by the endpoint. This is specified using an embedded bean definition. For more details, see the section called “Specifying the data binding”.</td>
</tr>
<tr>
<td>jaxrs:inInterceptors</td>
<td>Specifies a list of interceptors that process inbound responses. For more information see Part VII, “Developing Apache CXF Interceptors”.</td>
</tr>
<tr>
<td>jaxrs:inFaultInterceptors</td>
<td>Specifies a list of interceptors that process inbound fault messages. For more information see Part VII, “Developing Apache CXF Interceptors”.</td>
</tr>
<tr>
<td>jaxrs:outInterceptors</td>
<td>Specifies a list of interceptors that process outbound requests. For more information see Part VII, “Developing Apache CXF Interceptors”.</td>
</tr>
<tr>
<td>jaxrs:outFaultInterceptors</td>
<td>Specifies a list of interceptors that process outbound fault messages. For more information see Part VII, “Developing Apache CXF Interceptors”.</td>
</tr>
<tr>
<td>jaxrs:properties</td>
<td>Specifies a map of properties that are passed to the endpoint.</td>
</tr>
<tr>
<td>jaxrs:providers</td>
<td>Enables you to register one or more custom JAX-RS providers with this endpoint. The children of this element are instances of (bean element) or references to (ref element) JAX-RS providers.</td>
</tr>
<tr>
<td>jaxrs:modelBeans</td>
<td>Consists of a list of references to one or more org.apache.cxf.jaxrs.model.UserResource beans, which are the basic elements of a resource model (corresponding to jaxrs:resource elements). For details, see Section 18.3, “Defining REST Services with the Model Schema”.</td>
</tr>
<tr>
<td>jaxrs:model</td>
<td>Defines a resource model directly in this endpoint (that is, a jaxrs:model element containing one or more jaxrs:resource elements). For details, see Section 18.3, “Defining REST Services with the Model Schema”.</td>
</tr>
</tbody>
</table>
18.3. DEFINING REST SERVICES WITH THE MODEL SCHEMA

RESTful services without annotations

The JAX-RS model schema makes it possible to define RESTful services without annotating Java classes. That is, instead of adding annotations like `@Path`, `@PathParam`, `@Consumes`, `@Produces`, and so on, directly to a Java class (or interface), you can provide all of the relevant REST metadata in a separate XML file, using the model schema. This can be useful, for example, in cases where you are unable to modify the Java source that implements the service.

Example model schema

Example 18.1, “Sample JAX-RS Model Schema” shows an example of a model schema that defines service metadata for the `BookStoreNoAnnotations` root resource class.

```
<model xmlns="http://cxf.apache.org/jaxrs">
  <resource name="org.apache.cxf.systest.jaxrs.BookStoreNoAnnotations" path="bookstore"
    produces="application/json" consumes="application/json">
    <operation name="getBook" verb="GET" path="/books/{id}" produces="application/xml">
      <param name="id" type="PATH"/>
    </operation>
    <operation name="getBookChapter" path="/books/{id}/chapter">
      <param name="id" type="PATH"/>
    </operation>
    <operation name="updateBook" verb="PUT">
      <param name="book" type="REQUEST_BODY"/>
    </operation>
  </resource>
  <resource name="org.apache.cxf.systest.jaxrs.ChapterNoAnnotations">
    <operation name="getItself" verb="GET"/>
    <operation name="updateChapter" verb="PUT" consumes="application/xml">
      <param name="content" type="REQUEST_BODY"/>
    </operation>
  </resource>
</model>
```
Namespaces

The XML namespace that you use to define a model schema depends on whether you are defining the corresponding JAX-RS endpoint in Blueprint XML or in Spring XML. The following table shows which namespace to use for which XML language:

<table>
<thead>
<tr>
<th>XML Language</th>
<th>Namespace</th>
</tr>
</thead>
<tbody>
<tr>
<td>Blueprint</td>
<td><a href="http://cxf.apache.org/blueprint/jaxrs">http://cxf.apache.org/blueprint/jaxrs</a></td>
</tr>
<tr>
<td>Spring</td>
<td><a href="http://cxf.apache.org/jaxrs">http://cxf.apache.org/jaxrs</a></td>
</tr>
</tbody>
</table>

How to attach a model schema to an endpoint

To define and attach a model schema to an endpoint, perform the following steps:

1. Define the model schema, using the appropriate XML namespace for your chosen injection platform (Blueprint XML or Spring XML).

2. Add the model schema file to your project’s resources, so that the schema file is available on the classpath in the final package (JAR, WAR, or OSGi bundle file).

   **NOTE**

   Alternatively, it is also possible to embed a model schema directly into a JAX-RS endpoint, using the endpoint’s `jaxrs:model` child element.

3. Configure the endpoint to use the model schema, by setting the endpoint’s `modelRef` attribute to the location of the model schema on the classpath (using a classpath URL).

4. If necessary, instantiate the root resources explicitly, using the `jaxrs:serviceBeans` element. You can skip this step, if the model schema references root resource classes directly (instead of referencing base interfaces).

Configuration of model schema referencing a class

If the model schema applies directly to root resource classes, there is no need to define any root resource beans using the `jaxrs:serviceBeans` element, because the model schema automatically instantiates the root resource beans.

For example, given that `customer-resources.xml` is a model schema that associates metadata with customer resource classes, you could instantiate a `customerService` service endpoint as follows:

```xml
<jaxrs:server id="customerService"
    address="/customers"
    modelRef="classpath:/org/example/schemas/customer-resources.xml" />
```

Configuration of model schema referencing an interface

If the model schema applies to Java interfaces (which are the base interfaces of the root resources), you must instantiate the root resource classes using the `jaxrs:serviceBeans` element in the endpoint.
For example, given that `customer-interfaces.xml` is a model schema that associates metadata with customer interfaces, you could instantiate a `customerService` service endpoint as follows:

```xml
<jaxrs:server id="customerService"
    address="/customers"
    modelRef="classpath:/org/example/schemas/customer-interfaces.xml">
    <jaxrs:serviceBeans>
        <ref component-id="serviceBean" />
    </jaxrs:serviceBeans>
</jaxrs:server>

<bean id="serviceBean" class="service.CustomerService"/>
```

## Model Schema Reference

A model schema is defined using the following XML elements:

### model

Root element of the model schema. If you need to reference the model schema (for example, from a JAX-RS endpoint using the `modelRef` attribute), you should set the `id` attribute on this element.

### model/resource

The `resource` element is used to associate metadata with a specific root resource class (or with a corresponding interface). You can define the following attributes on the `resource` element:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the resource class (or corresponding interface) to which this resource model is applied.</td>
</tr>
<tr>
<td>path</td>
<td>The component of the REST URL path that maps to this resource.</td>
</tr>
<tr>
<td>consumes</td>
<td>Specifies the content type (Internet media type) consumed by this resource—for example, <code>application/xml</code> or <code>application/json</code>.</td>
</tr>
<tr>
<td>produces</td>
<td>Specifies the content type (Internet media type) produced by this resource—for example, <code>application/xml</code> or <code>application/json</code>.</td>
</tr>
</tbody>
</table>

### model/resource/operation

The `operation` element is used to associate metadata with Java methods. You can define the following attributes on an `operation` element:
<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>The name of the Java method to which this element is applied.</td>
</tr>
<tr>
<td>path</td>
<td>The component of the REST URL path that maps to this method. This attribute value can include parameter references, for example: <code>path=&quot;/books/{id}/chapter&quot;</code>, where <code>{id}</code> extracts the value of the <code>id</code> parameter from the path.</td>
</tr>
<tr>
<td>verb</td>
<td>Specifies the HTTP verb that maps to this method. Typically one of: <strong>GET</strong>, <strong>POST</strong>, <strong>PUT</strong>, or <strong>DELETE</strong>. If the HTTP verb is <strong>not</strong> specified, it is assumed that the Java method is a <strong>sub-resource locator</strong>, which returns a reference to a sub-resource object (where the sub-resource class must also be provided with metadata using a <strong>resource</strong> element).</td>
</tr>
<tr>
<td>consumes</td>
<td>Specifies the content type (Internet media type) consumed by this operation—for example, <strong>application/xml</strong> or <strong>application/json</strong>.</td>
</tr>
<tr>
<td>produces</td>
<td>Specifies the content type (Internet media type) produced by this operation—for example, <strong>application/xml</strong> or <strong>application/json</strong>.</td>
</tr>
<tr>
<td>oneway</td>
<td>If <strong>true</strong>, configures the operation to be <strong>oneway</strong>, meaning that no reply message is needed. Defaults to <strong>false</strong>.</td>
</tr>
</tbody>
</table>

### model/resource/operation/param

The **param** element is used to extract a value from the REST URL and inject it into one of the method parameters. You can define the following attributes on a **param** element:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Attribute</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-------------</td>
</tr>
<tr>
<td>name</td>
<td>The name of the Java method parameter to which this element is applied.</td>
</tr>
<tr>
<td>type</td>
<td>Specifies how the parameter value is extracted from the REST URL or message. It can be set to one of the following values: <strong>PATH, QUERY, MATRIX, HEADER, COOKIE, FORM, CONTEXT, REQUEST_BODY</strong>.</td>
</tr>
<tr>
<td>defaultValue</td>
<td>Default value to inject into the parameter, in case a value could not be extracted from the REST URL or message.</td>
</tr>
<tr>
<td>encoded</td>
<td>If true, the parameter value is injected in its URI encoded form (that is, using %nn encoding). Default is false. For example, when extracting a parameter from the URL path, /name/Joe%20Bloggs with encoded set to true, the parameter is injected as Joe%20Bloggs; otherwise, the parameter would be injected as Joe Bloggs.</td>
</tr>
</tbody>
</table>
CHAPTER 19. APACHE CXF LOGGING

Abstract
This chapter describes how to configure logging in the Apache CXF runtime.

19.1. OVERVIEW OF APACHE CXF LOGGING

Overview
Apache CXF uses the Java logging utility, java.util.logging. Logging is configured in a logging configuration file that is written using the standard java.util.Properties format. To run logging on an application, you can specify logging programmatically or by defining a property at the command that points to the logging configuration file when you start the application.

Default properties file
Apache CXF comes with a default logging.properties file, which is located in your InstallDir/etc directory. This file configures both the output destination for the log messages and the message level that is published. The default configuration sets the loggers to print message flagged with the WARNING level to the console. You can either use the default file without changing any of the configuration settings or you can change the configuration settings to suit your specific application.

Logging feature
Apache CXF includes a logging feature that can be plugged into your client or your service to enable logging. Example 19.1, "Configuration for Enabling Logging" shows the configuration to enable the logging feature.

Example 19.1. Configuration for Enabling Logging

```xml
<jaxws:endpoint...>
  <jaxws:features>
    <bean class="org.apache.cxf.feature.LoggingFeature"/>
  </jaxws:features>
</jaxws:endpoint>
```

For more information, see Section 19.6, "Logging Message Content".

Where to begin?
To run a simple example of logging follow the instructions outlined in a Section 19.2, "Simple Example of Using Logging".

For more information on how logging works in Apache CXF, read this entire chapter.

More information on java.util.logging
The java.util.logging utility is one of the most widely used Java logging frameworks. There is a lot of information available online that describes how to use and extend this framework. As a starting point, however, the following documents gives a good overview of java.util.logging:
19.2. SIMPLE EXAMPLE OF USING LOGGING

Changing the log levels and output destination

To change the log level and output destination of the log messages in the wsdl_first sample application, complete the following steps:

1. Run the sample server as described in the Running the demo using java section of the README.txt file in the InstallDir/samples/wsdl_first directory. Note that the server start command specifies the default logging.properties file, as follows:

<table>
<thead>
<tr>
<th>Platform</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows</td>
<td><code>start java -Djava.util.logging.config.file=%CXF_HOME%\etc\logging.properties demo.hw.server.Server</code></td>
</tr>
<tr>
<td>UNIX</td>
<td><code>java -Djava.util.logging.config.file=$CXF_HOME/etc/logging.properties demo.hw.server.Server &amp;</code></td>
</tr>
</tbody>
</table>

The default logging.properties file is located in the InstallDir/ directory. It configures the Apache CXF loggers to print WARNING level log messages to the console. As a result, you see very little printed to the console.

2. Stop the server as described in the README.txt file.

3. Make a copy of the default logging.properties file, name it mylogging.properties file, and save it in the same directory as the default logging.properties file.

4. Change the global logging level and the console logging levels in your mylogging.properties file to INFO by editing the following lines of configuration:

   ```
   .level= INFO
   java.util.logging.ConsoleHandler.level = INFO
   ```

5. Restart the server using the following command:

<table>
<thead>
<tr>
<th>Platform</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Platform</td>
<td>Command +</td>
</tr>
<tr>
<td>----------</td>
<td>-----------</td>
</tr>
<tr>
<td>Windows</td>
<td>start java -Djava.util.logging.config.file=%CXF_HOM\E%\etc\mylogging.properties demo.hw.server.Server +</td>
</tr>
<tr>
<td>UNIX</td>
<td>java -Djava.util.logging.config.file=$CXF_HOM\E/etc/mylogging.properties demo.hw.server.Server &amp; +</td>
</tr>
</tbody>
</table>

Because you configured the global logging and the console logger to log messages of level **INFO**, you see a lot more log messages printed to the console.

### 19.3. DEFAULT LOGGING CONFIGURATION FILE

#### 19.3.1. Overview of Logging Configuration

The default logging configuration file, **logging.properties**, is located in the **InstallDir/etc** directory. It configures the Apache CXF loggers to print **WARNING** level messages to the console. If this level of logging is suitable for your application, you do not have to make any changes to the file before using it. You can, however, change the level of detail in the log messages. For example, you can change whether log messages are sent to the console, to a file or to both. In addition, you can specify logging at the level of individual packages.

**NOTE**

This section discusses the configuration properties that appear in the default **logging.properties** file. There are, however, many other **java.util.logging** configuration properties that you can set. For more information on the **java.util.logging** API, see the **java.util.logging** javadoc at: [http://download.oracle.com/javase/1.5/docs/api/java/util/logging/package-summary.html](http://download.oracle.com/javase/1.5/docs/api/java/util/logging/package-summary.html).

#### 19.3.2. Configuring Logging Output

**Overview**

The Java logging utility, **java.util.logging**, uses handler classes to output log messages. **Table 19.1, “Java.util.logging Handler Classes”** shows the handlers that are configured in the default **logging.properties** file.

**Table 19.1. Java.util.logging Handler Classes**
<table>
<thead>
<tr>
<th>Handler Class</th>
<th>Outputs to</th>
</tr>
</thead>
<tbody>
<tr>
<td>ConsoleHandler</td>
<td>Outputs log messages to the console</td>
</tr>
<tr>
<td>FileHandler</td>
<td>Outputs log messages to a file</td>
</tr>
</tbody>
</table>

**IMPORTANT**

The handler classes must be on the system classpath in order to be installed by the Java VM when it starts. This is done when you set the Apache CXF environment.

### Configuring the console handler

Example 19.2, “Configuring the Console Handler” shows the code for configuring the console logger.

```java
handlers= java.util.logging.ConsoleHandler
```

The console handler also supports the configuration properties shown in Example 19.3, “Console Handler Properties”.

```java
java.util.logging.ConsoleHandler.level = WARNING
java.util.logging.ConsoleHandler.formatter = java.util.logging.SimpleFormatter
```

The configuration properties shown in Example 19.3, “Console Handler Properties” can be explained as follows:

The console handler supports a separate log level configuration property. This allows you to limit the log messages printed to the console while the global logging setting can be different (see Section 19.3.3, “Configuring Logging Levels”). The default setting is **WARNING**.

Specifies the `java.util.logging` formatter class that the console handler class uses to format the log messages. The default setting is the `java.util.logging.SimpleFormatter`.

### Configuring the file handler

Example 19.4, “Configuring the File Handler” shows code that configures the file handler.

```java
handlers= java.util.logging.FileHandler
```

The file handler also supports the configuration properties shown in Example 19.5, “File Handler Configuration Properties”.
Example 19.5. File Handler Configuration Properties

```
java.util.logging.FileHandler.pattern = %h/java%u.log
java.util.logging.FileHandler.limit = 50000
java.util.logging.FileHandler.count = 1
java.util.logging.FileHandler.formatter = java.util.logging.XMLFormatter
```

The configuration properties shown in Example 19.5, “File Handler Configuration Properties” can be explained as follows:

Specifies the location and pattern of the output file. The default setting is your home directory.

Specifies, in bytes, the maximum amount that the logger writes to any one file. The default setting is **50000**. If you set it to zero, there is no limit on the amount that the logger writes to any one file.

Specifies how many output files to cycle through. The default setting is **1**.

Specifies the **java.util.logging** formatter class that the file handler class uses to format the log messages. The default setting is the **java.util.logging.XMLFormatter**.

Configuring both the console handler and the file handler

You can set the logging utility to output log messages to both the console and to a file by specifying the console handler and the file handler, separated by a comma, as shown in Configuring Both Console Logging and File.

Configuring Both Console Logging and File

```
handlers= java.util.logging.FileHandler, java.util.logging.ConsoleHandler
```

19.3.3. Configuring Logging Levels

Logging levels

The **java.util.logging** framework supports the following levels of logging, from the least verbose to the most verbose:

- **SEVERE**
- **WARNING**
- **INFO**
- **CONFIG**
- **FINE**
- **FINER**
- **FINEST**
Configuring the global logging level

To configure the types of event that are logged across all loggers, configure the global logging level as shown in Example 19.6, “Configuring Global Logging Levels”.

Example 19.6. Configuring Global Logging Levels

```java
.level= WARNING
```

Configuring logging at an individual package

```java
level
```

The `java.util.logging` framework supports configuring logging at the level of an individual package. For example, the line of code shown in Example 19.7, “Configuring Logging at the Package Level” configures logging at a `SEVERE` level on classes in the `com.xyz.foo` package.

Example 19.7. Configuring Logging at the Package Level

```java
com.xyz.foo.level = SEVERE
```

19.4. ENABLING LOGGING AT THE COMMAND LINE

Overview

You can run the logging utility on an application by defining a `java.util.logging.config.file` property when you start the application. You can either specify the default `logging.properties` file or a `logging.properties` file that is unique to that application.

Specifying the log configuration file on application start-up

To specify logging on application start-up add the flag shown in Example 19.8, “Flag to Start Logging on the Command Line” when starting the application.

Example 19.8. Flag to Start Logging on the Command Line

```bash
-Djava.util.logging.config.file=myfile
```

19.5. LOGGING FOR SUBSYSTEMS AND SERVICES

Overview
You can use the `com.xyz.foo.level` configuration property described in the section called “Configuring logging at an individual package” to set fine-grained logging for specified Apache CXF logging subsystems.

Apache CXF logging subsystems

Table 19.2, “Apache CXF Logging Subsystems” shows a list of available Apache CXF logging subsystems.

Table 19.2. Apache CXF Logging Subsystems

<table>
<thead>
<tr>
<th>Subsystem</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>org.apache.cxf.aegis</td>
<td>Aegis binding</td>
</tr>
<tr>
<td>org.apache.cxf.binding.coloc</td>
<td>colocated binding</td>
</tr>
<tr>
<td>org.apache.cxf.binding.http</td>
<td>HTTP binding</td>

<td>JBI transport</td>
</tr>
</tbody>
</table>
## Example

The WS-Addressing sample is contained in the `InstallDir/samples/ws_addressing` directory. Logging is configured in the `logging.properties` file located in that directory. The relevant lines of configuration are shown in Example 19.9, "Configuring Logging for WS-Addressing".

### Example 19.9. Configuring Logging for WS-Addressing

```java
java.util.logging.ConsoleHandler.formatter = demos.ws_addressing.common.ConciseFormatter
...
org.apache.cxf.ws.addressing.soap.MAPCodec.level = INFO
```

The configuration in Example 19.9, "Configuring Logging for WS-Addressing" enables the snooping of log messages relating to WS-Addressing headers, and displays them to the console in a concise form.

For information on running this sample, see the README.txt file located in the `InstallDir/samples/ws_addressing` directory.

## 19.6. LOGGING MESSAGE CONTENT

### Overview

You can log the content of the messages that are sent between a service and a consumer. For example, you might want to log the contents of SOAP messages that are being sent between a service and a consumer.

### Configuring message content logging

To log the messages that are sent between a service and a consumer, and vice versa, complete the following steps:

1. Add the logging feature to your endpoint’s configuration.
2. Add the logging feature to your consumer’s configuration.

3. Configure the logging system log **INFO** level messages.

**Adding the logging feature to an endpoint**

Add the logging feature your endpoint’s configuration as shown in Example 19.10, “Adding Logging to Endpoint Configuration”.

```xml
<jaxws:endpoint ...>
  <jaxws:features>
    <bean class="org.apache.cxf.feature.LoggingFeature"/>
  </jaxws:features>
</jaxws:endpoint>
```

The example XML shown in Example 19.10, “Adding Logging to Endpoint Configuration” enables the logging of SOAP messages.

**Adding the logging feature to a consumer**

Add the logging feature your client’s configuration as shown in Example 19.11, “Adding Logging to Client Configuration”.

```xml
<jaxws:client ...>
  <jaxws:features>
    <bean class="org.apache.cxf.feature.LoggingFeature"/>
  </jaxws:features>
</jaxws:client>
```

The example XML shown in Example 19.11, “Adding Logging to Client Configuration” enables the logging of SOAP messages.

**Set logging to log INFO level messages**

Ensure that the **logging.properties** file associated with your service is configured to log **INFO** level messages, as shown in Example 19.12, “Setting the Logging Level to INFO”.

```properties
.level=INFO
java.util.logging.ConsoleHandler.level = INFO
```

**Logging SOAP messages**

To see the logging of SOAP messages modify the wsdl_first sample application located in...
To see the logging of SOAP messages modify the wsdl_first sample application located in the
InstallDir/samples/wsdl_first directory, as follows:

1. Add the `jaxws:features` element shown in Example 19.13, “Endpoint Configuration for Logging
SOAP Messages” to the `cxf.xml` configuration file located in the wsdl_first sample’s directory:

   Example 19.13. Endpoint Configuration for Logging SOAP Messages
   
   ```xml
   <jaxws:endpoint name="{http://apache.org/hello_world_soap_http}SoapPort"
                   createdFromAPI="true">
     <jaxws:properties>
       <entry key="schema-validation-enabled" value="true" />
     </jaxws:properties>
     <jaxws:features>
       <bean class="org.apache.cxf.feature.LoggingFeature"/>
     </jaxws:features>
   </jaxws:endpoint>
   
   2. The sample uses the default `logging.properties` file, which is located in the InstallDir/etc
directory. Make a copy of this file and name it `mylogging.properties`.

   3. In the `mylogging.properties` file, change the logging levels to `INFO` by editing the `.level` and
the `java.util.logging.ConsoleHandler.level` configuration properties as follows:

   ```properties
   .level= INFO
   java.util.logging.ConsoleHandler.level = INFO
   ```

   4. Start the server using the new configuration settings in both the `cxf.xml` file and the
`mylogging.properties` file as follows:

<table>
<thead>
<tr>
<th>Platform</th>
<th>Command</th>
</tr>
</thead>
<tbody>
<tr>
<td>Windows</td>
<td>start java -Djava.util.logging.config.file=%CXF_HOME%/etc/mylogging.properties demo.hw.server.Server</td>
</tr>
<tr>
<td>UNIX</td>
<td>java -Djava.util.logging.config.file=$CXF_HOME/etc/mylogging.properties demo.hw.server.Server &amp;</td>
</tr>
</tbody>
</table>

   5. Start the hello world client using the following command:

<table>
<thead>
<tr>
<th>Platform</th>
<th>Command</th>
</tr>
</thead>
</table>

```
<table>
<thead>

The SOAP messages are logged to the console.
CHAPTER 20. DEPLOYING WS-ADDRESSING

Abstract
Apache CXF supports WS-Addressing for JAX-WS applications. This chapter explains how to deploy WS-Addressing in the Apache CXF runtime environment.

20.1. INTRODUCTION TO WS-ADDRESSING

Overview
WS-Addressing is a specification that allows services to communicate addressing information in a transport neutral way. It consists of two parts:

- A structure for communicating a reference to a Web service endpoint
- A set of Message Addressing Properties (MAP) that associate addressing information with a particular message

Supported specifications
Apache CXF supports both the WS-Addressing 2004/08 specification and the WS-Addressing 2005/03 specification.

Further information
For detailed information on WS-Addressing, see the 2004/08 submission at http://www.w3.org/Submission/ws-addressing/.

20.2. WS-ADDRESSING INTERCEPTORS

Overview
In Apache CXF, WS-Addressing functionality is implemented as interceptors. The Apache CXF runtime uses interceptors to intercept and work with the raw messages that are being sent and received. When a transport receives a message, it creates a message object and sends that message through an interceptor chain. If the WS-Addressing interceptors are added to the application’s interceptor chain, any WS-Addressing information included with a message is processed.

WS-Addressing Interceptors
The WS-Addressing implementation consists of two interceptors, as described in Table 20.1, "WS-Addressing Interceptors".

Table 20.1. WS-Addressing Interceptors

<table>
<thead>
<tr>
<th>Interceptor</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>org.apache.cxf.ws.addressing.MAPAggregator</td>
<td>A logical interceptor responsible for aggregating the Message Addressing Properties (MAPs) for outgoing messages.</td>
</tr>
</tbody>
</table>
Interceptor | Description
--- | ---
org.apache.cxf.ws.addressing.soap.MAPCodec | A protocol-specific interceptor responsible for encoding and decoding the Message Addressing Properties (MAPs) as SOAP headers.

### 20.3. ENABLING WS-ADDRESSING

#### Overview

To enable WS-Addressing the WS-Addressing interceptors must be added to the inbound and outbound interceptor chains. This is done in one of the following ways:

- Apache CXF Features
- RMAssertion and WS-Policy Framework
- Using Policy Assertion in a WS-Addressing Feature

#### Adding WS-Addressing as a Feature

WS-Addressing can be enabled by adding the WS-Addressing feature to the client and the server configuration as shown in Example 20.1, "client.xml and Adding WS-Addressing Feature to Client Configuration" and Example 20.2, "server.xml and Adding WS-Addressing Feature to Server Configuration" respectively.

#### Example 20.1. client.xml and Adding WS-Addressing Feature to Client Configuration

```xml
<?xml version="1.0" encoding="UTF-8"?>
<beans xmlns="http://www.springframework.org/schema/beans"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xmlns:jaxws="http://cxf.apache.org/jaxws"
    xmlns:wsa="http://cxf.apache.org/ws/addressing"
    xsi:schemaLocation="
        http://www.springframework.org/schema/beans
        http://www.springframework.org/schema/beans/spring-beans.xsd
        http://cxf.apache.org/ws/addressing
        http://cxf.apache.org/schemas/ws-addr-conf.xsd">

    <jaxws:client ...>
        <jaxws:features>
            <wsa:addressing/>
        </jaxws:features>
    </jaxws:client>
</beans>
```

#### Example 20.2. server.xml and Adding WS-Addressing Feature to Server Configuration

```xml
<?xml version="1.0" encoding="UTF-8"?>
<beans xmlns="http://www.springframework.org/schema/beans"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xmlns:jaxws="http://cxf.apache.org/jaxws"
    xmlns:wsa="http://cxf.apache.org/ws/addressing"
    xsi:schemaLocation="
        http://www.springframework.org/schema/beans
        http://www.springframework.org/schema/beans/spring-beans.xsd
        http://cxf.apache.org/ws/addressing
        http://cxf.apache.org/schemas/ws-addr-conf.xsd">

</beans>
```
20.4. CONFIGURING WS-ADDRESSING ATTRIBUTES

Overview

The Apache CXF WS-Addressing feature element is defined in the namespace http://cxf.apache.org/ws/addressing. It supports the two attributes described in Table 20.2, "WS-Addressing Attributes".

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>allowDuplicates</td>
<td>A boolean that determines if duplicate MessageIDs are tolerated. The default setting is true.</td>
</tr>
<tr>
<td>usingAddressingAdvisory</td>
<td>A boolean that indicates if the presence of the UsingAddressing element in the WSDL is advisory only; that is, its absence does not prevent the encoding of WS-Addressing headers.</td>
</tr>
</tbody>
</table>

Configuring WS-Addressing attributes

Configure WS-Addressing attributes by adding the attribute and the value you want to set it to the WS-Addressing feature in your server or client configuration file. For example, the following configuration extract sets the allowDuplicates attribute to false on the server endpoint:

```xml
<beans ... xmlns:wsa="http://cxf.apache.org/ws/addressing" ...>
  <jaxws:endpoint ...>
    <jaxws:features>
      <wsa:addressing allowDuplicates="false"/>
    </jaxws:features>
  </jaxws:endpoint>
</beans>
```

Using a WS-Policy assertion embedded in a feature
In Example 20.3, “Using the Policies to Configure WS-Addressing” an addressing policy assertion to enable non-anonymous responses is embedded in the `policies` element.

Example 20.3. Using the Policies to Configure WS-Addressing

```xml
<?xml version="1.0" encoding="UTF-8"?>
<beans xmlns="http://www.springframework.org/schema/beans"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xmlns:wsa="http://cxf.apache.org/ws/addressing"
    xmlns:wsp="http://www.w3.org/2006/07/ws-policy"
    xmlns:policy="http://cxf.apache.org/policy-config"
    xmlns:wsu="http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-utility-1.0.xsd"
    xmlns:jaxws="http://cxf.apache.org/jaxws"
    xsi:schemaLocation="http://www.w3.org/2006/07/ws-policy http://www.w3.org/2006/07/ws-policy.xsd
    http://www.springframework.org/schema/beans
    http://www.springframework.org/schema/beans/spring-beans.xsd">
    <jaxws:endpoint name="{http://cxf.apache.org/greeter_control}GreeterPort"
        createdFromAPI="true">
        <jaxws:features>
            <policy:policies>
                <wsp:Policy xmlns:wsam="http://www.w3.org/2007/02/addressing/metadata">
                    <wsam:Addressing>
                        <wsp:Policy>
                            <wsam:NonAnonymousResponses/>
                        </wsp:Policy>
                    </wsam:Addressing>
                </wsp:Policy>
            </policy:policies>
        </jaxws:features>
    </jaxws:endpoint>
</beans>
```
CHAPTER 21. ENABLING RELIABLE MESSAGING

Abstract

Apache CXF supports WS-Reliable Messaging (WS-RM). This chapter explains how to enable and configure WS-RM in Apache CXF.

21.1. INTRODUCTION TO WS-RM

Overview

WS-ReliableMessaging (WS-RM) is a protocol that ensures the reliable delivery of messages in a distributed environment. It enables messages to be delivered reliably between distributed applications in the presence of software, system, or network failures.

For example, WS-RM can be used to ensure that the correct messages have been delivered across a network exactly once, and in the correct order.

How WS-RM works

WS-RM ensures the reliable delivery of messages between a source and a destination endpoint. The source is the initial sender of the message and the destination is the ultimate receiver, as shown in Figure 21.1, “Web Services Reliable Messaging”.

Figure 21.1. Web Services Reliable Messaging

The flow of WS-RM messages can be described as follows:

1. The RM source sends a CreateSequence protocol message to the RM destination. This contains a reference for the endpoint that receives acknowledgements (the wsrn:AcksTo endpoint).

2. The RM destination sends a CreateSequenceResponse protocol message back to the RM source. This message contains the sequence ID for the RM sequence session.
3. The RM source adds an RM **Sequence** header to each message sent by the application source. This header contains the sequence ID and a unique message ID.

4. The RM source transmits each message to the RM destination.

5. The RM destination acknowledges the receipt of the message from the RM source by sending messages that contain the RM **SequenceAcknowledgement** header.

6. The RM destination delivers the message to the application destination in an exactly-once-in-order fashion.

7. The RM source retransmits a message that it has not yet received an acknowledgement. The first retransmission attempt is made after a base retransmission interval. Successive retransmission attempts are made, by default, at exponential back-off intervals or, alternatively, at fixed intervals. For more details, see Section 21.5, "Configuring WS-RM".

This entire process occurs symmetrically for both the request and the response message; that is, in the case of the response message, the server acts as the RM source and the client acts as the RM destination.

**WS-RM delivery assurances**

WS-RM guarantees reliable message delivery in a distributed environment, regardless of the transport protocol used. Either the source or the destination endpoint logs an error if reliable delivery can not be assured.

**Supported specifications**

Apache CXF supports the following versions of the WS-RM specification:

**WS-ReliableMessaging 1.0**

*(Default)* Corresponds to the February 2005 submission version, which is now out of date. For reasons of backward compatibility, however, this version is used as the default. Version 1.0 of WS-RM uses the following namespace:

```plaintext
http://schemas.xmlsoap.org/ws/2005/02/rm/
```

This version of WS-RM can be used with either of the following WS-Addressing versions:

- `http://www.w3.org/2005/08/addressing`

Strictly speaking, in order to comply with the February 2005 submission version of WS-RM, you ought to use the first of these WS-Addressing versions (which is the default in Apache CXF). But most other Web service implementations have switched to the more recent WS-Addressing specification, so Apache CXF allows you to choose the WS-A version, to facilitate interoperability (see Section 21.4, "Runtime Control").

**WS-ReliableMessaging 1.1/1.2**

Corresponds to the official 1.1/1.2 Web Services Reliable Messaging specification. Versions 1.1 and 1.2 of WS-RM uses the following namespace:

```plaintext
http://docs.oasis-open.org/ws-rx/wsrmi/200702
```
The 1.1 and 1.2 versions of WS-RM use the following WS-Addressing version:

http://www.w3.org/2005/08/addressing

Selecting the WS-RM version

You can select which WS-RM specification version to use, as follows:

Server side

On the provider side, Apache CXF adapts to whichever version of WS-ReliableMessaging is used by the client and responds appropriately.

Client side

On the client side, the WS-RM version is determined either by the namespace that you use in the client configuration (see Section 21.5, “Configuring WS-RM”) or by overriding the WS-RM version at run time, using the runtime control options (see Section 21.4, “Runtime Control”).

21.2. WS-RM INTERCEPTORS

Overview

In Apache CXF, WS-RM functionality is implemented as interceptors. The Apache CXF runtime uses interceptors to intercept and work with the raw messages that are being sent and received. When a transport receives a message, it creates a message object and sends that message through an interceptor chain. If the application’s interceptor chain includes the WS-RM interceptors, the application can participate in reliable messaging sessions. The WS-RM interceptors handle the collection and aggregation of the message chunks. They also handle all of the acknowledgement and retransmission logic.

Apache CXF WS-RM Interceptors

The Apache CXF WS-RM implementation consists of four interceptors, which are described in Table 21.1, “Apache CXF WS-ReliableMessaging Interceptors”.

Table 21.1. Apache CXF WS-ReliableMessaging Interceptors

<table>
<thead>
<tr>
<th>Interceptor</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>org.apache.cxf.ws.rm.RMOutInterceptor</td>
<td>Deals with the logical aspects of providing reliability guarantees for outgoing messages. Responsible for sending the CreateSequence requests and waiting for their CreateSequenceResponse responses. Also responsible for aggregating the sequence properties—ID and message number—for an application message.</td>
</tr>
<tr>
<td>Interceptor</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-------------</td>
</tr>
<tr>
<td><code>org.apache.cxf.ws.rm.RMInInterceptor</code></td>
<td>Responsible for intercepting and processing RM protocol messages and <strong>SequenceAcknowlegdement</strong> messages that are piggybacked on application messages.</td>
</tr>
<tr>
<td><code>org.apache.cxf.ws.rm.RMCaptureInInterceptor</code></td>
<td>Caching incoming messages for persistent storage.</td>
</tr>
<tr>
<td><code>org.apache.cxf.ws.rm.RMDeliveryInterceptor</code></td>
<td>Assuring InOrder delivery of messages to the application.</td>
</tr>
<tr>
<td><code>org.apache.cxf.ws.rm.soap.RMSoapInterceptor</code></td>
<td>Responsible for encoding and decoding the reliability properties as SOAP headers.</td>
</tr>
<tr>
<td><code>org.apache.cxf.ws.rm.RetranmsissionInterceptor</code></td>
<td>Responsible for creating copies of application messages for future resending.</td>
</tr>
</tbody>
</table>

### Enabling WS-RM

The presence of the WS-RM interceptors on the interceptor chains ensures that WS-RM protocol messages are exchanged when necessary. For example, when intercepting the first application message on the outbound interceptor chain, the `RMOutInterceptor` sends a `CreateSequence` request and waits to process the original application message until it receives the `CreateSequenceResponse` response. In addition, the WS-RM interceptors add the sequence headers to the application messages and, on the destination side, extract them from the messages. It is not necessary to make any changes to your application code to make the exchange of messages reliable.

For more information on how to enable WS-RM, see Section 21.3, “Enabling WS-RM”.

### Configuring WS-RM Attributes

You control sequence demarcation and other aspects of the reliable exchange through configuration. For example, by default Apache CXF attempts to maximize the lifetime of a sequence, thus reducing the overhead incurred by the out-of-band WS-RM protocol messages. To enforce the use of a separate sequence per application message configure the WS-RM source’s sequence termination policy (setting the maximum sequence length to 1).

For more information on configuring WS-RM behavior, see Section 21.5, “Configuring WS-RM”.

### 21.3. ENABLING WS-RM

#### Overview

To enable reliable messaging, the WS-RM interceptors must be added to the interceptor chains for both inbound and outbound messages and faults. Because the WS-RM interceptors use WS-Addressing, the WS-Addressing interceptors must also be present on the interceptor chains.

You can ensure the presence of these interceptors in one of two ways:
• **Explicitly**, by adding them to the dispatch chains using Spring beans

• **Implicitly**, using WS-Policy assertions, which cause the Apache CXF runtime to transparently add the interceptors on your behalf.

## Spring beans: explicitly adding interceptors

To enable WS-RM add the WS–RM and WS–Addressing interceptors to the Apache CXF bus, or to a consumer or service endpoint using Spring bean configuration. This is the approach taken in the WS–RM sample that is found in the `InstallDir/samples/ws_rm` directory. The configuration file, `ws-rm.cxf`, shows the WS–RM and WS–Addressing interceptors being added one-by-one as Spring beans (see Example 21.1, “Enabling WS–RM Using Spring Beans”).

```xml
<?xml version="1.0" encoding="UTF-8"?>
<beans xmlns="http://www.springframework.org/schema/beans"
      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xsi:schemaLocation="http://www.springframework.org/schema/
      beans http://www.springframework.org/schema/beans-spring-beans.xsd">
  <bean id="mapAggregator" class="org.apache.cxf.ws.addressing.MAPAggregator"/>
  <bean id="mapCodec" class="org.apache.cxf.ws.addressing.soap.MAPCodec"/>
  <bean id="rmLogicalOut" class="org.apache.cxf.ws.rm.RMOutInterceptor">
    <property name="bus" ref="cxf"/>
  </bean>
  <bean id="rmLogicalIn" class="org.apache.cxf.ws.rm.RMInInterceptor">
    <property name="bus" ref="cxf"/>
  </bean>
  <bean id="rmCodec" class="org.apache.cxf.ws.rm.soap.RMSoapInterceptor"/>
  <bean id="cxf" class="org.apache.cxf.bus.CXFBusImpl">
    <property name="inInterceptors">
      <list>
        <ref bean="mapAggregator"/>
        <ref bean="mapCodec"/>
        <ref bean="rmLogicalIn"/>
        <ref bean="rmCodec"/>
      </list>
    </property>
    <property name="inFaultInterceptors">
      <list>
        <ref bean="mapAggregator"/>
        <ref bean="mapCodec"/>
        <ref bean="rmLogicalIn"/>
        <ref bean="rmCodec"/>
      </list>
    </property>
    <property name="outInterceptors">
      <list>
        <ref bean="mapAggregator"/>
        <ref bean="mapCodec"/>
        <ref bean="rmLogicalOut"/>
        <ref bean="rmCodec"/>
      </list>
    </property>
    <property name="outFaultInterceptors">
      <list>
        <ref bean="mapAggregator"/>
        <ref bean="mapCodec"/>
        <ref bean="rmLogicalOut"/>
        <ref bean="rmCodec"/>
      </list>
    </property>
  </bean>
</beans>
```
The code shown in Example 21.1, “Enabling WS-RM Using Spring Beans” can be explained as follows:

A Apache CXF configuration file is a Spring XML file. You must include an opening Spring `beans` element that declares the namespaces and schema files for the child elements that are encapsulated by the `beans` element.

Configures each of the WS-Addressing interceptors—MAPAggregator and MAPCodec. For more information on WS-Addressing, see Chapter 20, Deploying WS-Addressing.

Configures each of the WS-RM interceptors—RMOutInterceptor, RMIInInterceptor, and RMSoapInterceptor.

Adds the WS-Addressing and WS-RM interceptors to the interceptor chain for inbound messages.

Adds the WS-Addressing and WS-RM interceptors to the interceptor chain for inbound faults.

Adds the WS-Addressing and WS-RM interceptors to the interceptor chain for outbound messages.

Adds the WS-Addressing and WS-RM interceptors to the interceptor chain for outbound faults.

**WS-Policy framework: implicitly adding interceptors**

The WS-Policy framework provides the infrastructure and APIs that allow you to use WS-Policy. It is compliant with the November 2006 draft publications of the Web Services Policy 1.5—Framework and Web Services Policy 1.5—Attachment specifications.

To enable WS-RM using the Apache CXF WS-Policy framework, do the following:

1. Add the policy feature to your client and server endpoint. Example 21.2, “Configuring WS-RM using WS-Policy” shows a reference bean nested within a `jaxws:feature` element. The reference bean specifies the AddressingPolicy, which is defined as a separate element within the same configuration file.

**Example 21.2. Configuring WS-RM using WS-Policy**

```xml
<jaxws:client>
    <jaxws:features>
        <ref bean="AddressingPolicy"/>
    </jaxws:features>
</jaxws:client>
<wsp:Policy wsu:Id="AddressingPolicy"
    xmlns:wsam="http://www.w3.org/2007/02/addressing/metadata">
    <wsam:Addressing>
        <wsp:Policy>
            <wsam:NonAnonymousResponses/>
        </wsp:Policy>
    </wsam:Addressing>
</wsp:Policy>
```
2. Add a reliable messaging policy to the `<wsdl:service>` element—or any other WSDL element that can be used as an attachment point for policy or policy reference elements—to your WSDL file, as shown in Example 21.3, “Adding an RM Policy to Your WSDL File”.

Example 21.3. Adding an RM Policy to Your WSDL File

```xml
<wsp:Policy wsu:Id="RM"
xmlns:wsp="http://www.w3.org/2006/07/ws-policy"
xmlns:wsu="http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-utility-1.0.xsd">
  <wsam:Addressing xmlns:wsam="http://www.w3.org/2007/02/addressing/metadata">
    <wsp:Policy/>
  </wsam:Addressing>
  <wsrmp:RMAssertion xmlns:wsrmp="http://schemas.xmlsoap.org/ws/2005/02/rm/policy">
    <wsrmp:BaseRetransmissionInterval Milliseconds="10000"/>
  </wsrmp:RMAssertion>
</wsp:Policy>
...
<wsdl:service name="ReliableGreeterService">
  <wsdl:port binding="tns:GreeterSOAPBinding" name="GreeterPort">
    <soap:address location="http://localhost:9020/SoapContext/GreeterPort"/>
  </wsdl:port>
</wsdl:service>
```

### 21.4. RUNTIME CONTROL

**Overview**

Several message context property values can be set in client code to control WS-RM at runtime, with key values defined by public constants in the `org.apache.cxf.ws.rm.RMManager` class.

**Runtime control options**

The following table lists the keys defined by the `org.apache.cxf.ws.rm.RMManager` class.

<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
</tr>
</thead>
</table>
### Controlling WS-RM through JMX

You can also monitor and control many aspects of WS-RM using the JMX Management features of Apache CXF. The full list of JMX operations is defined by `org.apache.cxf.ws.rm.ManagedRMManager` and `org.apache.cxf.ws.rm.ManagedRMEndpoint`, but these operations include viewing the current RM state down to the individual message level. You can also use JXM to close or terminate a WS-RM sequence, and to receive notification of when previously-sent messages are acknowledged by the remote RM endpoint.

#### Example of JMX control

For example, if you have the JMX server enabled in your client configuration, you could use the following code to track the last acknowledgement number received:

```java
// Java
private static class AcknowledgementListener implements NotificationListener {
    private volatile long lastAcknowledgement;

    @Override
    public void handleNotification(Notification notification, Object handback) {
        if (notification instanceof AcknowledgementNotification) {
            AcknowledgementNotification ack = (AcknowledgementNotification)notification;
            lastAcknowledgement = ack.getMessageNumber();
        }
    }
}
```
// initialize client
...
// attach to JMX bean for notifications
// NOTE: you must have sent at least one message to initialize RM before executing this code
Endpoint ep = ClientProxy.getClient(client).getEndpoint();
InstrumentationManager im = bus.getExtension(InstrumentationManager.class);
MBeanServer mbs = im.getMBeanServer();
RMManager clientManager = bus.getExtension(RMManager.class);
ObjectName name = RMUtils.getManagedObjectName(clientManager, ep);
System.out.println("Looking for endpoint name "+ name);
AcknowledgementListener listener = new AcknowledgementListener();
//mbs.addNotificationListener(name, listener, null, null);

// send messages using RM with acknowledgement status reported to listener
...

21.5. CONFIGURING WS-RM

21.5.1. Configuring Apache CXF-Specific WS-RM Attributes

Overview

To configure the Apache CXF-specific attributes, use the rmManager Spring bean. Add the following to your configuration file:

- The http://cxf.apache.org/ws/rm/manager namespace to your list of namespaces.
- An rmManager Spring bean for the specific attribute that you want to configure.

Example 21.4, “Configuring Apache CXF-Specific WS-RM Attributes” shows a simple example.

Example 21.4. Configuring Apache CXF-Specific WS-RM Attributes

```xml
&lt;beans xmlns="http://www.springframework.org/schema/beans"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xmlns:wsrm-mgr="http://cxf.apache.org/ws/rm/manager"
    xsi:schemaLocation="http://www.springframework.org/schema/beans
    http://www.springframework.org/schema/beans/spring-beans.xsd
...
&lt;/wsrm-mgr:rmManager&gt;
```

Children of the rmManager Spring bean

Table 21.2, “Children of the rmManager Spring Bean” shows the child elements of the rmManager Spring bean, defined in the http://cxf.apache.org/ws/rm/manager namespace.
Table 21.2. Children of the rmManager Spring Bean

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RMAssertion</td>
<td>An element of type <strong>RMAssertion</strong></td>
</tr>
<tr>
<td>deliveryAssurance</td>
<td>An element of type <strong>DeliveryAssuranceType</strong> that describes the delivery assurance that should apply</td>
</tr>
<tr>
<td>sourcePolicy</td>
<td>An element of type <strong>SourcePolicyType</strong> that allows you to configure details of the RM source</td>
</tr>
<tr>
<td>destinationPolicy</td>
<td>An element of type <strong>DestinationPolicyType</strong> that allows you to configure details of the RM destination</td>
</tr>
</tbody>
</table>

Example

For an example, see the section called “Maximum unacknowledged messages threshold”.

21.5.2. Configuring Standard WS-RM Policy Attributes

Overview

You can configure standard WS-RM policy attributes in one of the following ways:

- the section called “RMAssertion in rmManager Spring bean”
- the section called “Policy within a feature”
- the section called “WSDL file”
- the section called “External attachment”

WS-Policy RMAssertion Children

Table 21.3, “Children of the WS-Policy RMAssertion Element” shows the elements defined in the http://schemas.xmlsoap.org/ws/2005/02/rm/policy namespace:

Table 21.3. Children of the WS-Policy RMAssertion Element

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>InactivityTimeout</td>
<td>Specifies the amount of time that must pass without receiving a message before an endpoint can consider an RM sequence to have been terminated due to inactivity.</td>
</tr>
</tbody>
</table>
### BaseRetransmissionInterval

Sets the interval within which an acknowledgement must be received by the RM Source for a given message. If an acknowledgement is not received within the time set by the **BaseRetransmissionInterval**, the RM Source will retransmit the message.

### ExponentialBackoff

Indicates the retransmission interval will be adjusted using the commonly known exponential backoff algorithm (Tanenbaum).

For more information, see *Computer Networks*, Andrew S. Tanenbaum, Prentice Hall PTR, 2003.

### AcknowledgementInterval

In WS-RM, acknowledgements are sent on return messages or sent stand-alone. If a return message is not available to send an acknowledgement, an RM Destination can wait for up to the acknowledgement interval before sending a stand-alone acknowledgement. If there are no unacknowledged messages, the RM Destination can choose not to send an acknowledgement.

---

**More detailed reference information**

For more detailed reference information, including descriptions of each element’s sub-elements and attributes, please refer to [http://schemas.xmlsoap.org/ws/2005/02/rm/wsr-policy.xsd](http://schemas.xmlsoap.org/ws/2005/02/rm/wsr-policy.xsd).

**RMAssertion in rmManager Spring bean**

You can configure standard WS-RM policy attributes by adding an *RMAssertion* within a Apache CXF *rmManager* Spring bean. This is the best approach if you want to keep all of your WS-RM configuration in the same configuration file; that is, if you want to configure Apache CXF-specific attributes and standard WS-RM policy attributes in the same file.

For example, the configuration in Example 21.5, “Configuring WS-RM Attributes Using an RMAssertion in an rmManager Spring Bean” shows:

- A standard WS-RM policy attribute, **BaseRetransmissionInterval**, configured using an *RMAssertion* within an *rmManager* Spring bean.

- An Apache CXF-specific RM attribute, **intraMessageThreshold**, configured in the same configuration file.

**Example 21.5. Configuring WS-RM Attributes Using an RMAssertion in an rmManager Spring Bean**

```xml
<beans xmlns:wsrm-policy="http://schemas.xmlsoap.org/ws/2005/02/rm/policy"
    xmlns:wsrm-mgr="http://cxf.apache.org/ws/rm/manager"
    ...>
  <wsrm-mgr:rmManager id="org.apache.cxf.ws.rm.RMManager">
    ...
  </wsrm-mgr:rmManager>
</beans>
```
Policy within a feature

You can configure standard WS-RM policy attributes within features, as shown in Example 21.6, “Configuring WS-RM Attributes as a Policy within a Feature”.

Example 21.6. Configuring WS-RM Attributes as a Policy within a Feature

```
<beans xmlns="http://www.springframework.org/schema/beans"
      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xmlns:wsa="http://cxf.apache.org/ws/addressing"
      xmlns:wsp="http://www.w3.org/2006/07/ws-policy"
      xmlns:wsu="http://docs.oasis-open.org/wss/2004/01/oasis-200401-wss-wssecurity-utility-1.0.xsd"
      xmlns:jaxws="http://cxf.apache.org/jaxws"
      xsi:schemaLocation="
        http://www.w3.org/2006/07/ws-policy http://www.w3.org/2006/07/ws-policy.xsd
  <jaxws:endpoint name="{http://cxf.apache.org/greeter_control}GreeterPort" createdFromAPI="true">
    <jaxws:features>
      <wsp:Policy>
        <wsrm:RMAssertion
          xmlns:wsrm="http://schemas.xmlsoap.org/ws/2005/02/rm/policy">
          <wsrm:AcknowledgementInterval Milliseconds="200" />  
        </wsrm:RMAssertion>
        <wsam:Addressing
          xmlns:wsam="http://www.w3.org/2007/02/addressing/metadata">
          <wsam:NonAnonymousResponses/>
        </wsam:Addressing>
      </wsp:Policy>
    </jaxws:features>
  </jaxws:endpoint>
</beans>
```

WSDL file

```xml
<wsrm-policy:RMAssertion>
  <wsrm-policy:BaseRetransmissionInterval Milliseconds="4000"/>
</wsrm-policy:RMAssertion>
<wsrm-mgr:destinationPolicy>
  <wsrm-mgr:acksPolicy intraMessageThreshold="0" />
</wsrm-mgr:destinationPolicy>
</wsrm-mgr:rmManager>
</beans>
```
If you use the WS-Policy framework to enable WS-RM, you can configure standard WS-RM policy attributes in a WSDL file. This is a good approach if you want your service to interoperate and use WS-RM seamlessly with consumers deployed to other policy-aware Web services stacks.

For an example, see the section called "WS-Policy framework: implicitly adding interceptors" where the base retransmission interval is configured in the WSDL file.

External attachment

You can configure standard WS-RM policy attributes in an external attachment file. This is a good approach if you cannot, or do not want to, change your WSDL file.

Example 21.7, “Configuring WS-RM in an External Attachment“ shows an external attachment that enables both WS-A and WS-RM (base retransmission interval of 30 seconds) for a specific EPR.

```xml
<attachments xmlns:wsp="http://www.w3.org/2006/07/ws-policy"
             xmlns:wsa="http://www.w3.org/2005/08/addressing">
    <wsp:PolicyAttachment>
        <wsp:AppliesTo>
            <wsa:EndpointReference>
            </wsa:EndpointReference>
        </wsp:AppliesTo>
        <wsp:Policy>
            <wsam:Addressing xmlns:wsam="http://www.w3.org/2007/02/addressing/metadata">
                <wsp:Policy />
            </wsam:Addressing>
            <wsrmp:RMAssertion xmlns:wsrmp="http://schemas.xmlsoap.org/ws/2005/02/rm/policy">
                <wsrmp:BaseRetransmissionInterval Milliseconds="30000"/>
            </wsrmp:RMAssertion>
        </wsp:Policy>
    </wsp:PolicyAttachment>
</attachments>
```

21.5.3. WS-RM Configuration Use Cases

Overview

This subsection focuses on configuring WS-RM attributes from a use case point of view. Where an attribute is a standard WS-RM policy attribute, defined in the `http://schemas.xmlsoap.org/ws/2005/02/rm/policy/` namespace, only the example of setting it in an `RMAssertion` within an `rmManager` Spring bean is shown. For details of how to set such attributes as a policy within a feature; in a WSDL file, or in an external attachment, see Section 21.5.2, “Configuring Standard WS-RM Policy Attributes”.

The following use cases are covered:

- the section called “Base retransmission interval”
- the section called “Exponential backoff for retransmission”
- the section called “Acknowledgement interval”
- the section called “Maximum unacknowledged messages threshold”
- the section called “Maximum length of an RM sequence”
- the section called “Message delivery assurance policies”

Base retransmission interval

The `BaseRetransmissionInterval` element specifies the interval at which an RM source retransmits a message that has not yet been acknowledged. It is defined in the http://schemas.xmlsoap.org/ws/2005/02/rm/wsrm-policy.xsd schema file. The default value is 3000 milliseconds.

Example 21.8, “Setting the WS-RM Base Retransmission Interval” shows how to set the WS-RM base retransmission interval.

Example 21.8. Setting the WS-RM Base Retransmission Interval

```xml
<beans xmlns:wsrm-policy="http://schemas.xmlsoap.org/ws/2005/02/rm/policy">
  ...
  <wsrm-mgr:rmManager id="org.apache.cxf.ws.rm.RMManager">
    <wsrm-policy:RMAssertion>
      <wsrm-policy:BaseRetransmissionInterval Milliseconds="4000"/>
    </wsrm-policy:RMAssertion>
  </wsrm-mgr:rmManager>
</beans>
```

Exponential backoff for retransmission

The `ExponentialBackoff` element determines if successive retransmission attempts for an unacknowledged message are performed at exponential intervals.

The presence of the `ExponentialBackoff` element enables this feature. An exponential backoff ratio of 2 is used by default. `ExponentialBackoff` is a flag. When the element is present, exponential backoff is enabled. When the element is absent, exponential backoff is disabled. No value is required.

Example 21.9, “Setting the WS-RM Exponential Backoff Property” shows how to set the WS-RM exponential backoff for retransmission.

Example 21.9. Setting the WS-RM Exponential Backoff Property

```xml
<beans xmlns:wsrm-policy="http://schemas.xmlsoap.org/ws/2005/02/rm/policy">
  ...
  <wsrm-mgr:rmManager id="org.apache.cxf.ws.rm.RMManager">
    <wsrm-policy:RMAssertion>
      <wsrm-policy:ExponentialBackoff/>
    </wsrm-policy:RMAssertion>
  </wsrm-mgr:rmManager>
</beans>
```

Acknowledgement interval
The `AcknowledgementInterval` element specifies the interval at which the WS-RM destination sends asynchronous acknowledgements. These are in addition to the synchronous acknowledgements that it sends on receipt of an incoming message. The default asynchronous acknowledgement interval is 0 milliseconds. This means that if the `AcknowledgementInterval` is not configured to a specific value, acknowledgements are sent immediately (that is, at the first available opportunity).

Asynchronous acknowledgements are sent by the RM destination only if both of the following conditions are met:

- The RM destination is using a non-anonymous `wsrm:acksTo` endpoint.
- The opportunity to piggyback an acknowledgement on a response message does not occur before the expiry of the acknowledgement interval.

Example 21.10, "Setting the WS-RM Acknowledgement Interval" shows how to set the WS-RM acknowledgement interval.

```
Example 21.10. Setting the WS-RM Acknowledgement Interval

<beans xmlns:wrm-policy="http://schemas.xmlsoap.org/ws/2005/02/rm/policy
...
<wrm-mgr:rmManager id="org.apache.cxf.ws.rm.RMManager">
  <wrm-policy:RMAssertion>
    <wrm-policy:AcknowledgementInterval Milliseconds="2000"/>
  </wrm-policy:RMAssertion>
</wrm-mgr:rmManager>
</beans>
```

**Maximum unacknowledged messages threshold**

The `maxUnacknowledged` attribute sets the maximum number of unacknowledged messages that can accrue per sequence before the sequence is terminated.

Example 21.11, "Setting the WS-RM Maximum Unacknowledged Message Threshold" shows how to set the WS-RM maximum unacknowledged messages threshold.

```
Example 21.11. Setting the WS-RM Maximum Unacknowledged Message Threshold

<beans xmlns:wrm-mgr="http://cxf.apache.org/ws/rm/manager
...
<wrm-mgr:reliableMessaging>
  <wrm-mgr:sourcePolicy>
    <wrm-mgr:sequenceTerminationPolicy maxUnacknowledged="20" />
  </wrm-mgr:sourcePolicy>
</wrm-mgr:reliableMessaging>
</beans>
```

**Maximum length of an RM sequence**

The `maxLength` attribute sets the maximum length of a WS-RM sequence. The default value is 0, which means that the length of a WS-RM sequence is unbound.
When this attribute is set, the RM endpoint creates a new RM sequence when the limit is reached, and after receiving all of the acknowledgements for the previously sent messages. The new message is sent using a new sequence.

Example 21.12, “Setting the Maximum Length of a WS-RM Message Sequence” shows how to set the maximum length of an RM sequence.

Example 21.12. Setting the Maximum Length of a WS-RM Message Sequence

```xml
<beans xmlns:wsrm-mgr="http://cxf.apache.org/ws/rm/manager">
  <wsrm-mgr:reliableMessaging>
    <wsrm-mgr:sourcePolicy>
      <wsrm-mgr:sequenceTerminationPolicy maxLength="100"/>
    </wsrm-mgr:sourcePolicy>
  </wsrm-mgr:reliableMessaging>
</beans>
```

Message delivery assurance policies

You can configure the RM destination to use the following delivery assurance policies:

- **AtMostOnce** – The RM destination delivers the messages to the application destination only once. If a message is delivered more than once an error is raised. It is possible that some messages in a sequence may not be delivered.

- **AtLeastOnce** – The RM destination delivers the messages to the application destination at least once. Every message sent will be delivered or an error will be raised. Some messages might be delivered more than once.

- **InOrder** – The RM destination delivers the messages to the application destination in the order that they are sent. This delivery assurance can be combined with the **AtMostOnce** or **AtLeastOnce** assurances.

Example 21.13. Setting the WS-RM Message Delivery Assurance Policy

```xml
<beans xmlns:wsrm-mgr="http://cxf.apache.org/ws/rm/manager">
  <wsrm-mgr:reliableMessaging>
    <wsrm-mgr:deliveryAssurance>
      <wsrm-mgr:AtLeastOnce/>
    </wsrm-mgr:deliveryAssurance>
  </wsrm-mgr:reliableMessaging>
</beans>
```

21.6. CONFIGURING WS-RM PERSISTENCE

Overview
The Apache CXF WS-RM features already described in this chapter provide reliability for cases such as network failures. WS-RM persistence provides reliability across other types of failure such as an RM source or an RM destination crash.

WS-RM persistence involves storing the state of the various RM endpoints in persistent storage. This enables the endpoints to continue sending and receiving messages when they are reincarnated.

Apache CXF enables WS-RM persistence in a configuration file. The default WS-RM persistence store is JDBC-based. For convenience, Apache CXF includes Derby for out-of-the-box deployment. In addition, the persistent store is also exposed using a Java API. To implement your own persistence mechanism, you can implement one using this API with your preferred DB.

**IMPORTANT**

WS-RM persistence is supported for oneway calls only, and it is disabled by default.

**How it works**

Apache CXF WS-RM persistence works as follows:

- At the RM source endpoint, an outgoing message is persisted before transmission. It is evicted from the persistent store after the acknowledgement is received.

- After a recovery from crash, it recovers the persisted messages and retransmits until all the messages have been acknowledged. At that point, the RM sequence is closed.

- At the RM destination endpoint, an incoming message is persisted, and upon a successful store, the acknowledgement is sent. When a message is successfully dispatched, it is evicted from the persistent store.

- After a recovery from a crash, it recovers the persisted messages and dispatches them. It also brings the RM sequence to a state where new messages are accepted, acknowledged, and delivered.

**Enabling WS-persistence**

To enable WS-RM persistence, you must specify the object implementing the persistent store for WS-RM. You can develop your own or you can use the JDBC based store that comes with Apache CXF.

The configuration shown in Example 21.14, “Configuration for the Default WS-RM Persistence Store” enables the JDBC-based store that comes with Apache CXF.

```xml
<bean id="RMTxStore" class="org.apache.cxf.ws.rm.persistence.jdbc.RMTxStore"/>
<wsrm-mgr:rmManager id="org.apache.cxf.ws.rm.RMManager">
    <property name="store" ref="RMTxStore"/>
</wsrm-mgr:rmManager>
```

**Configuring WS-persistence**

The JDBC-based store that comes with Apache CXF supports the properties shown in Table 21.4, “JDBC Store Properties”.
Table 21.4. JDBC Store Properties

<table>
<thead>
<tr>
<th>Attribute Name</th>
<th>Type</th>
<th>Default Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>driverClassName</td>
<td>String</td>
<td>org.apache.derby.jdbc.EmbeddedDriver</td>
</tr>
<tr>
<td>userName</td>
<td>String</td>
<td>null</td>
</tr>
<tr>
<td>passWord</td>
<td>String</td>
<td>null</td>
</tr>
<tr>
<td>url</td>
<td>String</td>
<td>jdbc:derby:rmdb;create=true</td>
</tr>
</tbody>
</table>

The configuration shown in Example 21.15, “Configuring the JDBC Store for WS-RM Persistence” enables the JDBC-based store that comes with Apache CXF, while setting the `driverClassName` and `url` to non-default values.

Example 21.15. Configuring the JDBC Store for WS-RM Persistence

```xml
<bean id="RMTxStore" class="org.apache.cxf.ws.rm.persistence.jdbc.RMTxStore">
  <property name="driverClassName" value="com.acme.jdbc.Driver"/>
  <property name="url" value="jdbc:acme:rmdb;create=true"/>
</bean>
```
CHAPTER 22. ENABLING HIGH AVAILABILITY

Abstract

This chapter explains how to enable and configure high availability in the Apache CXF runtime.

22.1. INTRODUCTION TO HIGH AVAILABILITY

Overview

Scalable and reliable applications require high availability to avoid any single point of failure in a distributed system. You can protect your system from single points of failure using replicated services.

A replicated service is comprised of multiple instances, or replicas, of the same service. Together these act as a single logical service. Clients invoke requests on the replicated service, and Apache CXF delivers the requests to one of the member replicas. The routing to a replica is transparent to the client.

HA with static failover

Apache CXF supports high availability (HA) with static failover in which replica details are encoded in the service WSDL file. The WSDL file contains multiple ports, and can contain multiple hosts, for the same service. The number of replicas in the cluster remains static as long as the WSDL file remains unchanged. Changing the cluster size involves editing the WSDL file.

22.2. ENABLING HA WITH STATIC FAILOVER

Overview

To enable HA with static failover, you must do the following:

1. the section called “Encode replica details in your service WSDL file”
2. the section called “Add the clustering feature to your client configuration”

Encode replica details in your service WSDL file

You must encode the details of the replicas in your cluster in your service WSDL file. Example 22.1, “Enabling HA with Static Failover: WSDL File” shows a WSDL file extract that defines a service cluster of three replicas.

Example 22.1. Enabling HA with Static Failover: WSDL File

```xml
<wSDL:service name="ClusteredService">
  <wSDL:port binding="tns:Greeter_SOAPBinding" name="Replica1">
    <soap:address location="http://localhost:9001/SoapContext/Replica1"/>
  </wSDL:port>

  <wSDL:port binding="tns:Greeter_SOAPBinding" name="Replica2">
    <soap:address location="http://localhost:9002/SoapContext/Replica2"/>
  </wSDL:port>

  <wSDL:port binding="tns:Greeter_SOAPBinding" name="Replica3">
    <soap:address location="http://localhost:9003/SoapContext/Replica3"/>
  </wSDL:port>
</wSDL:service>
```
The WSDL extract shown in Example 22.1, “Enabling HA with Static Failover: WSDL File” can be explained as follows:

Defines a service, **ClusterService**, which is exposed on three ports:

1. **Replica1**
2. **Replica2**
3. **Replica3**

Defines **Replica1** to expose the **ClusterService** as a SOAP over HTTP endpoint on port **9001**.

Defines **Replica2** to expose the **ClusterService** as a SOAP over HTTP endpoint on port **9002**.

Defines **Replica3** to expose the **ClusterService** as a SOAP over HTTP endpoint on port **9003**.

**Add the clustering feature to your client configuration**

In your client configuration file, add the clustering feature as shown in Example 22.2, “Enabling HA with Static Failover: Client Configuration”.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<beans xmlns="http://www.springframework.org/schema/beans"
       xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
       xmlns:jaxws="http://cxf.apache.org/jaxws"
       xmlns:clustering="http://cxf.apache.org/clustering"
    <jaxws:client name="{http://apache.org/hello_world_soap_http}Replica1" createdFromAPI="true">
        <jaxws:features>
            <clustering:failover/>
        </jaxws:features>
    </jaxws:client>

    <jaxws:client name="{http://apache.org/hello_world_soap_http}Replica2" createdFromAPI="true">
        <jaxws:features>
            <clustering:failover/>
        </jaxws:features>
    </jaxws:client>

    <jaxws:client name="{http://apache.org/hello_world_soap_http}Replica3"
```
22.3. CONFIGURING HA WITH STATIC FAILOVER

Overview

By default, HA with static failover uses a sequential strategy when selecting a replica service if the original service with which a client is communicating becomes unavailable, or fails. The sequential strategy selects a replica service in the same sequential order every time it is used. Selection is determined by Apache CXF’s internal service model and results in a deterministic failover pattern.

Configuring a random strategy

You can configure HA with static failover to use a random strategy instead of the sequential strategy when selecting a replica. The random strategy selects a random replica service each time a service becomes unavailable, or fails. The choice of failover target from the surviving members in a cluster is entirely random.

To configure the random strategy, add the configuration shown in Example 22.3, “Configuring a Random Strategy for Static Failover” to your client configuration file.

Example 22.3. Configuring a Random Strategy for Static Failover

```xml
<beans ...>
  <bean id="Random" class="org.apache.cxf.clustering.RandomStrategy"/>

  <jaxws:client name="[http://apache.org/hello_world_soap_http]Replica3"
    createdFromAPI="true">
    <jaxws:features>
      <clustering:failover/>
      <clustering:strategy>
        <ref bean="Random"/>
      </clustering:strategy>
    </jaxws:features>
  </jaxws:client>
</beans>
```

The configuration shown in Example 22.3, “Configuring a Random Strategy for Static Failover” can be explained as follows:

Defines a Random bean and implementation class that implements the random strategy.

Specifies that the random strategy is used when selecting a replica.

APPENDIX A. USING THE MAVEN OSGI TOOLING

Abstract

Manually creating a bundle, or a collection of bundles, for a large project can be cumbersome. The Maven bundle plug-in makes the job easier by automating the process and providing a number of shortcuts for specifying the contents of the bundle manifest.

A.1. THE MAVEN BUNDLE PLUG-IN

The Red Hat Fuse OSGi tooling uses the Maven bundle plug-in from Apache Felix. The bundle plug-in is based on the bnd tool from Peter Kriens. It automates the construction of OSGi bundle manifests by introspecting the contents of the classes being packaged in the bundle. Using the knowledge of the classes contained in the bundle, the plug-in can calculate the proper values to populate the Import-Packages and the Export-Package properties in the bundle manifest. The plug-in also has default values that are used for other required properties in the bundle manifest.

To use the bundle plug-in, do the following:

1. Section A.2, “Setting up a Red Hat Fuse OSGi project” the bundle plug-in to your project’s POM file.

2. Section A.3, “Configuring the Bundle Plug-In” the plug-in to correctly populate your bundle’s manifest.

A.2. SETTING UP A RED HAT FUSE OSGI PROJECT

Overview

A Maven project for building an OSGi bundle can be a simple single level project. It does not require any sub-projects. However, it does require that you do the following:

1. Add the bundle plug-in to your POM.

2. Instruct Maven to package the results as an OSGi bundle.

NOTE

There are several Maven archetypes you can use to set up your project with the appropriate settings.

Directory structure

A project that constructs an OSGi bundle can be a single level project. It only requires that you have a top-level POM file and a src folder. As in all Maven projects, you place all Java source code in the src/java folder, and you place any non-Java resources in the src/resources folder.

Non-Java resources include Spring configuration files, JBI endpoint configuration files, and WSDL contracts.
NOTE

Red Hat Fuse OSGi projects that use Apache CXF, Apache Camel, or another Spring configured bean also include a `beans.xml` file located in the `src/resources/META-INF/spring` folder.

Adding a bundle plug-in

Before you can use the bundle plug-in you must add a dependency on Apache Felix. After you add the dependency, you can add the bundle plug-in to the plug-in portion of the POM.

Example A.1, “Adding an OSGi bundle plug-in to a POM” shows the POM entries required to add the bundle plug-in to your project.

```xml
...<dependencies>
  <dependency>
    <groupId>org.apache.felix</groupId>
    <artifactId>org.osgi.core</artifactId>
    <version>1.0.0</version>
  </dependency>
...</dependencies>
...<build>
  <plugins>
    <plugin>
      <groupId>org.apache.felix</groupId>
      <artifactId>maven-bundle-plugin</artifactId>
      <configuration>
        <instructions>
          <Bundle-SymbolicName>${pom.artifactId}</Bundle-SymbolicName>
          <Import-Package>*:org.apache.camel.osgi</Import-Package>
          <Private-Package>org.apache.servicemix.examples.camel</Private-Package>
        </instructions>
      </configuration>
    </plugin>
  </plugins>
...</build>
...
```

The entries in Example A.1, “Adding an OSGi bundle plug-in to a POM” do the following:

Adds the dependency on Apache Felix

Adds the bundle plug-in to your project

Configures the plug-in to use the project’s artifact ID as the bundle’s symbolic name

Configures the plug-in to include all Java packages imported by the bundled classes; also imports the `org.apache.camel.osgi` package
Configures the plug-in to bundle the listed class, but not to include them in the list of exported packages

**NOTE**

Edit the configuration to meet the requirements of your project.

For more information on configuring the bundle plug-in, see Section A.3, "Configuring the Bundle Plug-In".

**Activating a bundle plug-in**

To have Maven use the bundle plug-in, instruct it to package the results of the project as a bundle. Do this by setting the POM file's `packaging` element to `bundle`.

**Useful Maven archetypes**

There are several Maven archetypes available to generate a project that is preconfigured to use the bundle plug-in:

- the section called “Spring OSGi archetype”
- the section called “Apache CXF code-first archetype”
- the section called “Apache CXF wsdl-first archetype”
- the section called “Apache Camel archetype”

**Spring OSGi archetype**

The Spring OSGi archetype creates a generic project for building an OSGi project using Spring DM, as shown:

```text
org.springframework.osgi/spring-bundle-osgi-archetype/1.1.2
```

You invoke the archetype using the following command:

```bash
mvn archetype:generate -DarchetypeGroupId=org.springframework.osgi -DarchetypeArtifactId=spring-osgi-bundle-archetype -DarchetypeVersion=1.1.2 -DgroupId=groupId -DartifactId=artifactId -Dversion=version
```

**Apache CXF code-first archetype**

The Apache CXF code-first archetype creates a project for building a service from Java, as shown:

```text
org.apache.servicemix.tooling/servicemix-osgi-cxf-code-first-archetype/2010.02.0-fuse-02-00
```

You invoke the archetype using the following command:

```bash
mvn archetype:generate -DarchetypeGroupId=org.apache.servicemix.tooling -DarchetypeArtifactId=servicemix-osgi-cxf-code-first-archetype -DarchetypeVersion=2010.02.0-fuse-02-00 -DgroupId=groupId -DartifactId=artifactId -Dversion=version
```
Apache CXF wsdl-first archetype

The Apache CXF wsdl-first archetype creates a project for creating a service from WSDL, as shown:

```
org.apache.servicemix.tooling/servicemix-osgi-cxf-wsdl-first-archetype/2010.02.0-fuse-02-00
```

You invoke the archetype using the following command:

```
mvn archetype:generate -DarchetypeGroupId=org.apache.servicemix.tooling -
         DarchetypeArtifactId=servicemix-osgi-cxf-wsdl-first-archetype -DarchetypeVersion=2010.02.0-fuse-02-00 -
         DgroupId=groupId -DartifactId=artifactId -Dversion=version
```

Apache Camel archetype

The Apache Camel archetype creates a project for building a route that is deployed into Red Hat Fuse, as shown:

```
org.apache.servicemix.tooling/servicemix-osgi-camel-archetype/2010.02.0-fuse-02-00
```

You invoke the archetype using the following command:

```
mvn archetype:generate -DarchetypeGroupId=org.apache.servicemix.tooling -
         DarchetypeArtifactId=servicemix-osgi-camel-archetype -DarchetypeVersion=2010.02.0-fuse-02-00 -
         DgroupId=groupId -DartifactId=artifactId -Dversion=version
```

A.3. CONFIGURING THE BUNDLE PLUG-IN

Overview

A bundle plug-in requires very little information to function. All of the required properties use default settings to generate a valid OSGi bundle.

While you can create a valid bundle using just the default values, you will probably want to modify some of the values. You can specify most of the properties inside the plug-in’s `instructions` element.

Configuration properties

Some of the commonly used configuration properties are:

- `Bundle-SymbolicName`
- `Bundle-Name`
- `Bundle-Version`
- `Export-Package`
- `Private-Package`
- `Import-Package`

Setting a bundle’s symbolic name
By default, the bundle plug-in sets the value for the Bundle-SymbolicName property to 
\texttt{groupId + "." + artifactId}, with the following exceptions:

- If \texttt{groupId} has only one section (no dots), the first package name with classes is returned.
  For example, if the group Id is \texttt{commons-logging:commons-logging}, the bundle’s symbolic name is \texttt{org.apache.commons.logging}.

- If \texttt{artifactId} is equal to the last section of \texttt{groupId}, then \texttt{groupId} is used.
  For example, if the POM specifies the group ID and artifact ID as \texttt{org.apache.maven:maven}, the bundle’s symbolic name is \texttt{org.apache.maven}.

- If \texttt{artifactId} starts with the last section of \texttt{groupId}, that portion is removed.
  For example, if the POM specifies the group ID and artifact ID as \texttt{org.apache.maven:maven-core}, the bundle’s symbolic name is \texttt{org.apache.maven.core}.

To specify your own value for the bundle’s symbolic name, add a Bundle-SymbolicName child in the plug-in’s instructions element, as shown in Example A.2, “Setting a bundle’s symbolic name”.

Example A.2. Setting a bundle’s symbolic name

```
<plugin>
  <groupId>org.apache.felix</groupId>
  <artifactId>maven-bundle-plugin</artifactId>
  <configuration>
    <instructions>
      <Bundle-SymbolicName>${project.artifactId}</Bundle-SymbolicName>
      ...
    </instructions>
  </configuration>
</plugin>
```

Setting a bundle’s name

By default, a bundle’s name is set to \texttt{${project.name}}.

To specify your own value for the bundle’s name, add a Bundle-Name child to the plug-in’s instructions element, as shown in Example A.3, “Setting a bundle’s name”.

Example A.3. Setting a bundle’s name

```
<plugin>
  <groupId>org.apache.felix</groupId>
  <artifactId>maven-bundle-plugin</artifactId>
  <configuration>
    <instructions>
      <Bundle-Name>JoeFred</Bundle-Name>
      ...
    </instructions>
  </configuration>
</plugin>
```
Setting a bundle’s version

By default, a bundle’s version is set to \${project.version}. Any dashes (-) are replaced with dots (.) and the number is padded up to four digits. For example, 4.2-SNAPSHOT becomes 4.2.0.SNAPSHOT.

To specify your own value for the bundle’s version, add a Bundle-Version child to the plug-in’s instructions element, as shown in Example A.4, “Setting a bundle’s version”.

Example A.4. Setting a bundle’s version

```xml
<plugin>
  <groupId>org.apache.felix</groupId>
  <artifactId>maven-bundle-plugin</artifactId>
  <configuration>
    <instructions>
      <Bundle-Version>1.0.3.1</Bundle-Version>
      ...
    </instructions>
  </configuration>
</plugin>
```

Specifying exported packages

By default, the OSGi manifest’s Export-Package list is populated by all of the packages in your local Java source code (under src/main/java), except for the default package, ., and any packages containing .impl or .internal.

IMPORTANT

If you use a Private-Package element in your plug-in configuration and you do not specify a list of packages to export, the default behavior includes only the packages listed in the Private-Package element in the bundle. No packages are exported.

The default behavior can result in very large packages and in exporting packages that should be kept private. To change the list of exported packages you can add an Export-Package child to the plug-in’s instructions element.

The Export-Package element specifies a list of packages that are to be included in the bundle and that are to be exported. The package names can be specified using the * wildcard symbol. For example, the entry com.fuse.demo.* includes all packages on the project’s classpath that start with com.fuse.demo.

You can specify packages to be excluded be prefixing the entry with !. For example, the entry !com.fuse.demo.private excludes the package com.fuse.demo.private.

When excluding packages, the order of entries in the list is important. The list is processed in order from the beginning and any subsequent contradicting entries are ignored.

For example, to include all packages starting with com.fuse.demo except the package com.fuse.demo.private, list the packages using:

```
!com.fuse.demo.private,com.fuse.demo.*
```
However, if you list the packages using `com.fuse.demo.*,!com.fuse.demo.private`, then `com.fuse.demo.private` is included in the bundle because it matches the first pattern.

**Specifying private packages**

If you want to specify a list of packages to include in a bundle **without** exporting them, you can add a `Private-Package` instruction to the bundle plug-in configuration. By default, if you do not specify a `Private-Package` instruction, all packages in your local Java source are included in the bundle.

**IMPORTANT**

If a package matches an entry in both the `Private-Package` element and the `Export-Package` element, the `Export-Package` element takes precedence. The package is added to the bundle and exported.

The `Private-Package` element works similarly to the `Export-Package` element in that you specify a list of packages to be included in the bundle. The bundle plug-in uses the list to find all classes on the project’s classpath that are to be included in the bundle. These packages are packaged in the bundle, but not exported (unless they are also selected by the `Export-Package` instruction).

Example A.5, “Including a private package in a bundle” shows the configuration for including a private package in a bundle

```
<plugin>
  <groupId>org.apache.felix</groupId>
  <artifactId>maven-bundle-plugin</artifactId>
  <configuration>
    <instructions>
      <Private-Package>org.apache.cxf.wsdlFirst.impl</Private-Package>
      ...
    </instructions>
  </configuration>
</plugin>
```

**Specifying imported packages**

By default, the bundle plug-in populates the OSGi manifest’s `Import-Package` property with a list of all the packages referred to by the contents of the bundle.

While the default behavior is typically sufficient for most projects, you might find instances where you want to import packages that are not automatically added to the list. The default behavior can also result in unwanted packages being imported.

To specify a list of packages to be imported by the bundle, add an `Import-Package` child to the plug-in’s `instructions` element. The syntax for the package list is the same as for the `Export-Package` element and the `Private-Package` element.
IMPORTANT

When you use the `Import-Package` element, the plug-in does not automatically scan the bundle’s contents to determine if there are any required imports. To ensure that the contents of the bundle are scanned, you must place an `*` as the last entry in the package list.

Example A.6, “Specifying the packages imported by a bundle” shows the configuration for specifying the packages imported by a bundle

```xml
<plugin>
  <groupId>org.apache.felix</groupId>
  <artifactId>maven-bundle-plugin</artifactId>
  <configuration>
    <instructions>
    </instructions>
  </configuration>
</plugin>
```

More information

For more information on configuring a bundle plug-in, see:

PART V. DEVELOPING APPLICATIONS USING JAX-WS

This guide describes how to develop Web services using the standard JAX-WS APIs.
CHAPTER 24. BOTTOM-UP SERVICE DEVELOPMENT

Abstract

There are many instances where you have Java code that already implements a set of functionality that you want to expose as part of a service oriented application. You may also simply want to avoid using WSDL to define your interface. Using JAX-WS annotations, you can add the information required to service enable a Java class. You can also create a Service Endpoint Interface (SEI) that can be used in place of a WSDL contract. If you want a WSDL contract, Apache CXF provides tools to generate a contract from annotated Java code.

24.1. INTRODUCTION TO JAX-WS SERVICE DEVELOPMENT

To create a service starting from Java you must do the following:

1. **Section 24.2, “Creating the SEI”** a Service Endpoint Interface (SEI) that defines the methods you want to expose as a service.

   **NOTE**

   You can work directly from a Java class, but working from an interface is the recommended approach. Interfaces are better suited for sharing with the developers who are responsible for developing the applications consuming your service. The interface is smaller and does not provide any of the service’s implementation details.

2. **Section 24.3, “Annotating the Code”** the required annotations to your code.

3. **Section 24.4, “Generating WSDL”** the WSDL contract for your service.

   **NOTE**

   If you intend to use the SEI as the service’s contract, it is not necessary to generate a WSDL contract.

4. **Chapter 31, Publishing a Service** the service as a service provider.

24.2. CREATING THE SEI

Overview

The service endpoint interface (SEI) is the piece of Java code that is shared between a service implementation and the consumers that make requests on that service. The SEI defines the methods implemented by the service and provides details about how the service will be exposed as an endpoint. When starting with a WSDL contract, the SEI is generated by the code generators. However, when starting from Java, it is the developer’s responsibility to create the SEI. There are two basic patterns for creating an SEI:

- Green field development – In this pattern, you are developing a new service without any existing Java code or WSDL. It is best to start by creating the SEI. You can then distribute the SEI to any developers that are responsible for implementing the service providers and consumers that use the SEI.
NOTE
The recommended way to do green field service development is to start by creating a WSDL contract that defines the service and its interfaces. See Chapter 26, A Starting Point WSDL Contract.

- Service enablement — In this pattern, you typically have an existing set of functionality that is implemented as a Java class, and you want to service enable it. This means that you must do two things:
  a. Create an SEI that contains only the operations that are going to be exposed as part of the service.
  b. Modify the existing Java class so that it implements the SEI.

NOTE
Although you can add the JAX-WS annotations to a Java class, it is not recommended.

Writing the interface

The SEI is a standard Java interface. It defines a set of methods that a class implements. It can also define a number of member fields and constants to which the implementing class has access.

In the case of an SEI the methods defined are intended to be mapped to operations exposed by a service. The SEI corresponds to a `wsdl:portType` element. The methods defined by the SEI correspond to `wsdl:operation` elements in the `wsdl:portType` element.

NOTE
JAX-WS defines an annotation that allows you to specify methods that are not exposed as part of a service. However, the best practice is to leave those methods out of the SEI.

Example 24.1, “Simple SEI” shows a simple SEI for a stock updating service.

Example 24.1. Simple SEI

```java
package com.fusesource.demo;

public interface quoteReporter {
    public Quote getQuote(String ticker);
}
```

Implementing the interface

Because the SEI is a standard Java interface, the class that implements it is a standard Java class. If you start with a Java class you must modify it to implement the interface. If you start with the SEI, the implementation class implements the SEI.
Example 24.2, “Simple Implementation Class” shows a class for implementing the interface in Example 24.1, “Simple SEI”.

Example 24.2. Simple Implementation Class

```java
package com.fusesource.demo;

import java.util.*;

public class stockQuoteReporter implements quoteReporter {
    ...
    public Quote getQuote(String ticker) {
        Quote retVal = new Quote();
        retVal.setID(ticker);
        retVal.setVal(Board.check(ticker));[1]
        Date retDate = new Date();
        retVal.setTime(retDate.toString());
        return(retVal);
    }
}
```

24.3. ANNOTATING THE CODE

24.3.1. Overview of JAX-WS Annotations

The JAX-WS annotations specify the metadata used to map the SEI to a fully specified service definition. Among the information provided in the annotations are the following:

- The target namespace for the service.
- The name of the class used to hold the request message
- The name of the class used to hold the response message
- If an operation is a one way operation
- The binding style the service uses
- The name of the class used for any custom exceptions
- The namespaces under which the types used by the service are defined

**NOTE**

Most of the annotations have sensible defaults and it is not necessary to provide values for them. However, the more information you provide in the annotations, the better your service definition is specified. A well-specified service definition increases the likelihood that all parts of a distributed application will work together.

24.3.2. Required Annotations
Overview

In order to create a service from Java code you are only required to add one annotation to your code. You must add the `@WebService` annotation on both the SEI and the implementation class.

The `@WebService` annotation

The `@WebService` annotation is defined by the `javax.jws.WebService` interface and it is placed on an interface or a class that is intended to be used as a service. `@WebService` has the properties described in Table 24.1, "@WebService Properties"

Table 24.1. @WebService Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Specifies the name of the service interface. This property is mapped to the <code>name</code> attribute of the <code>wsdl:portType</code> element that defines the service’s interface in a WSDL contract. The default is to append <code>PortType</code> to the name of the implementation class. [a]</td>
</tr>
<tr>
<td>targetNamespace</td>
<td>Specifies the target namespace where the service is defined. If this property is not specified, the target namespace is derived from the package name.</td>
</tr>
<tr>
<td>serviceName</td>
<td>Specifies the name of the published service. This property is mapped to the <code>name</code> attribute of the <code>wsdl:service</code> element that defines the published service. The default is to use the name of the service’s implementation class.</td>
</tr>
<tr>
<td>wsdlLocation</td>
<td>Specifies the URL where the service’s WSDL contract is stored. This must be specified using a relative URL. The default is the URL where the service is deployed.</td>
</tr>
<tr>
<td>endpointInterface</td>
<td>Specifies the full name of the SEI that the implementation class implements. This property is only specified when the attribute is used on a service implementation class.</td>
</tr>
<tr>
<td>portName</td>
<td>Specifies the name of the endpoint at which the service is published. This property is mapped to the <code>name</code> attribute of the <code>wsdl:port</code> element that specifies the endpoint details for a published service. The default is the append <code>Port</code> to the name of the service’s implementation class.</td>
</tr>
</tbody>
</table>

[a] When you generate WSDL from an SEI the interface’s name is used in place of the implementation class’ name.
NOTE

It is not necessary to provide values for any of the @WebService annotation’s properties. However, it is recommended that you provide as much information as you can.

Annotating the SEI

The SEI requires that you add the @WebService annotation. Because the SEI is the contract that defines the service, you should specify as much detail as possible about the service in the @WebService annotation’s properties.

Example 24.3, “Interface with the @WebService Annotation” shows the interface defined in Example 24.1, “Simple SEI” with the @WebService annotation.

Example 24.3. Interface with the @WebService Annotation

```java
package com.fusesource.demo;

import javax.jws.*;

@WebService(name="quoteUpdater",
           targetNamespace="http:\demos.redhat.com",
           serviceName="updateQuoteService",
           wsdlLocation="http:\demos.redhat.com\quoteExampleService?wsdl",
           portName="updateQuotePort")
public interface quoteReporter
{
    public Quote getQuote(String ticker);
}
```

The @WebService annotation in Example 24.3, “Interface with the @WebService Annotation” does the following:

- Specifies that the value of the name attribute of the wsdl:portType element defining the service interface is quoteUpdater.
- Specifies that the target namespace of the service is http:\demos.redhat.com.
- Specifies that the value of the name of the wsdl:service element defining the published service is updateQuoteService.
- Specifies that the service will publish its WSDL contract at http:\demos.redhat.com\quoteExampleService?wsdl.
- Specifies that the value of the name attribute of the wsdl:port element defining the endpoint exposing the service is updateQuotePort.

Annotating the service implementation

In addition to annotating the SEI with the @WebService annotation, you also must annotate the service implementation class with the @WebService annotation. When adding the annotation to the service implementation class you only need to specify the endpointInterface property. As shown in Example 24.4, “Annotated Service Implementation Class” the property must be set to the full name of the SEI.
Example 24.4. Annotated Service Implementation Class

```java
package org.eric.demo;
import javax.jws.*;
@WebService(endpointInterface="com.fusesource.demo.quoteReporter")
public class stockQuoteReporter implements quoteReporter
{
    public Quote getQuote(String ticker)
    {
        ...
    }
}
```

24.3.3. Optional Annotations

Abstract

While the `@WebService` annotation is sufficient for service enabling a Java interface or a Java class, it does not fully describe how the service will be exposed as a service provider. The JAX-WS programming model uses a number of optional annotations for adding details about your service, such as the binding it uses, to the Java code. You add these annotations to the service’s SEI.

The more details you provide in the SEI the easier it is for developers to implement applications that can use the functionality it defines. It also makes the WSDL documents generated by the tools more specific.

Overview

Defining the Binding Properties with Annotations

If you are using a SOAP binding for your service, you can use JAX-WS annotations to specify a number of the bindings properties. These properties correspond directly to the properties you can specify in a service’s WSDL contract. Some of the settings, such as the parameter style, can restrict how you implement a method. These settings can also effect which annotations can be used when annotating method parameters.

The `@SOAPBinding` annotation

The `@SOAPBinding` annotation is defined by the `javax.jws.soap.SOAPBinding` interface. It provides details about the SOAP binding used by the service when it is deployed. If the `@SOAPBinding` annotation is not specified, a service is published using a wrapped doc/literal SOAP binding.

You can put the `@SOAPBinding` annotation on the SEI and any of the SEI’s methods. When it is used on a method, setting of the method’s `@SOAPBinding` annotation take precedence.

Table 24.2, "@SOAPBinding Properties" shows the properties for the `@SOAPBinding` annotation.

Table 24.2. @SOAPBinding Properties
<table>
<thead>
<tr>
<th>Property</th>
<th>Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>style</strong></td>
<td>Style.DOCUMENT (default)</td>
<td>Specifies the style of the SOAP message. If RPC style is specified, each message part within the SOAP body is a parameter or return value and appears inside a wrapper element within the <code>&lt;soap:body&gt;</code> element. The message parts within the wrapper element correspond to operation parameters and must appear in the same order as the parameters in the operation. If DOCUMENT style is specified, the contents of the SOAP body must be a valid XML document, but its form is not as tightly constrained.</td>
</tr>
<tr>
<td></td>
<td>Style.RPC</td>
<td></td>
</tr>
<tr>
<td><strong>use</strong></td>
<td>Use.LITERAL (default)</td>
<td>Specifies how the data of the SOAP message is streamed.</td>
</tr>
<tr>
<td></td>
<td>Use.ENCODED[^a]</td>
<td></td>
</tr>
<tr>
<td><strong>parameterStyle[^b]</strong></td>
<td>ParameterStyle.BARE</td>
<td>Specifies how the method parameters, which correspond to message parts in a WSDL contract, are placed into the SOAP message body. If BARE is specified, each parameter is placed into the message body as a child element of the message root. If WRAPPED is specified, all of the input parameters are wrapped into a single element on a request message and all of the output parameters are wrapped into a single element in the response message.</td>
</tr>
<tr>
<td></td>
<td>ParameterStyle.WRAPPED (default)</td>
<td></td>
</tr>
</tbody>
</table>

[^a]: Use.ENCODED is not currently supported.

[^b]: If you set the **style** to RPC you must use the WRAPPED parameter style.

### Document bare style parameters

Document bare style is the most direct mapping between Java code and the resulting XML representation of the service. When using this style, the schema types are generated directly from the input and output parameters defined in the operation’s parameter list.

You specify you want to use bare document literal style by using the `@SOAPBinding` annotation with its **style** property set to Style.DOCUMENT, and its **parameterStyle** property set to ParameterStyle.BARE.
To ensure that an operation does not violate the restrictions of using document style when using bare parameters, your operations must adhere to the following conditions:

- The operation must have no more than one input or input/output parameter.
- If the operation has a return type other than `void`, it must not have any output or input/output parameters.
- If the operation has a return type of `void`, it must have no more than one output or input/output parameter.

**NOTE**

Any parameters that are placed in the SOAP header using the `@WebParam` annotation or the `@WebResult` annotation are not counted against the number of allowed parameters.

**Document wrapped parameters**

Document wrapped style allows a more RPC like mapping between the Java code and the resulting XML representation of the service. When using this style, the parameters in the method’s parameter list are wrapped into a single element by the binding. The disadvantage of this is that it introduces an extra-layer of indirection between the Java implementation and how the messages are placed on the wire.

To specify that you want to use wrapped document literal style use the `@SOAPBinding` annotation with its `style` property set to `Style.DOCUMENT`, and its `parameterStyle` property set to `ParameterStyle.WRAPPED`.

You have some control over how the wrappers are generated by using the the section called “The `@RequestWrapper` annotation” annotation and the the section called “The `@ResponseWrapper` annotation” annotation.

**Example**

Example 24.5, “Specifying a Document Bare SOAP Binding with the SOAP Binding Annotation” shows an SEI that uses document bare SOAP messages.

```java
package org.eric.demo;
import javax.jws.*;
import javax.jws.soap.*;
import javax.jws.soap.SOAPBinding.*;

@WebService(name="quoteReporter")
@SOAPBinding(parameterStyle=ParameterStyle.BARE)
public interface quoteReporter
{
    ...
}
```

**Overview**
Defining Operation Properties with Annotations

When the runtime maps your Java method definitions into XML operation definitions it provides details such as:

- What the exchanged messages look like in XML
- If the message can be optimized as a one way message
- The namespaces where the messages are defined

The @WebMethod annotation

The @WebMethod annotation is defined by the javax.jws.WebMethod interface. It is placed on the methods in the SEI. The @WebMethod annotation provides the information that is normally represented in the wsd1:operation element describing the operation to which the method is associated.

Table 24.3, "@WebMethod Properties" describes the properties of the @WebMethod annotation.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>operationName</td>
<td>Specifies the value of the associated wsd1:operation element’s name. The default value is the name of the method.</td>
</tr>
<tr>
<td>action</td>
<td>Specifies the value of the soapAction attribute of the soap:operation element generated for the method. The default value is an empty string.</td>
</tr>
<tr>
<td>exclude</td>
<td>Specifies if the method should be excluded from the service interface. The default is false.</td>
</tr>
</tbody>
</table>

The @RequestWrapper annotation

The @RequestWrapper annotation is defined by the javax.xml.ws.RequestWrapper interface. It is placed on the methods in the SEI. The @RequestWrapper annotation specifies the Java class implementing the wrapper bean for the method parameters of the request message starting a message exchange. It also specifies the element names, and namespaces, used by the runtime when marshalling and unmarshalling the request messages.

Table 24.4, "@RequestWrapper Properties" describes the properties of the @RequestWrapper annotation.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>property</td>
<td>Description</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>localName</strong></td>
<td>Specifies the local name of the wrapper element in the XML representation of the request message. The default value is either the name of the method, or the value of the section called “The @WebMethod annotation” annotation’s <code>operationName</code> property.</td>
</tr>
<tr>
<td><strong>targetNamespace</strong></td>
<td>Specifies the namespace under which the XML wrapper element is defined. The default value is the target namespace of the SEI.</td>
</tr>
<tr>
<td><strong>className</strong></td>
<td>Specifies the full name of the Java class that implements the wrapper element.</td>
</tr>
</tbody>
</table>

**NOTE**

Only the `className` property is required.

**IMPORTANT**

If the method is also annotated with the `@SOAPBinding` annotation, and its `parameterStyle` property is set to `ParameterStyle.BARE`, this annotation is ignored.

The `@ResponseWrapper` annotation

The `@ResponseWrapper` annotation is defined by the javax.xml.ws.ResponseWrapper interface. It is placed on the methods in the SEI. The `@ResponseWrapper` specifies the Java class implementing the wrapper bean for the method parameters in the response message in the message exchange. It also specifies the element names, and namespaces, used by the runtime when marshaling and unmarshalling the response messages.

Table 24.5, “@ResponseWrapper Properties” describes the properties of the `@ResponseWrapper` annotation.

**Table 24.5. @ResponseWrapper Properties**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>localName</strong></td>
<td>Specifies the local name of the wrapper element in the XML representation of the response message. The default value is either the name of the method with Response appended, or the value of the section called “The @WebMethod annotation” annotation’s <code>operationName</code> property with Response appended.</td>
</tr>
<tr>
<td><strong>targetNamespace</strong></td>
<td>Specifies the namespace where the XML wrapper element is defined. The default value is the target namespace of the SEI.</td>
</tr>
</tbody>
</table>
Specifies the full name of the Java class that implements the wrapper element.

**NOTE**

Only the `className` property is required.

**IMPORTANT**

If the method is also annotated with the `@SOAPBinding` annotation and its `parameterStyle` property is set to `ParameterStyle.BARE`, this annotation is ignored.

The `@WebFault` annotation

The `@WebFault` annotation is defined by the `javax.xml.ws.WebFault` interface. It is placed on exceptions that are thrown by your SEI. The `@WebFault` annotation is used to map the Java exception to a `wsdl:fault` element. This information is used to marshall the exceptions into a representation that can be processed by both the service and its consumers.

Table 24.6, "@WebFault Properties" describes the properties of the `@WebFault` annotation.

### Table 24.6. `@WebFault` Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>name</code></td>
<td>Specifies the local name of the fault element.</td>
</tr>
<tr>
<td><code>targetNamespace</code></td>
<td>Specifies the namespace under which the fault element is defined. The default value is the target namespace of the SEI.</td>
</tr>
<tr>
<td><code>faultName</code></td>
<td>Specifies the full name of the Java class that implements the exception.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

The `name` property is required.

The `@Oneway` annotation

The `@Oneway` annotation is defined by the `javax.jws.Oneway` interface. It is placed on the methods in the SEI that will not require a response from the service. The `@Oneway` annotation tells the run time that it can optimize the execution of the method by not waiting for a response and by not reserving any resources to process a response.

This annotation can only be used on methods that meet the following criteria:

- They return `void`
They have no parameters that implement the Holder interface

They do not throw any exceptions that can be passed back to a consumer

Example

Example 24.6, “SEI with Annotated Methods” shows an SEI with its methods annotated.

```java
import javax.jws.*;
import javax.xml.ws.*;

@WebService(name="quoteReporter")
public interface quoteReporter {
    @WebMethod(operationName="getStockQuote")
    @RequestWrapper(targetNamespace="http://demo.redhat.com/types",
                    className="java.lang.String")
    @ResponseWrapper(targetNamespace="http://demo.redhat.com/types",
                     className="org.eric.demo.Quote")
    public Quote getQuote(String ticker);
}
```

Overview

Defining Parameter Properties with Annotations

The method parameters in the SEI correspond to the `wsdl:message` elements and their `wsdl:part` elements. JAX-WS provides annotations that allow you to describe the `wsdl:part` elements that are generated for the method parameters.

The `@WebParam` annotation

The `@WebParam` annotation is defined by the `javax.jws.WebParam` interface. It is placed on the parameters of the methods defined in the SEI. The `@WebParam` annotation allows you to specify the direction of the parameter, if the parameter will be placed in the SOAP header, and other properties of the generated `wsdl:part`.

Table 24.7, “@WebParam Properties” describes the properties of the `@WebParam` annotation.

<table>
<thead>
<tr>
<th>Property</th>
<th>Values</th>
<th>Description</th>
</tr>
</thead>
</table>

Table 24.7. @WebParam Properties
<table>
<thead>
<tr>
<th>Property</th>
<th>Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td></td>
<td>Specifies the name of the parameter as it appears in the generated WSDL document. For RPC bindings, this is the name of the wsdl:part representing the parameter. For document bindings, this is the local name of the XML element representing the parameter. Per the JAX-WS specification, the default is argN, where N is replaced with the zero-based argument index (i.e., arg0, arg1, etc.).</td>
</tr>
<tr>
<td>targetNamespace</td>
<td></td>
<td>Specifies the namespace for the parameter. It is only used with document bindings where the parameter maps to an XML element. The default is to use the service’s namespace.</td>
</tr>
<tr>
<td>mode</td>
<td>Mode.IN (default)[^a]</td>
<td>Specifies the direction of the parameter.</td>
</tr>
<tr>
<td></td>
<td>Mode.OUT</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Mode.INOUT</td>
<td></td>
</tr>
<tr>
<td>header</td>
<td>false (default)</td>
<td>Specifies if the parameter is passed as part of the SOAP header.</td>
</tr>
<tr>
<td></td>
<td>true</td>
<td></td>
</tr>
<tr>
<td>partName</td>
<td></td>
<td>Specifies the value of the name attribute of the wsdl:part element for the parameter. This property is used for document style SOAP bindings.</td>
</tr>
</tbody>
</table>

\[^a\] Any parameter that implements the Holder interface is mapped to Mode.INOUT by default.

The @WebResult annotation

The @WebResult annotation is defined by the javax.jws.WebResult interface. It is placed on the methods defined in the SEI. The @WebResult annotation allows you to specify the properties of the wsdl:part that is generated for the method’s return value.

Table 24.8, "@WebResult Properties" describes the properties of the @WebResult annotation.

Table 24.8. @WebResult Properties
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Specifies the name of the return value as it appears in the generated WSDL document. For RPC bindings, this is the name of the <code>wsdl:part</code> representing the return value. For document bindings, this is the local name of the XML element representing the return value. The default value is <code>return</code>.</td>
</tr>
<tr>
<td>targetNamespace</td>
<td>Specifies the namespace for the return value. It is only used with document bindings where the return value maps to an XML element. The default is to use the service's namespace.</td>
</tr>
<tr>
<td>header</td>
<td>Specifies if the return value is passed as part of the SOAP header.</td>
</tr>
<tr>
<td>partName</td>
<td>Specifies the value of the <code>name</code> attribute of the <code>wsdl:part</code> element for the return value. This property is used for document style SOAP bindings.</td>
</tr>
</tbody>
</table>

**Example**

*Example 24.7, “Fully Annotated SEI”* shows an SEI that is fully annotated.

```java
package com.fusesource.demo;

import javax.jws.*;
import javax.xml.ws.*;
import javax.jws.soap.*;
import javax.jws.soap.SOAPBinding.*;
import javax.jws.WebParam.*;

@WebService(targetNamespace="http://demo.redhat.com",
    name="quoteReporter")
@SOAPBinding(style=Style.RPC, use=Use.LITERAL)
public interface quoteReporter
{
    @WebMethod(operationName="getStockQuote")
    @RequestWrapper(targetNamespace="http://demo.redhat.com/types",
        className="java.lang.String")
    @ResponseWrapper(targetNamespace="http://demo.redhat.com/types",
        className="org.eric.demo.Quote")
    @WebResult(targetNamespace="http://demo.redhat.com/types",
        name="updatedQuote")
    public Quote getQuote(
        @WebParam(targetNamespace="http://demo.redhat.com/types",
            name="stockTicker",
            mode=Mode.IN)
```
24.3.4. Apache CXF Annotations

24.3.4.1. WSDL Documentation

@WSDLDocumentation annotation

The @WSDLDocumentation annotation is defined by the org.apache.cxf.annotations.WSDLDocumentation interface. It can be placed on the SEI or the SEI methods.

This annotation enables you to add documentation, which will then appear within `wsdl:documentation` elements after the SEI is converted to WSDL. By default, the documentation elements appear inside the port type, but you can specify the placement property to make the documentation appear at other locations in the WSDL file. Section 24.3.4.2, “@WSDLDocumentation properties” shows the properties supported by the @WSDLDocumentation annotation.

24.3.4.2. @WSDLDocumentation properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>(Required) A string containing the documentation text.</td>
</tr>
<tr>
<td>placement</td>
<td>(Optional) Specifies where in the WSDL file this documentation is to appear. For the list of possible placement values, see the section called “Placement in the WSDL contract”.</td>
</tr>
<tr>
<td>faultClass</td>
<td>(Optional) If the placement is set to be <code>FAULT_MESSAGE</code>, <code>PORT_TYPE_OPERATION_FAULT</code>, or <code>BINDING_OPERATION_FAULT</code>, you must also set this property to the Java class that represents the fault.</td>
</tr>
</tbody>
</table>

@WSDLDocumentationCollection annotation

The @WSDLDocumentationCollection annotation is defined by the org.apache.cxf.annotations.WSDLDocumentationCollection interface. It can be placed on the SEI or the SEI methods.

This annotation is used to insert multiple documentation elements at a single placement location or at various placement locations.

Placement in the WSDL contract
To specify where the documentation should appear in the WSDL contract, you can specify the `placement` property, which is of type `WSDLDocumentation.Placement`. The placement can have one of the following values:

- `WSDLDocumentation.Placement.BINDING`
- `WSDLDocumentation.Placement.BINDING_OPERATION`
- `WSDLDocumentation.Placement.BINDING_OPERATION_FAULT`
- `WSDLDocumentation.Placement.BINDING_OPERATION_INPUT`
- `WSDLDocumentation.Placement.BINDING_OPERATION_OUTPUT`
- `WSDLDocumentation.Placement.DEFAULT`
- `WSDLDocumentation.Placement.FAULT_MESSAGE`
- `WSDLDocumentation.Placement.INPUT_MESSAGE`
- `WSDLDocumentation.Placement.OUTPUT_MESSAGE`
- `WSDLDocumentation.Placement.PORT_TYPE`
- `WSDLDocumentation.Placement.PORT_TYPE_OPERATION`
- `WSDLDocumentation.Placement.PORT_TYPE_OPERATION_FAULT`
- `WSDLDocumentation.Placement.PORT_TYPE_OPERATION_INPUT`
- `WSDLDocumentation.Placement.PORT_TYPE_OPERATION_OUTPUT`
- `WSDLDocumentation.Placement.SERVICE`
- `WSDLDocumentation.Placement.SERVICE_PORT`
- `WSDLDocumentation.Placement.TOP`

Example of `@WSDLDocumentation`

Section 24.3.4.3, “Using `@WSDLDocumentation`” shows how to add a `@WSDLDocumentation` annotation to the SEI and to one of its methods.

24.3.4.3. Using `@WSDLDocumentation`

```java
@WebService
@WebSDLDocumentation("A very simple example of an SEI")
public interface HelloWorld {
    @WSDLDocumentation("A traditional form of greeting")
    String sayHi(@WebParam(name = "text") String text);
}
```

When WSDL, shown in Section 24.3.4.4, “WSDL generated with documentation”, is generated from the SEI in Section 24.3.4.3, “Using `@WSDLDocumentation`”, the default placements of the documentation elements are, respectively, `PORT_TYPE` and `PORT_TYPE_OPERATION`. 
24.3.4.4. WSDL generated with documentation

```xml
<wSDL:definitions ... >
  ...
  <wsdl:portType name="HelloWorld">
    <wsdl:documentation>A very simple example of an SEI</wsdl:documentation>
    <wsdl:operation name="sayHi">
      <wsdl:documentation>A traditional form of greeting</wsdl:documentation>
      <wsdl:input name="sayHi" message="tns:sayHi">
        ...
      </wsdl:input>
      <wsdl:output name="sayHiResponse" message="tns:sayHiResponse">
        ...
      </wsdl:output>
    </wsdl:operation>
  </wsdl:portType>
  ...
</wsdl:definitions>
```

Example of `@WSDLDocumentationCollection`

Section 24.3.4.5, “Using `@WSDLDocumentationCollection`” shows how to add a `@WSDLDocumentationCollection` annotation to an SEI.

24.3.4.5. Using `@WSDLDocumentationCollection`

```java
@WebService
@WSDLDocumentationCollection(  
  {  
    @WSDLDocumentation("A very simple example of an SEI"),  
    @WSDLDocumentation(value = "My top level documentation", placement = WSDLDocumentation.Placement.TOP),  
    @WSDLDocumentation(value = "Binding documentation", placement = WSDLDocumentation.Placement.BINDING)  
  }  
)
public interface HelloWorld {  
  @WSDLDocumentation("A traditional form of Geeky greeting")  
  String sayHi(@WebParam(name = "text") String text);  
}
```

24.3.4.6. Schema Validation of Messages

`@SchemaValidation` annotation

The `@SchemaValidation` annotation is defined by the `org.apache.cxf.annotations.SchemaValidation` interface. It can be placed on the SEI and on individual SEI methods.

This annotation turns on schema validation of the XML messages sent to this endpoint. This can be useful for testing purposes, when you suspect there is a problem with the format of incoming XML messages. By default, validation is disabled, because it has a significant impact on performance.

Schema validation type
The schema validation behaviour is controlled by the type parameter, whose value is an enumeration of org.apache.cxf.annotations.SchemaValidation.SchemaValidationType type. Section 24.3.4.7, “Schema Validation Type Values” shows the list of available validation types.

### 24.3.4.7. Schema Validation Type Values

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IN</td>
<td>Apply schema validation to incoming messages on client and server.</td>
</tr>
<tr>
<td>OUT</td>
<td>Apply schema validation to outgoing messages on client and server.</td>
</tr>
<tr>
<td>BOTH</td>
<td>Apply schema validation to both incoming and outgoing messages on client and server.</td>
</tr>
<tr>
<td>NONE</td>
<td>All schema validation is disabled.</td>
</tr>
<tr>
<td>REQUEST</td>
<td>Apply schema validation to Request messages—that is, causing validation to be applied to outgoing client messages and to incoming server messages.</td>
</tr>
<tr>
<td>RESPONSE</td>
<td>Apply schema validation to Response messages—that is, causing validation to be applied to incoming client messages, and outgoing server messages.</td>
</tr>
</tbody>
</table>

### Example

The following example shows how to enable schema validation of messages for endpoints based on the MyService SEI. Note how the annotation can be applied to the SEI as a whole, as well as to individual methods in the SEI.

```java
@WebService  
@SchemaValidation(type = SchemaValidationType.BOTH)  
public interface MyService {  
    Foo validateBoth(Bar data);  
  
    @SchemaValidation(type = SchemaValidationType.NONE)  
    Foo validateNone(Bar data);  
  
    @SchemaValidation(type = SchemaValidationType.IN)  
    Foo validateIn(Bar data);  
  
    @SchemaValidation(type = SchemaValidationType.OUT)  
    Foo validateOut(Bar data);  
  
    @SchemaValidation(type = SchemaValidationType.REQUEST)  
    Foo validateRequest(Bar data);  
```
24.3.4.8. Specifying the Data Binding

@DataBinding annotation

The @DataBinding annotation is defined by the org.apache.cxf.annotations.DataBinding interface. It is placed on the SEI.

This annotation is used to associate a data binding with the SEI, replacing the default JAXB data binding. The value of the @DataBinding annotation must be the class that provides the data binding, ClassName.class.

Supported data bindings

The following data bindings are currently supported by Apache CXF:

- org.apache.cxf.jaxb.JAXBDataBinding
  (Default) The standard JAXB data binding.

- org.apache.cxf.sdo.SDODataBinding
  The Service Data Objects (SDO) data binding is based on the Apache Tuscany SDO implementation. If you want to use this data binding in the context of a Maven build, you need to add a dependency on the cxf-rt-databinding-sdo artifact.

- org.apache.cxf.aegis databinding.AegisDatabinding
  If you want to use this data binding in the context of a Maven build, you need to add a dependency on the cxf-rt-databinding-aegis artifact.

- org.apache.cxf.xmlbeans.XmlBeansDataBinding
  If you want to use this data binding in the context of a Maven build, you need to add a dependency on the cxf-rt-databinding-xmlbeans artifact.

- org.apache.cxf.databinding.source.SourceDataBinding
  This data binding belongs to the Apache CXF core.

- org.apache.cxf.databinding.stax.StaxDataBinding
  This data binding belongs to the Apache CXF core.

Example

Section 24.3.4.9, “Setting the data binding” shows how to associate the SDO binding with the HelloWorld SEI.

24.3.4.9. Setting the data binding

@WebService
@DataBinding(org.apache.cxf.sdo.SDODataBinding.class)
public interface HelloWorld {
    String sayHi(@WebParam(name = "text") String text);
}
24.3.4.10. Compressing Messages

@GZIP annotation

The @GZIP annotation is defined by the org.apache.cxf.annotations.GZIP interface. It is placed on the SEI.

Enables GZIP compression of messages. GZIP is a negotiated enhancement. That is, an initial request from a client will not be gzipped, but an Accept header will be added and, if the server supports GZIP compression, the response will be gzipped and any subsequent requests will be also.

Section 24.3.4.11, "@GZIP Properties" shows the optional properties supported by the @GZIP annotation.

24.3.4.11. @GZIP Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>threshold</td>
<td>Messages smaller than the size specified by this property are not gzipped. Default is -1 (no limit).</td>
</tr>
</tbody>
</table>

@FastInfoset

The @FastInfoset annotation is defined by the org.apache.cxf.annotations.FastInfoset interface. It is placed on the SEI.

Enables the use of FastInfoset format for messages. FastInfoset is a binary encoding format for XML, which aims to optimize both the message size and the processing performance of XML messages. For more details, see the following Sun article on Fast Infoset.

FastInfoset is a negotiated enhancement. That is, an initial request from a client will not be in FastInfoset format, but an Accept header will be added and, if the server supports FastInfoset, the response will be in FastInfoset and any subsequent requests will be also.

Section 24.3.4.12, "@FastInfoset Properties" shows the optional properties supported by the @FastInfoset annotation.

24.3.4.12. @FastInfoset Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>force</td>
<td>A boolean property that forces the use of FastInfoset format, instead of negotiating. When true, force the use of FastInfoset format; otherwise, negotiate. Default is false.</td>
</tr>
</tbody>
</table>

Example of @GZIP

Section 24.3.4.13, “Enabling GZIP” shows how to enable GZIP compression for the HelloWorld SEI.

24.3.4.13. Enabling GZIP
Exampe of @FastInfoset

Section 24.3.4.14, “Enabling FastInfoset” shows how to enable the FastInfoset format for the HelloWorld SEI.

24.3.4.14. Enabling FastInfoset

```java
@WebService
@FastInfoset
public interface HelloWorld {
    String sayHi(@WebParam(name = "text") String text);
}
```

24.3.4.15. Enable Logging on an Endpoint

@Logging annotation

The @Logging annotation is defined by the org.apache.cxf.annotations.Logging interface. It is placed on the SEI.

This annotation enables logging for all endpoints associated with the SEI. Section 24.3.4.16, “@Logging Properties” shows the optional properties you can set in this annotation.

24.3.4.16. @Logging Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>limit</td>
<td>Specifies the size limit, beyond which the message is truncated in the logs. Default is 64K.</td>
</tr>
<tr>
<td>inLocation</td>
<td>Specifies the location to log incoming messages. Can be either &lt;stderr&gt;, &lt;stdout&gt;, &lt;logger&gt;, or a filename. Default is &lt;logger&gt;.</td>
</tr>
<tr>
<td>outLocation</td>
<td>Specifies the location to log outgoing messages. Can be either &lt;stderr&gt;, &lt;stdout&gt;, &lt;logger&gt;, or a filename. Default is &lt;logger&gt;.</td>
</tr>
</tbody>
</table>

Example

Section 24.3.4.17, “Logging configuration using annotations” shows how to enable logging for the HelloWorld SEI, where incoming messages are sent to <stdout> and outgoing messages are sent to <logger>.
24.3.4.17. Logging configuration using annotations

```java
@WebService
@Logging(limit=16000, inLocation="<stdout>")
public interface HelloWorld {
    String sayHi(@WebParam(name = "text") String text);
}
```

24.3.4.18. Adding Properties and Policies to an Endpoint

Abstract

Both properties and policies can be used to associate configuration data with an endpoint. The essential difference between them is that **properties** are a Apache CXF specific configuration mechanism whereas **policies** are a standard WSDL configuration mechanism. Policies typically originate from WS specifications and standards and they are normally set by defining `wsdl:policy` elements that appear in the WSDL contract. By contrast, properties are Apache CXF-specific and they are normally set by defining `jaxws:properties` elements in the Apache CXF Spring configuration file.

It is also possible, however, to define property settings and WSDL policy settings in Java using annotations, as described here.

24.3.4.19. Adding properties

@EndpointProperty annotation

The `@EndpointProperty` annotation is defined by the `org.apache.cxf.annotations.EndpointProperty` interface. It is placed on the SEI.

This annotation adds Apache CXF-specific configuration settings to an endpoint. Endpoint properties can also be specified in a Spring configuration file. For example, to configure WS-Security on an endpoint, you could add endpoint properties using the `jaxws:properties` element in a Spring configuration file as follows:

```xml
<beans xmlns="http://www.springframework.org/schema/beans"
      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xmlns:jaxws="http://cxf.apache.org/jaxws"
      ... >

  <jaxws:endpoint
    id="MyService"
    address="https://localhost:9001/MyService"
    serviceName="interop:MyService"
    endpointName="interop:MyServiceEndpoint"
    implementor="com.foo.MyService">

  <jaxws:properties>
    <entry key="ws-security.callback-handler" value="interop.client.UTPasswordCallback"/>
    <entry key="ws-security.signature.properties" value="etc/keystore.properties"/>
    <entry key="ws-security.encryption.username" value="useReqSigCert"/>
  </jaxws:properties>

</jaxws:endpoint>
```

Red Hat Fuse 7.8 Apache CXF Development Guide
Alternatively, you could specify the preceding configuration settings in Java by adding `@EndpointProperty` annotations to the SEI, as shown in Section 24.3.4.20, "Configuring WS-Security Using @EndpointProperty Annotations".

### 24.3.4.20. Configuring WS-Security Using @EndpointProperty Annotations

```java
@WebService
@EndpointProperty(name="ws-security.callback-handler" 
value="interop.client.UTPasswordCallback")
@EndpointProperty(name="ws-security.signature.properties" value="etc/keystore.properties")
@EndpointProperty(name="ws-security.encryption.properties" value="etc/truststore.properties")
@EndpointProperty(name="ws-security.encryption.username" value="useReqSigCert")
public interface HelloWorld {
    String sayHi(@WebParam(name = "text") String text);
}
```

**@EndpointProperties annotation**

The `@EndpointProperties` annotation is defined by the `org.apache.cxf.annotations.EndpointProperties` interface. It is placed on the SEI.

This annotation provides a way of grouping multiple `@EndpointProperty` annotations into a list. Using `@EndpointProperties`, it is possible to re-write Section 24.3.4.20, "Configuring WS-Security Using @EndpointProperty Annotations" as shown in Section 24.3.4.21, "Configuring WS-Security Using an @EndpointProperties Annotation".

### 24.3.4.21. Configuring WS-Security Using an @EndpointProperties Annotation

```java
@WebService
@EndpointProperties(
    {
        @EndpointProperty(name="ws-security.callback-handler" 
            value="interop.client.UTPasswordCallback"),
        @EndpointProperty(name="ws-security.signature.properties" value="etc/keystore.properties"),
        @EndpointProperty(name="ws-security.encryption.properties" value="etc/truststore.properties"),
        @EndpointProperty(name="ws-security.encryption.username" value="useReqSigCert")
    })
public interface HelloWorld {
    String sayHi(@WebParam(name = "text") String text);
}
```

**24.3.4.22. Adding policies**

**@Policy annotation**

The `@Policy` annotation is defined by the `org.apache.cxf.annotations.Policy` interface. It can be placed on the SEI or the SEI methods.

This annotation is used to associate a WSDL policy with an SEI or an SEI method. The policy is specified...
by providing a URI that references an XML file containing a standard `wsdl:policy` element. If a WSDL contract is to be generated from the SEI (for example, using the `java2ws` command-line tool), you can specify whether or not you want to include this policy in the WSDL.

Section 24.3.4.23, "@Policy Properties" shows the properties supported by the `@Policy` annotation.

### 24.3.4.23. @Policy Properties

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>uri</td>
<td>(Required) The location of the file containing the policy definition.</td>
</tr>
<tr>
<td>includeInWSDL</td>
<td>(Optional) Whether to include the policy in the generated contract, when generating WSDL. Default is <code>true</code>.</td>
</tr>
<tr>
<td>placement</td>
<td>(Optional) Specifies where in the WSDL file this documentation is to appear. For the list of possible placement values, see the section called &quot;Placement in the WSDL contract&quot;.</td>
</tr>
<tr>
<td>faultClass</td>
<td>(Optional) If the placement is set to be <code>BINDING_OPERATION_FAULT</code> or <code>PORT_TYPE_OPERATION_FAULT</code>, you must also set this property to specify which fault this policy applies to. The value is the Java class that represents the fault.</td>
</tr>
</tbody>
</table>

**@Policies annotation**

The `@Policies` annotation is defined by the `org.apache.cxf.annotations.Policies` interface. It can be placed on the SEI or these SEI methods.

This annotation provides a way of grouping multiple `@Policy` annotations into a list.

**Placement in the WSDL contract**

To specify where the policy should appear in the WSDL contract, you can specify the `placement` property, which is of type `Policy.Placement`. The placement can have one of the following values:

- `Policy.Placement.BINDING`
- `Policy.Placement.BINDING_OPERATION`
- `Policy.Placement.BINDING_OPERATION_FAULT`
- `Policy.Placement.BINDING_OPERATION_INPUT`
- `Policy.Placement.BINDING_OPERATION_OUTPUT`
- `Policy.Placement.DEFAULT`
- `Policy.Placement.PORT_TYPE`
- `Policy.Placement.PORT_TYPE_OPERATION`
- `Policy.Placement.PORT_TYPE_OPERATION_FAULT`
- `Policy.Placement.PORT_TYPE_OPERATION_INPUT`
Example of @Policy

The following example shows how to associate WSDL policies with the HelloWorld SEI and how to associate a policy with the sayHi method. The policies themselves are stored in XML files in the file system, under the annotationpolicies directory.

```java
@WebService
@Policy(uri = "annotationpolicies/TestImplPolicy.xml",
placement = Policy.Placement.SERVICE_PORT),
@Policy(uri = "annotationpolicies/TestPortTypePolicy.xml",
placement = Policy.Placement.PORT_TYPE)
public interface HelloWorld {
    @Policy(uri = "annotationpolicies/TestOperationPTPolicy.xml",
placement = Policy.Placement.PORT_TYPE_OPERATION),
    String sayHi(@WebParam(name = "text") String text);
}
```

Example of @Policies

You can use the @Policies annotation to group multiple @Policy annotations into a list, as shown in the following example:

```java
@WebService
@Policies({
    @Policy(uri = "annotationpolicies/TestImplPolicy.xml",
placement = Policy.Placement.SERVICE_PORT),
    @Policy(uri = "annotationpolicies/TestPortTypePolicy.xml",
placement = Policy.Placement.PORT_TYPE)
})
public interface HelloWorld {
    @Policy(uri = "annotationpolicies/TestOperationPTPolicy.xml",
placement = Policy.Placement.PORT_TYPE_OPERATION),
    String sayHi(@WebParam(name = "text") String text);
}
```

### 24.4. GENERATING WSDL

#### Using Maven

Once your code is annotated, you can generate a WSDL contract for your service using the java2ws Maven plug-in’s -wsdl option. For a detailed listing of options for the java2ws Maven plug-in see Section 44.3, “java2ws”.

Example 24.8, “Generating WSDL from Java” shows how to set up the java2ws Maven plug-in to generate WSDL.

Example 24.8. Generating WSDL from Java

```xml
<plugin>
```
NOTE

Replace the value of className with the qualified className.

Example

Example 24.9, “Generated WSDL from an SEI” shows the WSDL contract that is generated for the SEI shown in Example 24.7, “Fully Annotated SEI”.

Example 24.9. Generated WSDL from anSEI

```xml
<?xml version="1.0" encoding="UTF-8"?>
<wsdl:definitions targetNamespace="http://demo.eric.org/"
    xmlns:tns="http://demo.eric.org/"
    xmlns:ns1=""
    xmlns:xsd="http://www.w3.org/2001/XMLSchema"
    xmlns:ns2="http://demo.eric.org/types"
    xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap/
    xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
    <wsdl:types>
    <xsd:schema>
    <xs:complexType name="quote">
    <xs:sequence>
    <xs:element name="ID" type="xs:string" minOccurs="0"/>
    <xs:element name="time" type="xs:string" minOccurs="0"/>
    <xs:element name="val" type="xs:float"/>
    </xs:sequence>
    </xsd:complexType>
    </xsd:schema>
    </wsdl:types>
    <wsdl:message name="getStockQuote">
    <wsdl:part name="stockTicker" type="xsd:string">
    </wsdl:part>
    </wsdl:message>
    <wsdl:message name="getStockQuoteResponse">
```
Board is an assumed class whose implementation is left to the reader.
CHAPTER 25. DEVELOPING A CONSUMER WITHOUT A WSDL CONTRACT

Abstract

You do not need a WSDL contract to develop a service consumer. You can create a service consumer from an annotated SEI. Along with the SEI you need to know the address at which the endpoint exposing the service is published, the QName of the service element that defines the endpoint exposing the service, and the QName of the port element defining the endpoint on which your consumer makes requests. This information can be specified in the SEI’s annotations or provided separately.

25.1. JAVA-FIRST CONSUMER DEVELOPMENT

To create a consumer without a WSDL contract you must do the following:

1. Create a Service object for the service on which the consumer will invoke operations.
2. Add a port to the Service object.
3. Get a proxy for the service using the Service object’s getPort() method.
4. Implement the consumer’s business logic.

25.2. CREATING A SERVICE OBJECT

Overview

The javax.xml.ws.Service class represents the wsdl:service element which contains the definition of all of the endpoints that expose a service. As such, it provides methods that allow you to get endpoints, defined by wsdl:port elements, that are proxies for making remote invocations on a service.

NOTE

The Service class provides the abstractions that allow the client code to work with Java types as opposed to working with XML documents.

The create() methods

The Service class has two static create() methods that can be used to create a new Service object. As shown in Example 25.1, “Service create() Methods”, both of the create() methods take the QName of the wsdl:service element the Service object will represent, and one takes a URI specifying the location of the WSDL contract.

NOTE

All services publish their WSDL contracts. For SOAP/HTTP services the URI is usually the URI for the service appended with ?wsdl.

Example 25.1. Service create() Methods

```java
public static Service create(URL wsdlLocation, QName serviceName) throws WebServiceException
public static Service create(QName serviceName) throws WebServiceException
```
The value of the `serviceName` parameter is a QName. The value of its namespace part is the target namespace of the service. The service’s target namespace is specified in the `targetNamespace` property of the `@WebService` annotation. The value of the QName’s local part is the value of `wsdl:service` element’s `name` attribute. You can determine this value in one of the following ways: . It is specified in the `serviceName` property of the `@WebService` annotation.

1. You append `Service` to the value of the `name` property of the `@WebService` annotation.
2. You append `Service` to the name of the SEI.

**IMPORTANT**

Programmatically-created CXF consumers deployed in OSGi environments require special handling to avoid the likelihood of incurring `ClassNotFoundException` errors. For each bundle that contains programmatically-created CXF consumers, you need to create a singleton CXF default bus and ensure that all of the bundle’s CXF consumers use it. Without this safeguard, one bundle could be assigned the CXF default bus created in another bundle, which could cause the inheriting bundle to fail.

For example, suppose bundle A did not explicitly set a CXF default bus and was assigned the CXF default bus created in bundle B. If the CXF bus in bundle A needed to be configured with additional features (such as SSL or WS-Security) or needed to load certain classes or resources from the application in bundle B, it would fail. This is so because the CXF bus instance sets a thread context class loader (TCCL) as the bundle class loader of the bundle that created it (in this case bundle B). Furthermore, certain frameworks, such as wss4j (implements WS-Security in CXF) use the TCCL to load resources, such as callback handler classes or other property files, from inside the bundle. Because bundle A is assigned bundle B’s default CXF bus and it’s TCCL, the wss4j layer cannot load the required resources from bundle A, which results in `ClassNotFoundException` errors.

To create the singleton CXF default bus, insert this code at the beginning of the `main` method that creates the service object, as shown in the section called "Example":

```java
BusFactory.setThreadDefaultBus(BusFactory.newInstance().createBus());
```

**Example**

Example 25.2, “Creating a `Service` Object” shows code for creating a `Service` object for the SEI shown in Example 24.7, “Fully Annotated SEI”.

**Example 25.2. Creating a `Service` Object**

```java
package com.fusesource.demo;

import javax.xml.namespace.QName;
import javax.xml.ws.Service;

public class Client
{
    public static void main(String args[])
    {
        BusFactory.setThreadDefaultBus(BusFactory.newInstance().createBus());
    }
```
The code in Example 25.2, “Creating a Service Object” does the following:

- Creates a singleton CXF default bus that is available to all CXF consumers of the service.
- Builds the QName for the service using the targetNamespace property and the name property of the @WebService annotation.
- Calls the single parameter create() method to create a new Service object.

**NOTE**

Using the single parameter create() frees you from having any dependencies on accessing a WSDL contract.

### 25.3. ADDING A PORT TO A SERVICE

**Overview**

The endpoint information for a service is defined in a `wsdl:port` element, and the Service object creates a proxy instance for each of the endpoints defined in a WSDL contract, if one is specified. If you do not specify a WSDL contract when you create your Service object, the Service object has no information about the endpoints that implement your service, and therefore cannot create any proxy instances. In this case, you must provide the Service object with the information needed to represent a `wsdl:port` element using the addPort() method.

**The addPort() method**

The Service class defines an addPort() method, shown in Example 25.3, “The addPort() Method”, that is used in cases where there is no WSDL contract available to the consumer implementation. The addPort() method allows you to give a Service object the information, which is typically stored in a `wsdl:port` element, necessary to create a proxy for a service implementation.

**Example 25.3. The addPort() Method**

```java
addPort(QName serviceName, String bindingId, String endpointAddress) throws WebServiceException
```

The value of the portName is a QName. The value of its namespace part is the target namespace of the service. The service’s target namespace is specified in the targetNamespace property of the @WebService annotation. The value of the QName’s local part is the value of the `wsdl:port` element’s name attribute. You can determine this value in one of the following ways:

1. Specify it in the portName property of the @WebService annotation.
2. Append Port to the value of the name property of the @WebService annotation.
3. Append Port to the name of the SEI.
The value of the `bindingId` parameter is a string that uniquely identifies the type of binding used by the endpoint. For a SOAP binding you use the standard SOAP namespace: `http://schemas.xmlsoap.org/soap/`. If the endpoint is not using a SOAP binding, the value of the `bindingId` parameter is determined by the binding developer. The value of the `endpointAddress` parameter is the address where the endpoint is published. For a SOAP/HTTP endpoint, the address is an HTTP address. Transports other than HTTP use different address schemes.

**Example**

Example 25.4, “Adding a Port to a Service Object” shows code for adding a port to the Service object created in Example 25.2, “Creating a Service Object”.

```java
package com.fusesource.demo;
import javax.xml.namespace.QName;
import javax.xml.ws.Service;
public class Client {
    public static void main(String args[]) {
        ...
        QName portName = new QName("http://demo.redhat.com", "stockQuoteReporterPort");
        s.addPort(portName,
                "http://schemas.xmlsoap.org/soap/",
                "http://localhost:9000/StockQuote");
        ...
    }
}
```

The code in Example 25.4, “Adding a Port to a Service Object” does the following:

- Creates the QName for the `portName` parameter.
- Calls the `addPort()` method.
- Specifies that the endpoint uses a SOAP binding.
- Specifies the address where the endpoint is published.

## 25.4. GETTING A PROXY FOR AN ENDPOINT

**Overview**

A service proxy is an object that provides all of the methods exposed by a remote service and handles all of the details required to make the remote invocations. The Service object provides service proxies for all of the endpoints it is aware of through the `getPort()` method. Once you have a service proxy, you can invoke its methods. The proxy forwards the invocation to the remote service endpoint using the connection details specified in the service’s contract.
The `getPort()` method

The `getPort()` method, shown in Example 25.5, “The `getPort()` Method”, returns a service proxy for the specified endpoint. The returned proxy is of the same class as the SEI.

Example 25.5. The `getPort()` Method

```java
public<T> T getPort(QName portName, Class<T> serviceEndpointInterface)
```

The value of the `portName` parameter is a QName that identifies the `wsdl:port` element that defines the endpoint for which the proxy is created. The value of the `serviceEndpointInterface` parameter is the fully qualified name of the SEI.

NOTE

When you are working without a WSDL contract the value of the `portName` parameter is typically the same as the value used for the `portName` parameter when calling `addPort()`.

Example

Example 25.6, “Getting a Service Proxy” shows code for getting a service proxy for the endpoint added in Example 25.4, “Adding a Port to a Service Object”.

Example 25.6. Getting a Service Proxy

```java
package com.fusesource.demo;

import javax.xml.namespace.QName;
import javax.xml.ws.Service;

public class Client
{
    public static void main(String args[])
    {
        ...
        quoteReporter proxy = s.getPort(portName, quoteReporter.class);
        ...
    }
}
```

25.5. IMPLEMENTING THE CONSUMER’S BUSINESS LOGIC

Overview

Once you instantiate a service proxy for a remote endpoint, you can invoke its methods as if it were a local object. The calls block until the remote method completes.

NOTE

If a method is annotated with the `@OneWay` annotation, the call returns immediately.
Example

Example 25.7, “Consumer Implemented without a WSDL Contract” shows a consumer for the service defined in Example 24.7, “Fully Annotated SEI”.

Example 25.7. Consumer Implemented without a WSDL Contract

```java
package com.fusesource.demo;

import java.io.File;
import java.net.URL;
import javax.xml.namespace.QName;
import javax.xml.ws.Service;

public class Client {
    public static void main(String args[]) {
        QName serviceName = new QName("http://demo.eric.org", "stockQuoteReporter");
        Service s = Service.create(serviceName);

        QName portName = new QName("http://demo.eric.org", "stockQuoteReporterPort");
        s.addPort(portName, "http://schemas.xmlsoap.org/soap/", "http://localhost:9000/EricStockQuote");

        quoteReporter proxy = s.getPort(portName, quoteReporter.class);

        Quote quote = proxy.getQuote("ALPHA");
        System.out.println("Stock " + quote.getID() + " is worth " + quote.getVal() + " as of " + quote.getTime());
    }
}
```

The code in Example 25.7, “Consumer Implemented without a WSDL Contract” does the following:

- Creates a **Service** object.

- Adds an endpoint definition to the **Service** object.

- Gets a service proxy from the **Service** object.

- Invokes an operation on the service proxy.
CHAPTER 26. A STARTING POINT WSDL CONTRACT

26.1. SAMPLE WSDL CONTRACT

Example 26.1, “HelloWorld WSDL Contract” shows the HelloWorld WSDL contract. This contract defines a single interface, Greeter, in the `wsdl:portType` element. The contract also defines the endpoint which will implement the service in the `wsdl:port` element.

Example 26.1. HelloWorld WSDL Contract

```xml
<?xml version="1.0" encoding="UTF-8"?>
<wsdl:definitions name="HelloWorld"
    targetNamespace="http://apache.org/hello_world_soap_http"
    xmlns="http://schemas.xmlsoap.org/wsdl/
    xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap/
    xmlns:tns="http://apache.org/hello_world_soap_http"
    xmlns:x1="http://apache.org/hello_world_soap_http/types"
    xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/
    xmlns:xsd="http://www.w3.org/2001/XMLSchema">
    <wsdl:types>
        <schema targetNamespace="http://apache.org/hello_world_soap_http/types"
            xmlns="http://www.w3.org/2001/XMLSchema"
            elementFormDefault="qualified">
            <element name="sayHiResponse">
                <complexType>
                    <sequence>
                        <element name="responseType" type="string"/>
                    </sequence>
                </complexType>
            </element>
            <element name="greetMe">
                <complexType>
                    <sequence>
                        <element name="requestType" type="string"/>
                    </sequence>
                </complexType>
            </element>
            <element name="greetMeResponse">
                <complexType>
                    <sequence>
                        <element name="responseType" type="string"/>
                    </sequence>
                </complexType>
            </element>
            <element name="greetMeOneWay">
                <complexType>
                    <sequence>
                        <element name="requestType" type="string"/>
                    </sequence>
                </complexType>
            </element>
            <element name="pingMe">
                <complexType/>
            </element>
            <element name="pingMeResponse">
                <complexType/>
            </element>
        </schema>
    </wsdl:types>
</wsdl:definitions>
```
<complexType/>
</element>
<element name="faultDetail">
<complexType>
<sequence>
<element name="minor" type="short"/>
<element name="major" type="short"/>
</sequence>
</complexType>
</element>
</schema>
</wsdl:types>

<wsdl:message name="sayHiRequest">
<wsdl:part element="x1:sayHi" name="in"/>
</wsdl:message>
<wsdl:message name="sayHiResponse">
<wsdl:part element="x1:sayHiResponse" name="out"/>
</wsdl:message>
<wsdl:message name="greetMeRequest">
<wsdl:part element="x1:greetMe" name="in"/>
</wsdl:message>
<wsdl:message name="greetMeResponse">
<wsdl:part element="x1:greetMeResponse" name="out"/>
</wsdl:message>
<wsdl:message name="greetMeOneWayRequest">
<wsdl:part element="x1:greetMeOneWay" name="in"/>
</wsdl:message>
<wsdl:message name="pingMeRequest">
<wsdl:part name="in" element="x1:pingMe"/>
</wsdl:message>
<wsdl:message name="pingMeResponse">
<wsdl:part name="out" element="x1:pingMeResponse"/>
</wsdl:message>
<wsdl:message name="pingMeFault">
<wsdl:part name="faultDetail" element="x1:faultDetail"/>
</wsdl:message>

<wsdl:portType name="Greeter">
<wsdl:operation name="sayHi">
<wsdl:input message="tns:sayHiRequest" name="sayHiRequest"/>
<wsdl:output message="tns:sayHiResponse" name="sayHiResponse"/>
</wsdl:operation>

<wsdl:operation name="greetMe">
<wsdl:input message="tns:greetMeRequest" name="greetMeRequest"/>
<wsdl:output message="tns:greetMeResponse" name="greetMeResponse"/>
</wsdl:operation>

<wsdl:operation name="greetMeOneWay">
<wsdl:input message="tns:greetMeOneWayRequest" name="greetMeOneWayRequest"/>
</wsdl:operation>

<wsdl:operation name="pingMe">
<wsdl:input name="pingMeRequest" message="tns:pingMeRequest"/>
<wsdl:output name="pingMeResponse" message="tns:pingMeResponse"/>
The Greeter interface defined in Example 26.1, “HelloWorld WSDL Contract” defines the following operations:

sayHi – Has a single output parameter, of `<xsd:string>`.

greetMe – Has an input parameter, of `<xsd:string>`, and an output parameter, of `<xsd:string>`.

greetMeOneWay – Has a single input parameter, of `<xsd:string>`. Because this operation has no output parameters, it is optimized to be a oneway invocation (that is, the consumer does not wait for a response from the server).

pingMe – Has no input parameters and no output parameters, but it can raise a fault exception.
CHAPTER 27. TOP-DOWN SERVICE DEVELOPMENT

Abstract

In the top-down method of developing a service provider you start from a WSDL document that defines the operations and methods the service provider will implement. Using the WSDL document, you generate starting point code for the service provider. Adding the business logic to the generated code is done using normal Java programming APIs.

27.1. OVERVIEW OF JAX-WS SERVICE PROVIDER DEVELOPMENT

Once you have a WSDL document, the process for developing a JAX-WS service provider is as follows:

1. Section 27.2, “Generating the Starting Point Code”  starting point code.
2. Implement the service provider’s operations.
3. Chapter 31, Publishing a Service the implemented service.

27.2. GENERATING THE STARTING POINT CODE

Overview

JAX-WS specifies a detailed mapping from a service defined in WSDL to the Java classes that will implement that service as a service provider. The logical interface, defined by the wsdl:portType element, is mapped to a service endpoint interface (SEI). Any complex types defined in the WSDL are mapped into Java classes following the mapping defined by the Java Architecture for XML Binding (JAXB) specification. The endpoint defined by the wsdl:service element is also generated into a Java class that is used by consumers to access service providers implementing the service.

The cxf-codegen-plugin Maven plug-in generates this code. It also provides options for generating starting point code for your implementation. The code generator provides a number of options for controlling the generated code.

Running the code generator

Example 27.1. Service Code Generation shows how to use the code generator to generate starting point code for a service.

Example 27.1. Service Code Generation

```xml
<plugin>
  <groupId>org.apache.cxf</groupId>
  <artifactId>cxf-codegen-plugin</artifactId>
  <version>${cxf.version}</version>
  <executions>
    <execution>
      <id>generate-sources</id>
      <phase>generate-sources</phase>
      <configuration>
        <sourceRoot>outputDir</sourceRoot>
        <wsdlOptions>
          <wsdlOption>
          </wsdlOption>
        </wsdlOptions>
      </configuration>
    </execution>
  </executions>
</plugin>
```
This does the following:

- The `-impl` option generates a shell implementation class for each `wsdl:portType` element in the WSDL contract.

- The `-server` option generates a simple `main()` to run your service provider as a stand alone application.

- The `sourceRoot` specifies that the generated code is written to a directory called `outputDir`.

- `wsdl` element specifies the WSDL contract from which code is generated.

For a complete list of the options for the code generator see Section 44.2, "cxf-codegen-plugin".

**Generated code**

Table 27.1, “Generated Classes for a Service Provider” describes the files generated for creating a service provider.

| Table 27.1. Generated Classes for a Service Provider |
|---------------------------------|--------------------------------------------------|
| **File**                        | **Description**                                 |
| `portTypeName.java`             | The SEI. This file contains the interface your service provider implements. You should not edit this file. |
| `serviceName.java`              | The endpoint. This file contains the Java class consumers use to make requests on the service. |
| `portTypeNameImpl.java`         | The skeleton implementation class. Modify this file to build your service provider. |
| `portTypeNameServer.java`       | A basic server mainline that allows you to deploy your service provider as a stand alone process. For more information see Chapter 31, *Publishing a Service*. |
In addition, the code generator will generate Java classes for all of the types defined in the WSDL contract.

**Generated packages**

The generated code is placed into packages based on the namespaces used in the WSDL contract. The classes generated to support the service (based on the `wsdl:portType` element, the `wsdl:service` element, and the `wsdl:port` element) are placed in a package based on the target namespace of the WSDL contract. The classes generated to implement the types defined in the `types` element of the contract are placed in a package based on the `targetNamespace` attribute of the `types` element.

The mapping algorithm is as follows:

1. The leading `http://` or `urn://` are stripped off the namespace.
2. If the first string in the namespace is a valid Internet domain, for example it ends in `.com` or `.gov`, then the leading `www.` is stripped off the string, and the two remaining components are flipped.
3. If the final string in the namespace ends with a file extension of the pattern `.xxx` or `.xx`, then the extension is stripped.
4. The remaining strings in the namespace are appended to the resulting string and separated by dots.
5. All letters are made lowercase.

**27.3. IMPLEMENTING THE SERVICE PROVIDER**

**Generating the implementation code**

You generate the implementation class used to build your service provider with the code generator’s `-impl` flag.

**NOTE**

If your service’s contract includes any custom types defined in XML Schema, you must ensure that the classes for the types are generated and available.

For more information on using the code generator see Section 44.2, "cxf-codegen-plugin".

**Generated code**

The implementation code consists of two files:

- `portTypeName.java` – The service interface(SEI) for the service.
- `portTypeNameImpl.java` – The class you will use to implement the operations defined by the service.

**Implement the operation’s logic**

To provide the business logic for your service’s operations complete the stub methods in `portTypeNameImpl.java`. You usually use standard Java to implement the business logic. If your service
uses custom XML Schema types, you must use the generated classes for each type to manipulate them. There are also some Apache CXF specific APIs that can be used to access some advanced features.

Example

For example, an implementation class for the service defined in Example 26.1, “HelloWorld WSDL Contract” may look like Example 27.2, “Implementation of the Greeter Service”. Only the code portions highlighted in bold must be inserted by the programmer.

Example 27.2. Implementation of the Greeter Service

```java
package demo.hw.server;

import org.apache.hello_world_soap_http.Greeter;

@javax.jws.WebService(portName = "SoapPort", serviceName = "SOAPService",
    targetNamespace = "http://apache.org/hello_world_soap_http",
    endpointInterface = "org.apache.hello_world_soap_http.Greeter")
public class GreeterImpl implements Greeter {

    public String greetMe(String me) {
        System.out.println("Executing operation greetMe"); System.out.println("Message received: "+me+"\n"); return "Hello "+me;
    }

    public void greetMeOneWay(String me) {
        System.out.println("Executing operation greetMeOneWay\n"); System.out.println("Hello there "+me);
    }

    public String sayHi() {
        System.out.println("Executing operation sayHi\n"); return "Bonjour";
    }

    public void pingMe() throws PingMeFault {
        FaultDetail faultDetail = new FaultDetail(); faultDetail.setMajor((short)2);
        faultDetail.setMinor((short)1); System.out.println("Executing operation pingMe, throwing
        PingMeFault exception\n"); throw new PingMeFault("PingMeFault raised by server", faultDetail);
    }
}
```
CHAPTER 28. DEVELOPING A CONSUMER FROM A WSDL CONTRACT

Abstract

One way of creating a consumer is to start from a WSDL contract. The contract defines the operations, messages, and transport details of the service on which a consumer makes requests. The starting point code for the consumer is generated from the WSDL contract. The functionality required by the consumer is added to the generated code.

28.1. GENERATING THE STUB CODE

Overview

The cxf-codegen-plugin Maven plug-in generates the stub code from the WSDL contract. The stub code provides the supporting code that is required to invoke operations on the remote service.

For consumers, the cxf-codegen-plugin Maven plug-in generates the following types of code:

- Stub code – Supporting files for implementing a consumer.
- Starting point code – Sample code that connects to the remote service and invokes every operation on the remote service.

Generating the consumer code

To generate consumer code use the cxf-codegen-plugin Maven plug-in. Example 28.1, “Consumer Code Generation” shows how to use the code generator to generate consumer code.

Example 28.1. Consumer Code Generation

```
<plugin>
  <groupId>org.apache.cxf</groupId>
  <artifactId>cxf-codegen-plugin</artifactId>
  <version>${cxf.version}</version>
  <executions>
    <execution>
      <id>generate-sources</id>
      <phase>generate-sources</phase>
      <configuration>
        <sourceRoot>outputDir</sourceRoot>
        <wsdlOptions>
          <wsdl>wsdl</wsdl>
          <extraargs>
            <extraarg>-client</extraarg>
          </extraargs>
        </wsdlOptions>
      </configuration>
    </execution>
  </executions>
  <goals>
    <goal>wsdl2java</goal>
  </goals>
</plugin>
```
Where `outputDir` is the location of a directory where the generated files are placed and `wsdl` specifies the WSDL contract’s location. The `-client` option generates starting point code for the consumer’s `main()` method.

For a complete list of the arguments available for the `cxf-codegen-plugin` Maven plug-in see Section 44.2, “cxf-codegen-plugin”.

**Generated code**

The code generation plug-in generates the following Java packages for the contract shown in Example 26.1, “HelloWorld WSDL Contract”:

- **org.apache.hello_world_soap_http** – This package is generated from the `http://apache.org/hello_world_soap_http` target namespace. All of the WSDL entities defined in this namespace (for example, the Greeter port type and the SOAPService service) map to Java classes in this Java package.

- **org.apache.hello_world_soap_http.types** – This package is generated from the `http://apache.org/hello_world_soap_http/types` target namespace. All of the XML types defined in this namespace (that is, everything defined in the `wsdl:types` element of the HelloWorld contract) map to Java classes in this Java package.

The stub files generated by the `cxf-codegen-plugin` Maven plug-in fall into the following categories:

- Classes representing WSDL entities in the `org.apache.hello_world_soap_http` package. The following classes are generated to represent WSDL entities:
  - **Greeter** – A Java interface that represents the Greeter `wsdl:portType` element. In JAX-WS terminology, this Java interface is the service endpoint interface (SEI).
  - **SOAPService** – A Java service class (extending `javax.xml.ws.Service`) that represents the SOAPService `wsdl:service` element.
  - **PingMeFault** – A Java exception class (extending `java.lang.Exception`) that represents the `pingMeFault` `wsdl:fault` element.

- Classes representing XML types in the `org.objectweb.hello_world_soap_http.types` package. In the HelloWorld example, the only generated types are the various wrappers for the request and reply messages. Some of these data types are useful for the asynchronous invocation model.

**28.2. IMPLEMENTING A CONSUMER**

**Overview**

To implement a consumer when starting from a WSDL contract, you must use the following stubs:

- Service class
- SEI
Using these stubs, the consumer code instantiates a service proxy to make requests on the remote service. It also implements the consumer’s business logic.

**Generated service class**

Example 28.2, “Outline of a Generated Service Class” shows the typical outline of a generated service class, `ServiceName_Service`\(^2\), which extends the `javax.xml.ws.Service` base class.

![Example 28.2. Outline of a Generated Service Class](image)

The `ServiceName` class in Example 28.2, “Outline of a Generated Service Class” defines the following methods:

- `ServiceName(URL wsdlLocation, QName serviceName)` — Constructs a service object based on the data in the `wsdl:service` element with the QName `ServiceName` service in the WSDL contract that is obtainable from `wsdlLocation`.

- `ServiceName()` — The default constructor. It constructs a service object based on the service name and the WSDL contract that were provided at the time the stub code was generated (for example, when running the `wsdl2java` tool). Using this constructor presupposes that the WSDL contract remains available at a specified location.

- `ServiceName(Bus bus)` — (CXF specific) An additional constructor that enables you to specify the Bus instance used to configure the Service. This can be useful in the context of a multi-threaded application, where multiple Bus instances can be associated with different threads. This constructor provides a simple way of ensuring that the Bus that you specify is the one that is used with this Service. Only available if you specify the `-fe cxf` option when invoking the `wsdl2java` tool.

- `getPortName()` — Returns a proxy for the endpoint defined by the `wsdl:port` element with the `name` attribute equal to `PortName`. A getter method is generated for every `wsdl:port` element defined by the `ServiceName` service. A `wsdl:service` element that contains multiple endpoint definitions results in a generated service class with multiple `getPortName()` methods.
Service endpoint interface

For every interface defined in the original WSDL contract, you can generate a corresponding SEI. A service endpoint interface is the Java mapping of a `wsdl:portType` element. Each operation defined in the original `wsdl:portType` element maps to a corresponding method in the SEI. The operation’s parameters are mapped as follows:

1. The first output parameter is mapped to a return value.

2. If there is more than one output parameter, the second and subsequent output parameters map to method arguments (moreover, the values of these arguments must be passed using `Holder` types).

For example, Example 28.3, “The Greeter Service Endpoint Interface” shows the Greeter SEI, which is generated from the `wsdl:portType` element defined in Example 26.1, “HelloWorld WSDL Contract”. For simplicity, Example 28.3, “The Greeter Service Endpoint Interface” omits the standard JAXB and JAX-WS annotations.

Example 28.3. The Greeter Service Endpoint Interface

```java
package org.apache.hello_world_soap_http;
...
public interface Greeter {
    public String sayHi();
    public String greetMe(String requestType);
    public void greetMeOneWay(String requestType);  // No throws clause
    public void pingMe() throws PingMeFault;
}
```

Consumer main function

Example 28.4, “Consumer Implementation Code” shows the code that implements the HelloWorld consumer. The consumer connects to the SoapPort port on the SOAPService service and then proceeds to invoke each of the operations supported by the Greeter port type.

Example 28.4. Consumer Implementation Code

```java
package demo.hw.client;

import java.io.File;
import java.net.URL;
import javax.xml.namespace.QName;
import org.apache.hello_world_soap_http.Greeter;
import org.apache.hello_world_soap_http.PingMeFault;
import org.apache.hello_world_soap_http.SOAPService;

public final class Client {

    private static final QName SERVICE_NAME =
            new QName("http://apache.org/hello_world_soap_http",
                       "SOAPService");

    private Client()
```
public static void main(String args[]) throws Exception
{
if (args.length == 0)
{
    System.out.println("please specify wsdl");
    System.exit(1);
}

URL wsdlURL;
File wsdlFile = new File(args[0]);
if (wsdlFile.exists())
{
    wsdlURL = wsdlFile.toURL();
}
else
{
    wsdlURL = new URL(args[0]);
}

System.out.println(wsdlURL);
SOAPService ss = new SOAPService(wsdlURL, SERVICE_NAME);
Greeter port = ss.getSoapPort();
String resp;

System.out.println("Invoking sayHi...");
resp = port.sayHi();
System.out.println("Server responded with: " + resp);
System.out.println();

System.out.println("Invoking greetMe...");
resp = port.greetMe(System.getProperty("user.name"));
System.out.println("Server responded with: " + resp);
System.out.println();

System.out.println("Invoking greetMeOneWay...");
port.greetMeOneWay(System.getProperty("user.name"));
System.out.println("No response from server as method is OneWay");
System.out.println();

try {
    System.out.println("Invoking pingMe, expecting exception...");
    port.pingMe();
} catch (PingMeFault ex) {
    System.out.println("Expected exception: PingMeFault has occurred.");
    System.out.println(ex.toString());
}
System.exit(0);
}

The Client.main() method from Example 28.4, "Consumer Implementation Code" proceeds as follows:
Provided that the Apache CXF runtime classes are on your classpath, the runtime is implicitly initialized. There is no need to call a special function to initialize Apache CXF.

The consumer expects a single string argument that gives the location of the WSDL contract for HelloWorld. The WSDL contract’s location is stored in `wsdlURL`.

You create a service object using the constructor that requires the WSDL contract’s location and service name. Call the appropriate `getPortName()` method to obtain an instance of the required port. In this case, the SOAPService service supports only the SoapPort port, which implements the `Greeter` service endpoint interface.

The consumer invokes each of the methods supported by the Greeter service endpoint interface.

In the case of the `pingMe()` method, the example code shows how to catch the PingMeFault fault exception.

### Client proxy generated with `-fe cxf` option

If you generate your client proxy by specifying the `-fe cxf` option in `wsdl2java` (thereby selecting the `cxf` frontend), the generated client proxy code is better integrated with Java 7. In this case, when you call a `getServiceNamePort()` method, you get back a type that is a sub-interface of the SEI and implements the following additional interfaces:

- `java.lang.AutoCloseable`
- `javax.xml.ws.BindingProvider` (JAX-WS 2.0)
- `org.apache.cxf.endpoint.Client`

To see how this simplifies working with a client proxy, consider the following Java code sample, written using a standard JAX-WS proxy object:

```java
// Programming with standard JAX-WS proxy object
//
(ServiceNamePortType port = service.getServiceNamePort();
((BindingProvider)port).getRequestContext().
.put(BindingProvider.ENDPOINT_ADDRESS_PROPERTY, address);
port.serviceMethod(...);
((Closeable)port).close();
```

And compare the preceding code with the following equivalent code sample, written using code generated by the `cxf` frontend:

```java
// Programming with proxy generated using `-fe cxf` option
//
try (ServiceNamePortTypeProxy port = service.getServiceNamePort()) {
    port.getRequestContext().put(BindingProvider.ENDPOINT_ADDRESS_PROPERTY, address);
    port.serviceMethod(...);
}
```

[2] If the `name` attribute of the `wsdl:service` element ends in Service the `_Service` is not used.
CHAPTER 29. FINDING WSDL AT RUNTIME

Abstract

Hard coding the location of WSDL documents into an application is not scalable. In real deployment environments, you will want to allow the WSDL document’s location be resolved at runtime. Apache CXF provides a number of tools to make this possible.

29.1. MECHANISMS FOR LOCATING THE WSDL DOCUMENT

When developing consumers using the JAX-WS APIs you are must provide a hard coded path to the WSDL document that defines your service. While this is OK in a small environment, using hard coded paths does not work well in enterprise deployments.

To address this issue, Apache CXF provides three mechanisms for removing the requirement of using hard coded paths:

- Section 29.2, “Instantiating a Proxy by Injection”
- Section 29.3, “Using a JAX-WS Catalog”
- Section 29.4, “Using a contract resolver”

NOTE

Injecting the proxy into your implementation code is generally the best option because it is the easiest to implement. It requires only a client endpoint and a configuration file for injecting and instantiating the service proxy.

29.2. INSTANTIATING A PROXY BY INJECTION

Overview

Apache CXF’s use of the Spring Framework allows you to avoid the hassle of using the JAX-WS APIs to create service proxies. It allows you to define a client endpoint in a configuration file and then inject a proxy directly into the implementation code. When the runtime instantiates the implementation object, it will also instantiate a proxy for the external service based on the configuration. The implementation is handed by reference to the instantiated proxy.

Because the proxy is instantiated using information in the configuration file, the WSDL location does not need to be hard coded. It can be changed at deployment time. You can also specify that the runtime should search the application’s classpath for the WSDL.

Procedure

To inject a proxy for an external service into a service provider’s implementation do the following:

1. Deploy the required WSDL documents in a well known location that all parts of the application can access.
NOTE

If you are deploying the application as a WAR file, it is recommended that you place all of the WSDL documents and XML Schema documents in the WEB-INF/wsdl folder of the WAR.

NOTE

If you are deploying the application as a JAR file, it is recommended that you place all of the WSDL documents and XML Schema documents in the META-INF/wsdl folder of the JAR.

2. **Configure** a JAX-WS client endpoint for the proxy that is being injected.

3. **Inject** the proxy into your service provider using the `@Resource` annotation.

**Configuring the proxy**

You configure a JAX-WS client endpoint using the `jaxws:client` element in your application’s configuration file. This tells the runtime to instantiate a `org.apache.cxf.jaxws.JaxWsClientProxy` object with the specified properties. This object is the proxy that will be injected into the service provider.

At a minimum you need to provide values for the following attributes:

- `id`—Specifies the ID used to identify the client to be injected.
- `serviceClass`—Specifies the SEI of the service on which the proxy makes requests.

**Example 29.1, “Configuration for a Proxy to be Injected into a Service Implementation”** shows the configuration for a JAX-WS client endpoint.

```xml
<beans ...
xmlns:jaxws="http://cxf.apache.org/jaxws"
...
  <jaxws:client id="bookClient"
               serviceClass="org.apache.cxf.demo.BookService"
               wsdlLocation="classpath:books.wsdl"/>
...
</beans>
```

*NOTE

In Example 29.1, “Configuration for a Proxy to be Injected into a Service Implementation” the `wsdlLocation` attribute instructs the runtime to load the WSDL from the classpath. If `books.wsdl` is on the classpath, the runtime will be able to find it.
For more information on configuring a JAX-WS client see Section 17.2, “Configuring Consumer Endpoints”.

Coding the provider implementation

You inject the configured proxy into a service implementation as a resource using the `@Resource` as shown in Example 29.2, “Injecting a Proxy into a Service Implementation”.

Example 29.2. Injecting a Proxy into a Service Implementation

```java
package demo.hw.server;

import org.apache.hello_world_soap_http.Greeter;

@javax.jws.WebService(portName = "SoapPort", serviceName = "SOAPService",
    targetNamespace = "http://apache.org/hello_world_soap_http",
    endpointInterface = "org.apache.hello_world_soap_http.Greeter")
public class StoreImpl implements Store {
    @Resource(name="bookClient") private BookService proxy;
}
```

The annotation’s `name` property corresponds to the value of the JAX-WS client’s `id` attribute. The configured proxy is injected into the `BookService` object declared immediately after the annotation. You can use this object to make invocations on the proxy’s external service.

29.3. USING A JAX-WS CATALOG

Overview

The JAX-WS specification mandates that all implementations support:

a standard catalog facility to be used when resolving any Web service document that is part of the description of a Web service, specifically WSDL and XML Schema documents.

This catalog facility uses the XML catalog facility specified by OASIS. All of the JAX-WS APIs and annotation that take a WSDL URI use the catalog to resolve the WSDL document’s location.

This means that you can provide an XML catalog file that rewrites the locations of your WSDL documents to suite specific deployment environments.

Writing the catalog

JAX-WS catalogs are standard XML catalogs as defined by the OASIS XML Catalogs 1.1 specification. They allow you to specify mapping:

- a document’s public identifier and/or a system identifier to a URI.
- the URI of a resource to another URI.

Table 29.1, “Common JAX-WS Catalog Elements” lists some common elements used for WSDL location resolution.
Table 29.1. Common JAX-WS Catalog Elements

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>uri</td>
<td>Maps a URI to an alternate URI.</td>
</tr>
<tr>
<td>rewriteURI</td>
<td>Rewrites the beginning of a URI. For example, this element allows you to map all URIs that start with <code>http://cxf.apache.org</code> to URIs that start with <code>classpath:</code>.</td>
</tr>
<tr>
<td>uriSuffix</td>
<td>Maps a URI to an alternate URI based on the suffix of the original URI. For example you could map all URIs that end in <code>foo.xsd</code> to <code>classpath:foo.xsd</code>.</td>
</tr>
</tbody>
</table>

Packaging the catalog

The JAX-WS specification mandates that the catalog used to resolve WSDL and XML Schema documents is assembled using all available resources named `META-INF/jax-ws-catalog.xml`. If your application is packaged into a single JAR, or WAR, you can place the catalog into a single file.

If your application is packaged as multiple JARs, you can split the catalog into a number of files. Each catalog file could be modularized to only deal with WSDLs accessed by the code in the specific JARs.

29.4. USING A CONTRACT RESOLVER

Overview

The most involved mechanism for resolving WSDL document locations at runtime is to implement your own custom contract resolver. This requires that you provide an implementation of the Apache CXF specific `ServiceContractResolver` interface. You also need to register your custom resolver with the bus.

Once properly registered, the custom contract resolver will be used to resolve the location of any required WSDL and schema documents.

Implementing the contract resolver

A contract resolver is an implementation of the `org.apache.cxf.endpoint.ServiceContractResolver` interface. As shown in Example 29.3, “ServiceContractResolver Interface”, this interface has a single method, `getContractLocation()`, that needs to be implemented. `getContractLocation()` takes the QName of a service and returns the URI for the service’s WSDL contract.

```
Example 29.3. ServiceContractResolver Interface

public interface ServiceContractResolver
{
    URI getContractLocation(QName qname);
}
```
The logic used to resolve the WSDL contract’s location is application specific. You can add logic that resolves contract locations from a UDDI registry, a database, a custom location on a file system, or any other mechanism you choose.

Registering the contract resolver programmatically

Before the Apache CXF runtime will use your contract resolver, you must register it with a contract resolver registry. Contract resolver registries implement the `org.apache.cxf.endpoint.ServiceContractResolverRegistry` interface. However, you do not need to implement your own registry. Apache CXF provides a default implementation in the `org.apache.cxf.endpoint.ServiceContractResolverRegistryImpl` class.

To register a contract resolver with the default registry you do the following:

1. Get a reference to the default bus object.
2. Get the service contract registry from the bus using the bus’ `getExtension()` method.
3. Create an instance of your contract resolver.
4. Register your contract resolver with the registry using the registry’s `register()` method.

Example 29.4, “Registering a Contract Resolver” shows the code for registering a contract resolver with the default registry.

```
Example 29.4. Registering a Contract Resolver
BusFactory bf=BusFactory.newInstance();
Bus bus=bf.createBus();
ServiceContractResolverRegistry registry = bus.getExtension(ServiceContractResolverRegistry);
JarServiceContractResolver resolver = new JarServiceContractResolver();
registry.register(resolver);
```

The code in Example 29.4, “Registering a Contract Resolver” does the following:

1. Gets a bus instance.
2. Gets the bus’ contract resolver registry.
3. Creates an instance of a contract resolver.
4. Registers the contract resolver with the registry.

Registering a contract resolver using configuration

You can also implement a contract resolver so that it can be added to a client through configuration. The contract resolver is implemented in such a way that when the runtime reads the configuration and instantiates the resolver, the resolver registers itself. Because the runtime handles the initialization, you can decide at runtime if a client needs to use the contract resolver.
To implement a contract resolver so that it can be added to a client through configuration do the following:

1. Add an `init()` method to your contract resolver implementation.

2. Add logic to your `init()` method that registers the contract resolver with the contract resolver registry as shown in Example 29.4, “Registering a Contract Resolver”.

3. Decorate the `init()` method with the `@PostConstruct` annotation.

Example 29.5, “Service Contract Resolver that can be Registered Using Configuration” shows a contract resolver implementation that can be added to a client using configuration.

```
Example 29.5. Service Contract Resolver that can be Registered Using Configuration

import javax.annotation.PostConstruct;
import javax.annotation.Resource;
import javax.xml.namespace.QName;
import org.apache.cxf.Bus;
import org.apache.cxf.BusFactory;

public class UddiResolver implements ServiceContractResolver
{
    private Bus bus;
    ...

    @PostConstruct
    public void init()
    {
        BusFactory bf = BusFactory.newInstance();
        Bus bus = bf.createBus();
        if (null != bus)
        {
            ServiceContractResolverRegistry resolverRegistry = bus.getExtension(ServiceContractResolverRegistry.class);
            if (resolverRegistry != null)
            {
                resolverRegistry.register(this);
            }
        }
    }

    public URI getContractLocation(QName serviceName)
    {
        ...
    }
}
```

To register the contract resolver with a client you need to add a `bean` element to the client’s configuration. The `bean` element’s `class` attribute is the name of the class implementing the contract resolver.

Example 29.6, “Bean Configuring a Contract Resolver” shows a bean for adding a configuration resolver implemented by the `org.apache.cxf.demos.myContractResolver` class.
Example 29.6. Bean Configuring a Contract Resolver

```xml
<beans xmlns="http://www.springframework.org/schema/beans"
      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xsi:schemaLocation="
        http://www.springframework.org/schema/beans
        http://www.springframework.org/schema/beans/spring-beans.xsd">
    <bean id="myResolver" class="org.apache.cxf.demos.myContractResolver" />
    ...
</beans>
```

Contract resolution order

When a new proxy is created, the runtime uses the contract registry resolver to locate the remote service’s WSDL contract. The contract resolver registry calls each contract resolver’s `getContractLocation()` method in the order in which the resolvers were registered. It returns the first URI returned from one of the registered contract resolvers.

If you registered a contract resolver that attempted to resolve the WSDL contract at a well known shared file system, it would be the only contract resolver used. However, if you subsequently registered a contract resolver that resolved WSDL locations using a UDDI registry, the registry could use both resolvers to locate a service’s WSDL contract. The registry would first attempt to locate the contract using the shared file system contract resolver. If that contract resolver failed, the registry would then attempt to locate it using the UDDI contract resolver.
CHAPTER 30. GENERIC FAULT HANDLING

Abstract

The JAX-WS specification defines two types of faults. One is a generic JAX-WS runtime exception. The other is a protocol specific class of exceptions that is thrown during message processing.

30.1. RUNTIME FAULTS

Overview

Most of the JAX-WS APIs throw a generic javax.xml.ws.WebServiceException exception.

APIs that throw WebServiceException

Table 30.1, “APIs that Throw WebServiceException” lists some of the JAX-WS APIs that can throw the generic WebServiceException exception.

Table 30.1. APIs that Throw WebServiceException

<table>
<thead>
<tr>
<th>API</th>
<th>Reason</th>
</tr>
</thead>
<tbody>
<tr>
<td>Binding.setHandlerChain()</td>
<td>There is an error in the handler chain configuration.</td>
</tr>
<tr>
<td>BindingProvider.getEndpointReference()</td>
<td>The specified class is not assigned from a W3CEndpointReference.</td>
</tr>
<tr>
<td>Dispatch.invoke()</td>
<td>There is an error in the Dispatch instance’s configuration or an error occurred while communicating with the service.</td>
</tr>
<tr>
<td>Dispatch.invokeAsync()</td>
<td>There is an error in the Dispatch instance’s configuration.</td>
</tr>
<tr>
<td>Dispatch.invokeOneWay()</td>
<td>There is an error in the Dispatch instance’s configuration or an error occurred while communicating with the service.</td>
</tr>
<tr>
<td>LogicalMessage.getPayload()</td>
<td>An error occurred when using a supplied JAXBContext to unmarshall the payload. The cause field of the WebServiceException contains the original JAXBException.</td>
</tr>
<tr>
<td>LogicalMessage.setPayload()</td>
<td>An error occurred when setting the payload of the message. If the exception is thrown when using a JAXBContext, the cause field of the WebServiceException contains the original JAXBException.</td>
</tr>
</tbody>
</table>
30.2. PROTOCOL FAULTS

Overview

Protocol exceptions are thrown when an error occurs during the processing of a request. All synchronous remote invocations can throw a protocol exception. The underlying cause occurs either in the consumer’s message handling chain or in the service provider.

The JAX-WS specification defines a generic protocol exception. It also specifies a SOAP-specific protocol exception and an HTTP-specific protocol exception.

Types of protocol exceptions

The JAX-WS specification defines three types of protocol exception. Which exception you catch depends on the transport and binding used by your application.

Table 30.2, “Types of Generic Protocol Exceptions” describes the three types of protocol exception and when they are thrown.

<table>
<thead>
<tr>
<th>Exception Class</th>
<th>When Thrown</th>
</tr>
</thead>
<tbody>
<tr>
<td>javax.xml.ws.ProtocolException</td>
<td>This exception is the generic protocol exception. It can be caught regardless of the protocol in use. It can be cast into a specific fault type if you are using the SOAP binding or the HTTP binding. When using the XML binding in combination with the HTTP or JMS transports, the generic protocol exception cannot be cast into a more specific fault type.</td>
</tr>
<tr>
<td>javax.xml.ws.soap.SOAPFaultException</td>
<td>This exception is thrown by remote invocations when using the SOAP binding. For more information see the section called “Using the SOAP protocol exception”.</td>
</tr>
<tr>
<td>javax.xml.ws.http.HTTPException</td>
<td>This exception is thrown when using the Apache CXF HTTP binding to develop RESTful Web services. For more information see Part VI, “Developing RESTful Web Services”.</td>
</tr>
</tbody>
</table>

Using the SOAP protocol exception

The SOAPFaultException exception wraps a SOAP fault. The underlying SOAP fault is stored in the fault field as a javax.xml.soap.SOAPFault object.
If a service implementation needs to throw an exception that does not fit any of the custom exceptions created for the application, it can wrap the fault in a SOAPFaultException using the exceptions creator and throw it back to the consumer. **Example 30.1, “Throwing a SOAP Protocol Exception”** shows code for creating and throwing a SOAPFaultException if the method is passed an invalid parameter.

**Example 30.1. Throwing a SOAP Protocol Exception**

```java
public Quote getQuote(String ticker)
{
    ...
    if(tickers.length()<3)
    {
        SOAPFault fault = SOAPFactory.newInstance().createFault();
        fault.setFaultString("Ticker too short");
        throw new SOAPFaultException(fault);
    }
    ...
}
```

When a consumer catches a SOAPFaultException exception they can retrieve the underlying cause of the exception by examining the wrapped SOAPFault exception. As shown in **Example 30.2, “Getting the Fault from a SOAP Protocol Exception”**, the SOAPFault exception is retrieved using the SOAPFaultException exception’s `getFault()` method.

**Example 30.2. Getting the Fault from a SOAP Protocol Exception**

```java
...
try
{
    proxy.getQuote(ticker);
}
catch (SOAPFaultException sfe)
{
    SOAPFault fault = sfe.getFault();
    ...
}
```
CHAPTER 31. PUBLISHING A SERVICE

Abstract

When you want to deploy a JAX-WS service as a standalone Java application, you must explicitly implement the code that publishes the service provider.

31.1. WHEN TO PUBLISH A SERVICE

Apache CXF provides a number of ways to publish a service as a service provider. How you publish a service depends on the deployment environment you are using. Many of the containers supported by Apache CXF do not require writing logic for publishing endpoints. There are two exceptions:

- deploying a server as a standalone Java application
- deploying a server into an OSGi container without Blueprint

For detailed information in deploying applications into the supported containers see Part IV, “Configuring Web Service Endpoints”.

31.2. APIS USED TO PUBLISH A SERVICE

Overview

The javax.xml.ws.Endpoint class does the work of publishing a JAX-WS service provider. To publishing an endpoint do the following:

1. Create an Endpoint object for your service provider.
2. Publish the endpoint.
3. Stop the endpoint when application shuts down.

The Endpoint class provides methods for creating and publishing service providers. It also provides a method that can create and publish a service provider in a single method call.

Instantiating an service provider

A service provider is instantiated using an Endpoint object. You instantiate an Endpoint object for your service provider using one of the following methods:

- staticEndpointcreateObjectimplementor This create() method returns an Endpoint for the specified service implementation. The Endpoint object is created using the information provided by the implementation class’ javax.xml.ws.BindingType annotation, if it is present. If the annotation is not present, the Endpoint uses a default SOAP 1.1/HTTP binding.

- staticEndpointcreateURIBindingIDObjectimplementor This create() method returns an Endpoint object for the specified implementation object using the specified binding. This method overrides the binding information provided by the javax.xml.ws.BindingType annotation, if it is present. If the bindingID cannot be resolved, or it is null, the binding specified in the javax.xml.ws.BindingType is used to create the Endpoint. If neither the bindingID or the javax.xml.ws.BindingType can be used, the Endpoint is created using a default SOAP 1.1/HTTP binding.
The `publish()` method creates an `Endpoint` object for the specified implementation, and publishes it. The binding used for the `Endpoint` object is determined by the URL scheme of the provided `address`. The list of bindings available to the implementation are scanned for a binding that supports the URL scheme. If one is found the `Endpoint` object is created and published. If one is not found, the method fails.

Using `publish()` is the same as invoking one of the `create()` methods, and then invoking the `publish()` method used in ???TITLE??.

**IMPORTANT**

The implementation object passed to any of the `Endpoint` creation methods must either be an instance of a class annotated with `javax.jws.WebService` and meeting the requirements for being an SEI implementation or it must be an instance of a class annotated with `javax.xml.ws.WebServiceProvider` and implementing the Provider interface.

**Publishing a service provider**

You can publish a service provider using either of the following `Endpoint` methods:

- **publish(String address** This `publish()` method publishes the service provider at the address specified.

  **IMPORTANT**

  The `address`'s URL scheme must be compatible with one of the service provider’s bindings.

- **publish(Object serverContext** This `publish()` method publishes the service provider based on the information provided in the specified server context. The server context must define an address for the endpoint, and the context must also be compatible with one of the service provider’s available bindings.

**Stopping a published service provider**

When the service provider is no longer needed you should stop it using its `stop()` method. The `stop()` method, shown in Example 31.1, “Method for Stopping a Published Endpoint”, shuts down the endpoint and cleans up any resources it is using.

**Example 31.1. Method for Stopping a Published Endpoint**

```
stop
```

**IMPORTANT**

Once the endpoint is stopped it cannot be republished.

### 31.3. PUBLISHING A SERVICE IN A PLAIN JAVA APPLICATION

**Overview**
When you want to deploy your application as a plain Java application, you need to implement the logic for publishing your endpoints in the application’s `main()` method. Apache CXF provides you two options for writing your application’s `main()` method:

- use the `main()` method generated by the `wsdl2java` tool
- write a custom `main()` method that publishes the endpoints

### Generating a Server Mainline

The code generators `-server` flag makes the tool generate a simple server mainline. The generated server mainline, as shown in Example 31.2, “Generated Server Mainline”, publishes one service provider for each `port` element in the specified WSDL contract.

For more information see Section 44.2, “cxf-codegen-plugin”.

Example 31.2, “Generated Server Mainline” shows a generated server mainline.

```java
package org.apache.hello_world_soap_http;

import javax.xml.ws.Endpoint;

public class GreeterServer {

    protected GreeterServer() throws Exception {
        System.out.println("Starting Server");
        Object implementor = new GreeterImpl();
        String address = "http://localhost:9000/SoapContext/SoapPort";
        Endpoint.publish(address, implementor);
    }

    public static void main(String args[]) throws Exception {
        new GreeterServer();
        System.out.println("Server ready...");

        Thread.sleep(5 * 60 * 1000);
        System.out.println("Server exiting");
        System.exit(0);
    }
}
```

The code in Example 31.2, “Generated Server Mainline” does the following:

Instantiates a copy of the service implementation object.

Creates the address for the endpoint based on the contents of the `address` child of the `wsdl:port` element in the endpoint’s contract.

Publishes the endpoint.

### Writing a Server Mainline
If you used the Java first development model or you do not want to use the generated server mainline, you can write your own. To write your server mainline you must do the following:

1. the section called “Instantiating an service provider” an `javax.xml.ws.Endpoint` object for the service provider.

2. Create an optional server context to use when publishing the service provider.

3. the section called “Publishing a service provider” the service provider using one of the `publish()` methods.

4. Stop the service provider when the application is ready to exit.

Example 31.3, “Custom Server Mainline” shows the code for publishing a service provider.

Example 31.3. Custom Server Mainline

```java
package org.apache.hello_world_soap_http;

import javax.xml.ws.Endpoint;

public class GreeterServer
{
  protected GreeterServer() throws Exception
  {
  }

  public static void main(String args[]) throws Exception
  {
    GreeterImpl impl = new GreeterImpl();
    Endpoint endpt.create(impl);
    endpt.publish("http://localhost:9000/SoapContext/SoapPort");

    boolean done = false;
    while(!done)
    {
      ...
    }

    endpt.stop();
    System.exit(0);
  }
}
```

The code in Example 31.3, “Custom Server Mainline” does the following:

Instantiates a copy of the service’s implementation object.

Creates an unpublished `Endpoint` for the service implementation.

Publishes the service provider at `http://localhost:9000/SoapContext/SoapPort`.

Loops until the server should be shutdown.

Stops the published endpoint.
31.4. PUBLISHING A SERVICE IN AN OSGI CONTAINER

Overview

When you develop an application that will be deployed into an OSGi container, you need to coordinate the publishing and stopping of your endpoints with the life-cycle of the bundle in which it is packaged. You want your endpoints published when the bundle is started and you want the endpoints stopped when the bundle is stopped.

You tie your endpoints life-cycle to the bundle’s life-cycle by implementing an OSGi bundle activator. A bundle activator is used by the OSGi container to create the resource for a bundle when it is started. The container also uses the bundle activator to clean up the bundles resources when it is stopped.

The bundle activator interface

You create a bundle activator for your application by implementing the org.osgi.framework.BundleActivator interface. The BundleActivator interface, shown in Example 31.4, “Bundle Activator Interface”, it has two methods that need to be implemented.

Example 31.4. Bundle Activator Interface

```java
interface BundleActivator {
    public void start(BundleContext context) throws java.lang.Exception;
    public void stop(BundleContext context) throws java.lang.Exception;
}
```

The `start()` method is called by the container when it starts the bundle. This is where you instantiate and publish the endpoints.

The `stop()` method is called by the container when it stops the bundle. This is where you would stop the endpoints.

Implementing the start method

The bundle activator’s start method is where you publish your endpoints. To publish your endpoints the start method must do the following:

1. the section called “Instantiating an service provider” an `javax.xml.ws.Endpoint` object for the service provider.
2. Create an optional server context to use when publishing the service provider.
3. the section called “Publishing a service provider” the service provider using one of the `publish()` methods.

Example 31.5, “Bundle Activator Start Method for Publishing an Endpoint” shows code for publishing a service provider.

Example 31.5. Bundle Activator Start Method for Publishing an Endpoint
The code in Example 31.5, “Bundle Activator Start Method for Publishing an Endpoint” does the following:

- Instantiates a copy of the service’s implementation object.
- Creates an unpublished Endpoint for the service implementation.
- Publish the service provider at http://localhost:9000/SoapContext/SoapPort.

**Implementing the stop method**

The bundle activator’s stop method is where you clean up the resources used by your application. Its implementation should include logic for stopping all of the endpoint’s published by the application.

Example 31.6, “Bundle Activator Stop Method for Stopping an Endpoint” shows a stop method for stopping a published endpoint.

```
package com.widgetvendor.osgi;

import javax.xml.ws.Endpoint;
import org.osgi.framework.BundleActivator;
import org.osgi.framework.BundleContext;

public class widgetActivator implements BundleActivator {
    private Endpoint endpt;
    ...

    public void start(BundleContext context) {
        WidgetOrderImpl impl = new WidgetOrderImpl();
        endpt = Endpoint.create(impl);
        endpt.publish("http://localhost:9000/SoapContext/SoapPort");
    }
    ...
}
```

```
package com.widgetvendor.osgi;

import javax.xml.ws.Endpoint;
import org.osgi.framework.BundleActivator;
import org.osgi.framework.BundleContext;

public class widgetActivator implements BundleActivator {
    private Endpoint endpt;
    ...

    public void start(BundleContext context) {
        WidgetOrderImpl impl = new WidgetOrderImpl();
        endpt = Endpoint.create(impl);
        endpt.publish("http://localhost:9000/SoapContext/SoapPort");
    }
    ...
}
```
Informing the container

You must add inform the container that the application’s bundle includes a bundle activator. You do this by adding the **Bundle-Activator** property to the bundle’s manifest. This property tells the container which class in the bundle to use when activating the bundle. Its value is the fully qualified name of the class implementing the bundle activator.

**Example 31.7, “Bundle Activator Manifest Entry”** shows a manifest entry for a bundle whose activator is implemented by the class `com.widgetvendor.osgi.widgetActivator`.

**Example 31.7. Bundle Activator Manifest Entry**

```plaintext
Bundle-Activator: com.widgetvendor.osgi.widgetActivator
```
CHAPTER 32. BASIC DATA BINDING CONCEPTS

Abstract

There are a number of general topics that apply to how Apache CXF handles type mapping.

32.1. INCLUDING AND IMPORTING SCHEMA DEFINITIONS

Overview

Apache CXF supports the including and importing of schema definitions, using the include and import schema tags. These tags enable you to insert definitions from external files or resources into the scope of a schema element. The essential difference between including and importing is:

- Including brings in definitions that belong to the same target namespace as the enclosing schema element.
- Importing brings in definitions that belong to a different target namespace from the enclosing schema element.

xsd:include syntax

The include directive has the following syntax:

```xml
<include schemaLocation="anyURI" />
```

The referenced schema, given by anyURI, must either belong to the same target namespace as the enclosing schema, or not belong to any target namespace at all. If the referenced schema does not belong to any target namespace, it is automatically adopted into the enclosing schema’s namespace when it is included.

Example 32.1, “Example of a Schema that Includes Another Schema” shows an example of an XML Schema document that includes another XML Schema document.

Example 32.1. Example of a Schema that Includes Another Schema

```xml
<definitions targetNamespace="http://schemas.redhat.com/tests/schema_parser"
    xmlns:tns="http://schemas.redhat.com/tests/schema_parser"
    xmlns:xsd="http://www.w3.org/2001/XMLSchema"
    xmlns="http://schemas.xmlsoap.org/wsdl/">
    <types>
        <schema targetNamespace="http://schemas.redhat.com/tests/schema_parser"
            xmlns="http://www.w3.org/2001/XMLSchema">
            <include schemaLocation="included.xsd"/>
            <complexType name="IncludingSequence">
                <sequence>
                    <element name="includedSeq" type="tns:IncludedSequence"/>
                </sequence>
            </complexType>
        </schema>
        ...
    </types>
</definitions>
```
Example 32.2, “Example of an Included Schema” shows the contents of the included schema file.

Example 32.2. Example of an Included Schema

```xml
<schema targetNamespace="http://schemas.redhat.com/tests/schema_parser"
    xmlns="http://www.w3.org/2001/XMLSchema">
    <!-- Included type definitions -->
    <complexType name="IncludedSequence">
        <sequence>
            <element name="varInt" type="int"/>
            <element name="varString" type="string"/>
        </sequence>
    </complexType>
</schema>
```

xsd:import syntax

The import directive has the following syntax:

```xml
<import namespace="namespaceAnyURI"
    schemaLocation="schemaAnyURI" />
```

The imported definitions must belong to the namespaceAnyURI target namespace. If namespaceAnyURI is blank or remains unspecified, the imported schema definitions are unqualified.

Example 32.3. Example of a Schema that Imports Another Schema

```xml
<definitions targetNamespace="http://schemas.redhat.com/tests/schema_parser"
    xmlns:tns="http://schemas.redhat.com/tests/schema_parser"
    xmlns:imp="http://schemas.redhat.com/tests/imported_types"
    xmlns:xsd="http://www.w3.org/2001/XMLSchema"
    xmlns="http://schemas.xmlsoap.org/wsdl/">
    <types>
        <schema targetNamespace="http://schemas.redhat.com/tests/schema_parser"
            xmlns="http://www.w3.org/2001/XMLSchema">
            <import namespace="http://schemas.redhat.com/tests/imported_types"
                schemaLocation="included.xsd"/>
            <complexType name="IncludingSequence">
                <sequence>
                    <element name="includedSeq" type="imp:IncludedSequence"/>
                </sequence>
            </complexType>
        </schema>
    </types>
    ...
</definitions>
```
Example 32.4, “Example of an Imported Schema” shows the contents of the imported schema file.

```xml
<schema targetNamespace="http://schemas.redhat.com/tests/imported_types"
   xmlns="http://www.w3.org/2001/XMLSchema">
<!-- Included type definitions -->
<complexType name="IncludedSequence">
  <sequence>
    <element name="varInt" type="int"/>
    <element name="varString" type="string"/>
  </sequence>
</complexType>
</schema>
```

Using non-referenced schema documents

Using types defined in a schema document that is not referenced in the service’s WSDL document is a three step process:

1. Convert the schema document to a WSDL document using the `xsd2wsdl` tool.
2. Generate Java for the types using the `wsdl2java` tool on the generated WSDL document.
   
   **IMPORTANT**
   
   You will get a warning from the `wsdl2java` tool stating that the WSDL document does not define any services. You can ignore this warning.

3. Add the generated classes to your classpath.

### 32.2. XML NAMESPACE MAPPING

**Overview**

XML Schema type, group, and element definitions are scoped using namespaces. The namespaces prevent possible naming clashes between entities that use the same name. Java packages serve a similar purpose. Therefore, Apache CXF maps the target namespace of a schema document into a package containing the classes necessary to implement the structures defined in the schema document.

**Package naming**

The name of the generated package is derived from a schema’s target namespace using the following algorithm:

1. The URI scheme, if present, is stripped.

   **NOTE**

   Apache CXF will only strip the `http`, `https`, and `urn` schemes.
For example, the namespace `http:\www.widgetvendor.com\types\widgetTypes.xsd` becomes `widgetvendor.com\types\widgetTypes.xsd`.

2. The trailing file type identifier, if present, is stripped.
   For example, `\www.widgetvendor.com\types\widgetTypes.xsd` becomes `\widgetvendor.com\types\widgetTypes`.

3. The resulting string is broken into a list of strings using `/` and `:` as separators.
   So, `\www.widgetvendor.com\types\widgetTypes` becomes the list `{"www.widgetvendor.com", "types", "widgetTypes"}`.

4. If the first string in the list is an internet domain name, it is decomposed as follows:
   a. The leading `www.` is stripped.
   b. The remaining string is split into its component parts using the `.` as the separator.
   c. The order of the list is reversed.
      So, `{"www.widgetvendor.com", "types", "widgetTypes"}` becomes `{"com", "widgetvendor", "types", "widgetTypes"}`

   NOTE
   Internet domain names end in one of the following: `.com`, `.net`, `.edu`, `.org`, `.gov`, or in one of the two-letter country codes.

5. The strings are converted into all lower case.
   So, `{"com", "widgetvendor", "types", "widgetTypes"}` becomes `{"com", "widgetvendor", "types", "widgettypes"}`.

6. The strings are normalized into valid Java package name components as follows:
   a. If the strings contain any special characters, the special characters are converted to an underscore `_`.
   b. If any of the strings are a Java keyword, the keyword is prefixed with an underscore `_`.
   c. If any of the strings begin with a numeral, the string is prefixed with an underscore `_`.

7. The strings are concatenated using `.` as a separator.
   So, `{"com", "widgetvendor", "types", "widgettypes"}` becomes the package name `com.widgetvendor.types.widgettypes`.

The XML Schema constructs defined in the namespace `http:\www.widgetvendor.com\types\widgetTypes.xsd` are mapped to the Java package `com.widgetvendor.types.widgettypes`.

Package contents

A JAXB generated package contains the following:

- A class implementing each complex type defined in the schema
  For more information on complex type mapping see Chapter 35, Using Complex Types.

- An enum type for any simple types defined using the `enumeration` facet
  For more information on how enumerations are mapped see Section 34.3, “Enumerations”.
- A public **ObjectFactory** class that contains methods for instantiating objects from the schema. For more information on the **ObjectFactory** class see Section 32.3, “The Object Factory”.

- A **package-info.java** file that provides metadata about the classes in the package

### 32.3. THE OBJECT FACTORY

#### Overview

JAXB uses an object factory to provide a mechanism for instantiating instances of JAXB generated constructs. The object factory contains methods for instantiating all of the XML schema defined constructs in the package’s scope. The only exception is that enumerations do not get a creation method in the object factory.

#### Complex type factory methods

For each Java class generated to implement an XML schema complex type, the object factory contains a method for creating an instance of the class. This method takes the form:

```java
typeName createtypeName();
```

For example, if your schema contained a complex type named **widgetType**, Apache CXF generates a class called **WidgetType** to implement it. Example 32.5, “Complex Type Object Factory Entry” shows the generated creation method in the object factory.

**Example 32.5. Complex Type Object Factory Entry**

```java
public class ObjectFactory
{
    ...
    WidgetType createWidgetType()
    {
        return new WidgetType();
    }
    ...
}
```

#### Element factory methods

For elements that are declared in the schema’s global scope, Apache CXF inserts a factory method into the object factory. As discussed in Chapter 33, *Using XML Elements*, XML Schema elements are mapped to **JAXBElement<T>** objects. The creation method takes the form:

```java
public JAXBElement<elementType> createelementName(elementType value);
```

For example if you have an element named **comment** of type **xsd:string**, Apache CXF generates the object factory method shown in Example 32.6, “Element Object Factory Entry”

**Example 32.6. Element Object Factory Entry**

```java
public class ObjectFactory
{
    ...
}
```
32.4. ADDING CLASSES TO THE RUNTIME MARSHALLER

Overview

When the Apache CXF runtime reads and writes XML data it uses a map that associates the XML Schema types with their representative Java types. By default, the map contains all of the types defined in the target namespace of the WSDL contract's schema element. It also contains any types that are generated from the namespaces of any schemas that are imported into the WSDL contract.

The addition of types from namespaces other than the schema namespace used by an application's schema element is accomplished using the @XmlSeeAlso annotation. If your application needs to work with types that are generated outside the scope of your application's WSDL document, you can edit the @XmlSeeAlso annotation to add them to the JAXB map.

Using the @XmlSeeAlso annotation

The @XmlSeeAlso annotation can be added to the SEI of your service. It contains a comma separated list of classes to include in the JAXB context. Example 32.7, "Syntax for Adding Classes to the JAXB Context" shows the syntax for using the @XmlSeeAlso annotation.

Example 32.7. Syntax for Adding Classes to the JAXB Context

```java
import javax.xml.bind.annotation.XmlSeeAlso;
@WebService()
@XmlSeeAlso({Class1.class, Class2.class, ..., ClassN.class})
public class GeneratedSEI {
    ...
}
```

In cases where you have access to the JAXB generated classes, it is more efficient to use the ObjectFactory classes generated to support the needed types. Including the ObjectFactory class includes all of the classes that are known to the object factory.

Example

Example 32.8, "Adding Classes to the JAXB Context" shows an SEI annotated with @XmlSeeAlso.

Example 32.8. Adding Classes to the JAXB Context

```java
... import javax.xml.bind.annotation.XmlSeeAlso;
```
... @WebService() @XmlSeeAlso({org.apache.schemas.types.test.ObjectFactory.class,
org.apache.schemas.tests.group_test.ObjectFactory.class})
public interface Foo {
    ...
}
CHAPTER 33. USING XML ELEMENTS

Abstract

XML Schema elements are used to define an instance of an element in an XML document. Elements are defined either in the global scope of an XML Schema document, or they are defined as a member of a complex type. When they are defined in the global scope, Apache CXF maps them to a JAXB element class that makes manipulating them easier.

OVERVIEW

An element instance in an XML document is defined by an XML Schema element element in the global scope of an XML Schema document. To make it easier for Java developers to work with elements, Apache CXF maps globally scoped elements to either a special JAXB element class or to a Java class that is generated to match its content type.

How the element is mapped depends on if the element is defined using a named type referenced by the type attribute or if the element is defined using an in-line type definition. Elements defined with in-line type definitions are mapped to Java classes.

It is recommended that elements are defined using a named type because in-line types are not reusable by other elements in the schema.

XML SCHEMA MAPPING

In XML Schema elements are defined using element elements. element elements has one required attribute. The name specifies the name of the element as it appears in an XML document.

In addition to the name attribute element elements have the optional attributes listed in Table 33.1, “Attributes Used to Define an Element”.

Table 33.1. Attributes Used to Define an Element

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>Specifies the type of the element. The type can be any XML Schema primitive type or any named complex type defined in the contract. If this attribute is not specified, you will need to include an in-line type definition.</td>
</tr>
<tr>
<td>nillable</td>
<td>Specifies if an element can be left out of a document entirely. If nillable is set to true, the element can be omitted from any document generated using the schema.</td>
</tr>
<tr>
<td>Attribute</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>abstract</strong></td>
<td>Specifies if an element can be used in an instance document. <strong>true</strong> indicates that the element cannot appear in the instance document. Instead, another element whose <strong>substitutionGroup</strong> attribute contains the QName of this element must appear in this element’s place. For information on how this attribute affects code generation see the section called “Java mapping of abstract elements”.</td>
</tr>
<tr>
<td><strong>substitutionGroup</strong></td>
<td>Specifies the name of an element that can be substituted with this element. For more information on using type substitution see Chapter 37, Element Substitution.</td>
</tr>
<tr>
<td><strong>default</strong></td>
<td>Specifies a default value for an element. For information on how this attribute affects code generation see the section called “Java mapping of elements with a default value”.</td>
</tr>
<tr>
<td><strong>fixed</strong></td>
<td>Specifies a fixed value for the element.</td>
</tr>
</tbody>
</table>

**Example 33.1, “Simple XML Schema Element Definition”** shows a simple element definition.

```
Example 33.1. Simple XML Schema Element Definition

  <element name="joeFred" type="xsd:string" />
```

An element can also define its own type using an in-line type definition. In-line types are specified using either a **complexType** element or a **simpleType** element. Once you specify whether the type of data is complex or simple, you can define any type of data needed using the tools available for each type of data.

**Example 33.2, “XML Schema Element Definition with an In-Line Type”** shows an element definition with an in-line type definition.

```
Example 33.2. XML Schema Element Definition with an In-Line Type

  <element name="skate">
    <complexType>
      <sequence>
        <element name="numWheels" type="xsd:int" />
        <element name="brand" type="xsd:string" />
      </sequence>
    </complexType>
  </element>
```
JAVA MAPPING OF ELEMENTS WITH A NAMED TYPE

By default, globally defined elements are mapped to `JAXBElement<T>` objects where the template class is determined by the value of the `element` element’s `type` attribute. For primitive types, the template class is derived using the wrapper class mapping described in the section called "Wrapper classes". For complex types, the Java class generated to support the complex type is used as the template class.

To support the mapping and to relieve the developer of unnecessary worry about an element’s QName, an object factory method is generated for each globally defined element, as shown in Example 33.3, “Object Factory Method for a Globally Scoped Element”.

Example 33.3. Object Factory Method for a Globally Scoped Element

```java
public class ObjectFactory {
    private final static QName _name_QNAME = new QName("targetNamespace", "localName");
    ...
    @XmlElementDecl(namespace = "targetNamespace", name = "localName")
    public JAXBElement<type> createName(type value);
}
```

For example, the element defined in Example 33.1, “Simple XML Schema Element Definition” results in the object factory method shown in Example 33.4, “Object Factory for a Simple Element”.

Example 33.4. Object Factory for a Simple Element

```java
public class ObjectFactory {
    private final static QName _JoeFred_QNAME = new QName("...", "joeFred");
    ...
    @XmlElementDecl(namespace = "...", name = "joeFred")
    public JAXBElement<String> createJoeFred(String value);
}
```

Example 33.5, “Using a Globally Scoped Element” shows an example of using a globally scoped element in Java.

Example 33.5. Using a Globally Scoped Element

```java
JAXBElement<String> element = createJoeFred("Green");
String color = element.getValue();
```
USING ELEMENTS WITH NAMED TYPES IN WSDL

If a globally scoped element is used to define a message part, the generated Java parameter is not an instance of JAXBElemet<T>. Instead it is mapped to a regular Java type or class.

Given the WSDL fragment shown in Example 33.6, "WSDL Using an Element as a Message Part", the resulting method has a parameter of type String.

Example 33.6. WSDL Using an Element as a Message Part

```xml
<?xml version="1.0" encoding="UTF-8"?>
<wsdl:definitions name="HelloWorld"
    targetNamespace="http://apache.org/hello_world_soap_http"
    xmlns="http://schemas.xmlsoap.org/wsdl/
    xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap/
    xmlns:tns="http://apache.org/hello_world_soap_http"
    xmlns:x1="http://apache.org/hello_world_soap_http/types"
    xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/
    xmlns:xsd="http://www.w3.org/2001/XMLSchema">
  <wsdl:types>
    <schema targetNamespace="http://apache.org/hello_world_soap_http/types"
      xmlns="http://www.w3.org/2001/XMLSchema"
      elementFormDefault="qualified">
      <element name="sayHi" type="string"/>
      <element name="sayHiResponse" type="string"/>
    </schema>
  </wsdl:types>

  <wsdl:message name="sayHiRequest">
    <wsdl:part element="x1:sayHi" name="in"/>
  </wsdl:message>

  <wsdl:message name="sayHiResponse">
    <wsdl:part element="x1:sayHiResponse" name="out"/>
  </wsdl:message>

  <wsdl:portType name="Greeter">
    <wsdl:operation name="sayHi">
      <wsdl:input message="tns:sayHiRequest" name="sayHiRequest"/>
      <wsdl:output message="tns:sayHiResponse" name="sayHiResponse"/>
    </wsdl:operation>
  </wsdl:portType>

  ...
</wsdl:definitions>
```

Example 33.7, "Java Method Using a Global Element as a Part" shows the generated method signature for the sayHi operation.

Example 33.7. Java Method Using a Global Element as a Part

```java
String sayHi(String in)
```

JAVA MAPPING OF ELEMENTS WITH AN IN-LINE TYPE
When an element is defined using an in-line type, it is mapped to Java following the same rules used for mapping other types to Java. The rules for simple types are described in Chapter 34, *Using Simple Types*. The rules for complex types are described in Chapter 35, *Using Complex Types*.

When a Java class is generated for an element with an in-line type definition, the generated class is decorated with the `@XmlRootElement` annotation. The `@XmlRootElement` annotation has two useful properties: `name` and `namespace`. These attributes are described in Table 33.2, "Properties for the `@XmlRootElement` Annotation".

### Table 33.2. Properties for the `@XmlRootElement` Annotation

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Specifies the value of the XML Schema element’s <code>name</code> attribute.</td>
</tr>
<tr>
<td>namespace</td>
<td>Specifies the namespace in which the element is defined.</td>
</tr>
</tbody>
</table>

The `@XmlRootElement` annotation is not used if the element meets one or more of the following conditions:

- The element’s `nillable` attribute is set to `true`
- The element is the head element of a substitution group
  For more information on substitution groups see Chapter 37, *Element Substitution*.

### JAVA MAPPING OF ABSTRACT ELEMENTS

When the element’s `abstract` attribute is set to `true` the object factory method for instantiating instances of the type is not generated. If the element is defined using an in-line type, the Java class supporting the in-line type is generated.

### JAVA MAPPING OF ELEMENTS WITH A DEFAULT VALUE

When the element’s `default` attribute is used the `defaultValue` property is added to the generated `@XmlElementDecl` annotation. For example, the element defined in Example 33.8, "XML Schema Element with a Default Value" results in the object factory method shown in Example 33.9, "Object Factory Method for an Element with a Default Value".

#### Example 33.8. XML Schema Element with a Default Value

```xml
<element name="size" type="xsd:int" default="7"/>
```

#### Example 33.9. Object Factory Method for an Element with a Default Value

```java
@XmlElementDecl(namespace = "...", name = "size", defaultValue = "7")
public JAXBElement<Integer> createUnionJoe(Integer value) {
    return new JAXBElement<Integer>(_Size_QNAME, Integer.class, null, value);
}
```
CHAPTER 34. USING SIMPLE TYPES

Abstract

XML Schema simple types are either XML Schema primitive types like `xsd:int`, or are defined using the `simpleType` element. They are used to specify elements that do not contain any children or attributes. They are generally mapped to native Java constructs and do not require the generation of special classes to implement them. Enumerated simple types do not result in generated code because they are mapped to Java `enum` types.

34.1. PRIMITIVE TYPES

Overview

When a message part is defined using one of the XML Schema primitive types, the generated parameter’s type is mapped to a corresponding Java native type. The same pattern is used when mapping elements that are defined within the scope of a complex type. The resulting field is of the corresponding Java native type.

Mappings

Table 34.1, “XML Schema Primitive Type to Java Native Type Mapping” lists the mapping between XML Schema primitive types and Java native types.

Table 34.1. XML Schema Primitive Type to Java Native Type Mapping

<table>
<thead>
<tr>
<th>XML Schema Type</th>
<th>Java Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>xsd:string</code></td>
<td><code>String</code></td>
</tr>
<tr>
<td><code>xsd:integer</code></td>
<td><code>BigInteger</code></td>
</tr>
<tr>
<td><code>xsd:int</code></td>
<td><code>int</code></td>
</tr>
<tr>
<td><code>xsd:long</code></td>
<td><code>long</code></td>
</tr>
<tr>
<td><code>xsd:short</code></td>

<td><code>QName</code></td>
</tr>
</tbody>
</table>

[a] For elements of this type.

[b] For attributes of this type.

**Wrapper classes**

Mapping XML Schema primitive types to Java primitive types does not work for all possible XML Schema constructs. Several cases require that an XML Schema primitive type is mapped to the Java primitive type’s corresponding wrapper type. These cases include:

- An **element** element with its **nullable** attribute set to **true** as shown:

  ```xml
  <element name="finned" type="xsd:boolean"
     nullable="true" />
  ```

- An **element** element with its **minOccurs** attribute set to 0 and its **maxOccurs** attribute set to 1, or its **maxOccurs** attribute not specified, as shown:

  ```xml
  <element name="plane" type="xsd:string" minOccurs="0" />
  ```
An attribute element with its use attribute set to optional, or not specified, and having neither its default attribute nor its fixed attribute specified, as shown:

```
<element name="date">
  <complexType>
    <sequence/>
    <attribute name="calType" type="xsd:string" use="optional" />
  </complexType>
</element>
```

Table 34.2, “Primitive Schema Type to Java Wrapper Class Mapping” shows how XML Schema primitive types are mapped into Java wrapper classes in these cases.

### Table 34.2. Primitive Schema Type to Java Wrapper Class Mapping

<table>
<thead>

</table>

34.2. SIMPLE TYPES DEFINED BY RESTRICTION

**Overview**

XML Schema allows you to create simple types by deriving a new type from another primitive type or simple type. Simple types are described using a `simpleType` element.
The new types are described by restricting the base type with one or more facets. These facets limit the possible valid values that can be stored in the new type. For example, you could define a simple type, SSN, which is a string of exactly 9 characters.

Each of the primitive XML Schema types has their own set of optional facets.

Procedure

To define your own simple type do the following:

1. Determine the base type for your new simple type.
2. Determine what restrictions define the new type based on the available facets for the chosen base type.
3. Using the syntax shown in this section, enter the appropriate simpleType element into the types section of your contract.

Defining a simple type in XML Schema

Example 34.1, “Simple type syntax” shows the syntax for describing a simple type.

Example 34.1. Simple type syntax

```
<simpleType name="typeName">
  <restriction base="baseType">
    <facet value="value" />
    <facet value="value" />
    ...
  </restriction>
</simpleType>
```

The type description is enclosed in a simpleType element and identified by the value of the name attribute. The base type from which the new simple type is being defined is specified by the base attribute of the xsd:restriction element. Each facet element is specified within the restriction element. The available facets and their valid settings depend on the base type. For example, xsd:string has a number of facets including:

- length
- minLength
- maxLength
- pattern
- whitespace

Example 34.2, “Postal Code Simple Type” shows the definition for a simple type that represents the two-letter postal code used for US states. It can only contain two, uppercase letters. TX is a valid value, but tx or tX are not valid values.

Example 34.2. Postal Code Simple Type
Mapping to Java

Apache CXF maps user-defined simple types to the Java type of the simple type’s base type. So, any message using the simple type `postalCode`, shown in Example 34.2, “Postal Code Simple Type”, is mapped to a `String` because the base type of `postalCode` is `xsd:string`. For example, the WSDL fragment shown in Example 34.3, “Credit Request with Simple Types” results in a Java method, `state()`, that takes a parameter, `postalCode`, of `String`.

Example 34.3. Credit Request with Simple Types

```xml
<message name="stateRequest">
  <part name="postalCode" type="postalCode" />
</message>
...

<portType name="postalSupport">
  <operation name="state">
    <input message="tns:stateRequest" name="stateRec" />
    <output message="tns:stateResponse" name="credResp" />
  </operation>
</portType>
```

Enforcing facets

By default, Apache CXF does not enforce any of the facets that are used to restrict a simple type. However, you can configure Apache CXF endpoints to enforce the facets by enabling schema validation.

To configure Apache CXF endpoints to use schema validation set the `schema-validation-enabled` property to `true`. Example 34.4, “Service Provider Configured to Use Schema Validation” shows the configuration for a service provider that uses schema validation

Example 34.4. Service Provider Configured to Use Schema Validation

```xml
<jaxws:endpoint name="{http://apache.org/hello_world_soap_http}SoapPort" wsdlLocation="wsdl/hello_world.wsdl" createdFromAPI="true">
  <jaxws:properties>
    <entry key="schema-validation-enabled" value="BOTH" />
  </jaxws:properties>
</jaxws:endpoint>
```

For more information on configuring schema validation, see Section 24.3.4.7, “Schema Validation Type Values”.
34.3. ENUMERATIONS

Overview

In XML Schema, enumerated types are simple types that are defined using the `xsd:enumeration` facet. Unlike atomic simple types, they are mapped to Java `enums`.

Defining an enumerated type in XML Schema

Enumerations are a simple type using the `xsd:enumeration` facet. Each `xsd:enumeration` facet defines one possible value for the enumerated type.

Example 34.5, "XML Schema Defined Enumeration" shows the definition for an enumerated type. It has the following possible values:

- big
- large
- mungo
- gargantuan

Example 34.5. XML Schema Defined Enumeration

```xml
<simpleType name="widgetSize">
  <restriction base="xsd:string">
    <enumeration value="big"/>
    <enumeration value="large"/>
    <enumeration value="mungo"/>
    <enumeration value="gargantuan"/>
  </restriction>
</simpleType>
```

Mapping to Java

XML Schema enumerations where the base type is `xsd:string` are automatically mapped to Java `enum` type. You can instruct the code generator to map enumerations with other base types to Java `enum` types by using the customizations described in Section 38.4, "Customizing Enumeration Mapping".

The `enum` type is created as follows:

1. The name of the type is taken from the `name` attribute of the simple type definition and converted to a Java identifier. In general, this means converting the first character of the XML Schema’s name to an uppercase letter. If the first character of the XML Schema’s name is an invalid character, an underscore (_) is prepended to the name.

2. For each `enumeration` facet, an enum constant is generated based on the value of the `value` attribute. The constant’s name is derived by converting all of the lowercase letters in the value to their uppercase equivalent.

3. A constructor is generated that takes the Java type mapped from the enumeration's base type.
4. A public method called `value()` is generated to access the facet value that is represented by an instance of the type. The return type of the `value()` method is the base type of the XML Schema type.

5. A public method called `fromValue()` is generated to create an instance of the enum type based on a facet value. The parameter type of the `value()` method is the base type of the XML Schema type.

6. The class is decorated with the `@XmlEnum` annotation.

The enumerated type defined in Example 34.5, “XML Schema Defined Enumeration” is mapped to the `enum` type shown in Example 34.6, “Generated Enumerated Type for a String Bases XML Schema Enumeration”.

**Example 34.6. Generated Enumerated Type for a String Bases XML Schema Enumeration**

```java
@XmlType(name = "widgetSize")
@XmlEnum
public enum WidgetSize {
    @XmlEnumValue("big")
    BIG("big"),
    @XmlEnumValue("large")
    LARGE("large"),
    @XmlEnumValue("mungo")
    MUNGO("mungo"),
    @XmlEnumValue("gargantuan")
    GARGANTUAN("gargantuan"),
    private final String value;

    WidgetSize(String v) {
        value = v;
    }

    public String value() {
        return value;
    }

    public static WidgetSize fromValue(String v) {
        for (WidgetSize c: WidgetSize.values()) {
            if (c.value.equals(v)) {
                return c;
            }
        }
        throw new IllegalArgumentException(v);
    }
}
```

### 34.4. LISTS

**Overview**
XML Schema supports a mechanism for defining data types that are a list of space separated simple types. An example of an element, **primeList**, using a list type is shown in Example 34.7, "List Type Example".

**Example 34.7. List Type Example**

```xml
<primeList>1 3 5 7 9 11 13</primeList>
```

XML Schema list types are generally mapped to Java `List<T>` objects. The only variation to this pattern is when a message part is mapped directly to an instance of an XML Schema list type.

**Defining list types in XML Schema**

XML Schema list types are simple types and as such are defined using a `simpleType` element. The most common syntax used to define a list type is shown in Example 34.8, "Syntax for XML Schema List Types".

**Example 34.8. Syntax for XML Schema List Types**

```xml
<simpleType name="listType">
  <list itemType="atomicType">
    <facet value="value" />
    <facet value="value" />
    ...
  </list>
</simpleType>
```

The value given for `atomicType` defines the type of the elements in the list. It can only be one of the built in XML Schema atomic types, like `xsd:int` or `xsd:string`, or a user-defined simple type that is not a list.

In addition to defining the type of elements listed in the list type, you can also use facets to further constrain the properties of the list type. Table 34.3, "List Type Facets" shows the facets used by list types.

**Table 34.3. List Type Facets**

<table>
<thead>
<tr>
<th>Facet</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>length</td>
<td>Defines the number of elements in an instance of the list type.</td>
</tr>
<tr>
<td>minLength</td>
<td>Defines the minimum number of elements allowed in an instance of the list type.</td>
</tr>
<tr>
<td>maxLength</td>
<td>Defines the maximum number of elements allowed in an instance of the list type.</td>
</tr>
<tr>
<td>enumeration</td>
<td>Defines the allowable values for elements in an instance of the list type.</td>
</tr>
</tbody>
</table>
pattern

Defines the lexical form of the elements in an instance of the list type. Patterns are defined using regular expressions.

For example, the definition for the `simpleList` element shown in Example 34.7, “List Type Example”, is shown in Example 34.9, “Definition of a List Type”.

Example 34.9. Definition of a List Type

```xml
<simpleType name="primeListType">
  <list itemType="int"/>
</simpleType>
[element name="primeList" type="primeListType"/>
```

In addition to the syntax shown in Example 34.8, “Syntax for XML Schema List Types”, you can also define a list type using the less common syntax shown in Example 34.10, “Alternate Syntax for List Types”.

Example 34.10. Alternate Syntax for List Types

```xml
<simpleType name="listType">
  <list>
    <simpleType>
      <restriction base="atomicType">
        <facet value="value"/>
        <facet value="value"/>
        ...
      </restriction>
    </simpleType>
  </list>
</simpleType>
```

Mapping list type elements to Java

When an element is defined a list type, the list type is mapped to a collection property. A collection property is a Java `List<T>` object. The template class used by the `List<T>` is the wrapper class mapped from the list’s base type. For example, the list type defined in Example 34.9, “Definition of a List Type” is mapped to a `List<Integer>`.

For more information on wrapper type mapping see the section called “Wrapper classes”.

Mapping list type parameters to Java

When a message part is defined as a list type, or is mapped to an element of a list type, the resulting method parameter is mapped to an array instead of a `List<T>` object. The base type of the array is the wrapper class of the list type’s base class.
For example, the WSDL fragment in Example 34.11, “WSDL with a List Type Message Part” results in the method signature shown in Example 34.12, “Java Method with a List Type Parameter”.

### Example 34.11. WSDL with a List Type Message Part

```xml
<definitions ...>
  ...
  <types ...>
    <schema ...>
      <simpleType name="primeListType">
        <list itemType="int"/>
      </simpleType>
      <element name="primeList" type="primeListType"/>
    </schemas>
    <message name="numRequest"> <part name="inputData" element="xsd1:primeList" />
  </message>
  <message name="numResponse">;
    <part name="outputData" type="xsd:int">
...
    <portType name="numberService">
      <operation name="primeProcessor">
        <input name="numRequest" message="tns:numRequest" />
        <output name="numResponse" message="tns:numResponse" />
      </operation>
      ...
    </portType>
    ...
  </definitions>
```

### Example 34.12. Java Method with a List Type Parameter

```java
public interface NumberService {
  @XmlList
  @WebResult(name = "outputData", targetNamespace = "", partName = "outputData")
  @WebMethod
  public int primeProcessor(
      @WebParam(partName = "inputData", name = "primeList", targetNamespace = ":..."))
  java.lang.Integer[] inputData
  );
}
```

### 34.5. UNIONS

#### Overview

In XML Schema, a union is a construct that allows you to describe a type whose data can be one of a number of simple types. For example, you can define a type whose value is either the integer 1 or the string first. Unions are mapped to Java Strings.
Defining in XML Schema

XML Schema unions are defined using a `simpleType` element. They contain at least one `union` element that defines the member types of the union. The member types of the union are the valid types of data that can be stored in an instance of the union. They are defined using the `union` element’s `memberTypes` attribute. The value of the `memberTypes` attribute contains a list of one or more defined simple type names. Example 34.13, “Simple Union Type” shows the definition of a union that can store either an integer or a string.

Example 34.13. Simple Union Type

```
<simpleType name="orderNumUnion">
  <union memberTypes="xsd:string xsd:int" />
</simpleType>
```

In addition to specifying named types as a member type of a union, you can also define an anonymous simple type as a member type of a union. This is done by adding the anonymous type definition inside of the `union` element. Example 34.14, “Union with an Anonymous Member Type” shows an example of a union containing an anonymous member type that restricts the possible values of a valid integer to the range 1 through 10.

Example 34.14. Union with an Anonymous Member Type

```
<simpleType name="restrictedOrderNumUnion">
  <union memberTypes="xsd:string">
    <simpleType>
      <restriction base="xsd:int">
        <minInclusive value="1" />
        <maxInclusive value="10" />
      </restriction>
    </simpleType>
  </union>
</simpleType>
```

Mapping to Java

XML Schema union types are mapped to Java `String` objects. By default, Apache CXF does not validate the contents of the generated object. To have Apache CXF validate the contents you will must configure the runtime to use schema validation as described in the section called “Enforcing facets”.

34.6. SIMPLE TYPE SUBSTITUTION

Overview

XML allows for simple type substitution between compatible types using the `xsi:type` attribute. The default mapping of simple types to Java primitive types, however, does not fully support simple type substitution. The runtime can handle basic simple type substitution, but information is lost. The code generators can be customized to generate Java classes that facilitate lossless simple type substitution.

Default mapping and marshaling
Because Java primitive types do not support type substitution, the default mapping of simple types to Java primitive types presents problems for supporting simple type substitution. The Java virtual machine will balk if an attempt is made to pass a `short` into a variable that expects an `int` even though the schema defining the types allows it.

To get around the limitations imposed by the Java type system, Apache CXF allows for simple type substitution when the value of the element’s `xsi:type` attribute meets one of the following conditions:

- It specifies a primitive type that is compatible with the element’s schema type.
- It specifies a type that derives by restriction from the element’s schema type.
- It specifies a complex type that derives by extension from the element’s schema type.

When the runtime does the type substitution it does not retain any knowledge of the type specified in the element’s `xsi:type` attribute. If the type substitution is from a complex type to a simple type, only the value directly related to the simple type is preserved. Any other elements and attributes added by extension are lost.

### Supporting lossless type substitution

You can customize the generation of simple types to facilitate lossless support of simple type substitution in the following ways:

- Set the `globalBindings` customization element’s `mapSimpleTypeDef` to `true`. This instructs the code generator to create Java value classes for all named simple types defined in the global scope.

  For more information see [Section 38.3, “Generating Java Classes for Simple Types”](#).

- Add a `javaType` element to the `globalBindings` customization element. This instructs the code generators to map all instances of an XML Schema primitive type to a specific class of object.

  For more information see [Section 38.2, “Specifying the Java Class of an XML Schema Primitive”](#).

- Add a `baseType` customization element to the specific elements you want to customize. The `baseType` customization element allows you to specify the Java type generated to represent a property. To ensure the best compatibility for simple type substitution, use `java.lang.Object` as the base type.

  For more information see [Section 38.6, “Specifying the Base Type of an Element or an Attribute”](#).
CHAPTER 35. USING COMPLEX TYPES

Abstract

Complex types can contain multiple elements and they can have attributes. They are mapped into Java classes that can hold the data represented by the type definition. Typically, the mapping is to a bean with a set of properties representing the elements and the attributes of the content model.

35.1. BASIC COMPLEX TYPE MAPPING

Overview

XML Schema complex types define constructs containing more complex information than a simple type. The most simple complex types define an empty element with an attribute. More intricate complex types are made up of a collection of elements.

By default, an XML Schema complex type is mapped to a Java class, with a member variable to represent each element and attribute listed in the XML Schema definition. The class has setters and getters for each member variable.

Defining in XML Schema

XML Schema complex types are defined using the `<complexType>` element. The `<complexType>` element wraps the rest of elements used to define the structure of the data. It can appear either as the parent element of a named type definition, or as the child of an `<element>` element anonymously defining the structure of the information stored in the element. When the `<complexType>` element is used to define a named type, it requires the use of the `<name>` attribute. The `<name>` attribute specifies a unique identifier for referencing the type.

Complex type definitions that contain one or more elements have one of the child elements described in Table 35.1, ”Elements for Defining How Elements Appear in a Complex Type”. These elements determine how the specified elements appear in an instance of the type.

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>all</td>
<td>All of the elements defined as part of the complex type must appear in an instance of the type. However, they can appear in any order.</td>
</tr>
<tr>
<td>choice</td>
<td>Only one of the elements defined as part of the complex type can appear in an instance of the type.</td>
</tr>
<tr>
<td>sequence</td>
<td>All of the elements defined as part of the complex type must appear in an instance of the type, and they must also appear in the order specified in the type definition.</td>
</tr>
</tbody>
</table>
NOTE

If a complex type definition only uses attributes, you do not need one of the elements described in Table 35.1, “Elements for Defining How Elements Appear in a Complex Type”.

After deciding how the elements will appear, you define the elements by adding one or more `element` element children to the definition.

Example 35.1, “XML Schema Complex Type” shows a complex type definition in XML Schema.

```
Example 35.1. XML Schema Complex Type

<complexType name="sequence">
  <sequence>
    <element name="name" type="xsd:string" />
    <element name="street" type="xsd:short" />
    <element name="city" type="xsd:string" />
    <element name="state" type="xsd:string" />
    <element name="zipCode" type="xsd:string" />
  </sequence>
</complexType>
```

Mapping to Java

XML Schema complex types are mapped to Java classes. Each element in the complex type definition is mapped to a member variable in the Java class. Getter and setter methods are also generated for each element in the complex type.

All generated Java classes are decorated with the `@XmlType` annotation. If the mapping is for a named complex type, the annotations `name` is set to the value of the `complexType` element’s `name` attribute. If the complex type is defined as part of an element definition, the value of the `@XmlType` annotation’s `name` property is the value of the `element` element’s `name` attribute.

NOTE

As described in the section called “Java mapping of elements with an in-line type“, the generated class is decorated with the `@XmlRootElement` annotation if it is generated for a complex type defined as part of an element definition.

To provide the runtime with guidelines indicating how the elements of the XML Schema complex type should be handled, the code generators alter the annotations used to decorate the class and its member variables.

All Complex Type

All complex types are defined using the `all` element. They are annotated as follows:

- The `@XmlType` annotation’s `propOrder` property is empty.
- Each element is decorated with the `@XmlElement` annotation.
- The `@XmlElement` annotation’s `required` property is set to `true`.

Red Hat Fuse 7.8 Apache CXF Development Guide
Example 35.2, "Mapping of an All Complex Type" shows the mapping for an all complex type with two elements.

```java
Example 35.2. Mapping of an All Complex Type

@XmlElement(name = "all", propOrder = {
    @XmlElement(required = true)
    protected BigDecimal amount;
    @XmlElement(required = true)
    protected String type;

    public BigDecimal getAmount() {
        return amount;
    }

    public void setAmount(BigDecimal value) {
        this.amount = value;
    }

    public String getType() {
        return type;
    }

    public void setType(String value) {
        this.type = value;
    }
})
```

Choice Complex Type

Choice complex types are defined using the `choice` element. They are annotated as follows:

- The `@XmlType` annotation’s `propOrder` property lists the names of the elements in the order they appear in the XML Schema definition.

- None of the member variables are annotated. Example 35.3, "Mapping of a Choice Complex Type" shows the mapping for a choice complex type with two elements.

```java
Example 35.3. Mapping of a Choice Complex Type

@XmlElement(name = "choice", propOrder = {
    "address",
    "floater"
})
public class Choice {

    protected Sequence address;
    protected Float floater;

    public Sequence getAddress() {
```
Sequence Complex Type

A sequence complex type is defined using the `sequence` element. It is annotated as follows:

- The `@XmlType` annotation’s `propOrder` property lists the names of the elements in the order they appear in the XML Schema definition.

- Each element is decorated with the `@XmlElement` annotation.

- The `@XmlElement` annotation’s `required` property is set to `true`.

Example 35.4, “Mapping of a Sequence Complex Type” shows the mapping for the complex type defined in Example 35.1, “XML Schema Complex Type”.

```
@XmlElement(required = true)
protected String name;
protected short street;
@XmlElement(required = true)
protected String city;
@XmlElement(required = true)
protected String state;
@XmlElement(required = true)
protected String zipCode;
```
35.2. ATTRIBUTES

Overview

Apache CXF supports the use of `attribute` elements and `attributeGroup` elements within the scope of a `complexType` element. When defining structures for an XML document attribute declarations provide a means of adding information that is specified within the tag, not the value that the tag contains. For example, when describing the XML element `<value currency="euro">410</value>` in XML Schema the `currency` attribute is described using an `attribute` element as shown in Example 35.5, “XML Schema Defining and Attribute”.

The `attributeGroup` element allows you to define a group of reusable attributes that can be referenced by all complex types defined by the schema. For example, if you are defining a series of elements that all use the attributes `category` and `pubDate`, you could define an attribute group with these attributes and reference them in all the elements that use them. This is shown in Example 35.7, “Attribute Group Definition”.

```java
public void setName(String value) {
    this.name = value;
}

public short getStreet() {
    return street;
}

public void setStreet(short value) {
    this.street = value;
}

public String getCity() {
    return city;
}

public void setCity(String value) {
    this.city = value;
}

public String getState() {
    return state;
}

public void setState(String value) {
    this.state = value;
}

public String getZipCode() {
    return zipCode;
}

public void setZipCode(String value) {
    this.zipCode = value;
}
```
When describing data types for use in developing application logic, attributes whose `use` attribute is set to either `optional` or `required` are treated as elements of a structure. For each attribute declaration contained within a complex type description, an element is generated in the class for the attribute, along with the appropriate getter and setter methods.

### Defining an attribute in XML Schema

An XML Schema `attribute` element has one required attribute, `name`, that is used to identify the attribute. It also has four optional attributes that are described in Table 35.2, “Optional Attributes Used to Define Attributes in XML Schema”.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>use</code></td>
<td>Specifies if the attribute is required. Valid values are <code>required</code>, <code>optional</code>, or <code>prohibited</code>. <code>optional</code> is the default value.</td>
</tr>
<tr>
<td><code>type</code></td>
<td>Specifies the type of value the attribute can take. If it is not used the schema type of the attribute must be defined in-line.</td>
</tr>
<tr>
<td><code>default</code></td>
<td>Specifies a default value to use for the attribute. It is only used when the <code>attribute</code> element’s <code>use</code> attribute is set to <code>optional</code>.</td>
</tr>
<tr>
<td><code>fixed</code></td>
<td>Specifies a fixed value to use for the attribute. It is only used when the <code>attribute</code> element’s <code>use</code> attribute is set to <code>optional</code>.</td>
</tr>
</tbody>
</table>

**Example 35.5, “XML Schema Defining and Attribute”** shows an attribute element defining an attribute, `currency`, whose value is a string.

```xml
<element name="value">
  <complexType>
    <xsd:simpleContent>
      <xsd:extension base="xsd:integer">
        <xsd:attribute name="currency" type="xsd:string" use="required"/>
      </xsd:extension>
    </xsd:simpleContent>
  </xsd:complexType>
</xsd:element>
```

If the `type` attribute is omitted from the `attribute` element, the format of the data must be described in-line. **Example 35.6, “Attribute with an In-Line Data Description”** shows an `attribute` element for an attribute, `category`, that can take the values `autobiography`, `non-fiction`, or `fiction`. 

---

322
**Example 35.6. Attribute with an In-Line Data Description**

```xml
<attribute name="category" use="required">
  <simpleType>
    <restriction base="xsd:string">
      <enumeration value="autobiography"/>
      <enumeration value="non-fiction"/>
      <enumeration value="fiction"/>
    </restriction>
  </simpleType>
</attribute>
```

**Using an attribute group in XML Schema**

Using an attribute group in a complex type definition is a two step process:

1. Define the attribute group.
   An attribute group is defined using an `attributeGroup` element with a number of `attribute` child elements. The `attributeGroup` requires a `name` attribute that defines the string used to refer to the attribute group. The `attribute` elements define the members of the attribute group and are specified as shown in the section called “Defining an attribute in XML Schema”. Example 35.7, “Attribute Group Definition” shows the description of the attribute group `catalogIndices`. The attribute group has two members: `category`, which is optional, and `pubDate`, which is required.

   **Example 35.7. Attribute Group Definition**

   ```xml
   <attributeGroup name="catalogIndices"> 
     <attribute name="category" type="categoryType" /> 
     <attribute name="pubDate" type="dateTime" use="required" /> 
   </attributeGroup>
   ```

2. Use the attribute group in the definition of a complex type.
   You use attribute groups in complex type definitions by using the `attributeGroup` element with the `ref` attribute. The value of the `ref` attribute is the name given the attribute group that you want to use as part of the type definition. For example if you want to use the attribute group `catalogIndices` in the complex type `dvdType`, you would use `<attributeGroup ref="catalogIndices" />` as shown in Example 35.8, “Complex Type with an Attribute Group”.

   **Example 35.8. Complex Type with an Attribute Group**

   ```xml
   <complexType name="dvdType">
     <sequence>
       <element name="title" type="xsd:string" /> 
       <element name="director" type="xsd:string" /> 
       <element name="numCopies" type="xsd:int" /> 
     </sequence>
     <attributeGroup ref="catalogIndices" />
   </complexType>
   ```
Mapping attributes to Java

Attributes are mapped to Java in much the same way that member elements are mapped to Java. Required attributes and optional attributes are mapped to member variables in the generated Java class. The member variables are decorated with the `@XmlAttribute` annotation. If the attribute is required, the `@XmlAttribute` annotation’s `required` property is set to `true`.

The complex type defined in Example 35.9, “techDoc Description” is mapped to the Java class shown in Example 35.10, “techDoc Java Class”.

Example 35.9. techDoc Description

```xml
<complexType name="techDoc">
  <all>
    <element name="product" type="xsd:string" />
    <element name="version" type="xsd:short" />
  </all>
  <attribute name="usefullness" type="xsd:float"
    use="optional" default="0.01" />
</complexType>
```

Example 35.10. techDoc Java Class

```java
@XmlElement(required = true)
protected String product;
protected short version;
@XmlAttribute
protected Float usefullness;

public String getProduct() {
  return product;
}

public void setProduct(String value) {
  this.product = value;
}

public short getVersion() {
  return version;
}

public void setVersion(short value) {
  this.version = value;
}

public float getUsefullness() { if (usefullness == null) { return 0.01F; } else { return usefullness; } }

public void setUsefullness(Float value) {
```
As shown in Example 35.10, “techDoc Java Class”, the default attribute and the fixed attribute instruct the code generators to add code to the getter method generated for the attribute. This additional code ensures that the specified value is returned if no value is set.

**IMPORTANT**

The fixed attribute is treated the same as the default attribute. If you want the fixed attribute to be treated as a Java constant you can use the customization described in Section 38.5, “Customizing Fixed Value Attribute Mapping”.

### Mapping attribute groups to Java

Attribute groups are mapped to Java as if the members of the group were explicitly used in the type definition. If the attribute group has three members, and it is used in a complex type, the generated class for that type will include a member variable, along with the getter and setter methods, for each member of the attribute group. For example, the complex type defined in Example 35.8, “Complex Type with an Attribute Group”, Apache CXF generates a class containing the member variables category and pubDate to support the members of the attribute group as shown in Example 35.11, “dvdType Java Class”.

**Example 35.11. dvdType Java Class**

```java
@XmlType(name = "dvdType", propOrder = {
    "title",
    "director",
    "numCopies"
})
public class DvdType {

    @XmlElement(required = true)
    protected String title;

    @XmlElement(required = true)
    protected String director;

    protected int numCopies;

    @XmlAttribute protected CatagoryType category;

    @XmlAttribute(required = true)
    @XmlSchemaType(name = "dateTime")
    protected XMLGregorianCalendar pubDate;

    public String getTitle() {
        return title;
    }

    public void setTitle(String value) {
        this.title = value;
    }

    public String getDirector() {
        return director;
    }
```
35.3. DERIVING COMPLEX TYPES FROM SIMPLE TYPES

Overview

Apache CXF supports derivation of a complex type from a simple type. A simple type has, by definition, neither sub-elements nor attributes. Hence, one of the main reasons for deriving a complex type from a simple type is to add attributes to the simple type.

There are two ways of deriving a complex type from a simple type:

- **By extension**
- **By restriction**

**Derivation by extension**

Example 35.12, "Deriving a Complex Type from a Simple Type by Extension” shows an example of a complex type, `internationalPrice`, derived by extension from the `xsd:decimal` primitive type to include a currency attribute.

```xml
<complexType name="internationalPrice">
  <!-- ... -->
</complexType>
```
The `simpleContent` element indicates that the new type does not contain any sub-elements. The `extension` element specifies that the new type extends `xsd:decimal`.

**Derivation by restriction**

Example 35.13, “Deriving a Complex Type from a Simple Type by Restriction” shows an example of a complex type, `idType`, that is derived by restriction from `xsd:string`. The defined type restricts the possible values of `xsd:string` to values that are ten characters in length. It also adds an attribute to the type.

```
<complexType name="idType">
  <simpleContent>
    <restriction base="xsd:string">
      <length value="10" />
      <attribute name="expires" type="xsd:dateTime" />  
    </restriction>
  </simpleContent>
</complexType>
```

As in Example 35.12, “Deriving a Complex Type from a Simple Type by Extension” the `simpleContent` element signals that the new type does not contain any children. This example uses a `restriction` element to constrain the possible values used in the new type. The `attribute` element adds the element to the new type.

**Mapping to Java**

A complex type derived from a simple type is mapped to a Java class that is decorated with the `@XmlType` annotation. The generated class contains a member variable, `value`, of the simple type from which the complex type is derived. The member variable is decorated with the `@XmlValue` annotation. The class also has a `getValue()` method and a `setValue()` method. In addition, the generated class has a member variable, and the associated getter and setter methods, for each attribute that extends the simple type.

Example 35.14, “idType Java Class” shows the Java class generated for the `idType` type defined in Example 35.13, “Deriving a Complex Type from a Simple Type by Restriction”.

```
@XmlElement(name = "idType", propOrder = {
    "value"
})
public class IdType {
```
35.4. DERIVING COMPLEX TYPES FROM COMPLEX TYPES

Overview

Using XML Schema, you can derive new complex types by either extending or restricting other complex types using the complexContent element. When generating the Java class to represent the derived complex type, Apache CXF extends the base type's class. In this way, the generated Java code preserves the inheritance hierarchy intended in the XML Schema.

Schema syntax

You derive complex types from other complex types by using the complexContent element, and either the extension element or the restriction element. The complexContent element specifies that the included data description includes more than one field. The extension element and the restriction element, which are children of the complexContent element, specify the base type being modified to create the new type. The base type is specified by the base attribute.

Extending a complex type

To extend a complex type use the extension element to define the additional elements and attributes that make up the new type. All elements that are allowed in a complex type description are allowable as part of the new type's definition. For example, you can add an anonymous enumeration to the new type, or you can use the choice element to specify that only one of the new fields can be valid at a time.

Example 35.15, "Deriving a Complex Type by Extension" shows an XML Schema fragment that defines two complex types, widgetOrderInfo and widgetOrderBillInfo. widgetOrderBillInfo is derived by extending widgetOrderInfo to include two new elements: orderNumber and amtDue.
Example 35.15. Deriving a Complex Type by Extension

```xml
<complexType name="widgetOrderInfo">
  <sequence>
    <element name="amount" type="xsd:int"/>
    <element name="order_date" type="xsd:dateTime"/>
    <element name="type" type="xsd1:widgetSize"/>
    <element name="shippingAddress" type="xsd1:Address"/>
  </sequence>
  <attribute name="rush" type="xsd:boolean" use="optional"/>
</complexType>
<complexType name="widgetOrderBillInfo">
  <complexContent>
    <extension base="xsd1:widgetOrderInfo">
      <sequence>
        <element name="amtDue" type="xsd:decimal"/>
        <element name="orderNumber" type="xsd:string"/>
      </sequence>
      <attribute name="paid" type="xsd:boolean" default="false"/>
    </extension>
  </complexContent>
</complexType>
```

Restricting a complex type

To restrict a complex type use the `restriction` element to limit the possible values of the base type’s elements or attributes. When restricting a complex type you must list all of the elements and attributes of the base type. For each element you can add restrictive attributes to the definition. For example, you can add a `maxOccurs` attribute to an element to limit the number of times it can occur. You can also use the `fixed` attribute to force one or more of the elements to have predetermined values.

Example 35.16, “Defining a Complex Type by Restriction” shows an example of defining a complex type by restricting another complex type. The restricted type, `wallawallaAddress`, can only be used for addresses in Walla Walla, Washington because the values for the `city` element, the `state` element, and the `zipCode` element are fixed.

Example 35.16. Defining a Complex Type by Restriction

```xml
<complexType name="Address">
  <sequence>
    <element name="name" type="xsd:string"/>
    <element name="street" type="xsd:short" maxOccurs="3"/>
    <element name="city" type="xsd:string"/>
    <element name="state" type="xsd:string"/>
    <element name="zipCode" type="xsd:string"/>
  </sequence>
</complexType>
<complexType name="wallawallaAddress">
  <complexContent>
    <restriction base="xsd1:Address">
      <sequence>
        <element name="name" type="xsd:string"/>
      </sequence>
    </restriction>
  </complexContent>
</complexType>
```
Mapping to Java

As it does with all complex types, Apache CXF generates a class to represent complex types derived from another complex type. The Java class generated for the derived complex type extends the Java class generated to support the base complex type. The base Java class is also modified to include the `@XmlSeeAlso` annotation. The base class’ `@XmlSeeAlso` annotation lists all of the classes that extend the base class.

When the new complex type is derived by extension, the generated class will include member variables for all of the added elements and attributes. The new member variables will be generated according to the same mappings as all other elements.

When the new complex type is derived by restriction, the generated class will have no new member variables. The generated class will simply be a shell that does not provide any additional functionality. It is entirely up to you to ensure that the restrictions defined in the XML Schema are enforced.

For example, the schema in Example 35.15, “Deriving a Complex Type by Extension” results in the generation of two Java classes: `WidgetOrderInfo` and `WidgetBillOrderInfo`. `WidgetOrderBillInfo` extends `WidgetOrderInfo` because `widgetOrderBillInfo` is derived by extension from `widgetOrderInfo`. Example 35.17, “WidgetOrderBillInfo” shows the generated class for `widgetOrderBillInfo`.

Example 35.17. WidgetOrderBillInfo

```java
@XmlElement(name = "widgetOrderBillInfo", propOrder = {
    "amtDue",
    "orderNumber"
})
public class WidgetOrderBillInfo
extends WidgetOrderInfo
{
    @XmlElement(required = true)
    protected BigDecimal amtDue;
    @XmlElement(required = true)
    protected String orderNumber;
    @XmlAttribute
    protected Boolean paid;

    public BigDecimal getAmtDue() {
        return amtDue;
    }
}
```
public void setAmtDue(BigDecimal value) {
    this.amtDue = value;
}

public String getOrderNumber() {
    return orderNumber;
}

public void setOrderNumber(String value) {
    this.orderNumber = value;
}

public boolean isPaid() {
    if (paid == null) {
        return false;
    } else {
        return paid;
    }
}

public void setPaid(Boolean value) {
    this.paid = value;
}

35.5. OCCURRENCE CONSTRAINTS

35.5.1. Schema Elements Supporting Occurrence Constraints

XML Schema allows you to specify the occurrence constraints on four of the XML Schema elements that make up a complex type definition:

- Section 35.5.2, “Occurrence Constraints on the All Element”
- Section 35.5.3, “Occurrence Constraints on the Choice Element”
- Section 35.5.4, “Occurrence Constraints on Elements”
- Section 35.5.5, “Occurrence Constraints on Sequences”

35.5.2. Occurrence Constraints on the All Element

XML Schema

Complex types defined with the all element do not allow for multiple occurrences of the structure defined by the all element. You can, however, make the structure defined by the all element optional by setting its minOccurs attribute to 0.

Mapping to Java

Setting the all element’s minOccurs attribute to 0 has no effect on the generated Java class.
35.5.3. Occurrence Constraints on the Choice Element

Overview

By default, the results of a choice element can only appear once in an instance of a complex type. You can change the number of times the element chosen to represent the structure defined by a choice element is allowed to appear using its minOccurs attribute and its mxOccurs attribute. Using these attributes you can specify that the choice type can occur zero to an unlimited number of times in an instance of a complex type. The element chosen for the choice type does not need to be the same for each occurrence of the type.

Using in XML Schema

The minOccurs attribute specifies the minimum number of times the choice type must appear. Its value can be any positive integer. Setting the minOccurs attribute to 0 specifies that the choice type does not need to appear inside an instance of the complex type.

The maxOccurs attribute specifies the maximum number of times the choice type can appear. Its value can be any non-zero, positive integer or unbounded. Setting the maxOccurs attribute to unbounded specifies that the choice type can appear an infinite number of times.

Example 35.18, “Choice Occurrence Constraints” shows the definition of a choice type, ClubEvent, with choice occurrence constraints. The choice type overall can be repeated 0 to unbounded times.

Example 35.18. Choice Occurrence Constraints

```xml
<complexType name="ClubEvent">
  <choice minOccurs="0" maxOccurs="unbounded">
    <element name="MemberName" type="xsd:string"/>
    <element name="GuestName" type="xsd:string"/>
  </choice>
</complexType>
```

Mapping to Java

Unlike single instance choice structures, XML Schema choice structures that can occur multiple times are mapped to a Java class with a single member variable. This single member variable is a List<T> object that holds all of the data for the multiple occurrences of the sequence. For example, if the sequence defined in Example 35.18, “Choice Occurrence Constraints” occurred two times, then the list would have two items.

The name of the Java class' member variable is derived by concatenating the names of the member elements. The element names are separated by Or and the first letter of the variable name is converted to lower case. For example, the member variable generated from Example 35.18, “Choice Occurrence Constraints” would be named memberNameOrGuestName.

The type of object stored in the list depends on the relationship between the types of the member elements. For example:

- If the member elements are of the same type the generated list will contain JAXBElement<T> objects. The base type of the JAXBElement<T> objects is determined by the normal mapping of the member elements’ type.
● If the member elements are of different types and their Java representations implement a common interface, the list will contain objects of the common interface.

● If the member elements are of different types and their Java representations extend a common base class, the list will contain objects of the common base class.

● If none of the other conditions are met, the list will contain **Object** objects.

The generated Java class will only have a getter method for the member variable. The getter method returns a reference to the live list. Any modifications made to the returned list will effect the actual object.

The Java class is decorated with the [@XmlType](#) annotation. The annotation’s **name** property is set to the value of the **name** attribute from the parent element of the XML Schema definition. The annotation’s **propOrder** property contains the single member variable representing the elements in the sequence.

The member variable representing the elements in the choice structure are decorated with the [@XmlElements](#) annotation. The [@XmlElements](#) annotation contains a comma separated list of [@XmlElement](#) annotations. The list has one [@XmlElement](#) annotation for each member element defined in the XML Schema definition of the type. The [@XmlElement](#) annotations in the list have their **name** property set to the value of the XML Schema element element’s **name** attribute and their **type** property set to the Java class resulting from the mapping of the XML Schema element element’s type.

Example 35.19, “Java Representation of Choice Structure with an Occurrence Constraint” shows the Java mapping for the XML Schema choice structure defined in Example 35.18, “Choice Occurrence Constraints”.

---

**Example 35.19. Java Representation of Choice Structure with an Occurrence Constraint**

```java
@XmlType(name = "ClubEvent", propOrder = {
        "memberNameOrGuestName"
    })
public class ClubEvent {

    @XmlElementRefs({
        @XmlElementRef(name = "GuestName", type = JAXBElement.class),
        @XmlElementRef(name = "MemberName", type = JAXBElement.class)
    })
    protected List<JAXBElement<String>> memberNameOrGuestName;

    public List<JAXBElement<String>> getMemberNameOrGuestName() {
        if (memberNameOrGuestName == null) {
            memberNameOrGuestName = new ArrayList<JAXBElement<String>>(0);
        }
        return this.memberNameOrGuestName;
    }
}
```

**minOccurs set to 0**

If only the **minOccurs** element is specified and its value is **0**, the code generators generate the Java class as if the **minOccurs** attribute were not set.
35.5.4. Occurrence Constraints on Elements

Overview

You can specify how many times a specific element in a complex type appears using the `element` element’s `minOccurs` attribute and `maxOccurs` attribute. The default value for both attributes is 1.

`minOccurs` set to 0

When you set one of the complex type’s member element’s `minOccurs` attribute to 0, the `@XmlElement` annotation decorating the corresponding Java member variable is changed. Instead of having its `required` property set to true, the `@XmlElement` annotation’s `required` property is set to false.

`minOccurs` set to a value greater than 1

In XML Schema you can specify that an element must occur more than once in an instance of the type by setting the `element` element’s `minOccurs` attribute to a value greater than one. However, the generated Java class will not support the XML Schema constraint. Apache CXF generates the supporting Java member variable as if the `minOccurs` attribute were not set.

Elements with `maxOccurs` set

When you want a member element to appear multiple times in an instance of a complex type, you set the element’s `maxOccurs` attribute to a value greater than 1. You can set the `maxOccurs` attribute’s value to unbounded to specify that the member element can appear an unlimited number of times.

The code generators map a member element with the `maxOccurs` attribute set to a value greater than 1 to a Java member variable that is a `List<T>` object. The base class of the list is determined by mapping the element’s type to Java. For XML Schema primitive types, the wrapper classes are used as described in the section called “Wrapper classes”. For example, if the member element is of type `xsd:int` the generated member variable is a `List<Integer>` object.

35.5.5. Occurrence Constraints on Sequences

Overview

By default, the contents of a `sequence` element can only appear once in an instance of a complex type. You can change the number of times the sequence of elements defined by a `sequence` element is allowed to appear using its `minOccurs` attribute and its `maxOccurs` attribute. Using these attributes you can specify that the sequence type can occur zero to an unlimited number of times in an instance of a complex type.

Using XML Schema

The `minOccurs` attribute specifies the minimum number of times the sequence must occur in an instance of the defined complex type. Its value can be any positive integer. Setting the `minOccurs` attribute to 0 specifies that the sequence does not need to appear inside an instance of the complex type.

The `maxOccurs` attribute specifies the upper limit for how many times the sequence can occur in an instance of the defined complex type. Its value can be any non-zero, positive integer or unbounded. Setting the `maxOccurs` attribute to unbounded specifies that the sequence can appear an infinite number of times.
Example 35.20, “Sequence with Occurrence Constraints” shows the definition of a sequence type, **CultureInfo**, with sequence occurrence constraints. The sequence can be repeated 0 to 2 times.

```xml
<complexType name="CultureInfo">
  <sequence minOccurs="0" maxOccurs="2">
    <element name="Name" type="string"/>
    <element name="Lcid" type="int"/>
  </sequence>
</complexType>
```

**Mapping to Java**

Unlike single instance sequences, XML Schema sequences that can occur multiple times are mapped to a Java class with a single member variable. This single member variable is a `List<T>` object that holds all of the data for the multiple occurrences of the sequence. For example, if the sequence defined in Example 35.20, “Sequence with Occurrence Constraints” occurred two times, then the list would have four items.

The name of the Java class' member variable is derived by concatenating the names of the member elements. The element names are separated by **And** and the first letter of the variable name is converted to lower case. For example, the member variable generated from Example 35.20, “Sequence with Occurrence Constraints” is named `nameAndLcid`.

The type of object stored in the list depends on the relationship between the types of the member elements. For example:

- If the member elements are of the same type the generated list will contain `JAXBElemen<T> objects. The base type of the `JAXBElemen<T> objects is determined by the normal mapping of the member elements' type.

- If the member elements are of different types and their Java representations implement a common interface, the list will contains objects of the common interface.

- If the member elements are of different types and their Java representations extend a common base class, the list will contain objects of the common base class.

- If none of the other conditions are met, the list will contain `Object objects.

The generated Java class only has a getter method for the member variable. The getter method returns a reference to the live list. Any modifications made to the returned list effects the actual object.

The Java class is decorated with the `@XmlType` annotation. The annotation’s `name` property is set to the value of the `name` attribute from the parent element of the XML Schema definition. The annotation’s `propOrder` property contains the single member variable representing the elements in the sequence.

The member variable representing the elements in the sequence are decorated with the `@XmlElement` annotation. The `@XmlElement` annotation contains a comma separated list of `@XmlElement` annotations. The list has one `@XmlElement` annotation for each member element defined in the XML Schema definition of the type. The `@XmlElement` annotations in the list have their `name` property set to the value of the XML Schema `element` element’s `name` attribute and their `type` property set to the Java class resulting from the mapping of the XML Schema `element` element’s type.
Example 35.21, "Java Representation of Sequence with an Occurrence Constraint" shows the Java mapping for the XML Schema sequence defined in Example 35.20, "Sequence with Occurrence Constraints".

```java
Example 35.21. Java Representation of Sequence with an Occurrence Constraint

```java
@XmlType(name = "CultureInfo", propOrder = {
    "nameAndLcid"
})
public class CultureInfo {

    @XmlElements({
        @XmlElement(name = "Name", type = String.class),
        @XmlElement(name = "Lcid", type = Integer.class)
    })
    protected List<Serializable> nameAndLcid;

    public List<Serializable> getNameAndLcid() {
        if (nameAndLcid == null) {
            nameAndLcid = new ArrayList<Serializable>();
        }
        return this.nameAndLcid;
    }
}
```

minOccurs set to 0

If only the minOccurs element is specified and its value is 0, the code generators generate the Java class as if the minOccurs attribute is not set.

### 35.6. USING MODEL GROUPS

**Overview**

XML Schema model groups are convenient shortcuts that allows you to reference a group of elements from a user-defined complex type. For example, you can define a group of elements that are common to several types in your application and then reference the group repeatedly. Model groups are defined using the group element, and are similar to complex type definitions. The mapping of model groups to Java is also similar to the mapping for complex types.

**Defining a model group in XML Schema**

You define a model group in XML Schema using the group element with the name attribute. The value of the name attribute is a string that is used to refer to the group throughout the schema. The group element, like the complexType element, can have the sequence element, the all element, or the choice element as its immediate child.

Inside the child element, you define the members of the group using element elements. For each member of the group, specify one element element. Group members can use any of the standard attributes for the element element including minOccurs and maxOccurs. So, if your group has three
elements and one of them can occur up to three times, you define a group with three element elements, one of which uses maxOccurs="3". Example 35.22, “XML Schema Model Group” shows a model group with three elements.

Example 35.22. XML Schema Model Group

```
<group name="passenger">
  <sequence>
    <element name="name" type="xsd:string" />
    <element name="clubNum" type="xsd:long" />
    <element name="seatPref" type="xsd:string" maxOccurs="3" />
  </sequence>
</group>
```

Using a model group in a type definition

Once a model group has been defined, it can be used as part of a complex type definition. To use a model group in a complex type definition, use the group element with the ref attribute. The value of the ref attribute is the name given to the group when it was defined. For example, to use the group defined in Example 35.22, “XML Schema Model Group” you use <group ref="tns:passenger" /> as shown in Example 35.23, “Complex Type with a Model Group”.

Example 35.23. Complex Type with a Model Group

```
<complexType name="reservation">
  <sequence>
    <group ref="tns:passenger" />
    <element name="origin" type="xsd:string" />
    <element name="destination" type="xsd:string" />
    <element name="fltNum" type="xsd:long" />
  </sequence>
</complexType>
```

When a model group is used in a type definition, the group becomes a member of the type. So an instance of reservation has four member elements. The first element is the passenger element and it contains the member elements defined by the group shown in Example 35.22, “XML Schema Model Group”. An example of an instance of reservation is shown in Example 35.24, “Instance of a Type with a Model Group”.

Example 35.24. Instance of a Type with a Model Group

```
<reservation>
  <passenger> <name>A. Smart</name> <clubNum>99</clubNum> <seatPref>isle1</seatPref> </passenger>
  <origin>LAX</origin> <destination>FRA</destination> <fltNum>34567</fltNum>
</reservation>
```
Mapping to Java

By default, a model group is only mapped to Java artifacts when it is included in a complex type definition. When generating code for a complex type that includes a model group, Apache CXF simply includes the member variables for the model group into the Java class generated for the type. The member variables representing the model group are annotated based on the definitions of the model group.

Example 35.25, “Type with a Group” shows the Java class generated for the complex type defined in Example 35.23, “Complex Type with a Model Group”.

Example 35.25. Type with a Group

```java
@XmlElement(required = true)
protected String name;
protected long clubNum;
@XmlElement(required = true)
protected List<String> seatPref;
@XmlElement(required = true)
protected String origin;
@XmlElement(required = true)
protected String destination;
protected long fltNum;
```
public String getOrigin() {
    return origin;
}

public void setOrigin(String value) {
    this.origin = value;
}

public String getDestination() {
    return destination;
}

public void setDestination(String value) {
    this.destination = value;
}

public long getFltNum() {
    return fltNum;
}

public void setFltNum(long value) {
    this.fltNum = value;
}

Multiple occurrences

You can specify that the model group appears more than once by setting the group element’s maxOccurs attribute to a value greater than one. To allow for multiple occurrences of the model group Apache CXF maps the model group to a List<T> object. The List<T> object is generated following the rules for the group’s first child:

- If the group is defined using a sequence element see Section 35.5.5, “Occurrence Constraints on Sequences”.
- If the group is defined using a choice element see Section 35.5.3, “Occurrence Constraints on the Choice Element”.
CHAPTER 36. USING WILD CARD TYPES

Abstract

There are instances when a schema author wants to defer binding elements or attributes to a defined type. For these cases, XML Schema provides three mechanisms for specifying wild card place holders. These are all mapped to Java in ways that preserve their XML Schema functionality.

36.1. USING ANY ELEMENTS

Overview

The XML Schema any element is used to create a wild card place holder in complex type definitions. When an XML element is instantiated for an XML Schema any element, it can be any valid XML element. The any element does not place any restrictions on either the content or the name of the instantiated XML element.

For example, given the complex type defined in Example 36.1, “XML Schema Type Defined with an Any Element” you can instantiate either of the XML elements shown in Example 36.2, “XML Document with an Any Element”.

Example 36.1. XML Schema Type Defined with an Any Element

```xml
<element name="FlyBoy">
  <complexType>
    <sequence>
      <any />
      <element name="rank" type="xsd:int" />
    </sequence>
  </complexType>
</element>
```

Example 36.2. XML Document with an Any Element

```xml
<FlyBoy>
  <learJet>CL-215</learJet>
  <rank>2</rank>
</element>

<FlyBoy>
  <viper>Mark II</viper>
  <rank>1</rank>
</element>
```

XML Schema any elements are mapped to either a Java Object object or a Java org.w3c.dom.Element object.

Specifying in XML Schema
The `any` element can be used when defining sequence complex types and choice complex types. In most cases, the `any` element is an empty element. It can, however, take an `annotation` element as a child.

Table 36.1, “Attributes of the XML Schema Any Element” describes the `any` element’s attributes.

Table 36.1. Attributes of the XML Schema Any Element

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>namespace</code></td>
<td>Specifies the namespace of the elements that can be used to instantiate the element in an XML document. The valid values are:</td>
</tr>
<tr>
<td></td>
<td><code>##any</code> Specifies that elements from any namespace can be used. This is the default.</td>
</tr>
<tr>
<td></td>
<td><code>##other</code> Specifies that elements from any namespace other than the parent element’s namespace can be used.</td>
</tr>
<tr>
<td></td>
<td><code>##local</code> Specifies elements without a namespace must be used.</td>
</tr>
<tr>
<td></td>
<td><code>##targetNamespace</code> Specifies that elements from the parent element’s namespace must be used.</td>
</tr>
<tr>
<td></td>
<td>A space delimited list of URIs <code>##local</code> and <code>##targetNamespace</code> Specifies that elements from any of the listed namespaces can be used.</td>
</tr>
<tr>
<td><code>maxOccurs</code></td>
<td>Specifies the maximum number of times an instance of the element can appear in the parent element. The default value is 1. To specify that an instance of the element can appear an unlimited number of times, you can set the attribute’s value to <code>unbounded</code>.</td>
</tr>
<tr>
<td><code>minOccurs</code></td>
<td>Specifies the minimum number of times an instance of the element can appear in the parent element. The default value is 1.</td>
</tr>
</tbody>
</table>
processContents

Specifies how the element used to instantiate the any element should be validated. Valid values are:

strict
Specifies that the element must be validated against the proper schema. This is the default value.
lax
Specifies that the element should be validated against the proper schema. If it cannot be validated, no errors are thrown.
skip
Specifies that the element should not be validated.

Example 36.3, “Complex Type Defined with an Any Element” shows a complex type defined with an any element.

Example 36.3. Complex Type Defined with an Any Element

```xml
<complexType name="surprisePackage">
  <sequence>
    <any processContents="lax" />
    <element name="to" type="xsd:string" />
    <element name="from" type="xsd:string" />
  </sequence>
</complexType>
```

Mapping to Java

XML Schema any elements result in the creation of a Java property named any. The property has associated getter and setter methods. The type of the resulting property depends on the value of the element’s processContents attribute. If the any element’s processContents attribute is set to skip, the element is mapped to a org.w3c.dom.Element object. For all other values of the processContents attribute an any element is mapped to a Java Object object.

The generated property is decorated with the @XmlAnyElement annotation. This annotation has an optional lax property that instructs the runtime what to do when marshaling the data. Its default value is false which instructs the runtime to automatically marshal the data into a org.w3c.dom.Element object. Setting lax to true instructs the runtime to attempt to marshal the data into JAXB types. When the any element’s processContents attribute is set to skip, the lax property is set to its default value. For all other values of the processContents attribute, lax is set to true.

Example 36.4, “Java Class with an Any Element” shows how the complex type defined in Example 36.3, “Complex Type Defined with an Any Element” is mapped to a Java class.

Example 36.4. Java Class with an Any Element

```java
public class SurprisePackage {
```
Marshalling

If the Java property for an any element has its lax set to false, or the property is not specified, the runtime makes no attempt to parse the XML data into JAXB objects. The data is always stored in a DOM Element object.

If the Java property for an any element has its lax set to true, the runtime attempts to marshal the XML data into the appropriate JAXB objects. The runtime attempts to identify the proper JAXB classes using the following procedure:

1. It checks the element tag of the XML element against the list of elements known to the runtime. If it finds a match, the runtime marshals the XML data into the proper JAXB class for the element.

2. It checks the XML element’s xsi:type attribute. If it finds a match, the runtime marshals the XML element into the proper JAXB class for that type.

3. If it cannot find a match it marshals the XML data into a DOM Element object.

Usually an application’s runtime knows about all of the types generated from the schema’s included in its contract. This includes the types defined in the contract’s wsdl:types element, any data types added to the contract through inclusion, and any types added to the contract through importing other schemas. You can also make the runtime aware of additional types using the @XmlSeeAlso annotation which is described in Section 32.4, “Adding Classes to the Runtime Marshaller”.

CHAPTER 36. USING WILD CARD TYPES
Unmarshalling

If the Java property for an any element has its lax set to false, or the property is not specified, the runtime will only accept DOM Element objects. Attempting to use any other type of object will result in a marshalling error.

If the Java property for an any element has its lax set to true, the runtime uses its internal map between Java data types and the XML Schema constructs they represent to determine the XML structure to write to the wire. If the runtime knows the class and can map it to an XML Schema construct, it writes out the data and inserts an xsi:type attribute to identify the type of data the element contains.

If the runtime cannot map the Java object to a known XML Schema construct, it will throw a marshaling exception. You can add types to the runtime’s map using the @XmlSeeAlso annotation which is described in Section 32.4, “Adding Classes to the Runtime Marshaller”.

36.2. USING THE XML SCHEMA ANYTYPE TYPE

Overview

The XML Schema type xsd:anyType is the root type for all XML Schema types. All of the primitives are derivatives of this type, as are all user defined complex types. As a result, elements defined as being of xsd:anyType can contain data in the form of any of the XML Schema primitives as well as any complex type defined in a schema document.

In Java the closest matching type is the Object class. It is the class from which all other Java classes are sub-typed.

Using in XML Schema

You use the xsd:anyType type as you would any other XML Schema complex type. It can be used as the value of an element element’s type element. It can also be used as the base type from which other types are defined.

Example 36.5, “Complex Type with a Wild Card Element” shows an example of a complex type that contains an element of type xsd:anyType.

Example 36.5. Complex Type with a Wild Card Element

```xml
<complexType name="wildStar">
  <sequence>
    <element name="name" type="xsd:string" />
    <element name="ship" type="xsd:anyType" />
  </sequence>
</complexType>
```

Mapping to Java

Elements that are of type xsd:anyType are mapped to Object objects. Example 36.6, “Java Representation of a Wild Card Element” shows the mapping of Example 36.5, “Complex Type with a Wild Card Element” to a Java class.

Example 36.6. Java Representation of a Wild Card Element
public class WildStar {
    @XmlElement(required = true)
    protected String name;
    @XmlElement(required = true) protected Object ship;

    public String getName() {
        return name;
    }

    public void setName(String value) {
        this.name = value;
    }

    public Object getShip() { return ship; }

    public void setShip(Object value) { this.ship = value; }
}

This mapping allows you to place any data into the property representing the wild card element. The Apache CXF runtime handles the marshaling and unmarshaling of the data into usable Java representation.

**Marshalling**

When Apache CXF marshals XML data into Java types, it attempts to marshal anyType elements into known JAXB objects. To determine if it is possible to marshal an anyType element into a JAXB generated object, the runtime inspects the element’s xsi:type attribute to determine the actual type used to construct the data in the element. If the xsi:type attribute is not present, the runtime attempts to identify the element’s actual data type by introspection. If the element’s actual data type is determined to be one of the types known by the application’s JAXB context, the element is marshaled into a JAXB object of the proper type.

If the runtime cannot determine the actual data type of the element, or the actual data type of the element is not a known type, the runtime marshals the content into a org.w3c.dom.Element object. You will then need to work with the element’s content using the DOM APIs.

An application’s runtime usually knows about all of the types generated from the schema’s included in its contract. This includes the types defined in the contract’s wsdl:types element, any data types added to the contract through inclusion, and any types added to the contract through importing other schema documents. You can also make the runtime aware of additional types using the @XmlSeeAlso annotation which is described in Section 32.4, “Adding Classes to the Runtime Marshaller”.

**Unmarshalling**

When Apache CXF unmarshals Java types into XML data, it uses an internal map between Java data types and the XML Schema constructs they represent to determine the XML structure to write to the wire. If the runtime knows the class and can map the class to an XML Schema construct, it writes out the data and inserts an xsi:type attribute to identify the type of data the element contains. If the data is stored in a org.w3c.dom.Element object, the runtime writes the XML structure represented by the object but it does not include an xsi:type attribute.
If the runtime cannot map the Java object to a known XML Schema construct, it throws a marshaling exception. You can add types to the runtime’s map using the @XmlSeeAlso annotation which is described in Section 32.4, “Adding Classes to the Runtime Marshaller”.

### 36.3. USING UNBOUND ATTRIBUTES

#### Overview

XML Schema has a mechanism that allows you to leave a place holder for an arbitrary attribute in a complex type definition. Using this mechanism, you can define a complex type that can have any attribute. For example, you can create a type that defines the elements `<robot name="epsilon" />`, `<robot age="10000" />`, or `<robot type="weevil" />` without specifying the three attributes. This can be particularly useful when flexibility in your data is required.

#### Defining in XML Schema

Undeclared attributes are defined in XML Schema using the **anyAttribute** element. It can be used wherever an attribute element can be used. The **anyAttribute** element has no attributes, as shown in Example 36.7, “Complex Type with an Undeclared Attribute”.

**Example 36.7. Complex Type with an Undeclared Attribute**

```xml
<complexType name="arbitter">
  <sequence>
    <element name="name" type="xsd:string" />
    <element name="rate" type="xsd:float" />
  </sequence>
  <anyAttribute />
</complexType>
```

The defined type, **arbitter**, has two elements and can have one attribute of any type. The elements three elements shown in Example 36.8, “Examples of Elements Defined with a Wild Card Attribute” can all be generated from the complex type **arbitter**.

**Example 36.8. Examples of Elements Defined with a Wild Card Attribute**

```xml
<officer rank="12"><name>...</name><rate>...</rate></officer>
<lawyer type="divorce"><name>...</name><rate>...</rate></lawyer>
<judge><name>...</name><rate>...</rate></judge>
```

#### Mapping to Java

When a complex type containing an **anyAttribute** element is mapped to Java, the code generator adds a member called **otherAttributes** to the generated class. **otherAttributes** is of type `java.util.Map<QName, String>` and it has a getter method that returns a live instance of the map. Because the map returned from the getter is live, any modifications to the map are automatically applied. Example 36.9, “Class for a Complex Type with an Undeclared Attribute” shows the class generated for the complex type defined in Example 36.7, “Complex Type with an Undeclared Attribute”.

**Example 36.9. Class for a Complex Type with an Undeclared Attribute**
public class Arbitter {
    @XmlElement(required = true)
    protected String name;
    protected float rate;

    @XmlAnyAttribute private Map<QName, String> otherAttributes = new HashMap<QName, String>();

    public String getName() {
        return name;
    }

    public void setName(String value) {
        this.name = value;
    }

    public float getRate() {
        return rate;
    }

    public void setRate(float value) {
        this.rate = value;
    }

    public Map<QName, String> getOtherAttributes() {
        return otherAttributes;
    }
}

Working with undeclared attributes

The `otherAttributes` member of the generated class expects to be populated with a `Map` object. The map is keyed using `QNames`. Once you get the map, you can access any attributes set on the object and set new attributes on the object.

Example 36.10, "Working with Undeclared Attributes" shows sample code for working with undeclared attributes.

Example 36.10. Working with Undeclared Attributes

Arbitter judge = new Arbitter();
Map<QName, String> otherAtts = judge.getOtherAttributes();

QName at1 = new QName("test.apache.org", "house");
QName at2 = new QName("test.apache.org", "veteran");

otherAtts.put(at1, "Cape");
otherAtts.put(at2, "false");

String vetStatus = otherAtts.get(at2);

The code in Example 36.10, "Working with Undeclared Attributes" does the following:
- Gets the map containing the undeclared attributes.
- Creates QNames to work with the attributes.
- Sets the values for the attributes into the map.
- Retrieves the value for one of the attributes.
CHAPTER 37. ELEMENT SUBSTITUTION

Abstract

XML Schema substitution groups allow you to define a group of elements that can replace a top level, or head, element. This is useful in cases where you have multiple elements that share a common base type or with elements that need to be interchangeable.

37.1. SUBSTITUTION GROUPS IN XML SCHEMA

Overview

A substitution group is a feature of XML schema that allows you to specify elements that can replace another element in documents generated from that schema. The replaceable element is called the head element and must be defined in the schema’s global scope. The elements of the substitution group must be of the same type as the head element or a type that is derived from the head element’s type.

In essence, a substitution group allows you to build a collection of elements that can be specified using a generic element. For example, if you are building an ordering system for a company that sells three types of widgets you might define a generic widget element that contains a set of common data for all three widget types. Then you can define a substitution group that contains a more specific set of data for each type of widget. In your contract you can then specify the generic widget element as a message part instead of defining a specific ordering operation for each type of widget. When the actual message is built, the message can contain any of the elements of the substitution group.

Syntax

Substitution groups are defined using the substitutionGroup attribute of the XML Schema element. The value of the substitutionGroup attribute is the name of the element that the element being defined replaces. For example, if your head element is widget, adding the attribute substitutionGroup="widget" to an element named woodWidget specifies that anywhere a widget element is used, you can substitute a woodWidget element. This is shown in Example 37.1, “Using a Substitution Group”.

Example 37.1. Using a Substitution Group

```xml
<element name="widget" type="xsd:string" />
<element name="woodWidget" type="xsd:string" substitutionGroup="widget"/>
```

Type restrictions

The elements of a substitution group must be of the same type as the head element or of a type derived from the head element’s type. For example, if the head element is of type xsd:int all members of the substitution group must be of type xsd:int or of a type derived from xsd:int. You can also define a substitution group similar to the one shown in Example 37.2, “Substitution Group with Complex Types” where the elements of the substitution group are of types derived from the head element’s type.

Example 37.2. Substitution Group with Complex Types

```xml
<complexType name="widgetType">
</complexType>
```
The head element of the substitution group, `widget`, is defined as being of type `widgetType`. Each element of the substitution group extends `widgetType` to include data that is specific to ordering that type of widget.

Based on the schema in Example 37.2, “Substitution Group with Complex Types”, the `part` elements in Example 37.3, “XML Document using a Substitution Group” are valid.

Example 37.3. XML Document using a Substitution Group

```
<part>
  <widget>
    <shape>round</shape>
    <color>blue</color>
  </widget>
</part>

<part>
  <plasticWidget>
    <shape>round</shape>
    <color>blue</color>
  </plasticWidget>
</part>
```
Abstract head elements

You can define an abstract head element that can never appear in a document produced using your schema. Abstract head elements are similar to abstract classes in Java because they are used as the basis for defining more specific implementations of a generic class. Abstract heads also prevent the use of the generic element in the final product.

You declare an abstract head element by setting the `abstract` attribute of an `element` element to `true`, as shown in Example 37.4, “Abstract Head Definition”. Using this schema, a valid `review` element can contain either a `positiveComment` element or a `negativeComment` element, but cannot contain a `comment` element.

Example 37.4. Abstract Head Definition

```xml
<element name="comment" type="xsd:string" abstract="true" />  
<element name="positiveComment" type="xsd:string"         
  substitutionGroup="comment" />  
<element name="negativeComment" type="xsd:string"         
  substitutionGroup="comment" />  
<element name="review">  
  <complexType>  
    <all>  
      <element name="custName" type="xsd:string" />  
      <element name="impression" ref="comment" />  
    </all>  
  </complexType>  
</element>
```

37.2. SUBSTITUTION GROUPS IN JAVA

Overview

Apache CXF, as specified in the JAXB specification, supports substitution groups using Java's native class hierarchy in combination with the ability of the `JAXBElement` class' support for wildcard definitions. Because the members of a substitution group must all share a common base type, the classes generated to support the elements' types also share a common base type. In addition, Apache CXF maps instances of the head element to `JAXBElement<? extends T>` properties.

Generated object factory methods
The object factory generated to support a package containing a substitution group has methods for each of the elements in the substitution group. For each of the members of the substitution group, except for the head element, the `@XmlElementDecl` annotation decorating the object factory method includes two additional properties, as described in Table 37.1, “Properties for Declaring a JAXB Element is a Member of a Substitution Group”.

Table 37.1. Properties for Declaring a JAXB Element is a Member of a Substitution Group

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>substitutionHeadNamespace</td>
<td>Specifies the namespace where the head element is defined.</td>
</tr>
<tr>
<td>substitutionHeadName</td>
<td>Specifies the value of the head element’s name attribute.</td>
</tr>
</tbody>
</table>

The object factory method for the head element of the substitution group’s `@XmlElementDecl` contains only the default `namespace` property and the default `name` property.

In addition to the element instantiation methods, the object factory contains a method for instantiating an object representing the head element. If the members of the substitution group are all of complex types, the object factory also contains methods for instantiating instances of each complex type used.

**Example 37.5, “Object Factory Method for a Substitution Group”** shows the object factory method for the substitution group defined in Example 37.2, “Substitution Group with Complex Types”.

```
public class ObjectFactory {

    private final static QName _Widget_QNAME = new QName(...);
    private final static QName _PlasticWidget_QNAME = new QName(...);
    private final static QName _WoodWidget_QNAME = new QName(...);

    public ObjectFactory() {
    }

    public WidgetType createWidgetType() {
        return new WidgetType();
    }

    public PlasticWidgetType createPlasticWidgetType() {
        return new PlasticWidgetType();
    }

    public WoodWidgetType createWoodWidgetType() {
        return new WoodWidgetType();
    }

    @XmlElementDecl(namespace="...", name = "widget")
    public JAXBELEMENT<WidgetType> createWidget(WidgetType value) {
        return new JAXBELEMENT<WidgetType>(_Widget_QNAME, WidgetType.class, null, value);
    }
}
```
Substitution groups in interfaces

If the head element of a substitution group is used as a message part in one of an operation’s messages, the resulting method parameter will be an object of the class generated to support that element. It will not necessarily be an instance of the `JAXBElement<? extends T>` class. The runtime relies on Java’s native type hierarchy to support the type substitution, and Java will catch any attempts to use unsupported types.

To ensure that the runtime knows all of the classes needed to support the element substitution, the SEI is decorated with the `@XmlSeeAlso` annotation. This annotation specifies a list of classes required by the runtime for marshalling. For more information on using the `@XmlSeeAlso` annotation see Section 32.4, “Adding Classes to the Runtime Marshaller”.

Example 37.7, “Generated Interface Using a Substitution Group” shows the SEI generated for the interface shown in Example 37.6, “WSDL Interface Using a Substitution Group”. The interface uses the substitution group defined in Example 37.2, “Substitution Group with Complex Types”.

Example 37.6. WSDL Interface Using a Substitution Group

```xml
<message name="widgetMessage">
  <part name="widgetPart" element="xsd1:widget" />
</message>
<message name="numWidgets">
  <part name="numInventory" type="xsd:int" />
</message>
<message name="badSize">
  <part name="numInventory" type="xsd:int" />
</message>
<portType name="orderWidgets">
  <operation name="placeWidgetOrder">
    <input message="tns:widgetOrder" name="order" />
    <output message="tns:widgetOrderBill" name="bill" />
    <fault message="tns:badSize" name="sizeFault" />
  </operation>
  <operation name="checkWidgets">
    <input message="tns:widgetMessage" name="request" />
```
Example 37.7. Generated Interface Using a Substitution Group

```java
@WebService(targetNamespace = "...", name = "orderWidgets")
@XmlSeeAlso({com.widgetvendor.types.widgettypes.ObjectFactory.class})
public interface OrderWidgets {
    @SOAPBinding(parameterStyle = SOAPBinding.ParameterStyle.BARE)
    @WebResult(name = "numInventory", targetNamespace = "", partName = "numInventory")
    @WebMethod
    public int checkWidgets(
        @WebParam(partName = "widgetPart", name = "widget", targetNamespace = "...")
        com.widgetvendor.types.widgettypes.WidgetType widgetPart
    );
}
```

The SEI shown in Example 37.7, “Generated Interface Using a Substitution Group” lists the object factory in the @XmlSeeAlso annotation. Listing the object factory for a namespace provides access to all of the generated classes for that namespace.

Substitution groups in complex types

When the head element of a substitution group is used as an element in a complex type, the code generator maps the element to a `JAXBElement<? extends T>` property. It does not map it to a property containing an instance of the generated class generated to support the substitution group.

For example, the complex type defined in Example 37.8, “Complex Type Using a Substitution Group” results in the Java class shown in Example 37.9, “Java Class for a Complex Type Using a Substitution Group”. The complex type uses the substitution group defined in Example 37.2, “Substitution Group with Complex Types”.

Example 37.8. Complex Type Using a Substitution Group

```xml
<complexType name="widgetOrderInfo">
    <sequence>
        <element name="amount" type="xsd:int"/>
        <element ref="xsd1:widget"/>
    </sequence>
</complexType>
```

Example 37.9. Java Class for a Complex Type Using a Substitution Group

```java
@XmlElement(type=WidgetOrderInfo.class)
public class WidgetOrderInfo {
    protected int amount;
}
```
@XmlElementRef(name = "widget", namespace = "...", type = JAXBElement.class) protected
JAXBElement<? extends WidgetType> widget;

public int getAmount() {
    return amount;
}

public void setAmount(int value) {
    this.amount = value;
}

public JAXBElement<? extends WidgetType> getWidget() { return widget; }

public void setWidget(JAXBElement<? extends WidgetType> value) {
    this.widget = ((JAXBElement<? extends WidgetType>) value);
}

Setting a substitution group property

How you work with a substitution group depends on whether the code generator mapped the group to a
straight Java class or to a `JAXBElement<? extends T>` class. When the element is simply mapped to an
object of the generated value class, you work with the object the same way you work with other Java
objects that are part of a type hierarchy. You can substitute any of the subclasses for the parent class.
You can inspect the object to determine its exact class, and cast it appropriately.

The JAXB specification recommends that you use the object factory methods for instantiating objects
of the generated classes.

When the code generators create a `JAXBElement<? extends T>` object to hold instances of a
substitution group, you must wrap the element’s value in a `JAXBElement<? extends T>` object. The
best method to do this is to use the element creation methods provided by the object factory. They
provide an easy means for creating an element based on its value.

Example 37.10, “Setting a Member of a Substitution Group” shows code for setting an instance of a
substitution group.

Example 37.10. Setting a Member of a Substitution Group

```
ObjectFactory of = new ObjectFactory();
PlasticWidgetType pWidget = of.createPlasticWidgetType();
pWidget.setShape = "round";
pWidget.setColor = "green";
pWidget.setMoldProcess = "injection";

JAXBElement<PlasticWidgetType> widget = of.createPlasticWidget(pWidget);

WidgetOrderInfo order = of.createWidgetOrderInfo();
order.setWidget(widget);
```

The code in Example 37.10, “Setting a Member of a Substitution Group” does the following:

Instantiates an object factory.
Instantiates a `PlasticWidgetType` object.

Instantiates a `JAXBElement<PlasticWidgetType>` object to hold a plastic widget element.

Instantiates a `WidgetOrderInfo` object.

Sets the `WidgetOrderInfo` object’s `widget` to the `JAXBElement` object holding the plastic widget element.

### Getting the value of a substitution group property

The object factory methods do not help when extracting the element’s value from a `JAXBElement<? extends T>` object. You must use the `JAXBElement<? extends T>` object’s `getValue()` method. The following options determine the type of object returned by the `getValue()` method:

- Use the `isInstance()` method of all the possible classes to determine the class of the element’s value object.

- Use the `JAXBElement<? extends T>` object’s `getName()` method to determine the element’s name.
  The `getName()` method returns a QName. Using the local name of the element, you can determine the proper class for the value object.

- Use the `JAXBElement<? extends T>` object’s `getDeclaredType()` method to determine the class of the value object.
  The `getDeclaredType()` method returns the `Class` object of the element’s value object.

**WARNING**

There is a possibility that the `getDeclaredType()` method will return the base class for the head element regardless of the actual class of the value object.

Example 37.11, “Getting the Value of a Member of the Substitution Group” shows code retrieving the value from a substitution group. To determine the proper class of the element’s value object, the example uses the element’s `getName()` method.

### Example 37.11. Getting the Value of a Member of the Substitution Group

```java
String elementName = order.getWidget().getName().getLocalPart();
if (elementName.equals("woodWidget")
    {  
        WoodWidgetType widget=order.getWidget().getValue();
    }
else if (elementName.equals("plasticWidget")
    {
        PlasticWidgetType widget=order.getWidget().getValue();
    }
else
```
37.3. WIDGET VENDOR EXAMPLE

37.3.1. Widget Ordering Interface

This section shows an example of substitution groups being used in Apache CXF to solve a real world application. A service and consumer are developed using the widget substitution group defined in Example 37.2, “Substitution Group with Complex Types”. The service offers two operations: checkWidgets and placeWidgetOrder. Example 37.12, "Widget Ordering Interface" shows the interface for the ordering service.

Example 37.12. Widget Ordering Interface

```xml
<message name="widgetOrder">
  <part name="widgetOrderForm" type="xsd1:widgetOrderInfo"/>
</message>
<message name="widgetOrderBill">
  <part name="widgetOrderConformation" type="xsd1:widgetOrderBillInfo"/>
</message>
<message name="widgetMessage">
  <part name="widgetPart" element="xsd1:widget" />
</message>
<message name="numWidgets">
  <part name="numInventory" type="xsd:int" />
</message>
<portType name="orderWidgets">
  <operation name="placeWidgetOrder">
    <input message="tns:widgetOrder" name="order"/>
    <output message="tns:widgetOrderBill" name="bill"/>
  </operation>
  <operation name="checkWidgets">
    <input message="tns:widgetMessage" name="request" />
    <output message="tns:numWidgets" name="response" />
  </operation>
</portType>
```

Example 37.13, "Widget Ordering SEI" shows the generated Java SEI for the interface.

Example 37.13. Widget Ordering SEI

```java
@WebService(targetNamespace = "http://widgetVendor.com/widgetOrderForm", name = "orderWidgets")
@XmlSeeAlso({com.widgetvendor.types.widgettypes.ObjectFactory.class})
public interface OrderWidgets {

  @SOAPBinding(parameterStyle = SOAPBinding.ParameterStyle.BARE)
  @WebResult(name = "numInventory", targetNamespace = "", partName = "numInventory")
```
@WebMethod
public int checkWidgets(
    @WebParam(partName = "widgetPart", name = "widget", targetNamespace = "http://widgetVendor.com/types/widgetTypes")
    com.widgetvendor.types.widgettypes.WidgetType widgetPart
);

@SOAPBinding(parameterStyle = SOAPBinding.ParameterStyle.BARE)
@WebResult(name = "widgetOrderConformation", targetNamespace = "", partName = "widgetOrderConformation")
@WebMethod
public com.widgetvendor.types.widgettypes.WidgetOrderBillInfo placeWidgetOrder(
    @WebParam(partName = "widgetOrderForm", name = "widgetOrderForm", targetNamespace = "")
    com.widgetvendor.types.widgettypes.WidgetOrderInfo widgetOrderForm
) throws BadSize;

NOTE
Because the example only demonstrates the use of substitution groups, some of the business logic is not shown.

37.3.2. The checkWidgets Operation

Overview
checkWidgets is a simple operation that has a parameter that is the head member of a substitution group. This operation demonstrates how to deal with individual parameters that are members of a substitution group. The consumer must ensure that the parameter is a valid member of the substitution group. The service must properly determine which member of the substitution group was sent in the request.

Consumer implementation
The generated method signature uses the Java class supporting the type of the substitution group’s head element. Because the member elements of a substitution group are either of the same type as the head element or of a type derived from the head element’s type, the Java classes generated to support the members of the substitution group inherit from the Java class generated to support the head element. Java’s type hierarchy natively supports using subclasses in place of the parent class.

Because of how Apache CXF generates the types for a substitution group and Java’s type hierarchy, the client can invoke checkWidgets() without using any special code. When developing the logic to invoke checkWidgets() you can pass in an object of one of the classes generated to support the widget substitution group.

Example 37.14, “Consumer Invoking checkWidgets()” shows a consumer invoking checkWidgets().

Example 37.14. Consumer Invoking checkWidgets()

System.out.println("What type of widgets do you want to order?");
System.out.println("1 - Normal");
System.out.println("2 - Wood");
System.out.println("3 - Plastic");
System.out.println("Selection [1-3]");
String selection = reader.readLine();
String trimmed = selection.trim();
char widgetType = trimmed.charAt(0);
switch (widgetType)
{
    case '1':
        WidgetType widget = new WidgetType();
        ...
        break;
    case '2':
        WoodWidgetType widget = new WoodWidgetType();
        ...
        break;
    case '3':
        PlasticWidgetType widget = new PlasticWidgetType();
        ...
        break;
    default :
        System.out.println("Invalid Widget Selection!!");
}
proxy.checkWidgets(widgets);

Service implementation

The service’s implementation of checkWidgets() gets a widget description as a WidgetType object, checks the inventory of widgets, and returns the number of widgets in stock. Because all of the classes used to implement the substitution group inherit from the same base class, you can implement checkWidgets() without using any JAXB specific APIs.

All of the classes generated to support the members of the substitution group for widget extend the WidgetType class. Because of this fact, you can use instanceof to determine what type of widget was passed in and simply cast the widgetPart object into the more restrictive type if appropriate. Once you have the proper type of object, you can check the inventory of the right kind of widget.

Example 37.15, “Service Implementation of checkWidgets()” shows a possible implementation.

Example 37.15. Service Implementation of checkWidgets()

    public int checkWidgets(WidgetType widgetPart)
    {
        if (widgetPart instanceof WidgetType)
        {
            return checkWidgetInventory(widgetType);
        }
        else if (widgetPart instanceof WoodWidgetType)
37.3.3. The placeWidgetOrder Operation

Overview

placeWidgetOrder uses two complex types containing the substitution group. This operation demonstrates to use such a structure in a Java implementation. Both the consumer and the service must get and set members of a substitution group.

Consumer implementation

To invoke placeWidgetOrder() the consumer must construct a widget order containing one element of the widget substitution group. When adding the widget to the order, the consumer should use the object factory methods generated for each element of the substitution group. This ensures that the runtime and the service can correctly process the order. For example, if an order is being placed for a plastic widget, the ObjectFactory.createPlasticWidget() method is used to create the element before adding it to the order.

Example 37.16, "Setting a Substitution Group Member" shows consumer code for setting the widget property of the WidgetOrderInfo object.

Example 37.16. Setting a Substitution Group Member

```
ObjectFactory of = new ObjectFactory();

WidgetOrderInfo order = new of.createWidgetOrderInfo();
...
System.out.println();
System.out.println("What color widgets do you want to order?");
String color = reader.readLine();
System.out.println();
System.out.println("What shape widgets do you want to order?");
String shape = reader.readLine();
System.out.println();
System.out.println("What type of widgets do you want to order?");
System.out.println("1 - Normal");
System.out.println("2 - Wood");
System.out.println("3 - Plastic");
String selection = reader.readLine();
System.out.println();
char widgetType = selection.charAt(0);
switch (widgetType)
```
{  
  case '1':
    {
      WidgetType widget = of.createWidgetType();
      widget.setColor(color);
      widget.setShape(shape);
      JAXB<WidgetType> widgetElement = of.createWidget(widget);
      order.setWidget(widgetElement);
      break;
    }
  case '2':
    {
      WoodWidgetType woodWidget = of.createWoodWidgetType();
      woodWidget.setColor(color);
      woodWidget.setShape(shape);
      System.out.println();
      System.out.println("What type of wood are your widgets?\n");
      String wood = reader.readLine();
      woodWidget.setWoodType(wood);
      JAXB<WoodWidgetType> widgetElement = of.createWoodWidget(woodWidget);
      order.setWoodWidget(widgetElement);
      break;
    }
  case '3':
    {
      PlasticWidgetType plasticWidget = of.createPlasticWidgetType();
      plasticWidget.setColor(color);
      plasticWidget.setShape(shape);
      System.out.println();
      System.out.println("What type of mold to use for your\nwidgets?\n");
      String mold = reader.readLine();
      plasticWidget.setMoldProcess(mold);
      JAXB<WidgetType> widgetElement = of.createPlasticWidget(plasticWidget);
      order.setPlasticWidget(widgetElement);
      break;
    }
  default:
    System.out.println("Invalid Widget Selection!!\n");
  }

Service implementation

The placeWidgetOrder() method receives an order in the form of a WidgetOrderInfo object, processes the order, and returns a bill to the consumer in the form of a WidgetOrderBillInfo object. The orders can be for a plain widget, a plastic widget, or a wooden widget. The type of widget ordered is determined by what type of object is stored in widgetOrderForm object’s widget property. The widget property is a substitution group and can contain a widget element, a woodWidget element, or a plasticWidget element.

The implementation must determine which of the possible elements is stored in the order. This can be accomplished using the JAXBElement<? extends T> object’s getName() method to determine the element’s QName. The QName can then be used to determine which element in the substitution group
is in the order. Once the element included in the bill is known, you can extract its value into the proper type of object.

Example 37.17, “Implementation of `placeWidgetOrder()`” shows a possible implementation.

```java
public com.widgetvendor.types.widgettypes.WidgetOrderBillInfo placeWidgetOrder(WidgetOrderInfo widgetOrderForm) {
    ObjectFactory of = new ObjectFactory();

    WidgetOrderBillInfo bill = new WidgetOrderBillInfo();
    // Copy the shipping address and the number of widgets
    // ordered from widgetOrderForm to bill
    ...

    int numOrdered = widgetOrderForm.getAmount();

    String elementName = widgetOrderForm.getWidget().getName().getLocalPart();
    if (elementName.equals("woodWidget")
    {
        WoodWidgetType widget=order.getWidget().getValue();
        buildWoodWidget(widget, numOrdered);
        // Add the widget info to bill
        JAXBElement<WoodWidgetType> widgetElement = of.createWoodWidget(widget);
        bill.setWidget(widgetElement);
        float amtDue = numOrdered * 0.75;
        bill.setAmountDue(amtDue);
    }
    else if (elementName.equals("plasticWidget")
    {
        PlasticWidgetType widget=order.getWidget().getValue();
        buildPlasticWidget(widget, numOrdered);
        // Add the widget info to bill
        JAXBElement<PlasticWidgetType> widgetElement = of.createPlasticWidget(widget);
        bill.setWidget(widgetElement);
        float amtDue = numOrdered * 0.90;
        bill.setAmountDue(amtDue);
    }
    else
    {
        WidgetType widget=order.getWidget().getValue();
        buildWidget(widget, numOrdered);
        // Add the widget info to bill
        JAXBElement<WidgetType> widgetElement = of.createWidget(widget);
        bill.setWidget(widgetElement);
        float amtDue = numOrdered * 0.30;
        bill.setAmountDue(amtDue);
    }
}
```
The code in Example 37.17, "Implementation of placeWidgetOrder()" does the following:

- Instantiates an object factory to create elements.
- Instantiates a WidgetOrderBillInfo object to hold the bill.
- Gets the number of widgets ordered.
- Gets the local name of the element stored in the order.
- Checks to see if the element is a woodWidget element.
- Extracts the value of the element from the order to the proper type of object.
- Creates a JAXBElement<T> object placed into the bill.
- Sets the bill object’s widget property.
- Sets the bill object’s amountDue property.
CHAPTER 38. CUSTOMIZING HOW TYPES ARE GENERATED

Abstract

The default JAXB mappings address most of the cases encountered when using XML Schema to define the objects for a Java application. For instances where the default mappings are insufficient, JAXB provides an extensive customization mechanism.

38.1. BASICS OF CUSTOMIZING TYPE MAPPINGS

Overview

The JAXB specification defines a number of XML elements that customize how Java types are mapped to XML Schema constructs. These elements can be specified in-line with XML Schema constructs. If you cannot, or do not want to, modify the XML Schema definitions, you can specify the customizations in external binding document.

Namespace

The elements used to customize the JAXB data bindings are defined in the namespace http://java.sun.com/xml/ns/jaxb. You must add a namespace declaration similar to the one shown in Example 38.1, “JAXB Customization Namespace”. This is added to the root element of all XML documents defining JAXB customizations.

Example 38.1. JAXB Customization Namespace

```xml
xmlns:jaxb="http://java.sun.com/xml/ns/jaxb"
```

Version declaration

When using the JAXB customizations, you must indicate the JAXB version being used. This is done by adding a `jaxb:version` attribute to the root element of the external binding declaration. If you are using in-line customization, you must include the `jaxb:version` attribute in the `schema` element containing the customizations. The value of the attribute is always 2.0.

Example 38.2, “Specifying the JAXB Customization Version” shows an example of the `jaxb:version` attribute used in a `schema` element.

Example 38.2. Specifying the JAXB Customization Version

```xml
< schema ... 
  jaxb:version="2.0">
```

Using in-line customization

The most direct way to customize how the code generators map XML Schema constructs to Java constructs is to add the customization elements directly to the XML Schema definitions. The JAXB customization elements are placed inside the `xsd:appinfo` element of the XML schema construct that is being modified.
Example 38.3, “Customized XML Schema” shows an example of a schema containing an in-line JAXB customization.

Example 38.3. Customized XML Schema

```xml
<schema targetNamespace="http://widget.com/types/widgetTypes"
  xmlns="http://www.w3.org/2001/XMLSchema"
  xmlns:jaxb="http://java.sun.com/xml/ns/jaxb"
  jaxb:version="2.0">
  <complexType name="size">
    <annotation>
      <appinfo>
        <jaxb:class name="widgetSize"/>
      </appinfo>
    </annotation>
    <sequence>
      <element name="longSize" type="xsd:string"/>
      <element name="numberSize" type="xsd:int"/>
    </sequence>
  </complexType>
</schema>
```

Using an external binding declaration

When you cannot, or do not want to, make changes to the XML Schema document that defines your type, you can specify the customizations using an external binding declaration. An external binding declaration consists of a number of nested `jaxb:bindings` elements. Example 38.4, “JAXB External Binding Declaration Syntax” shows the syntax of an external binding declaration.

Example 38.4. JAXB External Binding Declaration Syntax

```xml
<jxb:bindings xmlns:jxb="http://java.sun.com/xml/ns/jxb"
  xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  jxb:version="2.0">
  <jaxb:bindings [schemaLocation="schemaUri" | wsdlLocation="wsdlUri"ба>
    <jaxb:bindings node="nodeXPath" ba
      binding declaration
    </jaxb:bindings>
    ...
  </jaxb:bindings>
</jaxb:bindings>
```

The `schemaLocation` attribute and the `wsdlLocation` attribute are used to identify the schema document to which the modifications are applied. Use the `schemaLocation` attribute if you are generating code from a schema document. Use the `wsdlLocation` attribute if you are generating code from a WSDL document.

The `node` attribute is used to identify the specific XML schema construct that is to be modified. It is an XPath statement that resolves to an XML Schema element.

Given the schema document `widgetSchema.xsd`, shown in Example 38.5, “XML Schema File”, the external binding declaration shown in Example 38.6, “External Binding Declaration” modifies the generation of the complex type `size`.

Example 38.5. XML Schema File
Example 38.6. External Binding Declaration

```xml
  xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  jaxb:version="2.0">
  <jaxb:bindings schemaLocation="wsdlSchema.xsd">
    <jaxb:bindings node="xsd:complexType[@name='size']">
      <jaxb:class name="widgetSize" />
    </jaxb:bindings>
  </jaxb:bindings>
</jaxb:bindings>
```

To instruct the code generators to use the external binging declaration use the `wsdl2java` tool’s `-b binding-file` option, as shown below:

```
wsdl2java -b widgetBinding.xml widget.wsdl
```

### 38.2. SPECIFYING THE JAVA CLASS OF AN XML SCHEMA PRIMITIVE

#### Overview

By default, XML Schema types are mapped to Java primitive types. While this is the most logical mapping between XML Schema and Java, it does not always meet the requirements of the application developer. You might want to map an XML Schema primitive type to a Java class that can hold extra information, or you might want to map an XML primitive type to a class that allows for simple type substitution.

The JAXB `javaType` customization element allows you to customize the mapping between an XML Schema primitive type and a Java primitive type. It can be used to customize the mappings at both the global level and the individual instance level. You can use the `javaType` element as part of a simple type definition or as part of a complex type definition.

When using the `javaType` customization element you must specify methods for converting the XML representation of the primitive type to and from the target Java class. Some mappings have default conversion methods. For instances where there are no default mappings, Apache CXF provides JAXB methods to ease the development of the required methods.

#### Syntax
The **javaType** customization element takes four attributes, as described in Table 38.1, “Attributes for Customizing the Generation of a Java Class for an XML Schema Type”.

### Table 38.1. Attributes for Customizing the Generation of a Java Class for an XML Schema Type

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Required</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Yes</td>
<td>Specifies the name of the Java class to which the XML Schema primitive type is mapped. It must be either a valid Java class name or the name of a Java primitive type. You must ensure that this class exists and is accessible to your application. The code generator does not check for this class.</td>
</tr>
<tr>
<td>xmlType</td>
<td>No</td>
<td>Specifies the XML Schema primitive type that is being customized. This attribute is only used when the <strong>javaType</strong> element is used as a child of the <strong>globalBindings</strong> element.</td>
</tr>
<tr>
<td>parseMethod</td>
<td>No</td>
<td>Specifies the method responsible for parsing the string-based XML representation of the data into an instance of the Java class. For more information see the section called “Specifying the converters”.</td>
</tr>
<tr>
<td>printMethod</td>
<td>No</td>
<td>Specifies the method responsible for converting a Java object to the string-based XML representation of the data. For more information see the section called “Specifying the converters”.</td>
</tr>
</tbody>
</table>

The **javaType** customization element can be used in three ways:

- To modify all instances of an XML Schema primitive type – The **javaType** element modifies all instances of an XML Schema type in the schema document when it is used as a child of the **globalBindings** customization element. When it is used in this manner, you must specify a value for the **xmlType** attribute that identifies the XML Schema primitive type being modified.

**Example 38.7. Global Primitive Type Customization**

```xml
<schema targetNamespace="http://widget.com/types/widgetTypes"
         xmlns="http://www.w3.org/2001/XMLSchema">
```

CHAPTER 38. CUSTOMIZING HOW TYPES ARE GENERATED
To modify a simple type definition — The `javaType` element modifies the class generated for all instances of an XML simple type when it is applied to a named simple type definition. When using the `javaType` element to modify a simple type definition, do not use the `xmlType` attribute.

Example 38.8, "Binding File for Customizing a Simple Type" shows an external binding file that modifies the generation of a simple type named `zipCode`.

```
                xmlns:xsd="http://www.w3.org/2001/XMLSchema"
                jaxb:version="2.0">
  <jaxb:bindings wsdlLocation="widgets.wsdl">
    <jaxb:bindings node="xsd:simpleType[@name='zipCode']">
      <jaxb:javaType name="com.widgetVendor.widgetTypes.zipCodeType"
                     parseMethod="com.widgetVendor.widgetTypes.support.parseZipCode"
                     printMethod="com.widgetVendor.widgetTypes.support.printZipCode"/>
    </jaxb:bindings>
  </jaxb:bindings>
</jaxb:bindings>
```

To modify an element or attribute of a complex type definition — The `javaType` can be applied to individual parts of a complex type definition by including it as part of a JAXB property customization. The `javaType` element is placed as a child to the property’s `baseType` element. When using the `javaType` element to modify a specific part of a complex type definition, do not use the `xmlType` attribute.

Example 38.9, "Binding File for Customizing an Element in a Complex Type" shows a binding file that modifies an element of a complex type.

```
                xmlns:xsd="http://www.w3.org/2001/XMLSchema"
                jaxb:version="2.0">
  <jaxb:bindings schemaLocation="enumMap.xsd">
    <jaxb:bindings node="xsd:ComplexType[@name='widgetOrderInfo']">
      <jaxb:bindings node="xsd:element[@name='cost']">
        <jaxb:property>
```

<jaxb:property>
<jaxb:baseType>
<jaxb:javaType name="com.widgetVendor.widgetTypes.costType"
    parseMethod="parseCost"
    printMethod="printCost" />
</jaxb:baseType>
</jaxb:property>
</jaxb:bindings>
</jaxb:bindings>

For more information on using the **baseType** element see Section 38.6, “Specifying the Base Type of an Element or an Attribute”.

### Specifying the converters

The Apache CXF cannot convert XML Schema primitive types into random Java classes. When you use the **javaType** element to customize the mapping of an XML Schema primitive type, the code generator creates an adapter class that is used to marshal and unmarshal the customized XML Schema primitive type. A sample adapter class is shown in Example 38.10, “JAXB Adapter Class”.

**Example 38.10. JAXB Adapter Class**

```java
public class Adapter1 extends XmlAdapter<String, javaType>
{
    public javaType unmarshal(String value)
    {
        return(parseMethod(value));
    }

    public String marshal(javaType value)
    {
        return(printMethod(value));
    }
}
```

**parseMethod** and **printMethod** are replaced by the value of the corresponding **parseMethod** attribute and **printMethod** attribute. The values must identify valid Java methods. You can specify the method’s name in one of two ways:

- A fully qualified Java method name in the form of `packagename.ClassName.methodName`
- A simple method name in the form of `methodName`

When you only provide a simple method name, the code generator assumes that the method exists in the class specified by the **javaType** element’s **name** attribute.

**IMPORTANT**

The code generators **do not** generate parse or print methods. You are responsible for supplying them. For information on developing parse and print methods see the section called “Implementing converters”.

---

369
If a value for the `parseMethod` attribute is not provided, the code generator assumes that the Java class specified by the `name` attribute has a constructor whose first parameter is a Java `String` object. The generated adapter’s `unmarshal()` method uses the assumed constructor to populate the Java object with the XML data.

If a value for the `printMethod` attribute is not provided, the code generator assumes that the Java class specified by the `name` attribute has a `toString()` method. The generated adapter’s `marshal()` method uses the assumed `toString()` method to convert the Java object to XML data.

If the `javaType` element’s `name` attribute specifies a Java primitive type, or one of the Java primitive’s wrapper types, the code generators use the default converters. For more information on default converters see the section called “Default primitive type converters”.

**What is generated**

As mentioned in the section called “Specifying the converters”, using the `javaType` customization element triggers the generation of one adapter class for each customization of an XML Schema primitive type. The adapters are named in sequence using the pattern `AdapterN`. If you specify two primitive type customizations, the code generators create two adapter classes: `Adapter1` and `Adapter2`.

The code generated for an XML schema construct depends on whether the effected XML Schema construct is a globally defined element or is defined as part of a complex type.

When the XML Schema construct is a globally defined element, the object factory method generated for the type is modified from the default method as follows:

- The method is decorated with an `@XmlJavaTypeAdapter` annotation. The annotation instructs the runtime which adapter class to use when processing instances of this element. The adapter class is specified as a class object.
- The default type is replaced by the class specified by the `javaType` element’s `name` attribute.

Example 38.11, “Customized Object Factory Method for a Global Element” shows the object factory method for an element affected by the customization shown in Example 38.7, “Global Primitive Type Customization”.

```java
@XmlElementDecl(namespace = "http://widgetVendor.com/types/widgetTypes", name = "shorty")
@XmlJavaTypeAdapter(org.w3._2001.xmlschema.Adapter1.class)
public JAXBElement<Integer> createShorty(Integer value) {
    return new JAXBElement<Integer>(_Shorty_QNAME, Integer.class, null, value);
}
```

When the XML Schema construct is defined as part of a complex type, the generated Java property is modified as follows:

- The property is decorated with an `@XmlJavaTypeAdapter` annotation. The annotation instructs the runtime which adapter class to use when processing instances of this element. The adapter class is specified as a class object.
- The property’s `@XmlElement` includes a `type` property.
The value of the **type** property is the class object representing the generated object’s default base type. In the case of XML Schema primitive types, the class is **String**.

- The property is decorated with an [@XmlSchemaType](#) annotation. The annotation identifies the XML Schema primitive type of the construct.
- The default type is replaced by the class specified by the **javaType** element’s **name** attribute.

Example 38.12, “Customized Complex Type” shows the object factory method for an element affected by the customization shown in Example 38.7, “Global Primitive Type Customization”.

---

**Example 38.12. Customized Complex Type**

```java
public class NumInventory {

    @XmlElement(required = true, type = String.class) @XmlJavaTypeAdapter(Adapter1.class)
    @XmlSchemaType(name = "short") protected Integer numLeft;

    protected String size;

    public Integer getNumLeft() {
        return numLeft;
    }

    public void setNumLeft(Integer value) {
        this.numLeft = value;
    }

    public String getSize() {
        return size;
    }

    public void setSize(String value) {
        this.size = value;
    }

}
```

---

**Implementing converters**

The Apache CXF runtime does not know how to convert XML primitive types to and from the Java class specified by the **javaType** element, except that it should call the methods specified by the **parseMethod** attribute and the **printMethod** attribute. You are responsible for providing implementations of the methods the runtime calls. The implemented methods must be capable of working with the lexical structures of the XML primitive type.

To simplify the implementation of the data conversion methods, Apache CXF provides the `javax.xml.bind.DatatypeConverter` class. This class provides methods for parsing and printing all of the XML Schema primitive types. The parse methods take string representations of the XML data and they return an instance of the default type defined in Table 34.1, “XML Schema Primitive Type to Java Native Type Mapping”. The print methods take an instance of the default type and they return a string representation of the XML data.
The Java documentation for the DatatypeConverter class can be found at

Default primitive type converters

When specifying a Java primitive type, or one of the Java primitive type Wrapper classes, in the
javaType element’s name attribute, it is not necessary to specify values for the parseMethod attribute
or the printMethod attribute. The Apache CXF runtime substitutes default converters if no values are
provided.

The default data converters use the JAXB DatatypeConverter class to parse the XML data. The default
converters will also provide any type casting necessary to make the conversion work.

38.3. GENERATING JAVA CLASSES FOR SIMPLE TYPES

Overview

By default, named simple types do not result in generated types unless they are enumerations. Elements
defined using a simple type are mapped to properties of a Java primitive type.

There are instances when you need to have simple types generated into Java classes, such as is when
you want to use type substitution.

To instruct the code generators to generate classes for all globally defined simple types, set the
globalBindings customization element’s mapSimpleTypeDef to true.

Adding the customization

To instruct the code generators to create Java classes for named simple types add the globalBinding
element’s mapSimpleTypeDef attribute and set its value to true.

Example 38.13, “in-Line Customization to Force Generation of Java Classes for SimpleTypes” shows an
in-line customization that forces the code generator to generate Java classes for named simple types.

Example 38.13. in-Line Customization to Force Generation of Java Classes for SimpleTypes

```xml
<schema targetNamespace="http://widget.com/types/widgetTypes"
       xmlns="http://www.w3.org/2001/XMLSchema"
       xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
       xmlns:jaxb="http://java.sun.com/xml/ns/jaxb"
       jaxb:version="2.0">
  <annotation>
    <appinfo>
      <jaxb:globalBindings mapSimpleTypeDef="true" />
    </appinfo>
  </annotation>
  ...
</schema>
```

Example 38.14, “Binding File to Force Generation of Constants” shows an external binding file that
customizes the generation of simple types.

```xml
    xmlns:xsd="http://www.w3.org/2001/XMLSchema"
    jAXB:version="2.0">
    <jaxb:bindings schemaLocation="types.xsd">
        <jaxb:globalBindings mapSimpleTypeDef="true" />
    </jaxb:bindings>
</jaxb:bindings>
```

**IMPORTANT**

This customization only affects named simple types that are defined in the `global` scope.

**Generated classes**

The class generated for a simple type has one property called `value`. The `value` property is of the Java type defined by the mappings in Section 34.1, “Primitive Types”. The generated class has a getter and a setter for the `value` property.

Example 38.16, “Customized Mapping of a Simple Type” shows the Java class generated for the simple type defined in Example 38.15, “Simple Type for Customized Mapping”.

**Example 38.15. Simple Type for Customized Mapping**

```xml
<simpleType name="simpleton">
    <restriction base="xsd:string">
        <maxLength value="10"/>
    </restriction>
</simpleType>
```

**Example 38.16. Customized Mapping of a Simple Type**

```java
@XmlAccessorType(XmlAccessType.FIELD)
@XmlType(name = "simpleton", propOrder = {"value"})
public class Simpleton {

    @XmlValue
    protected String value;

    public String getValue() {
        return value;
    }

    public void setValue(String value) {
        this.value = value;
    }
}
```
38.4. CUSTOMIZING ENUMERATION MAPPING

Overview

If you want enumerated types that are based on a schema type other than `xsd:string`, you must instruct the code generator to map it. You can also control the name of the generated enumeration constants.

The customization is done using the `jaxb:typesafeEnumClass` element along with one or more `jaxb:typesafeEnumMember` elements.

There might also be instances where the default settings for the code generator cannot create valid Java identifiers for all of the members of an enumeration. You can customize how the code generators handle this by using an attribute of the `globalBindings` customization.

Member name customizer

If the code generator encounters a naming collision when generating the members of an enumeration or if it cannot create a valid Java identifier for a member of the enumeration, the code generator, by default, generates a warning and does not generate a Java `enum` type for the enumeration.

You can alter this behavior by adding the `globalBinding` element’s `typesafeEnumMemberName` attribute. The `typesafeEnumMemberName` attribute’s values are described in Table 38.2, “Values for Customizing Enumeration Member Name Generation”.

Table 38.2. Values for Customizing Enumeration Member Name Generation

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>skipGeneration</code></td>
<td>Specifies that the Java <code>enum</code> type is not generated and generates a warning.</td>
</tr>
<tr>
<td><code>generateName</code></td>
<td>Specifies that member names will be generated following the pattern <code>VALUE_N</code>.</td>
</tr>
<tr>
<td><code>generateError</code></td>
<td>Specifies that the code generator generates an error when it cannot map an enumeration to a Java <code>enum</code> type.</td>
</tr>
</tbody>
</table>

Example 38.17, “Customization to Force Type Safe Member Names” shows an in-line customization that forces the code generator to generate type safe member names.

Example 38.17. Customization to Force Type Safe Member Names

```xml
<schema targetNamespace="http://widget.com/types/widgetTypes"
    xmlns="http://www.w3.org/2001/XMLSchema"
    xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/
    xmlns:jaxb="http://java.sun.com/xml/ns/jaxb"
    jaxb:version="2.0">
    <annotation>
        <appinfo>
            <jaxb:globalBindings typesafeEnumMemberName="generateName" />
        </appinfo>
    </annotation>
</schema>
```
Class customizer

The `jaxb:typesafeEnumClass` element specifies that an XML Schema enumeration should be mapped to a Java `enum` type. It has two attributes that are described in Table 38.3, “Attributes for Customizing a Generated Enumeration Class”. When the `jaxb:typesafeEnumClass` element is specified in-line, it must be placed inside the `xsd:annotation` element of the simple type it is modifying.

Table 38.3. Attributes for Customizing a Generated Enumeration Class

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>Specifies the name of the generated Java <code>enum</code> type. This value must be a valid Java identifier.</td>
</tr>
<tr>
<td>map</td>
<td>Specifies if the enumeration should be mapped to a Java <code>enum</code> type. The default value is <code>true</code>.</td>
</tr>
</tbody>
</table>

Member customizer

The `jaxb:typesafeEnumMember` element specifies the mapping between an XML Schema `enumeration` facet and a Java `enum` type constant. You must use one `jaxb:typesafeEnumMember` element for each `enumeration` facet in the enumeration being customized.

When using in-line customization, this element can be used in one of two ways:

- It can be placed inside the `xsd:annotation` element of the `enumeration` facet it is modifying.
- They can all be placed as children of the `jaxb:typesafeEnumClass` element used to customize the enumeration.

The `jaxb:typesafeEnumMember` element has a `name` attribute that is required. The `name` attribute specifies the name of the generated Java `enum` type constant. It’s value must be a valid Java identifier.

The `jaxb:typesafeEnumMember` element also has a `value` attribute. The `value` is used to associate the `enumeration` facet with the proper `jaxb:typesafeEnumMember` element. The value of the `value` attribute must match one of the values of an `enumeration` facets’ `value` attribute. This attribute is required when you use an external binding specification for customizing the type generation, or when you group the `jaxb:typesafeEnumMember` elements as children of the `jaxb:typesafeEnumClass` element.

Examples

Example 38.18, “In-line Customization of an Enumerated Type” shows an enumerated type that uses in-line customization and has the enumeration’s members customized separately.
Example 38.19, “In-line Customization of an Enumerated Type Using a Combined Mapping” shows an enumerated type that uses in-line customization and combines the member’s customization in the class customization.

Example 38.19. In-line Customization of an Enumerated Type Using a Combined Mapping
38.5. CUSTOMIZING FIXED VALUE ATTRIBUTE MAPPING

Overview

By default, the code generators map attributes defined as having a fixed value to normal properties. When using schema validation, Apache CXF can enforce the schema definition (see Section 24.3.4.7, “Schema Validation Type Values”). However, using schema validation increases message processing time.

Another way to map attributes that have fixed values to Java is to map them to Java constants. You can
instruct the code generator to map fixed value attributes to Java constants using the `globalBindings` customization element. You can also customize the mapping of fixed value attributes to Java constants at a more localized level using the `property` element.

**Global customization**

You can alter this behavior by adding the `globalBinding` element’s `fixedAttributeAsConstantProperty` attribute. Setting this attribute to `true` instructs the code generator to map any attribute defined using `fixed` attribute to a Java constant.

Example 38.21, “in-Line Customization to Force Generation of Constants” shows an in-line customization that forces the code generator to generate constants for attributes with fixed values.

```
<schema targetNamespace="http://widget.com/types/widgetTypes"
    xmlns="http://www.w3.org/2001/XMLSchema"
    xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
    xmlns:jaxb="http://java.sun.com/xml/ns/jaxb"
    jaxb:version="2.0">
  <annotation>
    <appinfo>
      <jaxb:globalBindings fixedAttributeAsConstantProperty="true"/>
    </appinfo>
  </annotation>
  ...
</schema>
```

Example 38.22, “Binding File to Force Generation of Constants” shows an external binding file that customizes the generation of fixed attributes.

```
    xmlns:xsd="http://www.w3.org/2001/XMLSchema"
    jaxb:version="2.0">
  <jaxb:globalBindings fixedAttributeAsConstantProperty="true"/>
  ...
</jaxb:bindings>
```

**Local mapping**

You can customize attribute mapping on a per-attribute basis using the `property` element’s `fixedAttributeAsConstantProperty` attribute. Setting this attribute to `true` instructs the code generator to map any attribute defined using `fixed` attribute to a Java constant.

Example 38.23, “In-Line Customization to Force Generation of Constants” shows an in-line customization that forces the code generator to generate constants for a single attribute with a fixed value.
Example 38.23. In-Line Customization to Force Generation of Constants

```xml
<schema targetNamespace="http://widget.com/types/widgetTypes"
   xmlns="http://www.w3.org/2001/XMLSchema"
   xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
   xmlns:jaxb="http://java.sun.com/xml/ns/jaxb"
   jaxb:version="2.0">
   <complexType name="widgetAttr">
     <sequence>
       ...
     </sequence>
     <attribute name="fixer" type="xsd:int" fixed="7">
       <annotation>
         <appinfo>
           <jaxb:property fixedAttributeAsConstantProperty="true"/>
         </appinfo>
       </annotation>
     </attribute>
   </complexType>
</schema>
```

Example 38.24, “Binding File to Force Generation of Constants” shows an external binding file that customizes the generation of a fixed attribute.

Example 38.24. Binding File to Force Generation of Constants

```xml
   xmlns:xsd="http://www.w3.org/2001/XMLSchema"
   jaxb:version="2.0">
   <jaxb:bindings schemaLocation="types.xsd">
     <jaxb:bindings node="xsd:complexType[@name='widgetAttr']">
       <jaxb:bindings node="xsd:attribute[@name='fixer']">
         <jaxb:property fixedAttributeAsConstantProperty="true"/>
       </jaxb:bindings>
     </jaxb:bindings>
   </jaxb:bindings>
</jaxb:bindings>
```

Java mapping

In the default mapping, all attributes are mapped to standard Java properties with getter and setter methods. When this customization is applied to an attribute defined using the `fixed` attribute, the attribute is mapped to a Java constant, as shown in Example 38.25, “Mapping of a Fixed Value Attribute to a Java Constant”.

Example 38.25. Mapping of a Fixed Value Attribute to a Java Constant

```java
@XmlAttribute
public final static type NAME = value;
```

type is determined by mapping the base type of the attribute to a Java type using the mappings described in Section 34.1, “Primitive Types”.

NAME is determined by converting the value of the attribute element’s name attribute to all capital letters.

value is determined by the value of the attribute element’s fixed attribute.

For example, the attribute defined in Example 38.23, “In-Line Customization to Force Generation of Constants” is mapped as shown in Example 38.26, “Fixed Value Attribute Mapped to a Java Constant”.

Example 38.26. Fixed Value Attribute Mapped to a Java Constant

```java
@XmlElement(name = "widgetAttr")
public class WidgetAttr {
    ...
    @XmlAttribute
    public final static int FIXER = 7;
    ...
}
```

38.6. SPECIFYING THE BASE TYPE OF AN ELEMENT OR AN ATTRIBUTE

Overview

Occasionally you need to customize the class of the object generated for an element, or for an attribute defined as part of an XML Schema complex type. For example, you might want to use a more generalized class of object to allow for simple type substitution.

One way to do this is to use the JAXB base type customization. It allows a developer, on a case by case basis, to specify the class of object generated to represent an element or an attribute. The base type customization allows you to specify an alternate mapping between the XML Schema construct and the generated Java object. This alternate mapping can be a simple specialization or a generalization of the default base class. It can also be a mapping of an XML Schema primitive type to a Java class.

Customization usage

To apply the JAXB base type property to an XML Schema construct use the JAXB baseType customization element. The baseType customization element is a child of the JAXB property element, so it must be properly nested.

Depending on how you want to customize the mapping of the XML Schema construct to Java object, you add either the baseType customization element’s name attribute, or a javaType child element. The name attribute is used to map the default class of the generated object to another class within the same class hierarchy. The javaType element is used when you want to map XML Schema primitive types to a Java class.
IMPORTANT

You cannot use both the **name** attribute and a **javaType** child element in the same **baseType** customization element.

Specializing or generalizing the default mapping

The **baseType** customization element’s **name** attribute is used to redefine the class of the generated object to a class within the same Java class hierarchy. The attribute specifies the fully qualified name of the Java class to which the XML Schema construct is mapped. The specified Java class must be either a super-class or a sub-class of the Java class that the code generator normally generates for the XML Schema construct. For XML Schema primitive types that map to Java primitive types, the wrapper class is used as the default base class for the purpose of customization.

For example, an element defined as being of **xsd:int** uses **java.lang.Integer** as its default base class. The value of the **name** attribute can specify any super-class of **Integer** such as **Number** or **Object**.

For simple type substitution, the most common customization is to map the primitive types to an **Object** object.

**Example 38.27, “In-Line Customization of a Base Type”** shows an in-line customization that maps one element in a complex type to a Java **Object** object.

**Example 38.27. In-Line Customization of a Base Type**

```xml
<complexType name="widgetOrderInfo">
  <all>
    <element name="amount" type="xsd:int" />
    <element name="shippingAdress" type="Address">
      <annotation>
        <appinfo>
          <jaxb:property>
            <jaxb:baseType name="java.lang.Object" />
          </jaxb:property>
        </appinfo>
      </annotation>
    </element>
    <element name="type" type="xsd:string"/>
  </all>
</complexType>
```

**Example 38.28, “External Binding File to Customize a Base Type”** shows an external binding file for the customization shown in **Example 38.27, “In-Line Customization of a Base Type”**.

**Example 38.28. External Binding File to Customize a Base Type**

```xml
<jaxb:bindings xmlns:jxb="http://java.sun.com/xml/ns/jaxb"
  xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  jaxb:version="2.0">
  <jaxb:bindings schemaLocation="enumMap.xsd">
    <jaxb:bindings node="xsd:ComplexType[@name='widgetOrderInfo']">
      <jaxb:bindings node="xsd:element[@name='shippingAddress']">
        <jaxb:property>
          <jaxb:baseType name="java.lang.Object" />
        </jaxb:property>
      </jaxb:bindings>
    </jaxb:bindings>
  </jaxb:bindings>
</jaxb:bindings>
```

---

381
The resulting Java object’s @XmlElement annotation includes a type property. The value of the type property is the class object representing the generated object’s default base type. In the case of XML Schema primitive types, the class is the wrapper class of the corresponding Java primitive type.

Example 38.29, “Java Class with a Modified Base Class” shows the class generated based on the schema definition in Example 38.28, “External Binding File to Customize a Base Type”.

Example 38.29. Java Class with a Modified Base Class

```java
public class WidgetOrderInfo {

  protected int amount;
  @XmlElement(required = true)
  protected String type;

  @XmlElement(required = true, type = Address.class)
  protected Object shippingAddress;

...

  public Object getShippingAddress() {
    return shippingAddress;
  }

  public void setShippingAddress(Object value) {
    this.shippingAddress = value;
  }
}
```

Usage with javaType

The javaType element can be used to customize how elements and attributes defined using XML Schema primitive types are mapped to Java objects. Using the javaType element provides a lot more flexibility than simply using the baseType element’s name attribute. The javaType element allows you to map a primitive type to any class of object.

For a detailed description of using the javaType element, see Section 38.2, “Specifying the Java Class of an XML Schema Primitive”.
CHAPTER 39. USING A JAXBCONTEXT OBJECT

Abstract

The JAXBContext object allows the Apache CXF's runtime to transform data between XML elements and Java object. Application developers need to instantiate a JAXBContext object they want to use JAXB objects in message handlers and when implementing consumers that work with raw XML messages.

OVERVIEW

The JAXBContext object is a low-level object used by the runtime. It allows the runtime to convert between XML elements and their corresponding Java representations. An application developer generally does not need to work with JAXBContext objects. The marshaling and unmarshaling of XML data is typically handled by the transport and binding layers of a JAX-WS application.

However, there are instances when an application will need to manipulate the XML message content directly. In two of these instances:

- Section 41.1, “Using XML in a Consumer”
- Chapter 43, Writing Handlers

You will need instantiate a JAXBContext object using one of the two available JAXBContext.newInstance() methods.

BEST PRACTICES

JAXBContext objects are resource intensive to instantiate. It is recommended that an application create as few instances as possible. One way to do this is to create a single JAXBContext object that can manage all of the JAXB objects used by your application and share it among as many parts of your application as possible.

JAXBContext objects are thread safe.

GETTING A JAXBCONTEXT OBJECT USING AN OBJECT FACTORY

The JAXBContext class provides a newInstance() method, shown in Example 39.1, “Getting a JAXB Context Using Classes”, that takes a list of classes that implement JAXB objects.

Example 39.1. Getting a JAXB Context Using Classes

```
static JAXBContext newInstanceClass…classesToBeBoundJAXBException
```

The returned JAXBObject object will be able to marshal and unmarshal data for the JAXB object implemented by the classes passed into the method. It will also be able to work with any classes that are statically referenced from any of the classes passed into the method.

While it is possible to pass the name of every JAXB class used by your application to the newInstance() method it is not efficient. A more efficient way to accomplish the same goal is to pass in the object factory, or object factories, generated for your application. The resulting JAXBContext object will be able to manage any JAXB classes the specified object factories can instantiate.
GETTING A JAXBCONTEXT OBJECT USING PACKAGE NAMES

The `JAXBContext` class provides a `newInstance()` method, shown in Example 39.2, “Getting a JAXB Context Using Classes”, that takes a colon (:) separated list of package names. The specified packages should contain JAXB objects derived from XML Schema.

```java
Example 39.2. Getting a JAXB Context Using Classes

static JAXBContext newInstance(String contextPath) throws JAXBException
```

The returned `JAXBContext` object will be able to marshal and unmarshal data for all of the JAXB objects implemented by the classes in the specified packages.
CHAPTER 40. DEVELOPING ASYNCHRONOUS APPLICATIONS

Abstract

JAX-WS provides an easy mechanism for accessing services asynchronously. The SEI can specify additional methods that can be used to access a service asynchronously. The Apache CXF code generators generate the extra methods for you. You simply add the business logic.

40.1. TYPES OF ASYNCHRONOUS INVOCATION

In addition to the usual synchronous mode of invocation, Apache CXF supports two forms of asynchronous invocation:

- Polling approach – To invoke the remote operation using the polling approach, you call a method that has no output parameters, but returns a `javax.xml.ws.Response` object. The `Response` object (which inherits from the `javax.util.concurrent.Future` interface) can be polled to check whether or not a response message has arrived.

- Callback approach – To invoke the remote operation using the callback approach, you call a method that takes a reference to a callback object (of `javax.xml.ws.AsyncHandler` type) as one of its parameters. When the response message arrives at the client, the runtime calls back on the `AsyncHandler` object, and gives it the contents of the response message.

40.2. WSDL FOR ASYNCHRONOUS EXAMPLES

Example 40.1, “WSDL Contract for Asynchronous Example” shows the WSDL contract that is used for the asynchronous examples. The contract defines a single interface, GreeterAsync, which contains a single operation, `greetMeSometime`.

```
<?xml version="1.0" encoding="UTF-8"?>
<wsdl:definitions
 xmlns="http://schemas.xmlsoap.org/wsdl/"
 xmlns:soap="http://schemas.xmlsoap.org/wsdl/soap/"
 xmlns:tns="http://apache.org/hello_world_async_soap_http"
 xmlns:x1="http://apache.org/hello_world_async_soap_http/types"
 xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
 xmlns:xsd="http://www.w3.org/2001/XMLSchema"
 targetNamespace="http://apache.org/hello_world_async_soap_http"
 name="HelloWorld">
 <wsdl:types>
  <schema targetNamespace="http://apache.org/hello_world_async_soap_http/types"
   xmlns="http://www.w3.org/2001/XMLSchema"
   xmlns:x1="http://apache.org/hello_world_async_soap_http/types"
   elementFormDefault="qualified">
   <element name="greetMeSometime">
    <complexType>
     <sequence>
      <element name="requestType" type="xsd:string"/>
     </sequence>
    </complexType>
   </element>
  </schema>
 </wsdl:types>
</wsdl:definitions>
```
Overview

The asynchronous style of invocation requires extra stub code for the dedicated asynchronous methods defined on the SEI. This special stub code is not generated by default. To switch on the asynchronous feature and generate the requisite stub code, you must use the mapping customization feature from the WSDL 2.0 specification.

Customization enables you to modify the way the Maven code generation plug-in generates stub code. In particular, it enables you to modify the WSDL-to-Java mapping and to switch on certain features. Here, customization is used to switch on the asynchronous invocation feature. Customizations are
specified using a binding declaration, which you define using a `jaxws:bindings` tag (where the `jaxws` prefix is tied to the `http://java.sun.com/xml/ns/jaxws` namespace). There are two ways of specifying a binding declaration:

**External Binding Declaration**

When using an external binding declaration the `jaxws:bindings` element is defined in a file separate from the WSDL contract. You specify the location of the binding declaration file to code generator when you generate the stub code.

**Embedded Binding Declaration**

When using an embedded binding declaration you embed the `jaxws:bindings` element directly in a WSDL contract, treating it as a WSDL extension. In this case, the settings in `jaxws:bindings` apply only to the immediate parent element.

**Using an external binding declaration**

The template for a binding declaration file that switches on asynchronous invocations is shown in Example 40.2, “Template for an Asynchronous Binding Declaration”.

**Example 40.2. Template for an Asynchronous Binding Declaration**

```xml
<bindings xmlns:xsd="http://www.w3.org/2001/XMLSchema"
         xmlns:wsdl="http://schemas.xmlsoap.org/wsdl/"
         wsdlLocation="AffectedWSDL"
         xmlns="http://java.sun.com/xml/ns/jaxws">
  <bindings node="AffectedNode">
    <enableAsyncMapping>true</enableAsyncMapping>
  </bindings>
</bindings>
```

Where `AffectedWSDL` specifies the URL of the WSDL contract that is affected by this binding declaration. The `AffectedNode` is an XPath value that specifies which node (or nodes) from the WSDL contract are affected by this binding declaration. You can set `AffectedNode` to `wsdl:definitions`, if you want the entire WSDL contract to be affected. The `jaxws:enableAsyncMapping` element is set to `true` to enable the asynchronous invocation feature.

For example, if you want to generate asynchronous methods only for the GreeterAsync interface, you can specify `<bindings node="wsdl:definitions/wsdl:portType[@name='GreeterAsync']">` in the preceding binding declaration.

Assuming that the binding declaration is stored in a file, `async_binding.xml`, you would set up your POM as shown in Example 40.3, “Consumer Code Generation”.

**Example 40.3. Consumer Code Generation**

```xml
<plugin>
  <groupId>org.apache.cxf</groupId>
  <artifactId>cxf-codegen-plugin</artifactId>
  <version>${cxf.version}</version>
  <executions>
    <execution>
      <id>generate-sources</id>
      <phase>generate-sources</phase>
```
<configuration>
  <sourceRoot>outputDir</sourceRoot>
  <wsdlOptions>
    <wsdlOption>
      <wsdl>hello_world.wsdl</wsdl>
      <extraargs>
        <extraarg>-client</extraarg>
        <extraarg>-b async_binding.xml</extraarg>
      </extraargs>
    </wsdlOption>
  </wsdlOptions>
  </configuration>
  <goals>
    <goal>wsdl2java</goal>
  </goals>
</plugin>

The -b option tells the code generator where to locate the external binding file.

For more information on the code generator see Section 44.2, "cxf-codegen-plugin".

Using an embedded binding declaration

You can also embed the binding customization directly into the WSDL document defining the service by placing the jaxws:bindings element and its associated jaxws:enableAsynchMapping child directly into the WSDL. You also must add a namespace declaration for the jaxws prefix.

Example 40.4, “WSDL with Embedded Binding Declaration for Asynchronous Mapping” shows a WSDL file with an embedded binding declaration that activates the asynchronous mapping for an operation.

Example 40.4. WSDL with Embedded Binding Declaration for Asynchronous Mapping

```xml
<wSDL:definitions xmlns="http://schemas.xmlsoap.org/wsdl/">
  ...
  xmlns:jaxws="http://java.sun.com/xml/ns/jaxws"
  ...
  <wsdl:portType name="GreeterAsync">
    <wsdl:operation name="greetMeSometime">
      <jaxws:bindings>
        <jaxws:enableAsynchMapping>true</jaxws:enableAsynchMapping>
      </jaxws:bindings>
      <wsdl:input name="greetMeSometimeRequest" message="tns:greetMeSometimeRequest"/>
      <wsdl:output name="greetMeSometimeResponse" message="tns:greetMeSometimeResponse"/>
    </wsdl:operation>
  </wsdl:portType>
  ...
</wsdl:definitions>
```
When embedding the binding declaration into the WSDL document you can control the scope affected by the declaration by changing where you place the declaration. When the declaration is placed as a child of the \texttt{wsdl:definitions} element the code generator creates asynchronous methods for all of the operations defined in the WSDL document. If it is placed as a child of a \texttt{wsdl:portType} element the code generator creates asynchronous methods for all of the operations defined in the interface. If it is placed as a child of a \texttt{wsdl:operation} element the code generator creates asynchronous methods for only that operation.

It is not necessary to pass any special options to the code generator when using embedded declarations. The code generator will recognize them and act accordingly.

**Generated interface**

After generating the stub code in this way, the GreeterAsync SEI (in the file \texttt{GreeterAsync.java}) is defined as shown in Example 40.5, “Service Endpoint Interface with Methods for Asynchronous Invocations”.

Example 40.5. Service Endpoint Interface with Methods for Asynchronous Invocations

```java
package org.apache.hello_world_async_soap_http;
import org.apache.hello_world_async_soap_http.types.GreetMeSometimeResponse;
...
public interface GreeterAsync
{
  public Future<?> greetMeSometimeAsync(
    java.lang.String requestType,
    AsyncHandler<GreetMeSometimeResponse> asyncHandler
  );

  public Response<GreetMeSometimeResponse> greetMeSometimeAsync(
    java.lang.String requestType
  );

  public java.lang.String greetMeSometime(
    java.lang.String requestType
  );
}
```

In addition to the usual synchronous method, \texttt{greetMeSometime()}, two asynchronous methods are also generated for the greetMeSometime operation:

- **Callback approach**
  ```java
  public Future<?>
greetMeSometimeAsync(java.lang.String requestType,
  AsyncHandler<GreetMeSometimeResponse> asyncHandler
  );
  ```

- **Polling approach**
  ```java
  public Response<GreetMeSomeTimeResponse>
greetMeSometimeAsync(java.lang.String requestType
  );
  ```

**40.4. IMPLEMENTING AN ASYNCHRONOUS CLIENT WITH THE POLLING APPROACH**
Overview

The polling approach is the more straightforward of the two approaches to developing an asynchronous application. The client invokes the asynchronous method called `OperationNameAsync()` and is returned a `Response<T>` object that it polls for a response. What the client does while it is waiting for a response depends on the requirements of the application. There are two basic patterns for handling the polling:

- **Non-blocking polling** – You periodically check to see if the result is ready by calling the non-blocking `Response<T>.isDone()` method. If the result is ready, the client processes it. If it not, the client continues doing other things.
- **Blocking polling** – You call `Response<T>.get()` right away, and block until the response arrives (optionally specifying a timeout).

Using the non-blocking pattern

Example 40.6, “Non-Blocking Polling Approach for an Asynchronous Operation Call” illustrates using non-blocking polling to make an asynchronous invocation on the `greetMeSometime` operation defined in Example 40.1, “WSDL Contract for Asynchronous Example”. The client invokes the asynchronous operation and periodically checks to see if the result is returned.

Example 40.6. Non-Blocking Polling Approach for an Asynchronous Operation Call

```java
package demo.hw.client;

import java.io.File;
import java.util.concurrent.Future;
import javax.xml.namespace.QName;
import javax.xml.ws.Response;
import org.apache.hello_world_async_soap_http.*;

public final class Client {
    private static final QName SERVICE_NAME
        = new QName("http://apache.org/hello_world_async_soap_http",
                    "SOAPService");

    private Client() {}

    public static void main(String args[]) throws Exception {
        // set up the proxy for the client
        Response<GreetMeSometimeResponse> greetMeSomeTimeResp =
            port.greetMeSometimeAsync(System.getProperty("user.name"));

        while (!greetMeSomeTimeResp.isDone()) {
            // client does some work
        }

        GreetMeSometimeResponse reply = greetMeSomeTimeResp.get();
        // process the response

        System.exit(0);
    }
}
```
The code in Example 40.6, "Non-Blocking Polling Approach for an Asynchronous Operation Call" does the following:

Invokes the greetMeSometimeAsync() on the proxy.

The method call returns the Response<GreetMeSometimeResponse> object to the client immediately. The Apache CXF runtime handles the details of receiving the reply from the remote endpoint and populating the Response<GreetMeSometimeResponse> object.

NOTE

The runtime transmits the request to the remote endpoint’s greetMeSometime() method and handles the details of the asynchronous nature of the call transparently. The endpoint, and therefore the service implementation, never worries about the details of how the client intends to wait for a response.

Checks to see if a response has arrived by checking the isDone() of the returned Response object.

If the response has not arrived, the client continues working before checking again.

When the response arrives, the client retrieves it from the Response object using the get() method.

Using the blocking pattern

When using the block polling pattern, the Response object’s isDone() is never called. Instead, the Response object’s get() method is called immediately after invoking the remote operation. The get() blocks until the response is available.

You can also pass a timeout limit to the get() method.

Example 40.7, "Blocking Polling Approach for an Asynchronous Operation Call" shows a client that uses blocking polling.

Example 40.7. Blocking Polling Approach for an Asynchronous Operation Call

```java
package demo.hw.client;

import java.io.File;
import java.util.concurrent.Future;
import javax.xml.namespace.QName;
import javax.xml.ws.Response;
import org.apache.hello_world_async_soap_http.*;

import org.apache.hello_world_async_soap_http.*;

public final class Client {
    private static final QName SERVICE_NAME
        = new QName("http://apache.org/hello_world_async_soap_http",
        "SOAPService");

    private Client() {}

    public static void main(String args[]) throws Exception {
        System.out.println("Hello World!");
    }
}
```
// set up the proxy for the client

Response<GreetMeSometimeResponse> greetMeSomeTimeResp = port.greetMeSometimeAsync(System.getProperty("user.name"));
GreetMeSometimeResponse reply = greetMeSomeTimeResp.get();
// process the response
System.exit(0);

40.5. IMPLEMENTING AN ASYNCHRONOUS CLIENT WITH THE CALLBACK APPROACH

Overview

An alternative approach to making an asynchronous operation invocation is to implement a callback class. You then call the asynchronous remote method that takes the callback object as a parameter. The runtime returns the response to the callback object.

To implement an application that uses callbacks, do the following:

1. Create a callback class that implements the AsyncHandler interface.

   NOTE
   
   Your callback object can perform any amount of response processing required by your application.

2. Make remote invocations using the \texttt{operationNameAsync()} that takes the callback object as a parameter and returns a \texttt{Future\langle?\rangle} object.

3. If your client requires access to the response data, you can poll the returned \texttt{Future\langle?\rangle} object's \texttt{isDone()} method to see if the remote endpoint has sent the response. If the callback object does all of the response processing, it is not necessary to check if the response has arrived.

Implementing the callback

The callback class must implement the \texttt{javax.xml.ws.AsyncHandler} interface. The interface defines a single method: \texttt{handleResponse\langle Response\langle T \rangle \rangle res} The Apache CXF runtime calls the \texttt{handleResponse()} method to notify the client that the response has arrived. Example 40.8, “The \texttt{javax.xml.ws.AsyncHandler Interface}” shows an outline of the AsyncHandler interface that you must implement.

Example 40.8. The \texttt{javax.xml.ws.AsyncHandler Interface}

```
public interface javax.xml.ws.AsyncHandler
{
  void handleResponse(Response<T> res)
}
```
Example 40.9, “Callback Implementation Class” shows a callback class for the greetMeSometime operation defined in Example 40.1, “WSDL Contract for Asynchronous Example”.

Example 40.9. Callback Implementation Class

```java
package demo.hw.client;

import javax.xml.ws.AsyncHandler;
import javax.xml.ws.Response;
import org.apache.hello_world_async_soap_http.types.*;

public class GreeterAsyncHandler implements AsyncHandler<GreetMeSometimeResponse> {
    private GreetMeSometimeResponse reply;

    public void handleResponse(Response<GreetMeSometimeResponse> response) {
        try {
            reply = response.get();
        } catch (Exception ex) {
            ex.printStackTrace();
        }
    }

    public String getResponse() {
        return reply.getResponseType();
    }
}
```

The callback implementation shown in Example 40.9, “Callback Implementation Class” does the following:

- Defines a member variable, `response`, that holds the response returned from the remote endpoint.
- Implements `handleResponse()`.
- This implementation simply extracts the response and assigns it to the member variable `reply`.
- Implements an added method called `getResponse()`.
- This method is a convenience method that extracts the data from `reply` and returns it.

**Implementing the consumer**

Example 40.10, “Callback Approach for an Asynchronous Operation Call” illustrates a client that uses the callback approach to make an asynchronous call to the GreetMeSometime operation defined in Example 40.1, “WSDL Contract for Asynchronous Example”.
Example 40.10. Callback Approach for an Asynchronous Operation Call

```java
class Client {
    // Callback approach
    GreeterAsyncHandler callback = new GreeterAsyncHandler();

    Future<?> response =
        port.greetMeSometimeAsync(System.getProperty("user.name"),
                                   callback);
    while (!response.isDone())
        // Do some work
    resp = callback.getResponse();
}
```

The code in Example 40.10, "Callback Approach for an Asynchronous Operation Call" does the following:

- Instantiates a callback object.
- Invokes the `greetMeSometimeAsync()` that takes the callback object on the proxy.

The method call returns the `Future<?>` object to the client immediately. The Apache CXF runtime handles the details of receiving the reply from the remote endpoint, invoking the callback object’s `handleResponse()` method, and populating the `Response<GreetMeSometimeResponse>` object.

**NOTE**

The runtime transmits the request to the remote endpoint’s `greetMeSometime()` method and handles the details of the asynchronous nature of the call without the remote endpoint’s knowledge. The endpoint, and therefore the service implementation, does not need to worry about the details of how the client intends to wait for a response.

Uses the returned `Future<?>` object’s `isDone()` method to check if the response has arrived from the remote endpoint.
Invokes the callback object’s `getResponse()` method to get the response data.

## 40.6. CATCHING EXCEPTIONS RETURNED FROM A REMOTE SERVICE

### Overview

Consumers making asynchronous requests will not receive the same exceptions returned when they make synchronous requests. Any exceptions returned to the consumer asynchronously are wrapped in an `ExecutionException` exception. The actual exception thrown by the service is stored in the `ExecutionException` exception’s `cause` field.

### Catching the exception

Exceptions generated by a remote service are thrown locally by the method that passes the response to the consumer’s business logic. When the consumer makes a synchronous request, the method making the remote invocation throws the exception. When the consumer makes an asynchronous request, the `Response<T>` object’s `get()` method throws the exception. The consumer will not discover that an error was encountered in processing the request until it attempts to retrieve the response message.

Unlike the methods generated by the JAX-WS framework, the `Response<T>` object’s `get()` method throws neither user modeled exceptions nor generic JAX-WS exceptions. Instead, it throws a `java.util.concurrent.ExecutionException` exception.

### Getting the exception details

The framework stores the exception returned from the remote service in the `ExecutionException` exception’s `cause` field. The details about the remote exception are extracted by getting the value of the `cause` field and examining the stored exception. The stored exception can be any user defined exception or one of the generic JAX-WS exceptions.

### Example

**Example 40.11, “Catching an Exception using the Polling Approach”** shows an example of catching an exception using the polling approach.

### Example 40.11. Catching an Exception using the Polling Approach

```java
package demo.hw.client;

import java.io.File;
import java.util.concurrent.Future;
import javax.xml.namespace.QName;
import javax.xml.ws.Response;
import org.apache.hello_world_async_soap_http.*;

public final class Client {
    private static final QName SERVICE_NAME = new QName("http://apache.org/hello_world_async_soap_http", "SOAPService");

    private Client() {}
}
```
public static void main(String args[]) throws Exception
{
    // port is a previously established proxy object.
    Response<GreetMeSometimeResponse> resp =
        port.greetMeSometimeAsync(System.getProperty("user.name"));

    while (!resp.isDone())
    {
        // client does some work
    }

    try
    {
        GreetMeSometimeResponse reply = greetMeSomeTimeResp.get();
        // process the response
    }
    catch (ExecutionException ee)
    {
        Throwable cause = ee.getCause();
        System.out.println("Exception "+cause.getClass().getName()+" thrown by the remote service.");
    }
}

The code in Example 40.11, “Catching an Exception using the Polling Approach” does the following:

Wraps the call to the Response<T> object’s get() method in a try/catch block.

Catches a ExecutionException exception.

Extracts the cause field from the exception.

If the consumer was using the callback approach the code used to catch the exception would be placed in the callback object where the service’s response is extracted.
CHAPTER 41. USING RAW XML MESSAGES

Abstract
The high-level JAX-WS APIs shield the developer from using native XML messages by marshaling the
data into JAXB objects. However, there are cases when it is better to have direct access to the raw XML
message data that is passing on the wire. The JAX-WS APIs provide two interfaces that provide access
to the raw XML: the Dispatch interface is the client-side interface, and the Provider interface is the
server-side interface.

41.1. USING XML IN A CONSUMER

Abstract
The Dispatch interface is a low-level JAX-WS API that allows you work directly with raw messages. It
accepts and returns messages, or payloads, of a number of types including DOM objects, SOAP
messages, and JAXB objects. Because it is a low-level API, the Dispatch interface does not perform any
of the message preparation that the higher-level JAX-WS APIs perform. You must ensure that the
messages, or payloads, that you pass to the Dispatch object are properly constructed, and make sense
for the remote operation being invoked.

41.1.1. Usage Modes

Overview
Dispatch objects have two usage modes:

- **Message mode**
- **Message Payload** mode (Payload mode)

The usage mode you specify for a Dispatch object determines the amount of detail that is passed to the
user level code.

Message mode

In *message mode*, a Dispatch object works with complete messages. A complete message includes any
binding specific headers and wrappers. For example, a consumer interacting with a service that requires
SOAP messages must provide the Dispatch object’s `invoke()` method a fully specified SOAP message.
The `invoke()` method also returns a fully specified SOAP message. The consumer code is responsible
for completing and reading the SOAP message’s headers and the SOAP message’s envelope
information.

Message mode is not ideal when working with JAXB objects.

To specify that a Dispatch object uses message mode provide the value
`java.xml.ws.Service.Mode.MESSAGE` when creating the Dispatch object. For more information about
creating a Dispatch object see the section called “Creating a Dispatch object”.

Payload mode

In *payload mode*, also called message payload mode, a Dispatch object works with only the payload of a
message. For example, a Dispatch object working in payload mode works only with the body of a SOAP
message. The binding layer processes any binding level wrappers and headers. When a result is returned from the `invoke()` method the binding level wrappers and headers are already stripped away, and only the body of the message is left.

When working with a binding that does not use special wrappers, such as the Apache CXF XML binding, payload mode and message mode provide the same results.

To specify that a Dispatch object uses payload mode provide the value `java.xml.ws.Service.Mode.PAYLOAD` when creating the Dispatch object. For more information about creating a Dispatch object see the section called “Creating a Dispatch object”.

### 41.1.2. Data Types

#### Overview

Because Dispatch objects are low-level objects, they are not optimized for using the same JAXB generated types as the higher level consumer APIs. Dispatch objects work with the following types of objects:

- `javax.xml.transform.Source`
- `javax.xml.soap.SOAPMessage`
- `javax.activation.DataSource`
- the section called “Using JAXB objects”

#### Using Source objects

A Dispatch object accepts and returns objects that are derived from the `javax.xml.transform.Source` interface. Source objects are supported by any binding, and in either message mode or payload mode.

Source objects are low level objects that hold XML documents. Each Source implementation provides methods that access the stored XML documents and then manipulate its contents. The following objects implement the `Source` interface:

- **DOMSource**
  
  Holds XML messages as a Document Object Model (DOM) tree. The XML message is stored as a set of `Node` objects that are accessed using the `getNode()` method. Nodes can be either updated or added to the DOM tree using the `setNode()` method.

- **SAXSource**
  
  Holds XML messages as a Simple API for XML (SAX) object. SAX objects contain an `InputSource` object that holds the raw data and an `XMLReader` object that parses the raw data.

- **StreamSource**
  
  Holds XML messages as a data stream. The data stream can be manipulated the same as any other data stream.

If you create your Dispatch object so that it uses generic `Source` objects, Apache CXF returns the messages as `SAXSource` objects.

This behavior can be changed using the endpoint’s `source-preferred-format` property. See Part IV, “Configuring Web Service Endpoints” for information about configuring the Apache CXF runtime.
Using SOAPMessage objects

Dispatch objects can use `javax.xml.soap.SOAPMessage` objects when the following conditions are true:

- The Dispatch object is using the SOAP binding
- The Dispatch object is using message mode

A `SOAPMessage` object holds a SOAP message. They contain one `SOAPPart` object and zero or more `AttachmentPart` objects. The `SOAPPart` object contains the SOAP specific portions of the SOAP message including the SOAP envelope, any SOAP headers, and the SOAP message body. The `AttachmentPart` objects contain binary data that is passed as an attachment.

Using DataSource objects

Dispatch objects can use objects that implement the `javax.activation.DataSource` interface when the following conditions are true:

- The Dispatch object is using the HTTP binding
- The Dispatch object is using message mode

DataSource objects provide a mechanism for working with MIME typed data from a variety of sources, including URLs, files, and byte arrays.

Using JAXB objects

While Dispatch objects are intended to be low level APIs that allow you to work with raw messages, they also allow you to work with JAXB objects. To work with JAXB objects a Dispatch object must be passed a `JAXBContext` that can marshal and unmarshal the JAXB objects in use. The `JAXBContext` is passed when the Dispatch object is created.

You can pass any JAXB object understood by the `JAXBContext` object as the parameter to the `invoke()` method. You can also cast the returned message into any JAXB object understood by the `JAXBContext` object.

For information on creating a `JAXBContext` object see Chapter 39, *Using A JAXBContext Object*.

41.1.3. Working with Dispatch Objects

Procedure

To use a Dispatch object to invoke a remote service the following sequence should be followed:

1. Create a Dispatch object.
2. Construct a request message.
3. Call the proper `invoke()` method.
4. Parse the response message.

Creating a Dispatch object
To create a Dispatch object do the following:

1. Create a Service object to represent the \texttt{wsdl:service} element that defines the service on which the Dispatch object will make invocations. See Section 25.2, “Creating a Service Object”.

2. Create the Dispatch object using the Service object’s \texttt{createDispatch()} method, shown in Example 41.1, “The \texttt{createDispatch()} Method”.

Example 41.1. The \texttt{createDispatch()} Method

\begin{verbatim}
public Dispatch\langle T \rangle createDispatch(QName portName, java.lang.Class\langle T \rangle type, Service.Mode mode) throws WebServiceException
\end{verbatim}

\textbf{NOTE}

If you are using JAXB objects the method signature for \texttt{createDispatch()} is:

\begin{verbatim}
public Dispatch\langle T \rangle createDispatch(QName portName, javax.xml.bind.JAXBContext context, Service.Mode mode) throws WebServiceException
\end{verbatim}

Table 41.1, “Parameters for \texttt{createDispatch()}” describes the parameters for the \texttt{createDispatch()} method.

Table 41.1. Parameters for \texttt{createDispatch()}

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>\texttt{portName}</td>
<td>Specifies the QName of the \texttt{wsdl:port} element that represents the service provider where the Dispatch object will make invocations.</td>
</tr>
<tr>
<td>\texttt{type}</td>
<td>Specifies the data type of the objects used by the Dispatch object. See Section 41.1.2, “Data Types”. When working with JAXB objects, this parameter specifies the \texttt{JAXBContext} object used to marshal and unmarshal the JAXB objects.</td>
</tr>
<tr>
<td>\texttt{mode}</td>
<td>Specifies the usage mode for the Dispatch object. See Section 41.1.1, “Usage Modes”.</td>
</tr>
</tbody>
</table>

Example 41.2, “Creating a Dispatch Object” shows the code for creating a Dispatch object that works with \texttt{DOMSource} objects in payload mode.

Example 41.2. Creating a Dispatch Object

\begin{verbatim}
package com.fusesource.demo;

import javax.xml.namespace.QName;
import javax.xml.ws.Service;

public class Client
{

\end{verbatim}
public static void main(String args[]) {
    QName serviceName = new QName("http://org.apache.cxf", "stockQuoteReporter");
    Service s = Service.create(serviceName);

    QName portName = new QName("http://org.apache.cxf", "stockQuoteReporterPort");
    Dispatch<DOMSource> dispatch = s.createDispatch(portName,
        DOMSource.class,
        Service.Mode.PAYLOAD);
    ...

**Constructing request messages**

When working with Dispatch objects, requests must be built from scratch. The developer is responsible for ensuring that the messages passed to a Dispatch object match a request that the targeted service provider can process. This requires precise knowledge about the messages used by the service provider and what, if any, header information it requires.

This information can be provided by a WSDL document or an XML Schema document that defines the messages. While service providers vary greatly there are a few guidelines to be followed:

- The root element of the request is based in the value of the `name` attribute of the `wsdl:operation` element corresponding to the operation being invoked.

**WARNING**

If the service being invoked uses doc/literal bare messages, the root element of the request is based on the value of the `name` attribute of the `wsdl:part` element referred to by the `wsdl:operation` element.

- The root element of the request is namespace qualified.
- If the service being invoked uses rpc/literal messages, the top-level elements in the request will not be namespace qualified.

**IMPORTANT**

The children of top-level elements may be namespace qualified. To be certain you must check their schema definitions.

- If the service being invoked uses rpc/literal messages, none of the top-level elements can be null.
- If the service being invoked uses doc/literal messages, the schema definition of the message determines if any of the elements are namespace qualified.

For more information about how services use XML messages see, the [WS-I Basic Profile](http://docs.oasis-open.org/ws-sx/ws-i-bp/2.0/).
Synchronous invocation

For consumers that make synchronous invocations that generate a response, use the Dispatch object’s `invoke()` method shown in Example 41.3, “The Dispatch.invoke() Method”.

**Example 41.3. The Dispatch.invoke() Method**

```
T invoke(T msg) throws WebServiceException
```

The type of both the response and the request passed to the `invoke()` method are determined when the Dispatch object is created. For example if you create a Dispatch object using `createDispatch(portName, SOAPMessage.class, Service.Mode.MESSAGE)`, both the response and the request are `SOAPMessage` objects.

**NOTE**

When using JAXB objects, both the response and the request can be of any type the provided `JAXBContext` object can marshal and unmarshal. Also, the response and the request can be different JAXB objects.

Example 41.4, “Making a Synchronous Invocation Using a Dispatch Object” shows code for making a synchronous invocation on a remote service using a `DOMSource` object.

**Example 41.4. Making a Synchronous Invocation Using a Dispatch Object**

```
// Creating a DOMSource Object for the request
DocumentBuilder db = DocumentBuilderFactory.newDocumentBuilder();
Document requestDoc = db.newDocument();
Element root = requestDoc.createElementNS("http://org.apache.cxf/stockExample","getStockPrice");
root.setNodeValue("DOW");
DOMSource request = new DOMSource(requestDoc);

// Dispatch disp created previously
DOMSource response = disp.invoke(request);
```

Asynchronous invocation

Dispatch objects also support asynchronous invocations. As with the higher level asynchronous APIs discussed in Chapter 40, Developing Asynchronous Applications, Dispatch objects can use both the polling approach and the callback approach.

When using the polling approach, the `invokeAsync()` method returns a `Response<T>` object that can be polled to see if the response has arrived. Example 41.5, “The Dispatch.invokeAsync() Method for Polling” shows the signature of the method used to make an asynchronous invocation using the polling approach.

**Example 41.5. The Dispatch.invokeAsync() Method for Polling**

```
Response<T> invokeAsync(T msg) throws WebServiceException
```
For detailed information on using the polling approach for asynchronous invocations see Section 40.4, “Implementing an Asynchronous Client with the Polling Approach”.

When using the callback approach, the invokeAsync() method takes an AsyncHandler implementation that processes the response when it is returned. Example 41.6, “The Dispatch.invokeAsync() Method Using a Callback” shows the signature of the method used to make an asynchronous invocation using the callback approach.

Example 41.6. The Dispatch.invokeAsync() Method Using a Callback

Future<?>
invokeAsync(T
msg
AsyncHandler<T>
handler
WebServiceException

For detailed information on using the callback approach for asynchronous invocations see Section 40.5, “Implementing an Asynchronous Client with the Callback Approach”.

NOTE
As with the synchronous invoke() method, the type of the response and the type of the request are determined when you create the Dispatch object.

Oneway invocation

When a request does not generate a response, make remote invocations using the Dispatch object’s invokeOneWay(). Example 41.7, “The Dispatch.invokeOneWay() Method” shows the signature for this method.

Example 41.7. The Dispatch.invokeOneWay() Method

invokeOneWay(T
msg
WebServiceException

The type of object used to package the request is determined when the Dispatch object is created. For example if the Dispatch object is created using createDispatch(portName, DOMSource.class, Service.Mode.PAYLOAD), then the request is packaged into a DOMSource object.

NOTE
When using JAXB objects, the response and the request can be of any type the provided JAXBContext object can marshal and unmarshal.

Example 41.8, “Making a One Way Invocation Using a Dispatch Object” shows code for making a oneway invocation on a remote service using a JAXB object.

Example 41.8. Making a One Way Invocation Using a Dispatch Object

// Creating a JAXBContext and an Unmarshaller for the request
JAXBContext jbc = JAXBContext.newInstance("org.apache.cxf.StockExample");
Unmarshaller u = jbc.createUnmarshaller();

// Read the request from disk
File rf = new File("request.xml");
GetStockPrice request = (GetStockPrice)u.unmarshal(rf);
// Dispatch disp created previously
disp.invokeOneWay(request);

### 41.2. USING XML IN A SERVICE PROVIDER

#### Abstract

The Provider interface is a low-level JAX-WS API that allows you to implement a service provider that works directly with messages as raw XML. The messages are not packaged into JAXB objects before being passed to an object that implements the Provider interface.

#### 41.2.1. Messaging Modes

#### Overview

Objects that implement the Provider interface have two messaging modes:

- **Message** mode
- **Payload** mode

The messaging mode you specify determines the level of messaging detail that is passed to your implementation.

#### Message mode

When using **message mode**, a Provider implementation works with complete messages. A complete message includes any binding specific headers and wrappers. For example, a Provider implementation that uses a SOAP binding receives requests as fully specified SOAP message. Any response returned from the implementation must be a fully specified SOAP message.

To specify that a Provider implementation uses message mode by provide the value `java.xml.ws.Service.Mode.MESSAGE` as the value to the `javax.xml.ws.ServiceMode` annotation, as shown in Example 41.9, “Specifying that a Provider Implementation Uses Message Mode”.

**Example 41.9. Specifying that a Provider Implementation Uses Message Mode**

```java
@WebServiceProvider
@ServiceMode(value=Service.Mode.MESSAGE)
public class stockQuoteProvider implements Provider<SOAPMessage>
{
    ...
}
```

#### Payload mode

In **payload mode** a Provider implementation works with only the payload of a message. For example, a Provider implementation working in payload mode works only with the body of a SOAP message. The binding layer processes any binding level wrappers and headers.
When working with a binding that does not use special wrappers, such as the Apache CXF XML binding, payload mode and message mode provide the same results.

To specify that a Provider implementation uses payload mode by provide the value java.xml.ws.Service.Mode.PAYLOAD as the value to the javax.xml.ws.ServiceMode annotation, as shown in Example 41.10, “Specifying that a Provider Implementation Uses Payload Mode”.

Example 41.10. Specifying that a Provider Implementation Uses Payload Mode

```java
@WebServiceProvider
@ServiceMode(value=Service.Mode.PAYLOAD)
public class stockQuoteProvider implements Provider<DOMSource>
{
    ...
}
```

If you do not provide a value for the @ServiceMode annotation, the Provider implementation uses payload mode.

41.2.2. Data Types

Overview

Because they are low-level objects, Provider implementations cannot use the same JAXB generated types as the higher level consumer APIs. Provider implementations work with the following types of objects:

- javax.xml.transform.Source
- javax.xml.soap.SOAPMessage
- javax.activation.DataSource

Using Source objects

A Provider implementation can accept and return objects that are derived from the javax.xml.transform.Source interface. Source objects are low level objects that hold XML documents. Each Source implementation provides methods that access the stored XML documents and manipulate its contents. The following objects implement the Source interface:

DOMSource

Holds XML messages as a Document Object Model(DOM) tree. The XML message is stored as a set of Node objects that are accessed using the getNode() method. Nodes can be either updated or added to the DOM tree using the setNode() method.

SAXSource

Holds XML messages as a Simple API for XML (SAX) object. SAX objects contain an InputSource object that holds the raw data and an XMLReader object that parses the raw data.

StreamSource

Holds XML messages as a data stream. The data stream can be manipulated the same as any other data stream.
If you create your Provider object so that it uses generic Source objects, Apache CXF returns the messages as `SAXSource` objects.

This behavior can be changed using the endpoint’s `source-preferred-format` property. See Part IV, “Configuring Web Service Endpoints” for information about configuring the Apache CXF runtime.

**IMPORTANT**

When using Source objects the developer is responsible for ensuring that all required binding specific wrappers are added to the message. For example, when interacting with a service expecting SOAP messages, the developer must ensure that the required SOAP envelope is added to the outgoing request and that the SOAP envelope’s contents are correct.

**Using SOAPMessage objects**

Provider implementations can use `javax.xml.soap.SOAPMessage` objects when the following conditions are true:

- The Provider implementation is using the SOAP binding
- The Provider implementation is using message mode

A `SOAPMessage` object holds a SOAP message. They contain one `SOAPPart` object and zero or more `AttachmentPart` objects. The `SOAPPart` object contains the SOAP specific portions of the SOAP message including the SOAP envelope, any SOAP headers, and the SOAP message body. The `AttachmentPart` objects contain binary data that is passed as an attachment.

**Using DataSource objects**

Provider implementations can use objects that implement the `javax.activation.DataSource` interface when the following conditions are true:

- The implementation is using the HTTP binding
- The implementation is using message mode

DataSource objects provide a mechanism for working with MIME typed data from a variety of sources, including URLs, files, and byte arrays.

**41.2.3. Implementing a Provider Object**

**Overview**

The Provider interface is relatively easy to implement. It only has one method, `invoke()`, that must be implemented. In addition it has three simple requirements:

- An implementation must have the `@WebServiceProvider` annotation.
- An implementation must have a default public constructor.
- An implementation must implement a typed version of the Provider interface.
  In other words, you cannot implement a `Provider<T>` interface. You must implement a version of the interface that uses a concrete data type as listed in Section 41.2.2, “Data Types”. For example, you can implement an instance of a `Provider<SAXSource>`.
The complexity of implementing the Provider interface is in the logic handling the request messages and building the proper responses.

**Working with messages**

Unlike the higher-level SEI based service implementations, Provider implementations receive requests as raw XML data, and must send responses as raw XML data. This requires that the developer has intimate knowledge of the messages used by the service being implemented. These details can typically be found in the WSDL document describing the service.

**WS-I Basic Profile** provides guidelines about the messages used by services, including:

- The root element of a request is based in the value of the `name` attribute of the `wsdl:operation` element that corresponds to the operation that is invoked.

  **WARNING**

  If the service uses doc/literal bare messages, the root element of the request is based on the value of `name` attribute of the `wsdl:part` element referred to by the `wsdl:operation` element.

- The root element of all messages is namespace qualified.

- If the service uses rpc/literal messages, the top-level elements in the messages are not namespace qualified.

  **IMPORTANT**

  The children of top-level elements might be namespace qualified, but to be certain you will must check their schema definitions.

- If the service uses rpc/literal messages, none of the top-level elements can be null.

- If the service uses doc/literal messages, then the schema definition of the message determines if any of the elements are namespace qualified.

**The @WebServiceProvider annotation**

To be recognized by JAX-WS as a service implementation, a Provider implementation must be decorated with the `@WebServiceProvider` annotation.

Table 41.2, "@WebServiceProvider Properties" describes the properties that can be set for the `@WebServiceProvider` annotation.

**Table 41.2. @WebServiceProvider Properties**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>

407
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>portName</td>
<td>Specifies the value of the <code>name</code> attribute of the <code>wsdl:port</code> element that defines the service’s endpoint.</td>
</tr>
<tr>
<td>serviceName</td>
<td>Specifies the value of the <code>name</code> attribute of the <code>wsdl:service</code> element that contains the service’s endpoint.</td>
</tr>
<tr>
<td>targetNamespace</td>
<td>Specifies the target namespace of the service’s WSDL definition.</td>
</tr>
<tr>
<td>wsdlLocation</td>
<td>Specifies the URI for the WSDL document defining the service.</td>
</tr>
</tbody>
</table>

All of these properties are optional, and are empty by default. If you leave them empty, Apache CXF creates values using information from the implementation class.

**Implementing the `invoke()` method**

The Provider interface has only one method, `invoke()`, that must be implemented. The `invoke()` method receives the incoming request packaged into the type of object declared by the type of Provider interface being implemented, and returns the response message packaged into the same type of object. For example, an implementation of a `Provider<SOAPMessage>` interface receives the request as a `SOAPMessage` object and returns the response as a `SOAPMessage` object.

The messaging mode used by the Provider implementation determines the amount of binding specific information the request and the response messages contain. Implementations using message mode receive all of the binding specific wrappers and headers along with the request. They must also add all of the binding specific wrappers and headers to the response message. Implementations using payload mode only receive the body of the request. The XML document returned by an implementation using payload mode is placed into the body of the request message.

**Examples**

Example 41.11, “Provider<SOAPMessage> Implementation” shows a Provider implementation that works with `SOAPMessage` objects in message mode.

```java
import javax.xml.ws.Provider;
import javax.xml.ws.Service;
import javax.xml.ws.ServiceMode;
import javax.xml.ws.WebServiceProvider;

@WebServiceProvider(portName="stockQuoteReporterPort" serviceName="stockQuoteReporter")
@ServiceMode(value="Service.Mode.MESSAGE")
public class stockQuoteReporterProvider implements Provider<SOAPMessage> {

...}
```

Red Hat Fuse 7.8 Apache CXF Development Guide
The code in Example 41.11, “Provider<SOAPMessage> Implementation” does the following:

Specifies that the following class implements a Provider object that implements the service whose wsdl:service element is named stockQuoteReporter, and whose wsdl:port element is named stockQuoteReporterPort.

Specifies that this Provider implementation uses message mode.

Provides the required default public constructor.

Provides an implementation of the invoke() method that takes a SOAPMessage object and returns a SOAPMessage object.

Extracts the request message from the body of the incoming SOAP message.

Checks the root element of the request message to determine how to process the request.

Creates the factories required for building the response.

Builds the SOAP message for the response.

Returns the response as a SOAPMessage object.

Example 41.12, “Provider<DOMSource> Implementation” shows an example of a Provider implementation using DOMSource objects in payload mode.

Example 41.12. Provider<DOMSource> Implementation

```java
import javax.xml.ws.Provider;
```
The code in Example 41.12, "Provider<DOMSource> Implementation" does the following:

Specifies that the class implements a Provider object that implements the service whose `wsdl:service` element is named `stockQuoteReporter`, and whose `wsdl:port` element is named `stockQuoteReporterPort`.

Specifies that this Provider implementation uses payload mode.

Provides the required default public constructor.

Provides an implementation of the `invoke()` method that takes a `DOMSource` object and returns a `DOMSource` object.
CHAPTER 42. WORKING WITH CONTEXTS

Abstract

JAX-WS uses contexts to pass metadata along the messaging chain. This metadata, depending on its scope, is accessible to implementation level code. It is also accessible to JAX-WS handlers that operate on the message below the implementation level.

42.1. UNDERSTANDING CONTEXTS

Overview

In many instances it is necessary to pass information about a message to other parts of an application. Apache CXF does this using a context mechanism. Contexts are maps that hold properties relating to an outgoing or an incoming message. The properties stored in the context are typically metadata about the message, and the underlying transport used to communicate the message. For example, the transport specific headers used in transmitting the message, such as the HTTP response code or the JMS correlation ID, are stored in the JAX-WS contexts.

The contexts are available at all levels of a JAX-WS application. However, they differ in subtle ways depending upon where in the message processing stack you are accessing the context. JAX-WS Handler implementations have direct access to the contexts and can access all properties that are set in them. Service implementations access contexts by having them injected, and can only access properties that are set in the APPLICATION scope. Consumer implementations can only access properties that are set in the APPLICATION scope.

Figure 42.1, “Message Contexts and Message Processing Path” shows how the context properties pass through Apache CXF. As a message passes through the messaging chain, its associated message context passes along with it.
How properties are stored in a context

The message contexts are all implementations of the javax.xml.ws.handler.MessageContext interface. The MessageContext interface extends the java.util.Map<String key, Object value> interface. Map objects store information as key value pairs.

In a message context, properties are stored as name/value pairs. A property’s key is a String that identifies the property. The value of a property can be any value stored in any Java object. When the value is returned from a message context, the application must know the type to expect and cast accordingly. For example, if a property’s value is stored in a UserInfo object it is still returned from a message context as an Object object that must be cast back into a UserInfo object.

Properties in a message context also have a scope. The scope determines where a property can be accessed in the message processing chain.

Property scopes

Properties in a message context are scoped. A property can be in one of the following scopes:

APPLICATION

Properties scoped as APPLICATION are available to JAX-WS Handler implementations, consumer implementation code, and service provider implementation code. If a handler needs to pass a property to the service provider implementation, it sets the property’s scope to APPLICATION. All properties set from either the consumer implementation or the service provider implementation contexts are automatically scoped as APPLICATION.
Properties scoped as **HANDLER** are only available to JAX-WS Handler implementations. Properties stored in a message context from a Handler implementation are scoped as **HANDLER** by default.

You can change a property’s scope using the message context’s `setScope()` method. Example 42.1, “The `MessageContext.setScope()` Method” shows the method’s signature.

```
Example 42.1. The `MessageContext.setScope()` Method

```setScope(key, scope)`
```java
java.lang.IllegalArgumentException
```

The first parameter specifies the property’s key. The second parameter specifies the new scope for the property. The scope can be either:

- `MessageContext.Scope.APPLICATION`
- `MessageContext.Scope.HANDLER`

### Overview of contexts in handlers

Classes that implement the JAX-WS Handler interface have direct access to a message’s context information. The message’s context information is passed into the Handler implementation’s `handleMessage()`, `handleFault()`, and `close()` methods.

Handler implementations have access to all of the properties stored in the message context, regardless of their scope. In addition, logical handlers use a specialized message context called a `LogicalMessageContext`. `LogicalMessageContext` objects have methods that access the contents of the message body.

### Overview of contexts in service implementations

Service implementations can access properties scoped as **APPLICATION** from the message context. The service provider’s implementation object accesses the message context through the `WebServiceContext` object.

For more information see Section 42.2, “Working with Contexts in a Service Implementation”.

### Overview of contexts in consumer implementations

Consumer implementations have indirect access to the contents of the message context. The consumer implementation has two separate message contexts:

- Request context – holds a copy of the properties used for outgoing requests
- Response context – holds a copy of the properties from an incoming response

The dispatch layer transfers the properties between the consumer implementation’s message contexts and the message context used by the Handler implementations.

When a request is passed to the dispatch layer from the consumer implementation, the contents of the request context are copied into the message context that is used by the dispatch layer. When the response is returned from the service, the dispatch layer processes the message and sets the
appropriate properties into its message context. After the dispatch layer processes a response, it copies all of the properties scoped as **APPLICATION** in its message context to the consumer implementation’s response context.

For more information see Section 42.3, “Working with Contexts in a Consumer Implementation”.

### 42.2. WORKING WITH CONTEXTS IN A SERVICE IMPLEMENTATION

**Overview**

Context information is made available to service implementations using the WebServiceContext interface. From the WebServiceContext object you can obtain a **MessageContext** object that is populated with the current request’s context properties in the application scope. You can manipulate the values of the properties, and they are propagated back through the response chain.

**NOTE**

The MessageContext interface inherits from the java.util.Map interface. Its contents can be manipulated using the Map interface’s methods.

**Obtaining a context**

To obtain the message context in a service implementation do the following:

1. Declare a variable of type WebServiceContext.
2. Decorate the variable with the `javax.annotation.Resource` annotation to indicate that the context information is being injected into the variable.
3. Obtain the **MessageContext** object from the WebServiceContext object using the `getMessageContext()` method.

**IMPORTANT**

`getMessageContext()` can only be used in methods that are decorated with the `@WebMethod` annotation.

Example 42.2, “Obtaining a Context Object in a Service Implementation” shows code for obtaining a context object.

**Example 42.2. Obtaining a Context Object in a Service Implementation**

```java
import javax.xml.ws.*;
import javax.xml.ws.handler.*;
import javax.annotation.*

@WebServiceProvider
public class WidgetServiceImpl
{
    @Resource
    WebServiceContext wsc;

    @WebMethod
```
public String getColor(String itemNum) {
    MessageContext context = wsc.getMessageContext();
}

Reading a property from a context

Once you have obtained the MessageContext object for your implementation, you can access the properties stored there using the `get()` method shown in Example 42.3, “The `MessageContext.get()` Method”.

Example 42.3. The `MessageContext.get()` Method

```java
getObject(key)
```

NOTE

This `get()` is inherited from the Map interface.

The `key` parameter is the string representing the property you want to retrieve from the context. The `get()` returns an object that must be cast to the proper type for the property. Table 42.1, “Properties Available in the Service Implementation Context” lists a number of the properties that are available in a service implementation’s context.

IMPORTANT

Changing the values of the object returned from the context also changes the value of the property in the context.

Example 42.4, “Getting a Property from a Service’s Message Context” shows code for getting the name of the WSDL `operation` element that represents the invoked operation.

Example 42.4. Getting a Property from a Service’s Message Context

```java
import javax.xml.ws.handler.MessageContext;
import org.apache.cxf.message.Message;
...
// MessageContext context retrieved in a previous example
QName wsdl_operation = (QName)context.get(Message.WSDL_OPERATION);
```

Setting properties in a context

Once you have obtained the MessageContext object for your implementation, you can set properties, and change existing properties, using the `put()` method shown in Example 42.5, “The `MessageContext.put()` Method”.

```java
```
Example 42.5. The `MessageContext.put()` Method

**VputKkeyVvalue**

If the property being set already exists in the message context, the `put()` method replaces the existing value with the new value and returns the old value. If the property does not already exist in the message context, the `put()` method sets the property and returns `null`.

Example 42.6, “Setting a Property in a Service’s Message Context” shows code for setting the response code for an HTTP request.

Example 42.6. Setting a Property in a Service’s Message Context

```java
import javax.xml.ws.handler.MessageContext;
import org.apache.cxf.message.Message;
...
// MessageContext context retrieved in a previous example
context.put(Message.RESPONSE_CODE, new Integer(404));
```

Supported contexts

Table 42.1, “Properties Available in the Service Implementation Context” lists the properties accessible through the context in a service implementation object.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>org.apache.cxf.message.Message</code></td>
<td></td>
</tr>
<tr>
<td>PROTOCOL_HEADERS[a]</td>
<td>Specifies the transport specific header information. The value is stored as a <code>java.util.Map&lt;String, List&lt;String&gt;&gt;</code>.</td>
</tr>
<tr>
<td>RESPONSE_CODE</td>
<td>Specifies the response code returned to the consumer. The value is stored as an <code>Integer</code> object.</td>
</tr>
<tr>
<td>ENDPOINT_ADDRESS</td>
<td>Specifies the address of the service provider. The value is stored as a <code>String</code>.</td>
</tr>
<tr>
<td>HTTP_REQUEST_METHOD</td>
<td>Specifies the HTTP verb sent with a request. The value is stored as a <code>String</code>.</td>
</tr>
<tr>
<td>Property Name</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>PATH_INFO</td>
<td>Specifies the path of the resource being requested. The value is stored as a <strong>String</strong>. The path is the portion of the URI after the hostname and before any query string. For example, if an endpoint’s URI is <strong><a href="http://cxf.apache.org/demo/widgets">http://cxf.apache.org/demo/widgets</a></strong> the path is <strong>/demo/widgets</strong>.</td>
</tr>
<tr>
<td>QUERY_STRING</td>
<td>Specifies the query, if any, attached to the URI used to invoke the request. The value is stored as a <strong>String</strong>. Queries appear at the end of the URI after a <code>?</code>. For example, if a request is made to <strong><a href="http://cxf.apache.org/demo/widgets?color">http://cxf.apache.org/demo/widgets?color</a></strong> the query is <strong>color</strong>.</td>
</tr>
<tr>
<td>MTOM_ENABLED</td>
<td>Specifies whether or not the service provider can use MTOM for SOAP attachments. The value is stored as a <strong>Boolean</strong>.</td>
</tr>
<tr>
<td>SCHEMA_VALIDATION_ENABLED</td>
<td>Specifies whether or not the service provider validates messages against a schema. The value is stored as a <strong>Boolean</strong>.</td>
</tr>
<tr>
<td>FAULT_STACKTRACE_ENABLED</td>
<td>Specifies if the runtime provides a stack trace along with a fault message. The value is stored as a <strong>Boolean</strong>.</td>
</tr>
<tr>
<td>CONTENT_TYPE</td>
<td>Specifies the MIME type of the message. The value is stored as a <strong>String</strong>.</td>
</tr>
<tr>
<td>BASE_PATH</td>
<td>Specifies the path of the resource being requested. The value is stored as a <strong>java.net.URL</strong>. The path is the portion of the URI after the hostname and before any query string. For example, if an endpoint’s URL is <strong><a href="http://cxf.apache.org/demo/widgets">http://cxf.apache.org/demo/widgets</a></strong> the base path is <strong>/demo/widgets</strong>.</td>
</tr>
<tr>
<td>ENCODING</td>
<td>Specifies the encoding of the message. The value is stored as a <strong>String</strong>.</td>
</tr>
<tr>
<td>FIXED_PARAMETER_ORDER</td>
<td>Specifies whether the parameters must appear in the message in a particular order. The value is stored as a <strong>Boolean</strong>.</td>
</tr>
<tr>
<td>Property Name</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>MAINTAIN_SESSION</td>
<td>Specifies if the consumer wants to maintain the current session for future requests. The value is stored as a <strong>Boolean</strong>.</td>
</tr>
<tr>
<td>WSDL_DESCRIPTION</td>
<td>Specifies the WSDL document that defines the service being implemented. The value is stored as a <strong>org.xml.sax.InputSource</strong> object.</td>
</tr>
<tr>
<td>WSDL_SERVICE</td>
<td>Specifies the qualified name of the <strong>wsdl:service</strong> element that defines the service being implemented. The value is stored as a <strong>QName</strong>.</td>
</tr>
<tr>
<td>WSDL_PORT</td>
<td>Specifies the qualified name of the <strong>wsdl:port</strong> element that defines the endpoint used to access the service. The value is stored as a <strong>QName</strong>.</td>
</tr>
<tr>
<td>WSDL_INTERFACE</td>
<td>Specifies the qualified name of the <strong>wsdl:portType</strong> element that defines the service being implemented. The value is stored as a <strong>QName</strong>.</td>
</tr>
<tr>
<td>WSDL_OPERATION</td>
<td>Specifies the qualified name of the <strong>wsdl:operation</strong> element that corresponds to the operation invoked by the consumer. The value is stored as a <strong>QName</strong>.</td>
</tr>
<tr>
<td>javax.xml.ws.handler.MessageContext</td>
<td></td>
</tr>
<tr>
<td>MESSAGE_OUTBOUND_PROPERTY</td>
<td>Specifies if a message is outbound. The value is stored as a <strong>Boolean</strong>. true specifies that a message is outbound.</td>
</tr>
<tr>
<td>INBOUND_MESSAGE_ATTACHMENTS</td>
<td>Contains any attachments included in the request message. The value is stored as a <strong>java.util.Map&lt;String, DataHandler&gt;</strong>. The key value for the map is the MIME Content-ID for the header.</td>
</tr>
<tr>
<td>OUTBOUND_MESSAGE_ATTACHMENTS</td>
<td>Contains any attachments for the response message. The value is stored as a <strong>java.util.Map&lt;String, DataHandler&gt;</strong>. The key value for the map is the MIME Content-ID for the header.</td>
</tr>
<tr>
<td>WSDL_DESCRIPTION</td>
<td>Specifies the WSDL document that defines the service being implemented. The value is stored as a <strong>org.xml.sax.InputSource</strong> object.</td>
</tr>
<tr>
<td>Property Name</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>WSDL_SERVICE</td>
<td>Specifies the qualified name of the <code>wsdl:service</code> element that defines the service being implemented. The value is stored as a <a href="https://java.net/jdk8u-specs/jsr368/specs.equality/com/sun/xml/stream/soap11/impl/QNameImpl.html">QName</a>.</td>
</tr>
<tr>
<td>WSDL_PORT</td>
<td>Specifies the qualified name of the <code>wsdl:port</code> element that defines the endpoint used to access the service. The value is stored as a <a href="https://java.net/jdk8u-specs/jsr368/specs.equality/com/sun/xml/stream/soap11/impl/QNameImpl.html">QName</a>.</td>
</tr>
<tr>
<td>WSDL_INTERFACE</td>
<td>Specifies the qualified name of the <code>wsdl:portType</code> element that defines the service being implemented. The value is stored as a <a href="https://java.net/jdk8u-specs/jsr368/specs.equality/com/sun/xml/stream/soap11/impl/QNameImpl.html">QName</a>.</td>
</tr>
<tr>
<td>WSDL_OPERATION</td>
<td>Specifies the qualified name of the <code>wsdl:operation</code> element that corresponds to the operation invoked by the consumer. The value is stored as a <a href="https://java.net/jdk8u-specs/jsr368/specs.equality/com/sun/xml/stream/soap11/impl/QNameImpl.html">QName</a>.</td>
</tr>
<tr>
<td>HTTP_RESPONSE_CODE</td>
<td>Specifies the response code returned to the consumer. The value is stored as an <a href="https://docs.oracle.com/en/java/javase/11/docs/api/java.base/java/lang/Integer.html">Integer</a> object.</td>
</tr>
<tr>
<td>HTTP_REQUEST_HEADERS</td>
<td>Specifies the HTTP headers on a request. The value is stored as a <a href="https://docs.oracle.com/en/java/javase/11/docs/api/java.base/java/util/Map.html">java.util.Map&lt;String, List&lt;String&gt;&gt;</a>.</td>
</tr>
<tr>
<td>HTTP_RESPONSE_HEADERS</td>
<td>Specifies the HTTP headers for the response. The value is stored as a <a href="https://docs.oracle.com/en/java/javase/11/docs/api/java.base/java/util/Map.html">java.util.Map&lt;String, List&lt;String&gt;&gt;</a>.</td>
</tr>
<tr>
<td>HTTP_REQUEST_METHOD</td>
<td>Specifies the HTTP verb sent with a request. The value is stored as a <a href="https://docs.oracle.com/en/java/javase/11/docs/api/java.base/java/lang/String.html">String</a>.</td>
</tr>
<tr>
<td>SERVLET_CONTEXT</td>
<td>Contains the servlet’s context object. The value is stored as a <a href="https://docs.oracle.com/en/java/javase/11/docs/api/java.base/javax/servlet/ServletContext.html">javax.servlet.ServletContext</a>.</td>
</tr>
<tr>
<td>PATH_INFO</td>
<td>Specifies the path of the resource being requested. The value is stored as a <a href="https://docs.oracle.com/en/java/javase/11/docs/api/java.base/java/lang/String.html">String</a>.</td>
</tr>
</tbody>
</table>

The path is the portion of the URI after the hostname and before any query string. For example, if an endpoint’s URL is `http://cxf.apache.org/demo/widgets` the path is `/demo/widgets`.  

---

419
QUERY_STRING

Specifies the query, if any, attached to the URI used to invoke the request. The value is stored as a String.

Queries appear at the end of the URI after a ?. For example, if a request is made to http://cxf.apache.org/demo/widgets?color the query string is color.

REFERENCE_PARAMETERS

Specifies the WS-Addressing reference parameters. This includes all of the SOAP headers whose wsa:IsReferenceParameter attribute is set to true. The value is stored as a java.util.List.

org.apache.cxf.transport.jms.JMSConstants

JMS_SERVER_HEADERS

Contains the JMS message headers. For more information see Section 42.4, “Working with JMS Message Properties.”

[a] When using HTTP this property is the same as the standard JAX-WS defined property.

42.3. WORKING WITH CONTEXTS IN A CONSUMER IMPLEMENTATION

Overview

Consumer implementations have access to context information through the BindingProvider interface. The BindingProvider instance holds context information in two separate contexts:

- **Request Context** The request context enables you to set properties that affect outbound messages. Request context properties are applied to a specific port instance and, once set, the properties affect every subsequent operation invocation made on the port, until such time as a property is explicitly cleared. For example, you might use a request context property to set a connection timeout or to initialize data for sending in a header.

- **Response Context** The response context enables you to read the property values set by the response to the last operation invocation made from the current thread. Response context properties are reset after every operation invocation. For example, you might access a response context property to read header information received from the last inbound message.

**IMPORTANT**

Only information that is placed in the application scope of a message context can be accessed by the consumer implementation.

Obtaining a context

Contexts are obtained using the javax.xml.ws.BindingProvider interface. The BindingProvider interface has two methods for obtaining a context:
**getRequestContext()** The `getRequestContext()` method, shown in Example 42.7, "The `getRequestContext()` Method", returns the request context as a `Map` object. The returned `Map` object can be used to directly manipulate the contents of the context.

Example 42.7. The `getRequestContext()` Method

```java
Map<String, Object> getRequestContext
```

**getResponseContext()** The `getResponseContext()`, shown in Example 42.8, "The `getResponseContext()` Method", returns the response context as a `Map` object. The returned `Map` object’s contents reflect the state of the response context’s contents from the most recent successful request on a remote service made in the current thread.

Example 42.8. The `getResponseContext()` Method

```java
Map<String, Object> getResponseContext
```

Since proxy objects implement the BindingProvider interface, a BindingProvider object can be obtained by casting a proxy object. The contexts obtained from the BindingProvider object are only valid for operations invoked on the proxy object used to create it.

Example 42.9, “Getting a Consumer’s Request Context” shows code for obtaining the request context for a proxy.

Example 42.9. Getting a Consumer’s Request Context

```java
// Proxy widgetProxy obtained previously
BindingProvider bp = (BindingProvider)widgetProxy;
Map<String, Object> requestContext = bp.getRequestContext();
```

Reading a property from a context

Consumer contexts are stored in `java.util.Map<String, Object>` objects. The map has keys that are `String` objects and values that contain arbitrary objects. Use `java.util.Map.get()` to access an entry in the map of response context properties.

To retrieve a particular context property, `ContextPropertyName`, use the code shown in Example 42.10, “Reading a Response Context Property”.

Example 42.10. Reading a Response Context Property

```java
// Invoke an operation.
port.SomeOperation();

// Read response context property.
java.util.Map<String, Object> responseContext =
((javax.xml.ws.BindingProvider)port).getResponseContext();
PropertyType propValue = (PropertyType) responseContext.get(ContextPropertyName);
```

Setting properties in a context
Consumer contexts are hash maps stored in `java.util.Map<String, Object>` objects. The map has keys that are `String` objects and values that are arbitrary objects. To set a property in a context use the `java.util.Map.put()` method.

While you can set properties in both the request context and the response context, only the changes made to the request context have any impact on message processing. The properties in the response context are reset when each remote invocation is completed on the current thread.

The code shown in Example 42.11, “Setting a Request Context Property” changes the address of the target service provider by setting the value of the `BindingProvider.ENDPOINT_ADDRESS_PROPERTY`.

Example 42.11. Setting a Request Context Property

```java
// Set request context property.
java.util.Map<String, Object> requestContext =
    ((javax.xml.ws.BindingProvider)port).getRequestContext();
requestContext.put(BindingProvider.ENDPOINT_ADDRESS_PROPERTY,
    "http://localhost:8080/widgets");

// Invoke an operation.
port.SomeOperation();
```

**IMPORTANT**

Once a property is set in the request context its value is used for all subsequent remote invocations. You can change the value and the changed value will then be used.

**Supported contexts**

Apache CXF supports the following context properties in consumer implementations:

**Table 42.2. Consumer Context Properties**

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>javax.xml.ws.BindingProvider</code></td>
<td></td>
</tr>
<tr>
<td>ENDPOINT_ADDRESS_PROPERTY</td>
<td>Specifies the address of the target service. The value is stored as a <code>String</code>.</td>
</tr>
<tr>
<td>USERNAMEPROPERTY[a]</td>
<td>Specifies the username used for HTTP basic authentication. The value is stored as a <code>String</code>.</td>
</tr>
<tr>
<td>PASSWORDPROPERTY[b]</td>
<td>Specifies the password used for HTTP basic authentication. The value is stored as a <code>String</code>.</td>
</tr>
<tr>
<td>SESSION_MAINTAIN_PROPERTY[c]</td>
<td>Specifies if the client wants to maintain session information. The value is stored as a <code>Boolean</code> object.</td>
</tr>
<tr>
<td><code>org.apache.cxf.ws.addressing.JAXWSAConstants</code></td>

</tr>
</tbody>
</table>
### 42.4. WORKING WITH JMS MESSAGE PROPERTIES

#### Abstract

The Apache CXF JMS transport has a context mechanism that can be used to inspect a JMS message’s properties. The context mechanism can also be used to set a JMS message’s properties.

#### 42.4.1. Inspecting JMS Message Headers

##### Abstract

Consumers and services use different context mechanisms to access the JMS message header properties. However, both mechanisms return the header properties as a `org.apache.cxf.transports.jms.context.JMSMessageHeadersType` object.

##### Getting the JMS Message Headers in a Service

To get the JMS message header properties from the `WebServiceContext` object, do the following:

1. Obtain the context as described in the section called “Obtaining a context”.

2. Get the message headers from the message context using the message context’s `get()` method with the parameter `org.apache.cxf.transports.jms.JMSConstants.JMS_SERVER_HEADERS`.

   **Example 42.12. Getting JMS Message Headers in a Service Implementation** shows code for getting the JMS message headers from a service’s message context:

   ```java
   import org.apache.cxf.transport.jms.JMSConstants;
   import org.apache.cxf.transports.jms.context.JMSMessageHeadersType;
   ```
@WebService(serviceName = "HelloWorldService",
   portName = "HelloWorldPort",
   endpointInterface = "org.apache.cxf.hello_world.jms.HelloWorldPortType",
   targetNamespace = "http://cxf.apache.org/hello_world.jms")
public class GreeterImplTwoWayJMS implements HelloWorldPortType
{
   @Resource
   protected WebServiceContext wsContext;
   ...

   @WebMethod
   public String greetMe(String me)
   {
      MessageContext mc = wsContext.getMessageContext();
      JMSMessageHeadersType headers = (JMSMessageHeadersType)
      mc.get(JMSConstants.JMS_SERVER_HEADERS);
      ...
   }
}

Getting JMS Message Header Properties in a Consumer

Once a message is successfully retrieved from the JMS transport you can inspect the JMS header properties using the consumer’s response context. In addition, you can set or check the length of time the client will wait for a response before timing out, as described in the section called “Client Receive Timeout”. To get the JMS message headers from a consumer’s response context do the following:

1. Get the response context as described in the section called “Obtaining a context”.

2. Get the JMS message header properties from the response context using the context’s get() method with org.apache.cxf.transports.jms.JMSConstants.JMS_CLIENT_RESPONSE_HEADERS as the parameter.

Example 42.13, “Getting the JMS Headers from a Consumer Response Header” shows code for getting the JMS message header properties from a consumer’s response context.

Example 42.13. Getting the JMS Headers from a Consumer Response Header

```java
import org.apache.cxf.transports.jms.context.*;
// Proxy greeter initialized previously
BindingProvider bp = (BindingProvider)greeter;
Map<String, Object> responseContext = bp.getResponseContext();
JMSMessageHeadersType responseHdr = (JMSMessageHeadersType)
responseContext.get(JMSConstants.JMS_CLIENT_RESPONSE_HEADERS);
...
```
Casts the proxy to a BindingProvider.

Gets the response context.

Retrieves the JMS message headers from the response context.

### 42.4.2. Inspecting the Message Header Properties

#### Standard JMS Header Properties

Table 42.3, "JMS Header Properties" lists the standard properties in the JMS header that you can inspect.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Property Type</th>
<th>Getter Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>Correlation ID</td>
<td>string</td>
<td>getJMSCorrelationID()</td>
</tr>
<tr>
<td>Delivery Mode</td>
<td>int</td>
<td>getJMSDeliveryMode()</td>
</tr>
<tr>
<td>Message Expiration</td>
<td>long</td>
<td>getJMSExpiration()</td>
</tr>
<tr>
<td>Message ID</td>
<td>string</td>
<td>getJMSMessageID()</td>
</tr>
<tr>
<td>Priority</td>
<td>int</td>
<td>getJMSPriority()</td>
</tr>
<tr>
<td>Redelivered</td>
<td>boolean</td>
<td>getJMSRedelivered()</td>
</tr>
<tr>
<td>Time Stamp</td>
<td>long</td>
<td>getJMSTimeStamp()</td>
</tr>
<tr>
<td>Type</td>
<td>string</td>
<td>getJMSType()</td>
</tr>
<tr>
<td>Time To Live</td>
<td>long</td>
<td>getTimeToLive()</td>
</tr>
</tbody>
</table>

#### Optional Header Properties

In addition, you can inspect any optional properties stored in the JMS header using `JMSMessageHeadersType.getProperty()`. The optional properties are returned as a `List` of `org.apache.cxf.transports.jms.context.JMSPropertyType`. Optional properties are stored as name/value pairs.

#### Example

Example 42.14, "Reading the JMS Header Properties" shows code for inspecting some of the JMS properties using the response context.

```java
// JMSMessageHeadersType messageHdr retrieved previously
```
The code in Example 42.14, "Reading the JMS Header Properties" does the following:

Prints the value of the message’s correlation ID.

Prints the value of the message’s priority property.

Prints the value of the message’s redelivered property.

Gets the list of the message’s optional header properties.

Gets an Iterator to traverse the list of properties.

Iterates through the list of optional properties and prints their name and value.

### 42.4.3. Setting JMS Properties

**Abstract**

Using the request context in a consumer endpoint, you can set a number of the JMS message header properties and the consumer endpoint’s timeout value. These properties are valid for a single invocation. You must reset them each time you invoke an operation on the service proxy.

Note that you cannot set header properties in a service.

**JMS Header Properties**

Table 42.4, “Settable JMS Header Properties” lists the properties in the JMS header that can be set using the consumer endpoint’s request context.

**Table 42.4. Settable JMS Header Properties**

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Property Type</th>
<th>Setter Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>Correlation ID</td>
<td>string</td>
<td>setJMSCorrelationID()</td>
</tr>
<tr>
<td>Delivery Mode</td>
<td>int</td>
<td>setJMSDeliveryMode()</td>
</tr>
<tr>
<td>Priority</td>
<td>int</td>
<td>setJMSPriority()</td>
</tr>
</tbody>
</table>
To set these properties do the following:

1. Create an `org.apache.cxf.transports.jms.context.JMSMessageHeadersType` object.

2. Populate the values you want to set using the appropriate setter methods described in Table 42.4, “Settable JMS Header Properties”.

3. Set the values to the request context by calling the request context’s `put()` method using `org.apache.cxf.transports.jms.JMSCoreConstants.JMS_CLIENT_REQUEST_HEADERS` as the first argument, and the new `JMSMessageHeadersType` object as the second argument.

### Optional JMS Header Properties

You can also set optional properties to the JMS header. Optional JMS header properties are stored in the `JMSMessageHeadersType` object that is used to set the other JMS header properties. They are stored as a `List` object containing `org.apache.cxf.transports.jms.context.JMSPROPERTYTYPE` objects.

To add optional properties to the JMS header do the following:

1. Create a `JMSPROPERTYTYPE` object.

2. Set the property’s name field using `setName()`.

3. Set the property’s value field using `setValue()`.

4. Add the property to the JMS message header using `JMSMessageHeadersType.getProperty().add(JMSPROPERTYTYPE)`.

5. Repeat the procedure until all of the properties have been added to the message header.

### Client Receive Timeout

In addition to the JMS header properties, you can set the amount of time a consumer endpoint waits for a response before timing out. You set the value by calling the request context’s `put()` method with `org.apache.cxf.transports.jms.JMSCoreConstants.JMS_CLIENT_RECEIVE_TIMEOUT` as the first argument and a `long` representing the amount of time in milliseconds that you want the consumer to wait as the second argument.

### Example

Example 42.15, “Setting JMS Properties using the Request Context” shows code for setting some of the JMS properties using the request context.

```java
import org.apache.cxf.transports.jms.context.*;
// Proxy greeter initialized previously
InvocationHandler handler = Proxy.getInvocationHandler(greeter);
```
BindingProvider bp = null;
if (handler instanceof BindingProvider)
{
    bp = (BindingProvider)handler;
    Map<String, Object> requestContext = bp.getRequestContext();

    JMSMessageHeadersType requestHdr = new JMSMessageHeadersType();
    requestHdr.setJMSCorrelationID("WithBob");
    requestHdr.setJMSExpiration(3600000L);

    JMSPropertyType prop = new JMSPropertyType;
    prop.setName("MyProperty");
    prop.setValue("Bluebird");
    requestHdr.getProperty().add(prop);

    requestContext.put(JMSConstants.CLIENT_REQUEST_HEADERS, requestHdr);
    requestContext.put(JMSConstants.CLIENT_RECEIVE_TIMEOUT, new Long(1000));
}

The code in Example 42.15, “Setting JMS Properties using the Request Context” does the following:

- Gets the InvocationHandler for the proxy whose JMS properties you want to change.
- Checks to see if the InvocationHandler is a BindingProvider.
- Casts the returned InvocationHandler object into a BindingProvider object to retrieve the request context.
- Gets the request context.
- Creates a JMSMessageHeadersType object to hold the new message header values.
- Sets the Correlation ID.
- Sets the Expiration property to 60 minutes.
- Creates a new JMSPropertyType object.
- Sets the values for the optional property.
- Adds the optional property to the message header.
- Sets the JMS message header values into the request context.
- Sets the client receive timeout property to 1 second.
CHAPTER 43. WRITING HANDLERS

Abstract

JAX-WS provides a flexible plug-in framework for adding message processing modules to an application. These modules, known as handlers, are independent of the application level code and can provide low-level message processing capabilities.

43.1. HANDLERS: AN INTRODUCTION

Overview

When a service proxy invokes an operation on a service, the operation’s parameters are passed to Apache CXF where they are built into a message and placed on the wire. When the message is received by the service, Apache CXF reads the message from the wire, reconstructs the message, and then passes the operation parameters to the application code responsible for implementing the operation. When the application code is finished processing the request, the reply message undergoes a similar chain of events on its trip to the service proxy that originated the request. This is shown in Figure 43.1, “Message Exchange Path”.

Figure 43.1. Message Exchange Path

JAX-WS defines a mechanism for manipulating the message data between the application level code and the network. For example, you might want the message data passed over the open network to be encrypted using a proprietary encryption mechanism. You could write a JAX-WS handler that encrypted and decrypted the data. Then you could insert the handler into the message processing chains of all clients and servers.

As shown in Figure 43.2, “Message Exchange Path with Handlers”, the handlers are placed in a chain that is traversed between the application level code and the transport code that places the message onto the network.
**Handler types**

The JAX-WS specification defines two basic handler types:

- **Logical Handler** Logical handlers can process the message payload and the properties stored in the message context. For example, if the application uses pure XML messages, the logical handlers have access to the entire message. If the application uses SOAP messages, the logical handlers have access to the contents of the SOAP body. They do not have access to either the SOAP headers or any attachments unless they were placed into the message context. Logical handlers are placed closest to the application code on the handler chain. This means that they are executed first when a message is passed from the application code to the transport. When a message is received from the network and passed back to the application code, the logical handlers are executed last.

- **Protocol Handler** Protocol handlers can process the entire message received from the network and the properties stored in the message context. For example, if the application uses SOAP messages, the protocol handlers would have access to the contents of the SOAP body, the SOAP headers, and any attachments. Protocol handlers are placed closest to the transport on the handler chain. This means that they are executed first when a message is received from the network. When a message is sent to the network from the application code, the protocol handlers are executed last.

**NOTE**

The only protocol handler supported by Apache CXF is specific to SOAP.
Implementation of handlers

The differences between the two handler types are very subtle and they share a common base interface. Because of their common parentage, logical handlers and protocol handlers share a number of methods that must be implemented, including:

- handleMessage() The `handleMessage()` method is the central method in any handler. It is the method responsible for processing normal messages.

- handleFault() `handleFault()` is the method responsible for processing fault messages.

- close() `close()` is called on all executed handlers in a handler chain when a message has reached the end of the chain. It is used to clean up any resources consumed during message processing.

The differences between the implementation of a logical handler and the implementation of a protocol handler revolve around the following:

- The specific interface that is implemented
  All handlers implement an interface that derives from the Handler interface. Logical handlers implement the LogicalHandler interface. Protocol handlers implement protocol specific extensions of the Handler interface. For example, SOAP handlers implement the SOAPHandler interface.

- The amount of information available to the handler
  Protocol handlers have access to the contents of messages and all of the protocol specific information that is packaged with the message content. Logical handlers can only access the contents of the message. Logical handlers have no knowledge of protocol details.

Adding handlers to an application

To add a handler to an application you must do the following:

1. Determine whether the handler is going to be used on the service providers, the consumers, or both.

2. Determine which type of handler is the most appropriate for the job.

3. Implement the proper interface.
   To implement a logical handler see Section 43.2, “Implementing a Logical Handler”.

   To implement a protocol handler see Section 43.4, “Implementing a Protocol Handler”.

4. Configure your endpoint(s) to use the handlers. See Section 43.10, “Configuring Endpoints to Use Handlers”.

43.2. IMPLEMENTING A LOGICAL HANDLER

Overview

Logical handlers implement the javax.xml.ws.handler.LogicalHandler interface. The LogicalHandler interface, shown in Example 43.1, “LogicalHandler Synopsis” passes a `LogicalMessageContext` object to the `handleMessage()` method and the `handleFault()` method. The context object provides access to the body of the message and to any properties set into the message exchange’s context.

Example 43.1. LogicalHandler Synopsis
public interface LogicalHandler extends Handler
{
    boolean handleMessage(LogicalMessageContext context);
    boolean handleFault(LogicalMessageContext context);
    void close(LogicalMessageContext context);
}

Procedure

To implement a logical handler you do the following:

1. Implement any Section 43.6, "Initializing a Handler" logic required by the handler.
2. Implement the Section 43.3, "Handling Messages in a Logical Handler" logic.
3. Implement the Section 43.7, "Handling Fault Messages" logic.
4. Implement the logic for Section 43.8, "Closing a Handler" the handler when it is finished.
5. Implement any logic for Section 43.9, "Releasing a Handler" the handler’s resources before it is destroyed.

43.3. HANDLING MESSAGES IN A LOGICAL HANDLER

Overview

Normal message processing is handled by the handleMessage() method.

The handleMessage() method receives a LogicalMessageContext object that provides access to the message body and any properties stored in the message context.

The handleMessage() method returns either true or false depending on how message processing is to continue. It can also throw an exception.

Getting the message data

The LogicalMessageContext object passed into logical message handlers allows access to the message body using the context’s getMessage() method. The getMessage() method, shown in Example 43.2, “Method for Getting the Message Payload in a Logical Handler”, returns the message payload as a LogicalMessage object.

Example 43.2. Method for Getting the Message Payload in a Logical Handler

LogicalMessage

Once you have the LogicalMessage object, you can use it to manipulate the message body. The LogicalMessage interface, shown in Example 43.3, “Logical Message Holder”, has getters and setters for working with the actual message body.

Example 43.3. Logical Message Holder
IMPORTANT

The contents of the message payload are determined by the type of binding in use. The SOAP binding only allows access to the SOAP body of the message. The XML binding allows access to the entire message body.

Working with the message body as an XML object

One pair of getters and setters of the logical message work with the message payload as a *javax.xml.transform.dom.DOMSource* object.

The *getPayload()* method that has no parameters returns the message payload as a *DOMSource* object. The returned object is the actual message payload. Any changes made to the returned object change the message body immediately.

You can replace the body of the message with a *DOMSource* object using the *setPayload()* method that takes the single Source object.

Working with the message body as a JAXB object

The other pair of getters and setters allow you to work with the message payload as a JAXB object. They use a *JAXBContext* object to transform the message payload into JAXB objects.

To use the JAXB objects you do the following:

1. Get a *JAXBContext* object that can manage the data types in the message body.
   For information on creating a *JAXBContext* object see Chapter 39, *Using A JAXBContext Object*.

2. Get the message body as shown in Example 43.4, “Getting the Message Body as a JAXB Object”.

   **Example 43.4. Getting the Message Body as a JAXB Object**

   ```java
   JAXBContext jaxbc = JAXBContext(myObjectFactory.class);
   Object body = message.getPayload(jaxbc);
   ```

3. Cast the returned object to the proper type.

4. Manipulate the message body as needed.

5. Put the updated message body back into the context as shown in Example 43.5, “Updating the Message Body Using a JAXB Object”.

   **Example 43.5. Updating the Message Body Using a JAXB Object**

   ```java
   message.setPayload(body, jaxbc);
   ```
Working with context properties

The logical message context passed into a logical handler is an instance of the application’s message context and can access all of the properties stored in it. Handlers have access to properties at both the `APPLICATION` scope and the `HANDLER` scope.

Like the application’s message context, the logical message context is a subclass of Java Map. To access the properties stored in the context, you use the `get()` method and `put()` method inherited from the Map interface.

By default, any properties you set in the message context from inside a logical handler are assigned a scope of `HANDLER`. If you want the application code to be able to access the property you need to use the context’s `setScope()` method to explicitly set the property’s scope to `APPLICATION`.

For more information on working with properties in the message context see Section 42.1, “Understanding Contexts”.

Determining the direction of the message

It is often important to know the direction a message is passing through the handler chain. For example, you would want to retrieve a security token from incoming requests and attach a security token to an outgoing response.

The direction of the message is stored in the message context’s outbound message property. You retrieve the outbound message property from the message context using the `MessageContext.MESSAGE_OUTBOUND_PROPERTY` key as shown in Example 43.6, “Getting the Message’s Direction from the SOAP Message Context”.

Example 43.6. Getting the Message’s Direction from the SOAP Message Context

```java
Boolean outbound;
outbound = (Boolean)smc.get(MessageContext.MESSAGE_OUTBOUND_PROPERTY);
```

The property is stored as a `Boolean` object. You can use the object’s `booleanValue()` method to determine the property’s value. If the property is set to true, the message is outbound. If the property is set to false the message is inbound.

Determining the return value

How the `handleMessage()` method completes its message processing has a direct impact on how message processing proceeds. It can complete by doing one of the following actions:

1. Return true—Returning true signals to the Apache CXF runtime that message processing should continue normally. The next handler, if any, has its `handleMessage()` invoked.

2. Return false—Returning false signals to the Apache CXF runtime that normal message processing must stop. How the runtime proceeds depends on the message exchange pattern in use for the current message.
   For request-response message exchanges the following happens:
   a. The direction of message processing is reversed.
      For example, if a request is being processed by a service provider, the message stops progressing toward the service’s implementation object. Instead, it is sent back towards the binding for return to the consumer that originated the request.
b. Any message handlers that reside along the handler chain in the new processing direction have their `handleMessage()` method invoked in the order in which they reside in the chain.

c. When the message reaches the end of the handler chain it is dispatched. For one-way message exchanges the following happens:

d. Message processing stops.

e. All previously invoked message handlers have their `close()` method invoked.

f. The message is dispatched.

3. Throw a ProtocolException exception—Throwing a ProtocolException exception, or a subclass of this exception, signals the Apache CXF runtime that fault message processing is beginning. How the runtime proceeds depends on the message exchange pattern in use for the current message. For request–response message exchanges the following happens:

a. If the handler has not already created a fault message, the runtime wraps the message in a fault message.

b. The direction of message processing is reversed. For example, if a request is being processed by a service provider, the message stops progressing toward the service’s implementation object. Instead, it is sent back towards the binding for return to the consumer that originated the request.

c. Any message handlers that reside along the handler chain in the new processing direction have their `handleFault()` method invoked in the order in which they reside in the chain.

d. When the fault message reaches the end of the handler chain it is dispatched. For one-way message exchanges the following happens:

e. If the handler has not already created a fault message, the runtime wraps the message in a fault message.

f. Message processing stops.

g. All previously invoked message handlers have their `close()` method invoked.

h. The fault message is dispatched.

4. Throw any other runtime exception—Throwing a runtime exception other than a ProtocolException exception signals the Apache CXF runtime that message processing is to stop. All previously invoked message handlers have the `close()` method invoked and the exception is dispatched. If the message is part of a request–response message exchange, the exception is dispatched so that it is returned to the consumer that originated the request.

Example

Example 43.7, “Logical Message Handler Message Processing” shows an implementation of `handleMessage()` message for a logical message handler that is used by a service consumer. It processes requests before they are sent to the service provider.

Example 43.7. Logical Message Handler Message Processing

```java
public class SmallNumberHandler implements LogicalHandler<LogicalMessageContext>
```
public final boolean handleMessage(LogicalMessageContext messageContext) {
    try {
        boolean outbound = (Boolean)messageContext.get(MessageContext.MESSAGE_OUTBOUND_PROPERTY);

        if (outbound) {
            LogicalMessage msg = messageContext.getMessage();

            JAXBContext jaxbContext = JAXBContext.newInstance(ObjectFactory.class);
            Object payload = msg.getPayload(jaxbContext);
            if (payload instanceof JAXBElement) {
                payload = ((JAXBElement)payload).getValue();
            }

            if (payload instanceof AddNumbers) {
                AddNumbers req = (AddNumbers)payload;

                int a = req.getArg0();
                int b = req.getArg1();
                int answer = a + b;

                if (answer < 20) {
                    AddNumbersResponse resp = new AddNumbersResponse();
                    resp.setReturn(answer);
                    msg.setPayload(new ObjectFactory().createAddNumbersResponse(resp), jaxbContext);
                    return false;
                }
            } else {
                throw new WebServiceException("Bad Request");
            }
        } else {
            throw new WebServiceException("Bad Request");
        }
    } catch (JAXBException ex) {
        throw new ProtocolException(ex);
    }
    return true;
}

The code in Example 43.7, "Logical Message Handler Message Processing" does the following:

Checks if the message is an outbound request.
If the message is an outbound request, the handler does additional message processing.

Gets the LogicalMessage representation of the message payload from the message context.

Gets the actual message payload as a JAXB object.

Checks to make sure the request is of the correct type.

If it is, the handler continues processing the message.

Checks the value of the sum.

If it is less than the threshold of 20 then it builds a response and returns it to the client.

Builds the response.

Returns false to stop message processing and return the response to the client.

Throws a runtime exception if the message is not of the correct type.

This exception is returned to the client.

Returns true if the message is an inbound response or the sum does not meet the threshold.

Message processing continues normally.

 Throws a ProtocolException if a JAXB marshalling error is encountered.

The exception is passed back to the client after it is processed by the `handleFault()` method of the handlers between the current handler and the client.

### 43.4. IMPLEMENTING A PROTOCOL HANDLER

#### Overview

Protocol handlers are specific to the protocol in use. Apache CXF provides the SOAP protocol handler as specified by JAX-WS. A SOAP protocol handler implements the `javax.xml.ws.handler.soap.SOAPHandler` interface.

The SOAPHandler interface, shown in Example 43.8, “SOAPHandler Synopsis”, uses a SOAP specific message context that provides access to the message as a `SOAPMessage` object. It also allows you to access the SOAP headers.

Example 43.8. SOAPHandler Synopsis

```java
public interface SOAPHandler extends Handler {
    boolean handleMessage(SOAPMessageContext context);
    boolean handleFault(SOAPMessageContext context);
    void close(SOAPMessageContext context);
    Set<QName> getHeaders()
}
```
In addition to using a SOAP specific message context, SOAP protocol handlers require that you implement an additional method called \texttt{getHeaders()}. This additional method returns the QNames of the header blocks the handler can process.

**Procedure**

To implement a logical hander do the following:

1. Implement any Section 43.6, "Initializing a Handler" logic required by the handler.
2. Implement the Section 43.5, "Handling Messages in a SOAP Handler" logic.
3. Implement the Section 43.7, "Handling Fault Messages" logic.
4. Implement the \texttt{getHeaders()} method.
5. Implement the logic for Section 43.8, "Closing a Handler" the handler when it is finished.
6. Implement any logic for Section 43.9, "Releasing a Handler" the handler's resources before it is destroyed.

**Implementing the \texttt{getHeaders()} method**

The \texttt{getHeaders()}, shown in Example 43.9, "The \texttt{SOAPHander.getHeaders()} Method", method informs the Apache CXF runtime what SOAP headers the handler is responsible for processing. It returns the QNames of the outer element of each SOAP header the handler understands.

```
Example 43.9. The \texttt{SOAPHander.getHeaders()} Method

Set\textless QName\textgreater \texttt{getHeaders}
```

For many cases simply returning null is sufficient. However, if the application uses the \texttt{mustUnderstand} attribute of any of the SOAP headers, then it is important to specify the headers understood by the application's SOAP handlers. The runtime checks the set of SOAP headers that all of the registered handlers understand against the list of headers with the \texttt{mustUnderstand} attribute set to \texttt{true}. If any of the flagged headers are not in the list of understood headers, the runtime rejects the message and throws a SOAP must understand exception.

**43.5. HANDLING MESSAGES IN A SOAP HANDLER**

**Overview**

Normal message processing is handled by the \texttt{handleMessage()} method.

The \texttt{handleMessage()} method receives a \texttt{SOAPMessageContext} object that provides access to the message body as a \texttt{SOAPMessage} object and the SOAP headers associated with the message. In addition, the context provides access to any properties stored in the message context.

The \texttt{handleMessage()} method returns either true or false depending on how message processing is to continue. It can also throw an exception.

**Working with the message body**
You can get the SOAP message using the SOAP message context’s `getMessage()` method. It returns the message as a live `SOAPMessage` object. Any changes to the message in the handler are automatically reflected in the message stored in the context.

If you wish to replace the existing message with a new one, you can use the context’s `setMessage()` method. The `setMessage()` method takes a `SOAPMessage` object.

**Getting the SOAP headers**

You can access the SOAP message’s headers using the `SOAPMessage` object’s `getHeader()` method. This will return the SOAP header as a `SOAPHeader` object that you will need to inspect to find the header elements you wish to process.

The SOAP message context provides a `getHeaders()` method, shown in Example 43.10, “The `SOAPMessageContext.getHeaders()` Method”, that will return an array containing JAXB objects for the specified SOAP headers.

**Example 43.10. The `SOAPMessageContext.getHeaders()` Method**

```
Object[] getHeaders(QName header, JAXBContext context, boolean allRoles)
```

You specify the headers using the QName of their element. You can further limit the headers that are returned by setting the `allRoles` parameter to false. That instructs the runtime to only return the SOAP headers that are applicable to the active SOAP roles.

If no headers are found, the method returns an empty array.

For more information about instantiating a `JAXBContext` object see Chapter 39, *Using A `JAXBContext` Object*.

**Working with context properties**

The SOAP message context passed into a logical handler is an instance of the application’s message context and can access all of the properties stored in it. Handlers have access to properties at both the `APPLICATION` scope and the `Handler` scope.

Like the application’s message context, the SOAP message context is a subclass of Java Map. To access the properties stored in the context, you use the `get()` method and `put()` method inherited from the Map interface.

By default, any properties you set in the context from inside a logical handler will be assigned a scope of `HANDLER`. If you want the application code to be able to access the property you need to use the context’s `setScope()` method to explicitly set the property’s scope to `APPLICATION`.

For more information on working with properties in the message context see Section 42.1, “Understanding Contexts”.

**Determining the direction of the message**

It is often important to know the direction a message is passing through the handler chain. For example, you would want to add headers to an outgoing message and strip headers from an incoming message.

The direction of the message is stored in the message context’s outbound message property. You retrieve the outbound message property from the message context using the
MessageContext.MESSAGE_OUTBOUND_PROPERTY key as shown in Example 43.11, “Getting the Message’s Direction from the SOAP Message Context”.

Example 43.11. Getting the Message’s Direction from the SOAP Message Context

```java
Boolean outbound;
outbound = (Boolean)smc.get(MessageContext.MESSAGE_OUTBOUND_PROPERTY);
```

The property is stored as a `Boolean` object. You can use the object’s `booleanValue()` method to determine the property’s value. If the property is set to true, the message is outbound. If the property is set to false the message is inbound.

Determining the return value

How the `handleMessage()` method completes its message processing has a direct impact on how message processing proceeds. It can complete by doing one of the following actions:

1. return true—Returning true signals to the Apache CXF runtime that message processing should continue normally. The next handler, if any, has its `handleMessage()` invoked.

2. return false—Returning false signals to the Apache CXF runtime that normal message processing is to stop. How the runtime proceeds depends on the message exchange pattern in use for the current message.

   For request–response message exchanges the following happens:

   a. The direction of message processing is reversed.

   For example, if a request is being processed by a service provider, the message will stop progressing toward the service’s implementation object. It will instead be sent back towards the binding for return to the consumer that originated the request.

   b. Any message handlers that reside along the handler chain in the new processing direction have their `handleMessage()` method invoked in the order in which they reside in the chain.

   c. When the message reaches the end of the handler chain it is dispatched.

   For one-way message exchanges the following happens:

   d. Message processing stops.

   e. All previously invoked message handlers have their `close()` method invoked.

   f. The message is dispatched.

3. throw a ProtocolException exception—Throwing a ProtocolException exception, or a subclass of this exception, signals the Apache CXF runtime that fault message processing is to start. How the runtime proceeds depends on the message exchange pattern in use for the current message.

   For request–response message exchanges the following happens:

   a. If the handler has not already created a fault message, the runtime wraps the message in a fault message.

   b. The direction of message processing is reversed.
For example, if a request is being processed by a service provider, the message will stop progressing toward the service’s implementation object. It will be sent back towards the binding for return to the consumer that originated the request.

c. Any message handlers that reside along the handler chain in the new processing direction have their handleFault() method invoked in the order in which they reside in the chain.

d. When the fault message reaches the end of the handler chain it is dispatched. 
   For one-way message exchanges the following happens:

e. If the handler has not already created a fault message, the runtime wraps the message in a fault message.

f. Message processing stops.

g. All previously invoked message handlers have their close() method invoked.

h. The fault message is dispatched.

4. throw any other runtime exception—Throwing a runtime exception other than a
   ProtocolException exception signals the Apache CXF runtime that message processing is to
   stop. All previously invoked message handlers have the close() method invoked and the
   exception is dispatched. If the message is part of a request–response message exchange the
   exception is dispatched so that it is returned to the consumer that originated the request.

Example

Example 43.12, “Handling a Message in a SOAP Handler” shows a handleMessage() implementation that
prints the SOAP message to the screen.

Example 43.12. Handling a Message in a SOAP Handler

```java
public boolean handleMessage(SOAPMessageContext smc) {
    PrintStream out;

    Boolean outbound =
    (Boolean)smc.get(MessageContext.MESSAGE_OUTBOUND_PROPERTY);

    if (outbound.booleanValue())
    {
        out.println("Outbound message:"");
    }
    else
    {
        out.println("Inbound message:"");
    }

    SOAPMessage message = smc.getMessage();
    message.writeTo(out);
    out.println();
    return true;
}
```
The code in Example 43.12, "Handling a Message in a SOAP Handler" does the following:

Retrieves the outbound property from the message context.
Tests the messages direction and prints the appropriate message.
Retrieves the SOAP message from the context.
Prints the message to the console.

43.6. INITIALIZING A HANDLER

Overview

When the runtime creates an instance of a handler, it creates all of the resources the handler needs to process messages. While you can place all of the logic for doing this in the handler’s constructor, it may not be the most appropriate place. The handler framework performs a number of optional steps when it instantiates a handler. You can add resource injection and other initialization logic that will be executed during the optional steps.

You do not have to provide any initialization methods for a handler.

Order of initialization

The Apache CXF runtime initializes a handler in the following manner:

1. The handler’s constructor is called.
2. Any resources that are specified by the @Resource annotation are injected.
3. The method decorated with @PostConstruct annotation, if it is present, is called.

NOTE

Methods decorated with the @PostConstruct annotation must have a void return type and have no parameters.

4. The handler is place in the Ready state.

43.7. HANDLING FAULT MESSAGES

Overview

Handlers use the handleFault() method for processing fault messages when a ProtocolException exception is thrown during message processing.

The handleFault() method receives either a LogicalMessageContext object or SOAPMessageContext object depending on the type of handler. The received context gives the handler’s implementation access to the message payload.

The handleFault() method returns either true or false, depending on how fault message processing is to proceed. It can also throw an exception.
Getting the message payload

The context object received by the `handleFault()` method is similar to the one received by the `handleMessage()` method. You use the context’s `getMessage()` method to access the message payload in the same way. The only difference is the payload contained in the context.

For more information on working with a `LogicalMessageContext` see Section 43.3, “Handling Messages in a Logical Handler”.

For more information on working with a `SOAPMessageContext` see Section 43.5, “Handling Messages in a SOAP Handler”.

Determining the return value

How the `handleFault()` method completes its message processing has a direct impact on how message processing proceeds. It completes by performing one of the following actions:

Return true

Returning true signals that fault processing should continue normally. The `handleFault()` method of the next handler in the chain will be invoked.

Return false

Returning false signals that fault processing stops. The `close()` method of the handlers that were invoked in processing the current message are invoked and the fault message is dispatched.

Throw an exception

Throwing an exception stops fault message processing. The `close()` method of the handlers that were invoked in processing the current message are invoked and the exception is dispatched.

Example

Example 43.13, “Handling a Fault in a Message Handler” shows an implementation of `handleFault()` that prints the message body to the screen.

```java
Example 43.13. Handling a Fault in a Message Handler

public final boolean handleFault(LogicalMessageContext messageContext)
{
    System.out.println("handleFault() called with message:");

    LogicalMessage msg=messageContext.getMessage();
    System.out.println(msg.getPayload());

    return true;
}
```

43.8. CLOSING A HANDLER

When a handler chain is finished processing a message, the runtime calls each executed handler’s `close()` method. This is the appropriate place to clean up any resources that were used by the handler during message processing or resetting any properties to a default state.
If a resource needs to persist beyond a single message exchange, you should not clean it up during in the handler’s `close()` method.

### 43.9. RELEASING A HANDLER

#### Overview

The runtime releases a handler when the service or service proxy to which the handler is bound is shutdown. The runtime will invoke an optional release method before invoking the handler’s destructor. This optional release method can be used to release any resources used by the handler or perform other actions that would not be appropriate in the handler’s destructor.

You do not have to provide any clean-up methods for a handler.

#### Order of release

The following happens when the handler is released:

1. The handler finishes processing any active messages.

2. The runtime invokes the method decorated with the `@PreDestroy` annotation. This method should clean up any resources used by the handler.

3. The handler’s destructor is called.

### 43.10. CONFIGURING ENDPOINTS TO USE HANDLERS

#### 43.10.1. Programmatic Configuration

#### 43.10.1.1. Adding a Handler Chain to a Consumer

#### Overview

Adding a handler chain to a consumer involves explicitly building the chain of handlers. Then you set the handler chain directly on the service proxy’s Binding object.

**IMPORTANT**

Any handler chains configured using the Spring configuration override the handler chains configured programmaticaly.

#### Procedure

To add a handler chain to a consumer you do the following:

1. Create a `List<Handler>` object to hold the handler chain.

2. Create an instance of each handler that will be added to the chain.

3. Add each of the instantiated handler objects to the list in the order they are to be invoked by the runtime.

4. Get the Binding object from the service proxy.
Apache CXF provides an implementation of the Binding interface called \texttt{org.apache.cxf.jaxws.binding.DefaultBindingImpl}.

5. Set the handler chain on the proxy using the Binding object's \texttt{setHandlerChain()} method.

Example

Example 43.14, “Adding a Handler Chain to a Consumer” shows code for adding a handler chain to a consumer.

```java
import javax.xml.ws.BindingProvider;
import javax.xml.ws.handler.Handler;
import java.util.ArrayList;
import java.util.List;
import org.apache.cxf.jaxws.binding.DefaultBindingImpl;
...
SmallNumberHandler sh = new SmallNumberHandler();
List<Handler> handlerChain = new ArrayList<Handler>();
handlerChain.add(sh);
DefaultBindingImpl binding = ((BindingProvider)proxy).getBinding();
binding.getBinding().setHandlerChain(handlerChain);
```

The code in Example 43.14, “Adding a Handler Chain to a Consumer” does the following:

- Instantiates a handler.
- Creates a \texttt{List} object to hold the chain.
- Adds the handler to the chain.
- Gets the Binding object from the proxy as a \texttt{DefaultBindingImpl} object.
- Assigns the handler chain to the proxy’s binding.

43.10.1.2. Adding a Handler Chain to a Service Provider

Overview

You add a handler chain to a service provider by decorating either the SEI or the implementation class with the \texttt{@HandlerChain} annotation. The annotation points to a meta-data file defining the handler chain used by the service provider.

Procedure

To add handler chain to a service provider you do the following:

1. Decorate the provider’s implementation class with the \texttt{@HandlerChain} annotation.
2. Create a handler configuration file that defines the handler chain.
The @HandlerChain annotation

The javax.jws.HandlerChain annotation decorates service provider's implementation class. It instructs the runtime to load the handler chain configuration file specified by its file property.

The annotation's file property supports two methods for identifying the handler configuration file to load:

- a URL
- a relative path name

Example 43.15, "Service Implementation that Loads a Handler Chain" shows a service provider implementation that will use the handler chain defined in a file called handlers.xml. handlers.xml must be located in the directory from which the service provider is run.

Example 43.15. Service Implementation that Loads a Handler Chain

```java
import javax.jws.HandlerChain;
import javax.jws.WebService;
...

@WebService(name = "AddNumbers",
    targetNamespace = "http://apache.org/handlers",
    portName = "AddNumbersPort",
    endpointInterface = "org.apache.handlers.AddNumbers",
    serviceName = "AddNumbersService")
@HandlerChain(file = "handlers.xml")
public class AddNumbersImpl implements AddNumbers
{
    ...
}
```

Handler configuration file

The handler configuration file defines a handler chain using the XML grammar that accompanies JSR 109 (Web Services for Java EE, Version 1.2). This grammar is defined in the http://java.sun.com/xml/ns/javaee.

The root element of the handler configuration file is the handler-chains element. The handler-chains element has one or more handler-chain elements.

The handler-chain element define a handler chain. Table 43.1, "Elements Used to Define a Server-Side Handler Chain" describes the handler-chain element’s children.

Table 43.1. Elements Used to Define a Server-Side Handler Chain

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>handler</td>
<td>Contains the elements that describe a handler.</td>
</tr>
</tbody>
</table>
### Element Description

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>service-name-pattern</td>
<td>Specifies the QName of the WSDL service element defining the service to which the handler chain is bound. You can use * as a wildcard when defining the QName.</td>
</tr>
<tr>
<td>port-name-pattern</td>
<td>Specifies the QName of the WSDL port element defining the endpoint to which the handler chain is bound. You can use * as a wildcard when defining the QName.</td>
</tr>
<tr>
<td>protocol-binding</td>
<td>Specifies the message binding for which the handler chain is used. The binding is specified as a URI or using one of the following aliases: <code>##SOAP11_HTTP</code>, <code>##SOAP11_HTTP_MTOM</code>, <code>##SOAP12_HTTP</code>, <code>##SOAP12_HTTP_MTOM</code>, or <code>##XML_HTTP</code>. For more information about message binding URIs see Chapter 23, Apache CXF Binding IDs.</td>
</tr>
</tbody>
</table>

The **handler-chain** element is only required to have a single **handler** element as a child. It can, however, support as many **handler** elements as needed to define the complete handler chain. The handlers in the chain are executed in the order they specified in the handler chain definition.

**IMPORTANT**

The final order of execution will be determined by sorting the specified handlers into logical handlers and protocol handlers. Within the groupings, the order specified in the configuration will be used.

The other children, such as **protocol-binding**, are used to limit the scope of the defined handler chain. For example, if you use the **service-name-pattern** element, the handler chain will only be attached to service providers whose WSDL port element is a child of the specified WSDL service element. You can only use one of these limiting children in a **handler** element.

The **handler** element defines an individual handler in a handler chain. Its **handler-class** child element specifies the fully qualified name of the class implementing the handler. The **handler** element can also have an optional **handler-name** element that specifies a unique name for the handler.

**Example 43.16, “Handler Configuration File”** shows a handler configuration file that defines a single handler chain. The chain is made up of two handlers.

**Example 43.16. Handler Configuration File**

```xml
<handler-chains xmlns="http://java.sun.com/xml/ns/javaee"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://java.sun.com/xml/ns/javaee">
  <handler-chain>
    <handler>
      <handler-name>LoggingHandler</handler-name>
    </handler>
  </handler-chain>
</handler-chains>
```
43.10.2. Spring Configuration

Overview

The easiest way to configure an endpoint to use a handler chain is to define the chain in the endpoint’s configuration. This is done by adding a `<jaxws:handlers>` child to the element configuring the endpoint.

**IMPORTANT**

A handler chain added through the configuration file takes precedence over a handler chain configured programatically.

Procedure

To configure an endpoint to load a handler chain you do the following:

1. If the endpoint does not already have a configuration element, add one.
   For more information on configuring Apache CXF endpoints see Chapter 17, Configuring JAX-WS Endpoints.

2. Add a `<jaxws:handlers>` child element to the endpoint’s configuration element.

3. For each handler in the chain, add a `bean` element specifying the class that implements the handler.
   If your handler implementation is used in more than one place you can reference a `bean` element using the `ref` element.

The handlers element

The `<jaxws:handlers>` element defines a handler chain in an endpoint’s configuration. It can appear as a child to all of the JAX-WS endpoint configuration elements. These are:

- `<jaxws:endpoint>` configures a service provider.
- `<jaxws:server>` also configures a service provider.
- `<jaxws:client>` configures a service consumer.

You add handlers to the handler chain in one of two ways:

- add a `bean` element defining the implementation class
- use a `ref` element to refer to a named `bean` element from elsewhere in the configuration file
The order in which the handlers are defined in the configuration is the order in which they will be executed. The order may be modified if you mix logical handlers and protocol handlers. The run time will sort them into the proper order while maintaining the basic order specified in the configuration.

Example

Example 43.17, “Configuring an Endpoint to Use a Handler Chain In Spring” shows the configuration for a service provider that loads a handler chain.

Example 43.17. Configuring an Endpoint to Use a Handler Chain In Spring

```xml
<beans ...
   xmlns:jaxws="http://cxf.apache.org/jaxws"
   ...
   schemaLocation="...
   http://cxf.apache.org/jaxws http://cxf.apache.org/schemas/jaxws.xsd ...
   ...">
   <jaxws:endpoint id="HandlerExample"
       implementor="org.apache.cxf.example.DemoImpl"
       address="http://localhost:8080/demo">
       <jaxws:handlers> <bean class="demo.handlers.common.LoggingHandler" />
       <bean class="demo.handlers.common.AddHeaderHandler" />
    </jaxws:handlers>
   </jaxws:endpoint>
</beans>
```
CHAPTER 44. MAVEN TOOLING REFERENCE

44.1. PLUG-IN SETUP

Abstract

before you can use the Apache CXF plug-ins, you must first add the proper dependencies and repositories to your POM.

Dependencies

You need to add the following dependencies to your project’s POM:

- the JAX-WS frontend

  <dependency>
  <groupId>org.apache.cxf</groupId>
  <artifactId>cxf-rt-frontend-jaxws</artifactId>
  <version>version</version>
  </dependency>

- the HTTP transport

  <dependency>
  <groupId>org.apache.cxf</groupId>
  <artifactId>cxf-rt-transports-http</artifactId>
  <version>version</version>
  </dependency>

- the Undertow transport

  <dependency>
  <groupId>org.apache.cxf</groupId>
  <artifactId>cxf-rt-transports-http-undertow</artifactId>
  <version>version</version>
  </dependency>

44.2. CXF-CODEGEN-PLUGIN

Abstract

Generates JAX-WS compliant Java code from a WSDL document

Overview

Basic example

The following POM extract shows a simple example of how to configure the Maven cxf-codegen-plugin to process the myService.wsdl WSDL file:

  <plugin>
Basic configuration settings

In the preceding example, you can customize the following configuration settings

**configuration/sourceRoot**
- Specifies the directory where the generated Java files will be stored. Default is `target/generated-sources/cxf`.

**configuration/wsdlOptions/wsdlOption/wsdl**
- Specifies the location of the WSDL file.

Description

The `wsdl2java` task takes a WSDL document and generates fully annotated Java code from which to implement a service. The WSDL document must have a valid `portType` element, but it does not need to contain a `binding` element or a `service` element. Using the optional arguments you can customize the generated code.

WSDL options

At least one `wsdlOptions` element is required to configure the plug-in. The `wsdlOptions` element’s `wsdl` child is required and specifies a WSDL document to be processed by the plug-in. In addition to the `wsdl` element, the `wsdlOptions` element can take a number of children that can customize how the WSDL document is processed.

More than one `wsdlOptions` element can be listed in the plug-in configuration. Each element configures a single WSDL document for processing.

Default options

The `defaultOptions` element is an optional element. It can be used to set options that are used across all of the specified WSDL documents.
IMPORTANT

If an option is duplicated in the `wsdlOptions` element, the value in the `wsdlOptions` element takes precedent.

Specifying code generation options

To specify generic code generation options (corresponding to the switches supported by the Apache CXF `wsdl2java` command-line tool), you can add the `extraargs` element as a child of a `wsdlOption` element. For example, you can add the `-impl` option and the `-verbose` option as follows:

```xml
<configuration>
  <sourceRoot>target/generated/src/main/java</sourceRoot>
  <wsdlOptions>
    <wsdlOption>
      <wsdl>${basedir}/src/main/resources/wsdl/myService.wsdl</wsdl>
      <!-- you can set the options of wsdl2java command by using the <extraargs> -->
      <extraargs>
        <extraarg>-impl</extraarg>
        <extraarg>-verbose</extraarg>
      </extraargs>
    </wsdlOption>
  </wsdlOptions>
</configuration>
```

If a switch takes arguments, you can specify these using subsequent `extraarg` elements. For example, to specify the `jibx` data binding, you can configure the plug-in as follows:

```xml
<configuration>
  <sourceRoot>target/generated/src/main/java</sourceRoot>
  <wsdlOptions>
    <wsdlOption>
      <wsdl>${basedir}/src/main/resources/wsdl/myService.wsdl</wsdl>
      <extraargs>
        <extraarg>-databinding</extraarg>
        <extraarg>jibx</extraarg>
      </extraargs>
    </wsdlOption>
  </wsdlOptions>
</configuration>
```

Specifying binding files

To specify the location of one or more JAX-WS binding files, you can add the `bindingFiles` element as a child of `wsdlOption`—for example:

```xml
<configuration>
  <wsdlOptions>
    <wsdlOption>
      <wsdl>${basedir}/src/main/resources/wsdl/myService.wsdl</wsdl>
      <extraargs>
        <extraarg>-databinding</extraarg>
        <extraarg>jibx</extraarg>
      </extraargs>
    </wsdlOption>
  </wsdlOptions>
</configuration>
```
Generating code for a specific WSDL service

To specify the name of the WSDL service for which code is to be generated, you can add the \texttt{serviceName} element as a child of \texttt{wsdlOption} (the default behaviour is to generate code for every service in the WSDL document)—for example:

```
<configuration>
  <wsdlOptions>
    <wsdlOption>
      <wsdl>${basedir}/src/main/resources/wsdl/myService.wsdl</wsdl>
      <serviceName>MyWSDLService</serviceName>
    </wsdlOption>
  </wsdlOptions>
</configuration>
```

Generating code for multiple WSDL files

To generate code for multiple WSDL files, simply insert additional \texttt{wsdlOption} elements for the WSDL files. If you want to specify some common options that apply to all of the WSDL files, put the common options into the \texttt{defaultOptions} element as shown:

```
<configuration>
  <defaultOptions>
    <bindingFiles>
      <bindingFile>${basedir}/src/main/jaxb/bindings.xml</bindingFile>
    </bindingFiles>
    <noAddressBinding>true</noAddressBinding>
  </defaultOptions>
  <wsdlOptions>
    <wsdlOption>
      <wsdl>${basedir}/src/main/resources/wsdl/myService.wsdl</wsdl>
      <serviceName>MyWSDLService</serviceName>
    </wsdlOption>
    <wsdlOption>
      <wsdl>${basedir}/src/main/resources/wsdl/myOtherService.wsdl</wsdl>
      <serviceName>MyOtherWSDLService</serviceName>
    </wsdlOption>
  </wsdlOptions>
</configuration>
```

It is also possible to specify multiple WSDL files using wildcard matching. In this case, specify the directory containing the WSDL files using the \texttt{wsdlRoot} element and then select the required WSDL files using an \texttt{include} element, which supports wildcarding with the \texttt{*} character. For example, to select all
of the WSDL files ending in `Service.wsdl` from the `src/main/resources/wsdl` root directory, you could configure the plug-in as follows:

```xml
<configuration>
  <defaultOptions>
    <bindingFiles>
      <bindingFile>${basedir}/src/main/jaxb/bindings.xml</bindingFile>
    </bindingFiles>
  </defaultOptions>
  <wsdlRoot>${basedir}/src/main/resources/wsdl</wsdlRoot>
  <includes>
    <include>*Service.wsdl</include>
  </includes>
</configuration>
```

**Downloading WSDL from a Maven repository**

To download a WSDL file directly from a Maven repository, add a `wsdlArtifact` element as a child of the `wsdlOption` element and specify the coordinates of the Maven artifact, as follows:

```xml
...  
<wsdlOptions>
  <wsdlOption>
    <wsdlArtifact>
      <groupId>org.apache.pizza</groupId>
      <artifactId>PizzaService</artifactId>
      <version>1.0.0</version>
    </wsdlArtifact>
  </wsdlOption>
</wsdlOptions>
...  
```

**Encoding**

_(Requires JAXB 2.2)_ To specify the character encoding (Charset) used for the generated Java files, add an `encoding` element as a child of the `configuration` element, as follows:

```xml
...  
<wsdlOptions>
  <wsdlOption>
    <wsdl>${basedir}/src/main/resources/wsdl/myService.wsdl</wsdl>
  </wsdlOption>
</wsdlOptions>
<encoding>UTF-8</encoding>
</configuration>
...  
```

**Forking a separate process**
You can configure the codegen plug-in to fork a separate JVM for code generation, by adding the `fork` element as a child of the `configuration` element. The fork element can be set to one of the following values:

**`once`**

Fork a single new JVM to process all of the WSDL files specified in the codegen plug-in’s configuration.

**`always`**

Fork a new JVM to process each WSDL file specified in the codegen plug-in’s configuration.

**`false`**

*(Default)* Disables forking.

If the codegen plug-in is configured to fork a separate JVM (that is, the `fork` option is set to a non-false value), you can specify additional JVM arguments to the forked JVM through the `additionalJvmArgs` element. For example, the following fragment configures the codegen plug-in to fork a single JVM, which is restricted to access XML schemas from the local file system only (by setting the `javax.xml.accessExternalSchema` system property):

```xml
...<configuration>
  <wsdlOptions>
    <wsdl>${basedir}/src/main/resources/wsdl/myService.wsdl</wsdl>
  </wsdlOption>
  <fork>once</fork>
  <additionalJvmArgs>-Djavax.xml.accessExternalSchema=jar:file:/file</additionalJvmArgs>
</configuration>
...```

**Options reference**

The options used to manage the code generation process are reviewed in the following table.

<table>
<thead>
<tr>
<th>Option</th>
<th>Interpretation</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>-fe</code></td>
<td><code>-frontend frontend</code></td>
</tr>
<tr>
<td><code>-db</code></td>
<td><code>-databinding databinding</code></td>
</tr>
<tr>
<td>Option</td>
<td>Interpretation</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>-wv wsdlVersion</td>
<td>Specifies the WSDL version expected by the tool. Default is 1.1.(^a)</td>
</tr>
<tr>
<td>-p wsdlNamespace=PackageName</td>
<td>Specifies zero, or more, package names to use for the generated code. Optionally specifies the WSDL namespace to package name mapping.</td>
</tr>
<tr>
<td>-b bindingName</td>
<td>Specifies one or more JAXWS or JAXB binding files. Use a separate -b flag for each binding file.</td>
</tr>
<tr>
<td>-sn serviceName</td>
<td>Specifies the name of the WSDL service for which code is to be generated. The default is to generate code for every service in the WSDL document.</td>
</tr>
<tr>
<td>-reserveClass classname</td>
<td>Used with -autoNameResolution, defines a class names for wsdl-to-java not to use when generating classes. Use this option multiple times for multiple classes.</td>
</tr>
<tr>
<td>-catalog catalogUrl</td>
<td>Specifies the URL of an XML catalog to use for resolving imported schemas and WSDL documents.</td>
</tr>
<tr>
<td>-d output-directory</td>
<td>Specifies the directory into which the generated code files are written.</td>
</tr>
<tr>
<td>-compile</td>
<td>Compiles generated Java files.</td>
</tr>
<tr>
<td>-classdir compile-class-dir</td>
<td>Specifies the directory into which the compiled class files are written.</td>
</tr>
<tr>
<td>-clientjar jar-file-name</td>
<td>Generates the JAR file that contains all the client classes and the WSDL. The specified wsdlLocation does not work when this option is specified.</td>
</tr>
<tr>
<td>-client</td>
<td>Generates starting point code for a client mainline.</td>
</tr>
<tr>
<td>-server</td>
<td>Generates starting point code for a server mainline.</td>
</tr>
<tr>
<td>-impl</td>
<td>Generates starting point code for an implementation object.</td>
</tr>
<tr>
<td>-all</td>
<td>Generates all starting point code: types, service proxy, service interface, server mainline, client mainline, implementation object, and an Ant build.xml file.</td>
</tr>
<tr>
<td>Option</td>
<td>Interpretation</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>-ant</td>
<td>Generates the Ant build.xml file.</td>
</tr>
<tr>
<td>-autoNameResolution</td>
<td>Automatically resolve naming conflicts without requiring the use of binding customizations.</td>
</tr>
<tr>
<td>-defaultValue=DefaultValueProvider</td>
<td>Instructs the tool to generate default values for the generated client and the generated implementation. Optionally, you can also supply the name of the class used to generate the default values. By default, the RandomValueProvider class is used.</td>
</tr>
<tr>
<td>-nexclude schema-namespace=java-packagename</td>
<td>Ignore the specified WSDL schema namespace when generating code. This option may be specified multiple times. Also, optionally specifies the Java package name used by types described in the excluded namespace(s).</td>
</tr>
<tr>
<td>-exsh (true/false)</td>
<td>Enables or disables processing of extended soap header message binding. Default is false.</td>
</tr>
<tr>
<td>-noTypes</td>
<td>Turns off generating types.</td>
</tr>
<tr>
<td>-dns (true/false)</td>
<td>Enables or disables the loading of the default namespace package name mapping. Default is true.</td>
</tr>
<tr>
<td>-dex (true/false)</td>
<td>Enables or disables the loading of the default excludes namespace mapping. Default is true.</td>
</tr>
<tr>
<td>-xjcarargs</td>
<td>Specifies a comma separated list of arguments to be passed to directly to the XJC when the JAXB data binding is being used. To get a list of all possible XJC arguments use the -xjc-X.</td>
</tr>
<tr>
<td>-noAddressBinding</td>
<td>Instructs the tool to use the Apache CXF proprietary WS-Addressing type instead of the JAX-WS 2.1 compliant mapping.</td>
</tr>
<tr>
<td>-validate [all</td>
<td>basic</td>
</tr>
<tr>
<td>-keep</td>
<td>Instructs the tool to not overwrite any existing files.</td>
</tr>
<tr>
<td>-wsdlLocation =wsdlLocation</td>
<td>Specifies the value of the @WebService annotation’s wsdlLocation property.</td>
</tr>
<tr>
<td>-v</td>
<td>Displays the version number for the tool.</td>
</tr>
<tr>
<td>Option</td>
<td>Interpretation</td>
</tr>
<tr>
<td>--------</td>
<td>----------------</td>
</tr>
<tr>
<td>-verbose</td>
<td>-V</td>
</tr>
<tr>
<td>-quiet</td>
<td></td>
</tr>
<tr>
<td>-allowElementReferences=[true], -aer=[true]</td>
<td></td>
</tr>
<tr>
<td>-asyncMethods=[method1,method2,…]</td>
<td></td>
</tr>
<tr>
<td>-bareMethods=[method1,method2,…]</td>
<td></td>
</tr>
<tr>
<td>-mimeMethods=[method1,method2,…]</td>
<td></td>
</tr>
<tr>
<td>-faultSerialVersionUID fault-serialVersionUID</td>
<td></td>
</tr>
<tr>
<td>-encoding encoding</td>
<td></td>
</tr>
<tr>
<td>-exceptionSuper</td>
<td></td>
</tr>
<tr>
<td>-seiSuper interfaceName</td>
<td></td>
</tr>
<tr>
<td>-mark-generated</td>
<td></td>
</tr>
</tbody>
</table>

[a] Currently, Apache CXF only provides WSDL 1.1 support for the code generator.

44.3. JAVA2WS
Abstract
generates a WSDL document from Java code

Synopsis

```xml
<plugin>
  <groupId>org.apache.cxf</groupId>
  <artifactId>cxf-java2ws-plugin</artifactId>
  <version>version</version>
  <executions>
    <execution>
      <id>process-classes</id>
      <phase>process-classes</phase>
      <configuration>
        <className>className</className>
        <option>...</option>
      </configuration>
      <goals>
        <goal>java2ws</goal>
      </goals>
    </execution>
  </executions>
</plugin>
```

Description

The `java2ws` task takes a service endpoint implementation (SEI) and generates the support files used to implement a Web service. It can generate the following:

- a WSDL document
- the server code needed to deploy the service as a POJO
- client code for accessing the service
- wrapper and fault beans

Required configuration

The plug-in requires that the `className` configuration element is present. The element’s value is the fully qualified name of the SEI to be processed.

Optional configuration

The configuration element’s listed in the following table can be used to fine tune the WSDL generation.

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>frontend</td>
<td>Specifies front end to use for processing the SEI and generating the support classes. <code>jaxws</code> is the default. <code>simple</code> is also supported.</td>
</tr>
<tr>
<td>Element</td>
<td>Description</td>
</tr>
<tr>
<td>------------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>databinding</td>
<td>Specifies the data binding used for processing the SEI and generating the support classes. The default when using the JAX-WS front end is jaxb. The default when using the simple frontend is aegis.</td>
</tr>
<tr>
<td>genWsdl</td>
<td>Instructs the tool to generate a WSDL document when set to true.</td>
</tr>
<tr>
<td>genWrapperbean</td>
<td>Instructs the tool to generate the wrapper bean and the fault beans when set to true.</td>
</tr>
<tr>
<td>genClient</td>
<td>Instructs the tool to generate client code when set to true.</td>
</tr>
<tr>
<td>genServer</td>
<td>Instructs the tool to generate server code when set to true.</td>
</tr>
<tr>
<td>outputFile</td>
<td>Specifies the name of the generated WSDL file.</td>
</tr>
<tr>
<td>classpath</td>
<td>Specifies the classpath searched when processing the SEI.</td>
</tr>
<tr>
<td>soap12</td>
<td>Specifies that the generated WSDL document is to include a SOAP 1.2 binding when set to true.</td>
</tr>
<tr>
<td>targetNamespace</td>
<td>Specifies the target namespace to use in the generated WSDL file.</td>
</tr>
<tr>
<td>serviceName</td>
<td>Specifies the value of the generated service element’s name attribute.</td>
</tr>
</tbody>
</table>
PART VI. DEVELOPING RESTFUL WEB SERVICES

This guide describes how to use the JAX-RS APIs to implement Web services.
CHAPTER 45. INTRODUCTION TO RESTFUL WEB SERVICES

Abstract

Representational State Transfer (REST) is a software architecture style that centers around the transmission of data over HTTP, using only the four basic HTTP verbs. It also eschews the use of any additional wrappers such as a SOAP envelope and the use of any state data.

OVERVIEW

Representational State Transfer (REST) is an architectural style first described in a doctoral dissertation by a researcher named Roy Fielding. In RESTful systems, servers expose resources using a URI, and clients access these resources using the four HTTP verbs. As clients receive representations of a resource they are placed in a state. When they access a new resource, typically by following a link, they change, or transition, their state. In order to work, REST assumes that resources are capable of being represented using a pervasive standard grammar.

The World Wide Web is the most ubiquitous example of a system designed on REST principles. Web browsers act as clients accessing resources hosted on Web servers. The resources are represented using HTML or XML grammars that all Web browsers can consume. The browsers can also easily follow the links to new resources.

The advantages of RESTful systems is that they are highly scalable and highly flexible. Because the resources are accessed and manipulated using the four HTTP verbs, the resources are exposed using a URIs, and the resources are represented using standard grammars, clients are not as affected by changes to the servers. Also, RESTful systems can take full advantage of the scalability features of HTTP such as caching and proxies.

BASIC REST PRINCIPLES

RESTful architectures adhere to the following basic principles:

- Application state and functionality are divided into resources.
- Resources are addressable using standard URIs that can be used as hypermedia links.
- All resources use only the four HTTP verbs.
  - DELETE
  - GET
  - POST
  - PUT
- All resources provide information using the MIME types supported by HTTP.
- The protocol is stateless.
- Responses are cacheable.
- The protocol is layered.
RESOURCES

Resources are central to REST. A resource is a source of information that can be addressed using a URI. In the early days of the Web, resources were largely static documents. In the modern Web, a resource can be any source of information. For example a Web service can be a resource if it can be accessed using a URI.

RESTful endpoints exchange representations of the resources they address. A representation is a document containing the data provided by the resource. For example, the method of a Web service that provides access to a customer record would be a resource, the copy of the customer record exchanged between the service and the consumer is a representation of the resource.

REST BEST PRACTICES

When designing RESTful Web services it is helpful to keep in mind the following:

- Provide a distinct URI for each resource you wish to expose. For example, if you are building a system that deals with driving records, each record should have a unique URI. If the system also provides information on parking violations and speeding fines, each type of resource should also have a unique base. For example, speeding fines could be accessed through /speedingfines/driverID and parking violations could be accessed through /parkingfines/driverID.

- Use nouns in your URIs. Using nouns highlights the fact that resources are things and not actions. URIs such as /ordering imply an action, whereas /orders implies a thing.

- Methods that map to GET should not change any data.

- Use links in your responses. Putting links to other resources in your responses makes it easier for clients to follow a chain of data. For example, if your service returns a collection of resources, it would be easier for a client to access each of the individual resources using the provided links. If links are not included, a client needs to have additional logic to follow the chain to a specific node.

- Make your service stateless. Requiring the client or the service to maintain state information forces a tight coupling between the two. Tight couplings make upgrading and migrating more difficult. Maintaining state can also make recovery from communication errors more difficult.

DESIGNING A RESTFUL WEB SERVICE

Regardless of the framework you use to implement a RESTful Web service, there are a number of steps that should be followed:

1. Define the resources the service will expose. In general, a service will expose one or more resources that are organized as a tree. For example, a driving record service could be organized into three resources:

   - /license/driverID
   - /license/driverID/speedingfines
   - /license/driverID/parkingfines
2. Define what actions you want to be able to perform on each resource. For example, you may want to be able to update a diver’s address or remove a parking ticket from a driver’s record.

3. Map the actions to the appropriate HTTP verbs.

Once you have defined the service, you can implement it using Apache CXF.

IMPLEMENTING REST WITH APACHE CXF

Apache CXF provides an implementation of the Java API for RESTful Web Services (JAX-RS). JAX-RS provides a standardized way to map POJOs to resources using annotations.

When moving from the abstract service definition to a RESTful Web service implemented using JAX-RS, you need to do the following:

1. Create a root resource class for the resource that represents the top of the service’s resource tree. See Section 46.3, “Root resource classes”.

2. Map the service’s other resources into sub-resources. See Section 46.5, “Working with sub-resources”.

3. Create methods to implement each of the HTTP verbs used by each of the resources. See Section 46.4, “Working with resource methods”.

NOTE

Apache CXF continues to support the old HTTP binding to map Java interfaces into RESTful Web services. The HTTP binding provides basic functionality and has a number of limitations. Developers are encouraged to update their applications to use JAX-RS.

DATA BINDINGS

By default, Apache CXF uses Java Architecture for XML Binding (JAXB) objects to map the resources and their representations to Java objects. Provides clean, well defined mappings between Java objects and XML elements.

The Apache CXF JAX-RS implementation also supports exchanging data using JavaScript Object Notation (JSON). JSON is a popular data format used by Ajax developers. The marshaling of data between JSON and JAXB is handled by the Apache CXF runtime.
CHAPTER 46. CREATING RESOURCES

Abstract

In RESTful Web services all requests are handled by resources. The JAX-RS APIs implement resources as a Java class. A resource class is a Java class that is annotated with one, or more, JAX-RS annotations. The core of a RESTful Web service implemented using JAX-RS is a root resource class. The root resource class is the entry point to the resource tree exposed by a service. It may handle all requests itself, or it may provide access to sub-resources that handle requests.

46.1. INTRODUCTION

Overview

RESTful Web services implemented using JAX-RS APIs provide responses as representations of a resource implemented by Java classes. A resource class is a class that uses JAX-RS annotations to implement a resource. For most RESTful Web services, there is a collection of resources that need to be accessed. The resource class’ annotations provide information such as the URI of the resources and which HTTP verb each operation handles.

Types of resources

The JAX-RS APIs allow you to create two basic types of resources:

- A Section 46.3, “Root resource classes” is the entry point to a service’s resource tree. It is decorated with the @Path annotation to define the base URI for the resources in the service.

- Section 46.5, “Working with sub-resources” are accessed through the root resource. They are implemented by methods that are decorated with the @Path annotation. A sub-resource’s @Path annotation defines a URI relative to the base URI of a root resource.

Example

Example 46.1, “Simple resource class” shows a simple resource class.

Example 46.1. Simple resource class

```java
package demo.jaxrs.server;

import javax.ws.rs.GET;
import javax.ws.rs.Path;
import javax.ws.rs.PathParam;

@Path("/customerservice")
public class CustomerService
{
    public CustomerService()
    {
    }

    @GET
    public Customer getCustomer(@QueryParam("id") String id)
    {
```
Two items make the class defined in Example 46.1, “Simple resource class” a resource class:

The @Path annotation specifies the base URI for the resource.

The @GET annotation specifies that the method implements the HTTP GET method for the resource.

### 46.2. BASIC JAX-RS ANNOTATIONS

#### Overview

The most basic pieces of information required by a RESTful Web service implementation are:

- the URI of the service’s resources
- how the class’ methods are mapped to the HTTP verbs

JAX-RS defines a set of annotations that provide this basic information. All resource classes must have at least one of these annotations.

#### Setting the path

The @Path annotation specifies the URI of a resource. The annotation is defined by the javax.ws.rs.Path interface and it can be used to decorate either a resource class or a resource method. It takes a string value as its only parameter. The string value is a URI template that specifies the location of an implemented resource.

The URI template specifies a relative location for the resource. As shown in Example 46.2, “URI template syntax”, the template can contain the following:

- unprocessed path components
- parameter identifiers surrounded by { }

**NOTE**

Parameter identifiers can include regular expressions to alter the default path processing.

### Example 46.2. URI template syntax

```java
@Path("resourceName/{param1}/../{paramN}"")
```

For example, the URI template `widgets/{color}/{number}` would map to `widgets/blue/12`. The value of the color parameter is assigned to `blue`. The value of the number parameter is assigned `12`. 
How the URI template is mapped to a complete URI depends on what the @Path annotation is decorating. If it is placed on a root resource class, the URI template is the root URI of all resources in the tree and it is appended directly to the URI at which the service is published. If the annotation decorates a sub-resource, it is relative to the root resource URI.

Specifying HTTP verbs

JAX-RS uses five annotations for specifying the HTTP verb that will be used for a method:

- javax.ws.rs.DELETE specifies that the method maps to a DELETE.
- javax.ws.rs.GET specifies that the method maps to a GET.
- javax.ws.rs.POST specifies that the method maps to a POST.
- javax.ws.rs.PUT specifies that the method maps to a PUT.
- javax.ws.rs.HEAD specifies that the method maps to a HEAD.

When you map your methods to HTTP verbs, you must ensure that the mapping makes sense. For example, if you map a method that is intended to submit a purchase order, you would map it to a PUT or a POST. Mapping it to a GET or a DELETE would result in unpredictable behavior.

46.3. ROOT RESOURCE CLASSES

Overview

A root resource class is the entry point into a JAX-RS implemented RESTful Web service. It is decorated with a @Path that specifies the root URI of the resources implemented by the service. Its methods either directly implement operations on the resource or provide access to sub-resources.

Requirements

In order for a class to be a root resource class it must meet the following criteria:

- The class must be decorated with the @Path annotation. The specified path is the root URI for all of the resources implemented by the service. If the root resource class specifies that its path is widgets and one of its methods implements the GET verb, then a GET on widgets invokes that method. If a sub-resource specifies that its URI is {id}, then the full URI template for the sub-resource is widgets/{id} and it will handle requests made to URIs like widgets/12 and widgets/42.
- The class must have a public constructor for the runtime to invoke. The runtime must be able to provide values for all of the constructor’s parameters. The constructor’s parameters can include parameters decorated with the JAX-RS parameter annotations. For more information on the parameter annotations see Chapter 47, Passing Information into Resource Classes and Methods.
- At least one of the classes methods must either be decorated with an HTTP verb annotation or the @Path annotation.

Example

Example 46.3, “Root resource class” shows a root resource class that provides access to a sub-resource.
Example 46.3. Root resource class

```java
package demo.jaxrs.server;
import javax.ws.rs.DELETE;
import javax.ws.rs.GET;
import javax.ws.rs.POST;
import javax.ws.rs.PUT;
import javax.ws.rs.Path;
import javax.ws.rs.PathParam;
import javax.ws.rs.QueryParam;
import javax.ws.rs.core.Response;
@Path("/customerservice/")
public class CustomerService
{
    public CustomerService()
    {
        ...
    }
    @GET
    public Customer getCustomer(@QueryParam("id") String id)
    {
        ...
    }
    @DELETE
    public Response deleteCustomer(@QueryParam("id") String id)
    {
        ...
    }
    @PUT
    public Response updateCustomer(Customer customer)
    {
        ...
    }
    @POST
    public Response addCustomer(Customer customer)
    {
        ...
    }
    @Path("/orders/{orderId}/")
    public Order getOrder(@PathParam("orderId") String orderId)
    {
        ...
    }
}
```

The class in Example 46.3, “Root resource class” meets all of the requirements for a root resource class.
The class is decorated with the `@Path` annotation. The root URI for the resources exposed by the service is `customerservice`.

The class has a public constructor. In this case the no argument constructor is used for simplicity.

The class implements each of the four HTTP verbs for the resource.

The class also provides access to a sub-resource through the `getOrder()` method. The URI for the sub-resource, as specified using the `@Path` annotation, is `customerservice/order/id`. The sub-resource is implemented by the `Order` class.

For more information on implementing sub-resources see Section 46.5, “Working with sub-resources”.

### 46.4. WORKING WITH RESOURCE METHODS

#### Overview

Resource methods are annotated using JAX-RS annotations. They have one of the HTTP method annotation specifying the types of requests that the method processes. JAX-RS places several constraints on resource methods.

#### General constraints

All resource methods must meet the following conditions:

- It must be public.
- It must be decorated with one of the HTTP method annotations described in the section called “Specifying HTTP verbs”.
- It must not have more than one entity parameter as described in the section called “Parameters”.

#### Parameters

Resource method parameters take two forms:

- **entity parameters**—Entity parameters are not annotated. Their value is mapped from the request entity body. An entity parameter can be of any type for which your application has an entity provider. Typically they are JAXB objects.

  **IMPORTANT**

  A resource method can have only one entity parameter.

  For more information on entity providers see Chapter 51, *Entity Support*.

- **annotated parameters**—Annotated parameters use one of the JAX-RS annotations that specify how the value of the parameter is mapped from the request. Typically, the value of the parameter is mapped from portions of the request URI.
  
  For more information about using the JAX-RS annotations for mapping request data to method parameters see Chapter 47, *Passing Information into Resource Classes and Methods*. 
Example 46.4, “Resource method with a valid parameter list” shows a resource method with a valid parameter list.

```java
@POST
@Path("disaster/monster/giant/{id}"")
public void addDaikaiju(Kaiju kaiju,
    @PathParam("id") String id)
{
    ...
}
```

Example 46.5, “Resource method with an invalid parameter list” shows a resource method with an invalid parameter list. It has two parameters that are not annotated.

```java
@POST
@Path("disaster/monster/giant/")
public void addDaikaiju(Kaiju kaiju,
    String id)
{
    ...
}
```

Return values

Resource methods can return one of the following:

- **void**

- any Java class for which the application has an entity provider
  For more information on entity providers see Chapter 51, Entity Support.

- a **Response** object
  For more information on Response objects see Section 48.3, “Fine tuning an application’s responses”.

- a **GenericEntity<T>** object
  For more information on GenericEntity<T> objects see Section 48.4, “Returning entities with generic type information”.

All resource methods return an HTTP status code to the requester. When the return type of the method is **void** or the value being returned is **null**, the resource method sets the HTTP status code to **204**. When the resource method returns any value other than **null**, it sets the HTTP status code to **200**.

### 46.5. WORKING WITH SUB-RESOURCES

Overview
It is likely that a service will need to be handled by more than one resource. For example, in an order processing service best-practices suggests that each customer would be handled as a unique resource. Each order would also be handled as a unique resource.

Using the JAX-RS APIs, you would implement the customer resources and the order resources as sub-resources. A sub-resource is a resource that is accessed through a root resource class. They are defined by adding a @Path annotation to a resource class’ method. Sub-resources can be implemented in one of two ways:

- Sub-resource method—directly implements an HTTP verb for a sub-resource and is decorated with one of the annotations described in the section called “Specifying HTTP verbs”.
- Sub-resource locator—points to a class that implements the sub-resource.

**Specifying a sub-resource**

Sub-resources are specified by decorating a method with the @Path annotation. The URI of the sub-resource is constructed as follows:

1. Append the value of the sub-resource’s @Path annotation to the value of the sub-resource’s parent resource’s @Path annotation.
   The parent resource’s @Path annotation maybe located on a method in a resource class that returns an object of the class containing the sub-resource.

2. Repeat the previous step until the root resource is reached.

3. The assembled URI is appended to the base URI at which the service is deployed.

For example the URI of the sub-resource shown in Example 46.6, “Order sub-resource” could be `baseURI/customerservice/order/12`.

```java
Example 46.6. Order sub-resource
...
@Path("/customerservice/")
public class CustomerService
{
  ...
  @Path("/orders/{orderId}"")
  @GET
  public Order getOrder(@PathParam("orderId") String orderId)
  {
    ...
  }
}
```

**Sub-resource methods**

A sub-resource method is decorated with both a @Path annotation and one of the HTTP verb annotations. The sub-resource method is directly responsible for handling a request made on the resource using the specified HTTP verb.

**Example 46.7, “Sub-resource methods”** shows a resource class with three sub-resource methods:
- `getOrder()` handles HTTP GET requests for resources whose URI matches `/customerservice/orders/{orderId}/`.

- `updateOrder()` handles HTTP PUT requests for resources whose URI matches `/customerservice/orders/{orderId}/`.

- `newOrder()` handles HTTP POST requests for the resource at `/customerservice/orders/`.

Example 46.7. Sub-resource methods

```java
...
@Path("/customerservice/")
public class CustomerService {
    ...
    @Path("/orders/{orderId}/")
    @GET
    public Order getOrder(@PathParam("orderId") String orderId)
    {
        ...
    }

    @Path("/orders/{orderId}/")
    @PUT
    public Order updateOrder(@PathParam("orderId") String orderId, Order order)
    {
        ...
    }

    @Path("/orders/")
    @POST
    public Order newOrder(Order order)
    {
        ...
    }
}
```

NOTE

Sub-resource methods with the same URI template are equivalent to resource class returned by a sub-resource locator.

Sub-resource locators

Sub-resource locators are not decorated with one of the HTTP verb annotations and do not directly handle a request on the sub-resource. Instead, a sub-resource locator returns an instance of a resource class that can handle the request.

In addition to not having an HTTP verb annotation, sub-resource locators also cannot have any entity parameters. All of the parameters used by a sub-resource locator method must use one of the annotations described in Chapter 47, Passing Information into Resource Classes and Methods.

As shown in Example 46.8, “Sub-resource locator returning a specific class”, sub-resource locator allows
you to encapsulate a resource as a reusable class instead of putting all of the methods into one super class. The `processOrder()` method is a sub-resource locator. When a request is made on a URI matching the URI template `/orders/{orderId}/` it returns an instance of the `Order` class. The `Order` class has methods that are decorated with HTTP verb annotations. A PUT request is handled by the `updateOrder()` method.

```java
@Path("/customerservice/")
public class CustomerService {
 ...

@Path("/orders/{orderId}/")
public Order processOrder(@PathParam("orderId") String orderId) {
 ...
}

public class Order {
 ...

@GET
public Order getOrder(@PathParam("orderId") String orderId) {
 ...

@PUT
public Order updateOrder(@PathParam("orderId") String orderId, Order order) {
 ...

Sub-resource locators are processed at runtime so that they can support polymorphism. The return value of a sub-resource locator can be a generic `Object`, an abstract class, or the top of a class hierarchy. For example, if your service needed to process both PayPal orders and credit card orders, the `processOrder()` method’s signature from Example 46.8, “Sub-resource locator returning a specific class” could remain unchanged. You would simply need to implement two classes, `ppOrder` and `ccOrder`, that extended the `Order` class. The implementation of `processOrder()` would instantiate the desired implementation of the sub-resource based on what ever logic is required.

### 46.6. RESOURCE SELECTION METHOD

**Overview**

It is possible for a given URI to map to one or more resource methods. For example the URI
customerservice/12/ma could match the templates @Path("customerservice/{id}") or @Path("customerservice/{id}/state"). JAX-RS specifies a detailed algorithm for matching a resource method to a request. The algorithm compares the normalized URI, the HTTP verb, and the media types of the request and response entities to the annotations on the resource classes.

The basic selection algorithm

The JAX-RS selection algorithm is broken down into three stages:

1. Determine the root resource class.
   The request URI is matched against all of the classes decorated with the @Path annotation. The classes whose @Path annotation matches the request URI are determined.
   If the value of the resource class’ @Path annotation matches the entire request URI, the class’ methods are used as input into the third stage.

2. Determine the object will handle the request.
   If the request URI is longer than the value of the selected class’ @Path annotation, the values of the resource methods’ @Path annotations are used to look for a sub-resource that can process the request.
   If one or more sub-resource methods match the request URI, these methods are used as input for the third stage.
   If the only matches for the request URI are sub-resource locaters, the resource methods of the object created by the sub-resource locater to match the request URI. This stage is repeated until a sub-resource method matches the request URI.

3. Select the resource method that will handle the request.
   The resource method whose HTTP verb annotation matches the HTTP verb in the request. In addition, the selected resource method must accept the media type of the request entity body and be capable of producing a response that conforms to the media type(s) specified in the request.

Selecting from multiple resource classes

The first two stages of the selection algorithm determine the resource that will handle the request. In some cases the resource is implemented by a resource class. In other cases, it is implemented by one or more sub-resources that use the same URI template. When there are multiple resources that match a request URI, resource classes are preferred over sub-resources.

If more than one resource still matches the request URI after sorting between resource classes and sub-resources, the following criteria are used to select a single resource:

1. Prefer the resource with the most literal characters in its URI template.
   Literal characters are characters that are not part of a template variable. For example, /widgets/{id}/{color} has ten literal characters and /widgets/1/{color} has eleven literal characters. So, the request URI /widgets/1/red would be matched to the resource with /widgets/1/{color} as its URI template.

   NOTE
   A trailing slash (/) counts as a literal character. So /joefred/ will be preferred over /joefred.
2. Prefer the resource with the most variables in its URI template. The request URI /widgets/30/green could match both /widgets/{id}/{color} and /widgets/{amount}/. However, the resource with the URI template /widgets/{id}/{color} will be selected because it has two variables.

3. Prefer the resource with the most variables containing regular expressions. The request URI /widgets/30/green could match both /widgets/{number}/{color} and /widgets/{id:.}/{color}*. However, the resource with the URI template */widgets/{id:.}/{color} will be selected because it has a variable containing a regular expression.

Selecting from multiple resource methods

In many cases, selecting a resource that matches the request URI results in a single resource method that can process the request. The method is determined by matching the HTTP verb specified in the request with a resource method’s HTTP verb annotation. In addition to having the appropriate HTTP verb annotation, the selected method must also be able to handle the request entity included in the request and be able to produce the proper type of response specified in the request’s metadata.

**NOTE**

The type of request entity a resource method can handle is specified by the @Consumes annotation. The type of responses a resource method can produce are specified using the @Produces annotation.

When selecting a resource produces multiple methods that can handle a request the following criteria is used to select the resource method that will handle the request:

1. Prefer resource methods over sub-resources.

2. Prefer sub-resource methods over sub-resource locaters.

3. Prefer methods that use the most specific values in the @Consumes annotation and the @Produces annotation.
   For example, a method that has the annotation @Consumes("text/xml") would be preferred over a method that has the annotation @Consumes("text/"*""). Both methods would be preferred over a method without an @Consumes annotation or the annotation @Consumes(".*/*").

4. Prefer methods that most closely match the content type of the request body entity.

   **NOTE**
   The content type of the request body entity is specified in the HTTP Content-Type property.

5. Prefer methods that most closely match the content type accepted as a response.

   **NOTE**
   The content types accepted as a response are specified in the HTTP Accept property.
Customizing the selection process

In some cases, developers have reported the algorithm being somewhat restrictive in the way multiple resource classes are selected. For example, if a given resource class has been matched and if this class has no matching resource method, then the algorithm stops executing. It never checks the remaining matching resource classes.

Apache CXF provides the org.apache.cxf.jaxrs.ext.ResourceComparator interface which can be used to customize how the runtime handles multiple matching resource classes. The ResourceComparator interface, shown in Example 46.9, "Interface for customizing resource selection", has to methods that need to be implemented. One compares two resource classes and the other compares two resource methods.

Example 46.9. Interface for customizing resource selection

```java
package org.apache.cxf.jaxrs.ext;

import org.apache.cxf.jaxrs.model.ClassResourceInfo;
import org.apache.cxf.jaxrs.model.OperationResourceInfo;
import org.apache.cxf.message.Message;

public interface ResourceComparator
{
    int compare(ClassResourceInfo cri1,
                 ClassResourceInfo cri2,
                 Message message);

    int compare(OperationResourceInfo oper1,
                 OperationResourceInfo oper2,
                 Message message);
}
```

Custom implementations select between the two resources as follows:

- Return 1 if the first parameter is a better match than the second parameter
- Return -1 if the second parameter is a better match than the first parameter

If 0 is returned then the runtime will proceed with the default selection algorithm

You register a custom ResourceComparator implementation by adding a `resourceComparator` child to the service’s `jaxrs:server` element.
CHAPTER 47. PASSING INFORMATION INTO RESOURCE CLASSES AND METHODS

Abstract

JAX-RS specifies a number of annotations that allow the developer to control where the information passed into resources come from. The annotations conform to common HTTP concepts such as matrix parameters in a URI. The standard APIs allow the annotations to be used on method parameters, bean properties, and resource class fields. Apache CXF provides an extension that allows for the injection of a sequence of parameters to be injected into a bean.

47.1. BASICS OF INJECTING DATA

Overview

Parameters, fields, and bean properties that are initialized using data from the HTTP request message have their values injected into them by the runtime. The specific data that is injected is specified by a set of annotations described in Section 47.2, “Using JAX-RS APIs”.

The JAX-RS specification places a few restrictions on when the data is injected. It also places a few restrictions on the types of objects into which request data can be injected.

When data is injected

Request data is injected into objects when they are instantiated due to a request. This means that only objects that directly correspond to a resource can use the injection annotations. As discussed in Chapter 46, Creating Resources, these objects will either be a root resource decorated with the @Path annotation or an object returned from a sub-resource locator method.

Supported data types

The specific set of data types that data can be injected into depends on the annotation used to specify the source of the injected data. However, all of the injection annotations support at least the following set of data types:

- primitives such as int, char, or long
- Objects that have a constructor that accepts a single String argument
- Objects that have a static valueOf() method that accepts a single String argument
- List<T>, Set<T>, or SortedSet<T> objects where T satisfies the other conditions in the list

NOTE

Where injection annotations have different requirements for supported data types, the differences will be highlighted in the discussion of the annotation.

47.2. USING JAX-RS APIs

47.2.1. JAX-RS Annotation Types
The standard JAX-RS API specifies annotations that can be used to inject values into fields, bean properties, and method parameters. The annotations can be split up into three distinct types:

- Section 47.2.2, “Injecting data from a request URI”
- Section 47.2.3, "Injecting data from the HTTP message header"
- Section 47.2.4, “Injecting data from HTML forms”

### 47.2.2. Injecting data from a request URI

#### Overview

One of the best practices for designing a RESTful Web service is that each resource should have a unique URI. A developer can use this principle to provide a good deal of information to the underlying resource implementation. When designing URI templates for a resource, a developer can build the templates to include parameter information that can be injected into the resource implementation. Developers can also leverage query and matrix parameters for feeding information into the resource implementations.

#### Getting data from the URI’s path

One of the more common mechanisms for getting information about a resource is through the variables used in creating the URI templates for a resource. This is accomplished using the `javax.ws.rsPathParam` annotation. The `@PathParam` annotation has a single parameter that identifies the URI template variable from which the data will be injected.

In **Example 47.1, “Injecting data from a URI template variable”** the `@PathParam` annotation specifies that the value of the URI template variable `color` is injected into the `itemColor` field.

```java
import javax.ws.rs.Path;
import javax.ws.rsPathParam
...
@Path("/boxes/{shape}/{color}")
class Box
{
...

@PathParam("color")
String itemColor;

...}
```

The data types supported by the `@PathParam` annotation are different from the ones described in the section called “Supported data types”. The entity into which the `@PathParam` annotation injects data must be one of the following types:

- PathSegment
  The value will be the final segment of the matching part of the path.
Using query parameters

A common way of passing information on the Web is to use query parameters in a URI. Query parameters appear at the end of the URI and are separated from the resource location portion of the URI by a question mark (?). They consist of one, or more, name value pairs where the name and value are separated by an equal sign (=). When more than one query parameter is specified, the pairs are separated from each other by either a semicolon (;) or an ampersand (&). Example 47.2, “URI with a query string” shows the syntax of a URI with query parameters.

Example 47.2. URI with a query string

http://fusesource.org?name=value;name2=value2;...

NOTE
You can use either the semicolon or the ampersand to separate query parameters, but not both.

The javax.ws.rs.QueryParam annotation extracts the value of a query parameter and injects it into a JAX-RS resource. The annotation takes a single parameter that identifies the name of the query parameter from which the value is extracted and injected into the specified field, bean property, or parameter. The @QueryParam annotation supports the types described in the section called “Supported data types”.

Example 47.3, “Resource method using data from a query parameter” shows a resource method that injects the value of the query parameter id into the method’s id parameter.

Example 47.3. Resource method using data from a query parameter

import javax.ws.rs.QueryParam;
import javax.ws.rsPathParam;
import javax.ws.rs.POST;
import javax.ws.rs.Path;
...

@Path("/monstersforhire/")
public class MonsterService
{
  ...
  @POST
  @Path("/(type)")
  public void updateMonster(@PathParam("type") String type,
                            @QueryParam("id") String id)
To process an HTTP POST to /monstersforhire/daikaiju?id=jonas the updateMonster() method’s type is set to daikaiju and the id is set to jonas.

Using matrix parameters

URI matrix parameters, like URI query parameters, are name/value pairs that can provide additional information selecting a resource. Unlike query parameters, matrix parameters can appear anywhere in a URI and they are separated from the hierarchical path segments of the URI using a semicolon(;) .

/mostersforhire/daikaiju;id=jonas has one matrix parameter called id and /monstersforhire/japan;type=daikaiju/flying;wingspan=40 has two matrix parameters called type and wingspan.

**NOTE**

Matrix parameters are not evaluated when computing a resource’s URI. So, the URI used to locate the proper resource to handle the request URI /monstersforhire/japan;type=daikaiju/flying;wingspan=40 is /monstersforhire/japan/flying.

The value of a matrix parameter is injected into a field, parameter, or bean property using the javax.ws.rs.MatrixParam annotation. The annotation takes a single parameter that identifies the name of the matrix parameter from which the value is extracted and injected into the specified field, bean property, or parameter. The @MatrixParam annotation supports the types described in the section called “Supported data types”.

Example 47.4, “Resource method using data from matrix parameters” shows a resource method that injects the value of the matrix parameters type and id into the method’s parameters.

Example 47.4. Resource method using data from matrix parameters

```
import javax.ws.rs.MatrixParam;
import javax.ws.rs.POST;
import javax.ws.rs.Path;
...

@Path("/monstersforhire/")
public class MonsterService
{
    ...
    @POST
    public void updateMonster(@MatrixParam("type") String type,
                                @MatrixParam("id") String id)
    {
        ...
    }
    ...
}
```
To process an HTTP POST to `/monstersforhire;type=daikaiju;id=whale` the `updateMonster()` method’s `type` is set to `daikaiju` and the `id` is set to `whale`.

**NOTE**

JAX-RS evaluates all of the matrix parameters in a URI at once, so it cannot enforce constraints on a matrix parameters location in a URI. For example `/monstersforhire/japan;type=daikaiju/flying;wingspan=40`, `/monstersforhire/japan/flying;type=daikaiju;wingspan=40`, and `/monstersforhire/japan;type=daikaiju;wingspan=40/flying` are all treated as equivalent by a RESTful Web service implemented using the JAX-RS APIs.

### Disabling URI decoding

By default all request URIs are decoded. So the URI `/monster/night%20stalker` and the URI `/monster/night stalker` are equivalent. The automatic URI decoding makes it easy to send characters outside of the ASCII character set as parameters.

If you do not wish to have URI automatically decoded, you can use the `javax.ws.rs.Encoded` annotation to deactivate the URI decoding. The annotation can be used to deactivate URI decoding at the following levels:

- **class level**—Decorating a class with the `@Encoded` annotation deactivates the URI decoding for all parameters, field, and bean properties in the class.

- **method level**—Decorating a method with the `@Encoded` annotation deactivates the URI decoding for all parameters of the class.

- **parameter/field level**—Decorating a parameter or field with the `@Encoded` annotation deactivates the URI decoding for all parameters of the class.

**Example 47.5, “Disabling URI decoding”** shows a resource whose `getMonster()` method does not use URI decoding. The `addMonster()` method only disables URI decoding for the `type` parameter.

**Example 47.5. Disabling URI decoding**

```java
@Path("/monstersforhire/")
public class MonsterService
{
...

@GET
@Encoded
@Path("/{type}")
public Monster getMonster(@PathParam("type") String type,
                        @QueryParam("id") String id)
{
...
}

@PUT
@Path("/{id}")
public void addMonster(@Encoded @PathParam("type") String type,
                      @QueryParam("id") String id)
```
Error handling

If an error occurs when attempting to inject data using one of the URI injection annotations a WebApplicationException exception wrapping the original exception is generated. The WebApplicationException exception’s status is set to 404.

47.2.3. Injecting data from the HTTP message header

Overview

In normal usage the HTTP headers in a request message pass along generic information about the message, how it is to be handled in transit, and details about the expected response. While a few standard headers are commonly recognized and used, the HTTP specification allows for any name/value pair to be used as an HTTP header. The JAX-RS APIs provide an easy mechanism for injecting HTTP header information into a resource implementation.

One of the most commonly used HTTP headers is the cookie. Cookies allow HTTP clients and servers to share static information across multiple request/response sequences. The JAX-RS APIs provide an annotation inject data directly from a cookie into a resource implementation.

Injecting information from the HTTP headers

The javax.ws.rs.HeaderParam annotation is used to inject the data from an HTTP header field into a parameter, field, or bean property. It has a single parameter that specifies the name of the HTTP header field from which the value is extracted and injected into the resource implementation. The associated parameter, field, or bean property must conform to the data types described in the section called “Supported data types”.

Injecting the If-Modified-Since header shows code for injecting the value of the HTTP If-Modified-Since header into a class’ oldestDate field.

Injecting the If-Modified-Since header

```java
import javax.ws.rs.HeaderParam;
...
class RecordKeeper
{
    ...
    @HeaderParam("If-Modified-Since")
    String oldestDate;
    ...
}
```

Injecting information from a cookie

Cookies are a special type of HTTP header. They are made up of one or more name/value pairs that are
passed to the resource implementation on the first request. After the first request, the cookie is passed back and forth between the provider and consumer with each message. Only the consumer, because they generate requests, can change the cookie. Cookies are commonly used to maintain session across multiple request/response sequences, storing user settings, and other data that can persist.

The `javax.ws.rs.CookieParam` annotation extracts the value from a cookie’s field and injects it into a resource implementation. It takes a single parameter that specifies the name of the cookie’s field from which the value is to be extracted. In addition to the data types listed in the section called “Supported data types”, entities decorated with the `@CookieParam` can also be a `Cookie` object.

Example 47.6, “Injecting a cookie” shows code for injecting the value of the `handle` cookie into a field in the `CB` class.

```java
import javax.ws.rs.CookieParam;
...

class CB {
    ...
    @CookieParam("handle")
    String handle;
    ...
}
```

Error handling

If an error occurs when attempting to inject data using one of the HTTP message injection annotations a `WebApplicationException` exception wrapping the original exception is generated. The `WebApplicationException` exception’s status is set to `400`.

47.2.4. Injecting data from HTML forms

Overview

HTML forms are an easy means of getting information from a user and they are also easy to create. Form data can be used for HTTP `GET` requests and HTTP `POST` requests:

**GET**

When form data is sent as part of an HTTP `GET` request the data is appended to the URI as a set of query parameters. Injecting data from query parameters is discussed in the section called “Using query parameters”.

**POST**

When form data is sent as part of an HTTP `POST` request the data is placed in the HTTP message body. The form data can be handled using a regular entity parameter that supports the form data. It can also be handled by using the `@FormParam` annotation to extract the data and inject the pieces into resource method parameters.

Using the `@FormParam` annotation to inject form data

The `javax.ws.rs.FormParam` annotation extracts field values from form data and injects the value into resource method parameters. The annotation takes a single parameter that specifies the key of the field.
from which it extracts the values. The associated parameter must conform to the data types described in the section called “Supported data types”.

**IMPORTANT**

The JAX-RS API Javadoc states that the `@FormParam` annotation can be placed on fields, methods, and parameters. However, the `@FormParam` annotation is only meaningful when placed on resource method parameters.

**Example**

*Injecting form data into resource method parameters* shows a resource method that injects form data into its parameters. The method assumes that the client’s form includes three fields—`title`, `tags`, and `body`—that contain string data.

```
import javax.ws.rs.FormParam;
import javax.ws.rs.POST;
...
@POST
public boolean updatePost(@FormParam("title") String title,
                          @FormParam("tags") String tags,
                          @FormParam("body") String post)
{
  ...
}
```

47.2.5. Specifying a default value to inject

**Overview**

To provide for a more robust service implementation, you may want to ensure that any optional parameters can be set to a default value. This can be particularly useful for values that are taken from query parameters and matrix parameters since entering long URI strings is highly error prone. You may also want to set a default value for a parameter extracted from a cookie since it is possible for a requesting system not have the proper information to construct a cookie with all the values.

The `javax.ws.rs.DefaultValue` annotation can be used in conjunction with the following injection annotations:

- `@PathParam`
- `@QueryParam`
- `@MatrixParam`
- `@FormParam`
- `@HeaderParam`
- `@CookieParam`
The @DefaultValue annotation specifies a default value to be used when the data corresponding to the injection annotation is not present in the request.

**Syntax**

*Syntax for setting the default value of a parameter* shows the syntax for using the @DefaultValue annotation.

**Syntax for setting the default value of a parameter**

```java
import javax.ws.rs.DefaultValue;
...
void resourceMethod(@MatrixParam("matrix")
    @DefaultValue("value")
    int someValue, ... )
...
```

The annotation must come before the parameter, bean, or field, it will effect. The position of the @DefaultValue annotation relative to the accompanying injection annotation does not matter.

The @DefaultValue annotation takes a single parameter. This parameter is the value that will be injected into the field if the proper data cannot be extracted based on the injection annotation. The value can be any String value. The value should be compatible with type of the associated field. For example, if the associated field is of type int, a default value of blue results in an exception.

**Dealing with lists and sets**

If the type of the annotated parameter, bean or field is List, Set, or SortedSet then the resulting collection will have a single entry mapped from the supplied default value.

**Example**

*Setting default values* shows two examples of using the @DefaultValue to specify a default value for a field whose value is injected.

**Setting default values**

```java
import javax.ws.rs.DefaultValue;
import javax.ws.rs.PathParam;
import javax.ws.rs.QueryParam;
import javax.ws.rs.GET;
import javax.ws.rs.Path;

@Path("/monster")
public class MonsterService
{

    @Get
    public Monster getMonster(@QueryParam("id") @DefaultValue("42") int id,
        @QueryParam("type") @DefaultValue("bogeyman") String type)
    {
        ...
    }
}
```
The `getMonster()` method in Setting default values is invoked when a GET request is sent to `baseURI/monster`. The method expects two query parameters, `id` and `type`, appended to the URI. So a GET request using the URI `baseURI/monster?id=1&type=fomóiri` would return the Fomóiri with the id of one.

Because the `@DefaultValue` annotation is placed on both parameters, the `getMonster()` method can function if the query parameters are omitted. A GET request sent to `baseURI/monster` is equivalent to a GET request using the URI `baseURI/monster?id=42&type=bogeyman`.

47.2.6. Injecting Parameters into a Java Bean

Overview

When posting HTML forms over REST, a common pattern on the server side is to create a Java bean to encapsulate all of the data received in the form (and possibly data from other parameters and HTML headers, as well). Normally, creating this Java bean would be a two step process: a resource method receives the form values by injection (for example, by adding `@FormParam` annotations to its method parameters), and the resource method then calls the bean’s constructor, passing in the form data.

Using the JAX-RS 2.0 `@BeanParam` annotation, it is possible to implement this pattern in a single step. The form data can be injected directly into the fields of the bean class and the bean itself is created automatically by the JAX-RS runtime. This is most easily explained by example.

Injection target

The `@BeanParam` annotation can be attached to resource method parameters, resource fields, or bean properties. A parameter target is the only kind of target that can be used with all resource class lifecycles, however. The other kinds of target are restricted to the per-request lifecycle. This situation is summarized in Table 47.1, “@BeanParam Injection Targets”.

<table>
<thead>
<tr>
<th>Target</th>
<th>Resource Class Lifecycles</th>
</tr>
</thead>
<tbody>
<tr>
<td>PARAMETER</td>
<td>All</td>
</tr>
<tr>
<td>FIELD</td>
<td>Per-request (default)</td>
</tr>
<tr>
<td>METHOD</td>
<td>Per-request (default)</td>
</tr>
</tbody>
</table>

Example without BeanParam annotation

The following example shows how you might go about capturing form data in a Java bean using the conventional approach (without using `@BeanParam`):

```java
// Java
import javax.ws.rs.POST;
import javax.ws.rs.FormParam;
```
import javax.ws.rs.core.Response;
...
@POST
public Response orderTable(@FormParam("orderId") String orderId,
                          @FormParam("color") String color,
                          @FormParam("quantity") String quantity,
                          @FormParam("price") String price)
{
    ...  
    TableOrder bean = new TableOrder(orderId, color, quantity, price);
    ...  
    return Response.ok().build();
}

In this example, the `orderTable` method processes a form that is used to order a quantity of tables from a furniture Web site. When the order form is posted, the form values are injected into the parameters of the `orderTable` method, and the `orderTable` method explicitly creates an instance of the `TableOrder` class, using the injected form data.

Example with BeanParam annotation

The previous example can be refactored to take advantage of the `@BeanParam` annotation. When using the `@BeanParam` approach, the form parameters can be injected directly into the fields of the bean class, `TableOrder`. In fact, you can use any of the standard JAX-RS parameter annotations in the bean class: including `@PathParam`, `@QueryParam`, `@FormParam`, `@MatrixParam`, `@CookieParam`, and `@HeaderParam`. The code for processing the form can be refactored as follows:

```java
// Java
import javax.ws.rs.POST;
import javax.ws.rs.FormParam;
import javax.ws.rs.core.Response;
...
public class TableOrder {
    @FormParam("orderId")
    private String orderId;
    @FormParam("color")
    private String color;
    @FormParam("quantity")
    private String quantity;
    @FormParam("price")
    private String price;
    ...
    // Define public getter/setter methods
    // (Not shown)
    ...  
    @POST
    public Response orderTable(@BeanParam TableOrder orderBean)
    {
        ...  
        // Do whatever you like with the 'orderBean' bean
```
Now that the form annotations have been added to the bean class, TableOrder, you can replace all of
the @FormParam annotations in the signature of the resource method with just a single @BeanParam
annotation, as shown. Now, when the form is posted to the orderTable resource method, the JAX-RS
runtime automatically creates a TableOrder instance, orderBean, and injects all of the data specified by
the parameter annotations on the bean class.

47.3. PARAMETER CONVERTERS

Overview

Using parameter converters, it is possible to inject a parameter (of String type) into any type of field,
bean property, or resource method argument. By implementing and binding a suitable parameter
converter, you can extend the JAX-RS runtime so that it is capable of converting the parameter String
value to the target type.

Automatic conversions

Parameters are received as instances of String, so you can always inject them directly into fields, bean
properties, and method parameters of String type. In addition, the JAX-RS runtime has the capability to
convert parameter strings automatically to the following types:

1. Primitive types.
2. Types that have a constructor that accepts a single String argument.
3. Types that have a static method named valueOf or fromString with a single String argument
   that returns an instance of the type.
4. List<T>, Set<T>, or SortedSet<T>, if T is one of the types described in 2 or 3.

Parameter converters

In order to inject a parameter into a type not covered by automatic conversion, you can define a custom
parameter converter for the type. A parameter converter is a JAX-RS extension that enables you to
define conversion from String to a custom type, and also in the reverse direction, from the custom type
to a String.

Factory pattern

The JAX-RS parameter converter mechanism uses a factory pattern. So, instead of registering a
parameter converter directly, you must register a parameter converter provider (of type,
javax.ws.rs.ext.ParamConverterProvider), which creates a parameter converter (of type,
javax.ws.rs.ext.ParamConverter) on demand.

ParamConverter interface

The javax.ws.rs.ext.ParamConverter interface is defined as follows:

```java
// Java
```
To implement your own `ParamConverter` class, you must implement this interface, overriding the `fromString` method (to convert the parameter string to your target type) and the `toString` method (to convert your target type back to a string).

**ParamConverterProvider interface**

The `javax.ws.rs.ext.ParamConverterProvider` interface is defined as follows:

```java
package javax.ws.rs.ext;
import java.lang.annotation.Annotation;
import java.lang.reflect.Type;
public interface ParamConverterProvider {
    public <T> ParamConverter<T> getConverter(Class<T> rawType, Type genericType, Annotation annotations[]);
}
```

To implement your own `ParamConverterProvider` class, you must implement this interface, overriding the `getConverter` method, which is a factory method that creates `ParamConverter` instances.

**Binding the parameter converter provider**

To bind the parameter converter provider to the JAX-RS runtime (thus making it available to your application), you must annotate your implementation class with the `@Provider` annotation, as follows:

```java
@Provider
... import javax.ws.rs.ext.ParamConverterProvider; import javax.ws.rs.ext.Provider;
```
public class TargetTypeProvider implements ParamConverterProvider {
    ...
}

This annotation ensures that your parameter converter provider is automatically registered during the scanning phase of deployment.

Example

The following example shows how to implement a ParamConverterProvider and a ParamConverter which has the capability to convert parameter strings to and from the TargetType type:

```java
// Java
import java.lang.annotation.Annotation;
import java.lang.reflect.Type;

import javax.ws.rs.ext.ParamConverter;
import javax.ws.rs.ext.ParamConverterProvider;
import javax.ws.rs.ext.Provider;

@Provider
public class TargetTypeProvider implements ParamConverterProvider {

    @Override
    public <T> ParamConverter<T> getConverter(
        Class<T> rawType,
        Type genericType,
        Annotation[] annotations
    ) {
        if (rawType.getName().equals(TargetType.class.getName())) {
            return new ParamConverter<T>() {
                @Override
                public T fromString(String value) {
                    // Perform conversion of value
                    // ...
                    TargetType convertedValue = // ... ;
                    return convertedValue;
                }

                @Override
                public String toString(T value) {
                    if (value == null) { return null; }
                    // Assuming that TargetType.toString is defined
                    return value.toString();
                }
            };
        }
        return null;
    }
}

Using the parameter converter
Now that you have defined a parameter converter for `TargetType`, it is possible to inject parameters directly into `TargetType` fields and arguments, for example:

```java
// Java
import javax.ws.rs.FormParam;
import javax.ws.rs.POST;
...
@POST
public Response updatePost(@FormParam("target") TargetType target)
{
    ...
}
```

**Lazy conversion of default value**

If you specify default values for your parameters (using the `@DefaultValue` annotation), you can choose whether the default value is converted to the target type right away (default behaviour), or whether the default value should be converted only when required (lazy conversion). To select lazy conversion, add the `@ParamConverter.Lazy` annotation to the target type. For example:

```java
// Java
import javax.ws.rs.FormParam;
import javax.ws.rs.POST;
import javax.ws.rs.DefaultValue;
import javax.ws.rs.ext.ParamConverter.Lazy;
...
@POST
public Response updatePost(
    @FormParam("target")
    @DefaultValue("default val")
    @ParamConverter.Lazy
    TargetType target)
{
    ...
}
```

### 47.4. USING APACHE CXF EXTENSIONS

**Overview**

Apache CXF provides an extension to the standard JAX-WS injection mechanism that allows developers to replace a sequence of injection annotations with a single annotation. The single annotation is placed on a bean containing fields for the data that is extracted using the annotation. For example, if a resource method is expecting a request URI to include three query parameters called `id`, `type`, and `size`, it could use a single `@QueryParam` annotation to inject all of the parameters into a bean with corresponding fields.

**NOTE**

Consider using the `@BeanParam` annotation instead (available since JAX-RS 2.0). The standardized `@BeanParam` approach is more flexible than the proprietary Apache CXF extension, and is thus the recommended alternative. For details, see Section 47.2.6, “Injecting Parameters into a Java Bean”.  

491
Supported injection annotations

This extension does not support all of the injection parameters. It only supports the following ones:

- `@PathParam`
- `@QueryParam`
- `@MatrixParam`
- `@FormParam`

Syntax

To indicate that an annotation is going to use serial injection into a bean, you need to do two things:

1. Specify the annotation’s parameter as an empty string. For example `@PathParam("")` specifies that a sequence of URI template variables are to be serialized into a bean.
2. Ensure that the annotated parameter is a bean with fields that match the values being injected.

Example

Example 47.7, “Injecting query parameters into a bean” shows an example of injecting a number of Query parameters into a bean. The resource method expect the request URI to include two query parameters: `type` and `id`. Their values are injected into the corresponding fields of the `Monster` bean.

Example 47.7. Injecting query parameters into a bean

```java
import javax.ws.rs.QueryParam;
import javax.ws.rsPathParam;
import javax.ws.rs.POST;
import javax.ws.rs.Path;
...

@Path("/monstersforhire")
public class MonsterService
{
    ...
    @POST
    public void updateMonster(@QueryParam("") Monster bean)
    {
        ...
    }
    ...
}

public class Monster
{
    String type;
    String id;
    ...
}
CHAPTER 48. RETURNING INFORMATION TO THE CONSUMER

Abstract

RESTful requests require that at least an HTTP response code be returned to the consumer. In many cases, a request can be satisfied by returning a plain JAXB object or a GenericEntity object. When the resource method needs to return additional metadata along with the response entity, JAX-RS resource methods can return a Response object containing any needed HTTP headers or other metadata.

48.1. RETURN TYPES

The information returned to the consumer determines the exact type of object a resource method returns. This may seem obvious, but the mapping between Java return objects and what is returned to a RESTful consumer is not one-to-one. At a minimum, RESTful consumers need to be returned a valid HTTP return code in addition to any response entity body. The mapping of the data contained within a Java object to a response entity is effected by the MIME types a consumer is willing to accept.

To address the issues involved in mapping Java object to RESTful response messages, resource methods are allowed to return four types of Java constructs:

- **Section 48.2, “Returning plain Java constructs”** return basic information with HTTP return codes determined by the JAX-RS runtime.
- **Section 48.2, “Returning plain Java constructs”** return complex information with HTTP return codes determined by the JAX-RS runtime.
- **Section 48.3, “Fine tuning an application’s responses”** return complex information with a programmatically determined HTTP return status. The Response object also allows HTTP headers to be specified.
- **Section 48.4, “Returning entities with generic type information”** return complex information with HTTP return codes determined by the JAX-RS runtime. The GenericEntity object provides more information to the runtime components serializing the data.

48.2. RETURNING PLAIN JAVA CONSTRUCTS

Overview

In many cases a resource class can return a standard Java type, a JAXB object, or any object for which the application has an entity provider. In these cases the runtime determines the MIME type information using the Java class of the object being returned. The runtime also determines the appropriate HTTP return code to send to the consumer.

Returnable types

Resource methods can return void or any Java type for which an entity writer is provided. By default, the runtime has providers for the following:

- the Java primitives
- the Number representations of the Java primitives
- JAXB objects

The section called “Natively supported types” lists all of the return types supported by default. The section called “Custom writers” describes how to implement a custom entity writer.

MIME types

The runtime determines the MIME type of the returned entity by first checking the resource method and resource class for a @Produces annotation. If it finds one, it uses the MIME type specified in the annotation. If it does not find one specified by the resource implementation, it relies on the entity providers to determine the proper MIME type.

By default the runtime assign MIME types as follows:

- Java primitives and their Number representations are assigned a MIME type of application/octet-stream.
- JAXB objects are assigned a MIME type of application/xml.

Applications can use other mappings by implementing custom entity providers as described in the section called “Custom writers”.

Response codes

When resource methods return plain Java constructs, the runtime automatically sets the response’s status code if the resource method completes without throwing an exception. The status code is set as follows:

- **204 (No Content)**—the resource method’s return type is void
- **204 (No Content)**—the value of the returned entity is null
- **200 (OK)**—the value of the returned entity is not null

If an exception is thrown before the resource method completes the return status code is set as described in Chapter 50, Handling Exceptions.

48.3. FINE TUNING AN APPLICATION’S RESPONSES

48.3.1. Basics of building responses

Overview

RESTful services often need more precise control over the response returned to a consumer than is allowed when a resource method returns a plain Java construct. The JAX-RS Response class allows a resource method to have some control over the return status sent to the consumer and to specify HTTP message headers and cookies in the response.

Response objects wrap the object representing the entity that is returned to the consumer. Response objects are instantiated using the ResponseBuilder class as a factory.

The ResponseBuilder class also has many of the methods used to manipulate the response’s metadata. For instance the ResponseBuilder class contains the methods for setting HTTP headers and cache control directives.
Relationship between a response and a response builder

The `Response` class has a protected constructor, so they cannot be instantiated directly. They are created using the `ResponseBuilder` class enclosed by the `Response` class. The `ResponseBuilder` class is a holder for all of the information that will be encapsulated in the response created from it. The `ResponseBuilder` class also has all of the methods responsible for setting HTTP header properties on the message.

The `Response` class does provide some methods that ease setting the proper response code and wrapping the entity. There are methods for each of the common response status codes. The methods corresponding to status that include an entity body, or required metadata, include versions that allow for directly setting the information into the associated response builder.

The `ResponseBuilder` class' `build()` method returns a response object containing the information stored in the response builder at the time the method is invoked. After the response object is returned, the response builder is returned to a clean state.

Getting a response builder

There are two ways to get a response builder:

- Using the static methods of the `Response` class as shown in Getting a response builder using the Response class.

```
import javax.ws.rs.core.Response;

Response r = Response.ok().build();
```

When getting a response builder this way you do not get access to an instance you can manipulate in multiple steps. You must string all of the actions into a single method call.

- Using the Apache CXF specific `ResponseBuilderImpl` class. This class allows you to work directly with a response builder. However, it requires that you manually set all of the response builders information manually.

  Example 48.1, “Getting a response builder using the ResponseBuilderImpl class” shows how getting a response builder using the `Response` class could be rewritten using the `ResponseBuilderImpl` class.

```
import javax.ws.rs.core.Response;
import org.apache.cxf.jaxrs.impl.ResponseBuilderImpl;

ResponseBuilderImpl builder = new ResponseBuilderImpl();
builder.status(200);
Response r = builder.build();
```

NOTE

You could also simply assign the `ResponseBuilder` returned from a `Response` class' method to a `ResponseBuilderImpl` object.
48.3.2. Creating responses for common use cases

Overview

The **Response** class provides shortcut methods for handling the more common responses that a RESTful service will need. These methods handle setting the proper headers using either provided values or default values. They also handle populating the entity body when appropriate.

Creating responses for successful requests

When a request is successfully processed the application needs to send a response to acknowledge that the request has been fulfilled. That response may contain an entity.

The most common response when successfully completing a response is **OK**. An **OK** response typically contains an entity that corresponds to the request. The **Response** class has an overloaded **ok()** method that sets the response status to **200** and adds a supplied entity to the enclosed response builder. There are five versions of the **ok()** method. The most commonly used variant are:

- **Response.ok()**—creates a response with a status of **200** and an empty entity body.
- **Response.ok(java.lang.Object entity)**—creates a response with a status of **200**, stores the supplied object in the responses entity body, and determines the entities media type by introspecting the object.

Creating a response with an **200** response shows an example of creating a response with an **OK** status.

```java
import javax.ws.rs.core.Response;
import demo.jaxrs.server.Customer;
...

Customer customer = new Customer("Jane", 12);
return Response.ok(customer).build();
```

For cases where the requester is not expecting an entity body, it may be more appropriate to send a **204 No Content** status instead of an **200 OK** status. The **Response.noContent()** method will create an appropriate response object.

Creating a response with a **204** status shows an example of creating a response with an **204** status.

Creating a response with a **204** status
Creating responses for redirection

The **Response** class provides methods for handling three of the redirection response statuses.

### 303 See Other

The **303 See Other** status is useful when the requested resource needs to permanently redirect the consumer to a new resource to process the request. The **Response** class's **seeOther()** method creates a response with a **303** status and places the new resource URI in the message's **Location** field. The **seeOther()** method takes a single parameter that specifies the new URI as a **java.net.URI** object.

### 304 Not Modified

The **304 Not Modified** status can be used for different things depending on the nature of the request. It can be used to signify that the requested resource has not changed since a previous **GET** request. It can also be used to signify that a request to modify the resource did not result in the resource being changed. The **Response** class's **notModified()** methods create a response with a **304** status and sets the modified date property on the HTTP message. There are three versions of the **notModified()** method:

- **notModified**
- **notModified(javax.ws.rs.core.Entity)**
- **notModified(java.lang.String)**

### 307 Temporary Redirect

The **307 Temporary Redirect** status is useful when the requested resource needs to direct the consumer to a new resource, but wants the consumer to continue using this resource to handle future requests. The **Response** class's **temporaryRedirect()** method creates a response with a **307** status and places the new resource URI in the message's **Location** field. The **temporaryRedirect()** method takes a single parameter that specifies the new URI as a **java.net.URI** object.

Creating a response with a **304** status shows an example of creating a response with an **304** status.

### Creating a response with a **304** status

```java
import javax.ws.rs.core.Response;
return Response.notModified().build();
```

Creating responses to signal errors

The **Response** class provides methods to create responses for two basic processing errors:

- **serverError**—creates a response with a status of **500 Internal Server Error**.
• `notAcceptable(java.util.List<javax.ws.rs.core.Variant>`variants`)—creates a response with a 406 Not Acceptable status and an entity body containing a list of acceptable resource types.

Creating a response with a 500 status shows an example of creating a response with an 500 status.

```java
import javax.ws.rs.core.Response;
return Response.serverError().build();
```

48.3.3. Handling more advanced responses

Overview

The `Response` class methods provide short cuts for creating responses for common cases. When you need to address more complicated cases such as specifying cache control directives, adding custom HTTP headers, or sending a status not handled by the `Response` class, you need to use the `ResponseBuilder` classes methods to populate the response before using the `build()` method to generate the response object.

As discussed in the section called “Getting a response builder”, you can use the Apache CXF `ResponseBuilderImpl` class to create a response builder instance that can be manipulated directly.

Adding custom headers

Custom headers are added to a response using the `ResponseBuilder` class’ `header()` method. The `header()` method takes two parameters:

- `name`—a string specifying the name of the header
- `value`—a Java object containing the data stored in the header

You can set multiple headers on the message by calling the `header()` method repeatedly.

Adding a header to a response shows code for adding a header to a response.

```java
import javax.ws.rs.core.Response;
import org.apache.cxf.jaxrs.impl.ResponseBuilderImpl;
ResponseBuilderImpl builder = new ResponseBuilderImpl();
builder.header("username", "joe");
Response r = builder.build();
```

Adding a cookie

Custom headers are added to a response using the `ResponseBuilder` class’ `cookie()` method. The `cookie()` method takes one or more cookies. Each cookie is stored in a `javax.ws.rs.core.NewCookie` object. The easiest of the `NewCookie` class’ constructors to use takes two parameters:

- `name`—a string specifying the name of the cookie
• **value**—a string specifying the value of the cookie

You can set multiple cookies by calling the `cookie()` method repeatedly.

**Adding a cookie to a response** shows code for adding a cookie to a response.

**Adding a cookie to a response**

```java
import javax.ws.rs.core.Response;
import javax.ws.rs.core.NewCookie;

NewCookie cookie = new NewCookie("username", "joe");
Response r = Response.ok().cookie(cookie).build();
```

**WARNING**

Calling the `cookie()` method with a **null** parameter list erases any cookies already associated with the response.

**Setting the response status**

When you want to return a status other than one of the statuses supported by the `Response` class’ helper methods, you can use the `ResponseBuilder` class’ `status()` method to set the response’s status code. The `status()` method has two variants. One takes an `int` that specifies the response code. The other takes a `Response.Status` object to specify the response code.

The `Response.Status` class is an enumeration enclosed in the `Response` class. It has entries for most of the defined HTTP response codes.

**Adding a header to a response** shows code for setting the response status to **404 Not Found**.

**Adding a header to a response**

```java
import javax.ws.rs.core.Response;
import org.apache.cxf.jaxrs.impl.ResponseBuilderImpl;

ResponseBuilderImpl builder = new ResponseBuilderImpl();
builder.status(404);
Response r = builder.build();
```

**Setting cache control directives**

The `ResponseBuilder` class’ `cacheControl()` method allows you to set the cache control headers on the response. The `cacheControl()` method takes a `javax.ws.rs.CacheControl` object that specifies the cache control directives for the response.

The `CacheControl` class has methods that correspond to all of the cache control directives supported by the HTTP specification. Where the directive is a simple on or off value the setter method takes a `boolean` value. Where the directive requires a numeric value, such as the **max-age** directive, the setter
takes an \texttt{int} value.

Adding a header to a response shows code for setting the \texttt{no-store} cache control directive.

Adding a header to a response

```java
import javax.ws.rs.core.Response;
import javax.ws.rs.core.CacheControl;
import org.apache.cxf.jaxrs.impl.ResponseBuilderImpl;

CacheControl cache = new CacheControl();
    cache.setNoCache(true);

ResponseBuilderImpl builder = new ResponseBuilderImpl();
builder.cacheControl(cache);
Response r = builder.build();
```

48.4. RETURNING ENTITIES WITH GENERIC TYPE INFORMATION

Overview

There are occasions where the application needs more control over the MIME type of the returned object or the entity provider used to serialize the response. The JAX-RS \texttt{javax.ws.rs.core.GenericEntity<T>} class provides finer control over the serializing of entities by providing a mechanism for specifying the generic type of the object representing the entity.

Using a \texttt{GenericEntity<T>} object

One of the criteria used for selecting the entity provider that serializes a response is the generic type of the object. The generic type of an object represents the Java type of the object. When a common Java type or a JAXB object is returned, the runtime can use Java reflection to determine the generic type. However, when a JAX-RS Response object is returned, the runtime cannot determine the generic type of the wrapped entity and the actual Java class of the object is used as the Java type.

To ensure that the entity provider is provided with correct generic type information, the entity can be wrapped in a \texttt{GenericEntity<T>} object before being added to the \texttt{Response} object being returned.

Resource methods can also directly return a \texttt{GenericEntity<T>} object. In practice, this approach is rarely used. The generic type information determined by reflection of an unwrapped entity and the generic type information stored for an entity wrapped in a \texttt{GenericEntity<T>} object are typically the same.

Creating a \texttt{GenericEntity<T>} object

There are two ways to create a \texttt{GenericEntity<T>} object:

1. Create a subclass of the \texttt{GenericEntity<T>} class using the entity being wrapped. Creating a \texttt{GenericEntity<T>} object using a subclass shows how to create a \texttt{GenericEntity<T>} object containing an entity of type \texttt{List<String>} whose generic type will be available at runtime.

Creating a \texttt{GenericEntity<T>} object using a subclass

```java
import javax.ws.rs.core.GenericEntity;

List<String> list = new ArrayList<String>();
```
2. Create an instance directly by supplying the generic type information with the entity. Example 48.2, “Directly instantiating a GenericEntity<T> object” shows how to create a response containing an entity of type AtomicInteger.

Example 48.2. Directly instantiating a GenericEntity<T> object

```java
import javax.ws.rs.core.GenericEntity;

AtomicInteger result = new AtomicInteger(12);
GenericEntity<AtomicInteger> entity =
    new GenericEntity<AtomicInteger>(result,
        result.getClass().getGenericSuperclass());
Response response = Response.ok(entity).build();
```

48.5. ASYNCHRONOUS RESPONSE

48.5.1. Asynchronous Processing on the Server

Overview

The purpose of asynchronous processing of invocations on the server side is to enable more efficient use of threads and, ultimately, to avoid the scenario where client connection attempts are refused because all of the server’s request threads are blocked. When an invocation is processed asynchronously, the request thread is freed up almost immediately.

**NOTE**

Note that even when asynchronous processing is enabled on the server side, a client will still remain blocked until it receives a response from the server. If you want to see asynchronous behaviour on the client side, you must implement client-side asynchronous processing. See Section 49.6, “Asynchronous Processing on the Client”.

Basic model for asynchronous processing

Figure 48.1, “Threading Model for Asynchronous Processing” shows an overview of the basic model for asynchronous processing on the server side.
In outline, a request is processed as follows in the asynchronous model:

1. An asynchronous resource method is invoked within a request thread (and receives a reference to an `AsyncResponse` object, which will be needed later to send back the response).

2. The resource method encapsulates the suspended request in a `Runnable` object, which contains all of the information and processing logic required to process the request.

3. The resource method pushes the `Runnable` object onto the blocking queue of the executor thread pool.

4. The resource method can now return, thus freeing up the request thread.

5. When the `Runnable` object gets to the top of the queue, it is processed by one of the threads in the executor thread pool. The encapsulated `AsyncResponse` object is then used to send the response back to the client.

Thread pool implementation with Java executor

The `java.util.concurrent` API is a powerful API that enables you to create a complete thread pool implementation very easily. In the terminology of the Java concurrency API, a thread pool is called an `executor`. It requires only a single line of code to create a complete working thread pool, including the working threads and the blocking queue that feeds them.

For example, to create a complete working thread pool like the `Executor Thread Pool` shown in Figure 48.1, “Threading Model for Asynchronous Processing”, create a `java.util.concurrent.Executor` instance, as follows:

```java
Executor executor = new ThreadPoolExecutor(
    5,                                    // Core pool size
    5,                                    // Maximum pool size
    0,                                    // Keep-alive time
    TimeUnit.SECONDS,                     // Time unit
    new ArrayBlockingQueue<Runnable>(10)  // Blocking queue
);
```

This constructor creates a new thread pool with five threads, fed by a single blocking queue with which can hold up to 10 `Runnable` objects. To submit a task to the thread pool, call the `executor.execute` method, passing in a reference to a `Runnable` object (which encapsulates the asynchronous task).
Defining an asynchronous resource method

To define a resource method that is asynchronous, inject an argument of type `javax.ws.rs.container.AsyncResponse` using the `@Suspended` annotation and make sure that the method returns `void`. For example:

```
// Java
...
import javax.ws.rs.GET;
import javax.ws.rs.Path;
import javax.ws.rs.PathParam;
import javax.ws.rs.container.AsyncResponse;
import javax.ws.rs.container.Suspended;

@Path("/bookstore")
public class BookContinuationStore {
    ...
    @GET
    @Path("/{id}")
    public void handleRequestInPool(@PathParam("id") String id,
                                      @Suspended AsyncResponse response) {
        ...
    }
    ...
}
```

Note that the resource method must return `void`, because the injected `AsyncResponse` object will be used to return the response at a later time.

AsyncResponse class

The `javax.ws.rs.container.AsyncResponse` class provides an abstract handle on an incoming client connection. When an `AsyncResponse` object is injected into a resource method, the underlying TCP client connection is initially in a `suspended` state. At a later time, when you are ready to return the response, you can re-activate the underlying TCP client connection and pass back the response, by calling `resume` on the `AsyncResponse` instance. Alternatively, if you need to abort the invocation, you could call `cancel` on the `AsyncResponse` instance.

Encapsulating a suspended request as a Runnable

In the asynchronous processing scenario shown in Figure 48.1, “Threading Model for Asynchronous Processing”, you push the suspended request onto a queue, from where it can be processed at a later time by a dedicated thread pool. In order for this approach to work, however, you need to have some way of encapsulating the suspended request in an object. The suspended request object needs to encapsulate the following things:

- Parameters from the incoming request (if any).
- The `AsyncResponse` object, which provides a handle on the incoming client connection and a way of sending back the response.
- The logic of the invocation.

A convenient way to encapsulate these things is to define a `Runnable` class to represent the suspended request, where the `Runnable.run()` method encapsulates the logic of the invocation. The most elegant way to do this is to implement the `Runnable` as a local class, as shown in the following example.
Example of asynchronous processing

To implement the asynchronous processing scenario, the implementation of the resource method must pass a Runnable object (representing the suspended request) to the executor thread pool. In Java 7 and 8, you can exploit some novel syntax to define the Runnable class as a local class, as shown in the following example:

```java
// Java
package org.apache.cxf.systest.jaxrs;

import java.util.HashMap;
import java.util.Map;
import java.util.concurrent.ArrayBlockingQueue;
import java.util.concurrent.Executor;
import java.util.concurrent.ThreadPoolExecutor;
import java.util.concurrent.TimeUnit;
import java.util.concurrent.atomic.AtomicInteger;
import javax.ws.rs.GET;
import javax.ws.rs.NotFoundException;
import javax.ws.rs.Path;
import javax.ws.rs.PathParam;
import javax.ws.rs.Produces;
import javax.ws.rs.container.AsyncResponse;
import javax.ws.rs.container.CompletionCallback;
import javax.ws.rs.container.ConnectionCallback;
import javax.ws.rs.container.Suspended;
import javax.ws.rs.container.TimeoutHandler;
import org.apache.cxf.phase.PhaseInterceptorChain;

@Path("/bookstore")
public class BookContinuationStore {

private Map<String, String> books = new HashMap<String, String>();
private Executor executor = new ThreadPoolExecutor(5, 5, 0, TimeUnit.SECONDS,
        new ArrayBlockingQueue<Runnable>(10));

public BookContinuationStore() {
    init();
}
...

@GET
@Path("/{id}")
public void handleRequestInPool(final @PathParam("id") String id,
        final @Suspended AsyncResponse response) {
    executor.execute(new Runnable() {
        public void run() {
            // Retrieve the book data for 'id'
            // which is presumed to be a very slow, blocking operation
            // ...
            bookdata = ...
            // Re-activate the client connection with 'resume'
            // and send the 'bookdata' object as the response
            response.resume(bookdata);
        }
    });
}
```
Note how the resource method arguments, \texttt{id} and \texttt{response}, are passed straight into the definition of the \texttt{Runnable} local class. This special syntax enables you to use the resource method arguments directly in the \texttt{Runnable.run()} method, without having to define corresponding fields in the local class.

\textbf{IMPORTANT}

In order for this special syntax to work, the resource method parameters must be declared as \texttt{final} (which implies that they must not be changed in the method implementation).

48.5.2. Timeouts and Timeout Handlers

\textbf{Overview}

The asynchronous processing model also provides support for imposing timeouts on REST invocations. By default, a timeout results in a HTTP error response being sent back to the client. But you also have the option of registering a timeout handler callback, which enables you to customize the response to a timeout event.

\textbf{Example of setting a timeout without a handler}

To define a simple invocation timeout, without specifying a timeout handler, call the \texttt{setTimeout} method on the \texttt{AsyncResponse} object, as shown in the following example:

```java
// Java
// Java
...
import java.util.concurrent.TimeUnit;
...
import javax.ws.rs.GET;
import javax.ws.rs.NotFoundException;
import javax.ws.rs.Path;
import javax.ws.rs.PathParam;
import javax.ws.rs.Produces;
import javax.ws.rs.container.AsyncResponse;
import javax.ws.rs.container.Suspended;
import javax.ws.rs.container.TimeoutHandler;

@Path("/bookstore")
public class BookContinuationStore {
  ...
  @GET
  @Path("/books/defaulttimeout")
  public void getBookDescriptionWithTimeout(@Suspended AsyncResponse async) {
    async.setTimeout(2000, TimeUnit.MILLISECONDS);
    // Optionally, send request to executor queue for processing
    // ...
  }

```
Note that you can specify the timeout value using any time unit from the `java.util.concurrent.TimeUnit` class. The preceding example does not show the code for sending the request to the executor thread pool. If you just wanted to test the timeout behaviour, you could include just the call to `async.setTimeout` in the resource method body, and the timeout would be triggered on every invocation.

The `AsyncResponse.NO_TIMEOUT` value represents an infinite timeout.

**Default timeout behaviour**

By default, if the invocation timeout is triggered, the JAX-RS runtime raises a `ServiceUnavailableException` exception and sends back a HTTP error response with the status `503`.

**TimeoutHandler interface**

If you want to customize the timeout behaviour, you must define a timeout handler, by implementing the `TimeoutHandler` interface:

```java
// Java
package javax.ws.rs.container;

public interface TimeoutHandler {
    public void handleTimeout(AsyncResponse asyncResponse);
}
```

When you override the `handleTimeout` method in your implementation class, you can choose between the following approaches to dealing with the timeout:

- Cancel the response, by calling the `asyncResponse.cancel` method.
- Send a response, by calling the `asyncResponse.resume` method with the response value.
- Extend the waiting period, by calling the `asyncResponse.setTimeout` method. (For example, to wait for a further 10 seconds, you could call `asyncResponse.setTimeout(10, TimeUnit.SECONDS)`).

**Example of setting a timeout with a handler**

To define an invocation timeout with a timeout handler, call both the `setTimeout` method and the `setTimeoutHandler` method on the `AsyncResponse` object, as shown in the following example:

```java
// Java
...
import javax.ws.rs.GET;
import javax.ws.rs.NotFoundException;
import javax.ws.rs.Path;
import javax.ws.rsPathParam;
import javax.ws.rs.Produces;
import javax.ws.rs.container.AsyncResponse;
import javax.ws.rs.container.Suspended;
import javax.ws.rs.container.TimeoutHandler;
```
@Path("/bookstore")
public class BookContinuationStore {
    ...
    @GET
    @Path("/books/cancel")
    public void getBookDescriptionWithCancel(@PathParam("id") String id,
        @Suspended AsyncResponse async) {
        async.setTimeout(2000, TimeUnit.MILLISECONDS);
        async.setTimeoutHandler(new CancelTimeoutHandlerImpl());
        // Optionally, send request to executor queue for processing
        // ...
    }
    ...
}

Where this example registers an instance of the CancelTimeoutHandlerImpl timeout handler to handle the invocation timeout.

Using a timeout handler to cancel the response

The CancelTimeoutHandlerImpl timeout handler is defined as follows:

```java
// Java
... import javax.ws.rs.container.AsyncResponse;
... import javax.ws.rs.container.TimeoutHandler;

@Path("/bookstore")
public class BookContinuationStore {
    ...
    private class CancelTimeoutHandlerImpl implements TimeoutHandler {
        @Override
        public void handleTimeout(AsyncResponse asyncResponse) {
            asyncResponse.cancel();
        }
    }
    ...
}
```

The effect of calling cancel on the AsyncResponse object is to send a HTTP 503 (Service unavailable) error response to the client. You can optionally specify an argument to the cancel method (either an int or a java.util.Date value), which would be used to set a Retry-After: HTTP header in the response message. Clients often ignore the Retry-After: header, however.

Dealing with a cancelled response in the Runnable instance

If you have encapsulated a suspended request as a Runnable instance, which is queued for processing in an executor thread pool, you might find that the AsyncResponse has been cancelled by the time the thread pool gets around to processing the request. For this reason, you ought to add some code to your Runnable instance, which enables it to cope with a cancelled AsyncResponse object. For example:
48.5.3. Handling Dropped Connections

Overview

It is possible to add a callback to deal with the case where the client connection is lost.

ConnectionCallback interface

To add a callback for dropped connections, you must implement the
javax.ws.rs.container.ConnectionCallback interface, which is defined as follows:

```java
package javax.ws.rs.container;

public interface ConnectionCallback {
    public void onDisconnect(AsyncResponse disconnected);
}
```

Registering a connection callback

After implementing a connection callback, you must register it with the current AsyncResponse object, by calling one of the register methods. For example, to register a connection callback of type, MyConnectionCallback:

```java
asyncResponse.register(new MyConnectionCallback());
```

Typical scenario for connection callback

Typically, the main reason for implementing a connection callback would be to free up resources associated with the dropped client connection (where you could use the AsyncResponse instance as the key to identify the resources that need to be freed).
48.5.4. Registering Callbacks

Overview

You can optionally add a callback to an AsyncResponse instance, in order to be notified when the invocation has completed. There are two alternative points in the processing when this callback can be invoked, either:

- After the request processing is finished and the response has already been sent back to the client, or
- After the request processing is finished and an unmapped Throwable has been propagated to the hosting I/O container.

CompletionCallback interface

To add a completion callback, you must implement the javax.ws.rs.container.CompletionCallback interface, which is defined as follows:

```java
// Java
package javax.ws.rs.container;

public interface CompletionCallback {
    public void onComplete(Throwable throwable);
}
```

Usually, the throwable argument is null. However, if the request processing resulted in an unmapped exception, throwable contains the unmapped exception instance.

Registering a completion callback

After implementing a completion callback, you must register it with the current AsyncResponse object, by calling one of the register methods. For example, to register a completion callback of type, MyCompletionCallback:

```java
asyncResponse.register(new MyCompletionCallback());
```
CHAPTER 49. JAX-RS 2.0 CLIENT API

Abstract

JAX-RS 2.0 defines a full-featured client API which can be used for making REST invocations or any HTTP client invocations. This includes a fluent API (to simplify building up requests), a framework for parsing messages (based on a type of plug-in known as an entity provider), and support for asynchronous invocations on the client side.

49.1. INTRODUCTION TO THE JAX-RS 2.0 CLIENT API

Overview

JAX-RS 2.0 defines a fluent API for JAX-RS clients, which enables you to build up a HTTP request step-by-step and then invoke the request using the appropriate HTTP verb (GET, POST, PUT, or DELETE).

NOTE

It is also possible to define a JAX-RS client in Blueprint XML or Spring XML (using the jaxrs:client element). For details of this approach, see Section 18.2, "Configuring JAX-RS Client Endpoints".

Dependencies

To use the JAX-RS 2.0 client API in your application, you must add the following Maven dependency to your project’s pom.xml file:

```xml
<dependency>
  <groupId>org.apache.cxf</groupId>
  <artifactId>cxf-rt-rs-client</artifactId>
  <version>3.3.6.fuse-780029-redhat-00001</version>
</dependency>
```

If you plan to use the asynchronous invocation feature (see Section 49.6, "Asynchronous Processing on the Client"), you also need the following Maven dependency:

```xml
<dependency>
  <groupId>org.apache.cxf</groupId>
  <artifactId>cxf-rt-transports-http-hc</artifactId>
  <version>3.3.6.fuse-780029-redhat-00001</version>
</dependency>
```

Client API package

The JAX-RS 2.0 client interfaces and classes are located in the following Java package:

```java
javax.ws.rs.client
```

When developing JAX-RS 2.0 Java clients, you also typically need to access classes from the core package:
javax.ws.rs.core

Example of a simple client request

The following code fragment shows a simple example, where the JAX-RS 2.0 client API is used to make an invocation on the http://example.org/bookstore JAX-RS service, invoking with the GET HTTP method:

```java
// Java
import javax.ws.rs.client.ClientBuilder;
import javax.ws.rs.client.Client;
import javax.ws.rs.core.Response;
...
Client client = ClientBuilder.newClient();
Response res = client.target("http://example.org/bookstore/books/123")
 .request("application/xml").get();
```

Fluent API

The JAX-RS 2.0 client API is designed as a fluent API (sometimes called a Domain Specific Language). In the fluent API, a chain of Java methods is invoked in a single statement, in such a way that the Java methods look like the commands from a simple language. In JAX-RS 2.0, the fluent API is used to build and invoke a REST request.

Steps to make a REST invocation

Using the JAX-RS 2.0 client API, a client invocation is built and invoked in a series of steps, as follows:

1. Bootstrap the client.
2. Configure the target.
3. Build and make the invocation.
4. Parse the response.

Bootstrap the client

The first step is to bootstrap the client, by creating a `javax.ws.rs.client.Client` object. This `Client` instance is a relatively heavyweight object, which represents the stack of technologies required to support a JAX-RS client (possibly including, interceptors and additional CXF features). Ideally, you should re-use client objects when you can, instead of creating new ones.

To create a new `Client` object, invoke a static method on the `ClientBuilder` class, as follows:

```java
// Java
import javax.ws.rs.client.ClientBuilder;
import javax.ws.rs.client.Client;
...
Client client = ClientBuilder.newClient();
...
```

Configure the target
By configuring the target, you effectively define the URI that will be used for the REST invocation. The following example shows how you can define a base URI, base, and then add additional path segments to the base URI, using the `path(String)` method:

```java
// Java
import javax.ws.rs.client.WebTarget;
...
WebTarget base = client.target("http://example.org/bookstore/");
WebTarget books = base.path("books").path("{id}");
...
```

**Build and make the invocation**

This is really two steps rolled up into one: firstly, you build up the HTTP request (including headers, accepted media types, and so on); and secondly, you invoke the relevant HTTP method (optionally providing a request message body, if one is required).

For example, to create and invoke a request that accepts the `application/xml` media type:

```java
// Java
import javax.ws.rs.core.Response;
...
Response resp = books.resolveTemplate("id", "123").request("application/xml").get();
```

**Parse the response**

Finally, you need to parse the response, `resp`, obtained in the previous step. Usually, the response is returned in the form of a `javax.ws.rs.core.Response` object, which encapsulates HTTP headers, along with other HTTP metadata, and the HTTP message body (if any).

If you want to access the returned HTTP message in `String` format, you can easily do so by invoking the `readEntity` method with a `String.class` argument, as follows:

```java
// Java
...
String msg = resp.readEntity(String.class);
```

You can always access the message body of a response as a `String`, by specifying `String.class` as the argument to `readEntity`. For more general transformations or conversions of the message body, you can provide an `entity provider` to perform the conversion. For more details, see  
Section 49.4, “Parsing Requests and Responses”.

### 49.2. BUILDING THE CLIENT TARGET

**Overview**

After creating the initial `Client` instance, the next step is to build up the request URI. The `WebTarget` builder class enables you to configure all aspects of the URI, including the URI path and query parameters.

**WebTarget builder class**
Create the client target

To create a WebTarget instance, invoke one of the target methods on a javax.ws.rs.client.Client instance. For example:

// Java
import javax.ws.rs.client.WebTarget;
...
WebTarget base = client.target("http://example.org/bookstore/");

Base path and path segments

You can specify the complete path all in one go, using the target method; or you can specify a base path, and then add path segments piece by piece, using a combination of the target method and the path methods. The advantage of combining a base path with path segments is that you can easily reuse the base path WebTarget object for multiple invocations on slightly different targets. For example:

// Java
import javax.ws.rs.client.WebTarget;
...
WebTarget base = client.target("http://example.org/bookstore/");
WebTarget headers = base.path("bookheaders");
// Now make some invocations on the 'headers' target...
...
WebTarget collections = base.path("collections");
// Now make some invocations on the 'collections' target...
...

URI template parameters

The syntax of the target path also supports URI template parameters. That is, a path segment can be initialized with a template parameter, \{param\}, which subsequently gets resolved to a specify value. For example:

// Java
import javax.ws.rs.client.WebTarget;
import javax.ws.rs.core.Response;
...
WebTarget base = client.target("http://example.org/bookstore/");
WebTarget books = base.path("books").path("{id}");
...
Response resp = books.resolveTemplate("id", "123").request("application/xml").get();

Where the resolveTemplate method replaces the path segment, \{id\}, with the value 123.

Define query parameters

Query parameters can be appended to the URI path, where the beginning of the query parameters is marked by a single ? character. This mechanism enables you to set a series of name/value pairs, using the syntax: ?name1=value1&name2=value2&...
A `WebTarget` instance enables you to define query parameters using the `QueryParam` method, as follows:

```java
// Java
WebTarget target = client.target("http://example.org/bookstore/")
    .queryParam("userId","Agamemnon")
    .queryParam("lang","gr");
```

Define matrix parameters

Matrix parameters are somewhat similar to query parameters, but are not as widely supported and use a different syntax. To define a matrix parameter on a `WebTarget` instance, invoke the `matrixParam(String, Object)` method.

### 49.3. BUILDING THE CLIENT INVOCATION

**Overview**

After building the target URI, using the `WebTarget` builder class, the next step is to configure the other aspects of the request—such as HTTP headers, cookies, and so on—using the `Invocation.Builder` class. The final step in building the invocation is to invoke the appropriate HTTP verb (GET, POST, PUT, or DELETE) and provide a message body, if required.

**Invocation.Builder class**

The `javax.ws.rs.client.Invocation.Builder` builder class provides the part of the fluent API that enables you to build up the contents of the HTTP message and to invoke a HTTP method.

**Create the invocation builder**

To create an `Invocation.Builder` instance, invoke one of the `request` methods on a `javax.ws.rs.client.WebTarget` instance. For example:

```java
// Java
import javax.ws.rs.client.WebTarget;
import javax.ws.rs.client.Invocation.Builder;
...
WebTarget books = client.target("http://example.org/bookstore/books/123");
Invocation.Builder invbuilder = books.request();
```

**Define HTTP headers**

You can add a HTTP header to the request message using the `header` method, as follows:

```java
Invocation.Builder invheader = invbuilder.header("From", "fionn@example.org");
```

**Define cookies**

You can add a cookie to the request message using the `cookie` method, as follows:

```java
Invocation.Builder invcookie = invbuilder.cookie("myrestclient", "123xyz");
```
Define properties

You can set a property in the context of this request using the property method, as follows:

```java
Invocation.Builder invproperty = invbuilder.property("Name", "Value");
```

Define accepted media types, languages, or encodings

You can define accepted media types, languages, or encodings, as follows:

```java
Invocation.Builder invmedia = invbuilder.accept("application/xml")
   .acceptLanguage("en-US")
   .acceptEncoding("gzip");
```

Invoke HTTP method

The process of building a REST invocation is terminated by invoking a HTTP method, which performs the HTTP invocation. The following methods (inherited from the `javax.ws.rs.client.SyncInvoker` base class) can be invoked:

- get
- post
- delete
- put
- head
- trace
- options

If the specific HTTP verb you want to invoke is not on this list, you can use the generic `method` method to invoke any HTTP method.

Typed responses

All of the HTTP invocation methods are provided with an untyped variant and a typed variant (which takes an extra argument). If you invoke a request using the default `get()` method (taking no arguments), a `javax.ws.rs.core.Response` object is returned from the invocation. For example:

```java
Response res = client.target("http://example.org/bookstore/books/123")
   .request("application/xml").get();
```

It is also possible, however, to ask for the response to be returned as a specific type, using the `get(Class<T>)` method. For example, to invoke a request and ask for the response to be returned as a `BookInfo` object:

```java
BookInfo res = client.target("http://example.org/bookstore/books/123")
   .request("application/xml").get(BookInfo.class);
```

In order for this to work, however, you must register a suitable `entity provider` with the `Client` instance, which is capable of mapping the response format, `application/xml`, to the requested type. For more details about entity providers, see Section 49.4, “Parsing Requests and Responses”.

Specifying the outgoing message in post or put
For HTTP methods that include a message body in the request (such as POST or PUT), you must specify the message body as the first argument of the method. The message body must be specified as a `javax.ws.rs.client.Entity` object, where the `Entity` encapsulates the message contents and its associated media type. For example, to invoke a POST method, where the message contents are provided as a `String` type:

```java
import javax.ws.rs.client.Entity;
...
Response res = client.target("http://example.org/bookstore/registerbook")
    .request("application/xml")
    .put(Entity.entity("Red Hat Install Guide", "text/plain"));
```

If necessary, the `Entity.entity()` constructor method will automatically map the supplied message instance to the specified media type, using the registered entity providers. It is always possible to specify the message body as a simple `String` type.

**Delayed invocation**

Instead of invoking the HTTP request right away (for example, by invoking the `get()` method), you have the option of creating an `javax.ws.rs.client.Invocation` object, which can be invoked at a later time. The `Invocation` object encapsulates all of the details of the pending invocation, including the HTTP method.

The following methods can be used to build an `Invocation` object:

```java
buildGet
buildPost
buildDelete
buildPut
build
```

For example, to create a GET `Invocation` object and invoke it at a later time, you can use code like the following:

```java
import javax.ws.rs.client.Invocation;
import javax.ws.rs.core.Response;
...
Invocation getBookInfo = client.target("http://example.org/bookstore/books/123")
    .request("application/xml").buildGet();
...
// Later on, in some other part of the application:
Response = getBookInfo.invoke();
```

**Asynchronous invocation**

The JAX-RS 2.0 client API supports asynchronous invocations on the client side. To make an asynchronous invocation, simply invoke the `async()` method in the chain of methods following `request()`. For example:

```java
Future<Response> res = client.target("http://example.org/bookstore/books/123")
    .request("application/xml")
    .async()
    .get();
```
When you make an asynchronous invocation, the returned value is a `java.util.concurrent.Future` object. For more details about asynchronous invocations, see Section 49.6, “Asynchronous Processing on the Client”.

49.4. PARSING REQUESTS AND RESPONSES

Overview

An essential aspect of making HTTP invocations is that the client must be able to parse the outgoing request messages and the incoming responses. In JAX-RS 2.0, the key concept is the `Entity` class, which represents a raw message tagged with a media type. In order to parse the raw message, you can register multiple `entity providers`, which have the capability to convert media types to and from particular Java types.

In other words, in the context of JAX-RS 2.0, an `Entity` is the representation of a raw message and an entity provider is the plug-in that provides the capability to parse the raw message (based on the media type).

Entities

An `Entity` is a message body augmented by metadata (media type, language, and encoding). An `Entity` instance holds the message in a raw format and is associated with a specific media type. To convert the contents of an `Entity` object to a Java object you require an `entity provider`, which is capable of mapping the given media type to the required Java type.

Variants

A `javax.ws.rs.core.Variant` object encapsulates the metadata associated with an `Entity`, as follows:

- Media type,
- Language,
- Encoding.

Effectively, you can think of an `Entity` as consisting of the HTTP message contents, augmented by `Variant` metadata.

Entity providers

An entity provider is a class that provides the capability of mapping between a media type and a Java type. Effectively, you can think of an entity provider as a class that provides the ability to parse messages of a particular media type (or possibly of multiple media types). There are two different varieties of entity provider:

`MessageBodyReader`

Provides the capability of mapping from media type(s) to a Java type.

`MessageBodyWriter`

Provides the capability of mapping from a Java type to a media type.

Standard entity providers

Entity providers for the following Java and media type combinations are provided as standard:
byte[
  All media types (*/*).
java.lang.String
  All media types (*/*).
java.io.InputStream
  All media types (*/*).
java.io.Reader
  All media types (*/*).
java.io.File
  All media types (*/*).
javax.activation.DataSource
  All media types (*/*).
javax.xml.transform.Source
  XML types (text/xml, application/xml, and media types of the form application/*+xml).
javax.xml.bind.JAXBElement and application-supplied JAXB classes
  XML types (text/xml, application/xml, and media types of the form application/*+xml).
java.util.Map<String,String>
  Form content (application/x-www-form-urlencoded).
  Only for text/plain. Corresponding primitive types supported through boxing/unboxing conversion.

Response object

The default return type is the javax.ws.rs.core.Response type, which represents an untyped response. The Response object provides access to the complete HTTP response, including the message body, HTTP status, HTTP headers, media type, and so on.

Accessing the response status

You can access the response status, either through the getStatus method (which returns the HTTP status code):

```java
int status = resp.getStatus();
```

Or though the getStatusInfo method, which also provides a description string:

```java
String statusReason = resp.getStatusInfo().getReasonPhrase();
```

Accessing the returned headers

You can access the HTTP headers using any of the following methods:

```
MultivaluedMap<String,Object> getHeaders()
```
MultivaluedMap<String, String> getStringHeaders()

String getHeaderString(String name)

For example, if you know that the Response has a Date header, you could access it as follows:

```java
String dateAsString = resp.getHeaderString("Date");
```

**Accessing the returned cookies**

You can access any new cookies set on the Response using the get_cookies method, as follows:

```java
import javax.ws.rs.core.NewCookie;
...
java.util.Map<String, NewCookie> cookieMap = resp.getCookies();
java.util.Collection<NewCookie> cookieCollection = cookieMap.values();
```

**Accessing the returned message content**

You can access the returned message content by invoking one of the readEntity methods on the Response object. The readEntity method automatically invokes the available entity providers to convert the message to the requested type (specified as the first argument of readEntity). For example, to access the message content as a String type:

```java
String messageBody = resp.readEntity(String.class);
```

**Collection return value**

If you need to access the returned message as a Java generic type—for example, as a List or Collection type—you can specify the request message type using the javax.ws.rs.core.GenericType<T> construction. For example:

```java
import javax.ws.rs.client.ClientBuilder;
import javax.ws.rs.client.Client;
import javax.ws.rs.core.GenericType;
import java.util.List;
...
GenericType<List<String>> stringListType = new GenericType<List<String>>() {};

Client client = ClientBuilder.newClient();
List<String> bookNames = client.target("http://example.org/bookstore/booknames")
 .request("text/plain")
 .get(stringListType);
```

---

49.5. CONFIGURING THE CLIENT ENDPOINT

**Overview**
It is possible to augment the functionality of the base `javax.ws.rs.client.Client` object by registering and configuring features and providers.

**Example**

The following example shows a client configured to have a logging feature, a custom entity provider, and to set the `prettyLogging` property to `true`:

```java
// Java
import javax.ws.rs.client.ClientBuilder;
import javax.ws.rs.client.Client;
import org.apache.cxf.feature.LoggingFeature;
...
Client client = ClientBuilder.newClient();
client.register(LoggingFeature.class)
    .register(MyCustomEntityProvider.class)
    .property("LoggingFeature.prettyLogging","true");
```

**Configurable API for registering objects**

The `Client` class supports the `Configurable` API for registering objects, which provides several variants of the `register` method. In most cases, you would register either a class or an object instance, as shown in the following examples:

```java
client.register(LoggingFeature.class)
client.register(new LoggingFeature())
```

For more details about the `register` variants, see the reference documentation for `Configurable`.

**What can you configure on the client?**

You can configure the following aspects of a client endpoint:

- Features
- Providers
- Properties
- Filters
- Interceptors

**Features**

A `javax.ws.rs.core.Feature` is effectively a plug-in that adds an extra feature or functionality to a JAX-RS client. Often, a feature installs one or more interceptors in order to provide the required functionality.

**Providers**

A provider is a particular kind of client plug-in that provides a mapping capability. The JAX-RS 2.0 specification defines the following kinds of provider:
Entity providers

An entity provider provides the capability of mapping between a specific media type a Java type. For more details, see Section 49.4, “Parsing Requests and Responses”.

Exception mapping providers

An exception mapping provider maps a checked runtime exception to an instance of Response.

Context providers

A context provider is used on the server side, to supply context to resource classes and other service providers.

Filters

A JAX-RS 2.0 filter is a plug-in that gives you access to the URI, headers, and miscellaneous context data at various points (extension points) of the message processing pipeline. For details, see Chapter 61, JAX-RS 2.0 Filters and Interceptors.

Interceptors

A JAX-RS 2.0 interceptor is a plug-in that gives you access to the message body of a request or response as it is being read or written. For details, see Chapter 61, JAX-RS 2.0 Filters and Interceptors.

Properties

By setting one or more properties on the client, you can customize the configuration of a registered feature or a registered provider.

Other configurable types

It is possible, not only to configure a javax.ws.rs.client.Client (and javax.ws.rs.client.ClientBuilder) object, but also a WebTarget object. When you change the configuration of a WebTarget object, the underlying client configuration is deep copied to give the new WebTarget configuration. Hence, it is possible to change the configuration of the WebTarget object without changing the configuration of the original Client object.

49.6. ASYNCHRONOUS PROCESSING ON THE CLIENT

Overview

JAX-RS 2.0 supports asynchronous processing of invocations on the client side. Two different styles of asynchronous processing are supported: either using a java.util.concurrent.Future<V> return value; or by registering an invocation callback.

Asynchronous invocation with Future<V> return value

Using the Future<V> approach to asynchronous processing, you can invoke a client request asynchronously, as follows:

```java
// Java
import javax.ws.rs.client.ClientBuilder;
import javax.ws.rs.client.Client;
import java.util.concurrent.Future;
import javax.ws.rs.core.Response;
```
Client client = ClientBuilder.newClient();
Future<Response> futureResp = client.target("http://example.org/bookstore/books/123")
    .request("application/xml")
    .async()
    .get();

// At a later time, check (and wait) for the response:
Response resp = futureResp.get();

You can use a similar approach for typed responses. For example, to get a response of type, BookInfo:

Client client = ClientBuilder.newClient();
Future<BookInfo> futureResp = client.target("http://example.org/bookstore/books/123")
    .request("application/xml")
    .async()
    .get(BookInfo.class);

// At a later time, check (and wait) for the response:
BookInfo resp = futureResp.get();

Asynchronous invocation with invocation callback

Instead of accessing the return value using a Future<V> object, you can define an invocation callback
(using javax.ws.rs.client.InvocationCallback<RESPONSE>), as follows:

// Java
import javax.ws.rs.client.ClientBuilder;
import javax.ws.rs.client.Client;
import java.util.concurrent.Future;
import javax.ws.rs.core.Response;
import javax.ws.rs.client.InvocationCallback;
...
Client client = ClientBuilder.newClient();
Future<Response> futureResp = client.target("http://example.org/bookstore/books/123")
    .request("application/xml")
    .async()
    .get(
        new InvocationCallback<Response>() {
            @Override
            public void completed(final Response resp) {
                // Do something when invocation is complete
                ...
            }
            @Override
            public void failed(final Throwable throwable) {
                throwable.printStackTrace();
            }
        });
...

You can use a similar approach for typed responses:
// Java
import javax.ws.rs.client.ClientBuilder;
import javax.ws.rs.client.Client;
import java.util.concurrent.Future;
import javax.ws.rs.core.Response;
import javax.ws.rs.client.InvocationCallback;
...
Client client = ClientBuilder.newClient();
Future<BookInfo> futureResp = client.target("http://example.org/bookstore/books/123")
    .request("application/xml")
    .async()
    .get(
        new InvocationCallback<BookInfo>() {
            @Override
            public void completed(final BookInfo resp) {
                // Do something when invocation is complete
                ...
            }

            @Override
            public void failed(final Throwable throwable) {
                throwable.printStackTrace();
                }
        });
...
CHAPTER 50. HANDLING EXCEPTIONS

Abstract

When possible, exceptions caught by a resource method should cause a useful error to be returned to the requesting consumer. JAX-RS resource methods can throw a WebApplicationException exception. You can also provide ExceptionMapper<E> implementations to map exceptions to appropriate responses.

50.1. OVERVIEW OF JAX-RS EXCEPTION CLASSES

Overview

In JAX-RS 1.x, the only available exception class is WebApplicationException. Since JAX-WS 2.0, however, a number of additional JAX-RS exception classes have been defined.

JAX-RS runtime level exceptions

The following exceptions are meant to be thrown by the JAX-RS runtime only (that is, you must not throw these exceptions from your application level code):

ProcessingException

(JAX-RS 2.0 only) The javax.ws.rs.ProcessingException can be thrown during request processing or during response processing in the JAX-RS runtime. For example, this error could be thrown due to errors in the filter chain or interceptor chain processing.

ResponseProcessingException

(JAX-RS 2.0 only) The javax.ws.rs.client.ResponseProcessingException is a subclass of ProcessingException, which can be thrown when errors occur in the JAX-RS runtime on the client side.

JAX-RS application level exceptions

The following exceptions are intended to be thrown (and caught) in your application level code:

WebApplicationException

The javax.ws.rs.WebApplicationException is a generic application level JAX-RS exception, which can be thrown in application code on the server side. This exception type can encapsulate a HTTP status code, an error message, and (optionally) a response message. For details, see Section 50.2, “Using WebApplicationException exceptions to report”.

ClientErrorException

(JAX-RS 2.0 only) The javax.ws.rs.ClientErrorException exception class inherits from WebApplicationException and is used to encapsulate HTTP 4xx status codes.

ServerErrorException

(JAX-RS 2.0 only) The javax.ws.rs.ServerErrorException exception class inherits from WebApplicationException and is used to encapsulate HTTP 5xx status codes.

RedirectionException

(JAX-RS 2.0 only) The javax.ws.rs.RedirectionException exception class inherits from WebApplicationException and is used to encapsulate HTTP 3xx status codes.
50.2. USING WEBAPPLICATIONEXCEPTION EXCEPTIONS TO REPORT ERRORS

Overview

The JAX-RS API introduced the WebApplicationException runtime exception to provide an easy way for resource methods to create exceptions that are appropriate for RESTful clients to consume. WebApplicationException exceptions can include a Response object that defines the entity body to return to the originator of the request. It also provides a mechanism for specifying the HTTP status code to be returned to the client if no entity body is provided.

Creating a simple exception

The easiest means of creating a WebApplicationException exception is to use either the no argument constructor or the constructor that wraps the original exception in a WebApplicationException exception. Both constructors create a WebApplicationException with an empty response.

When an exception created by either of these constructors is thrown, the runtime returns a response with an empty entity body and a status code of 500 Server Error.

Setting the status code returned to the client

When you want to return an error code other than 500, you can use one of the four WebApplicationException constructors that allow you to specify the status. Two of these constructors, shown in Example 50.1, “Creating a WebApplicationException with a status code”, take the return status as an integer.

Example 50.1. Creating a WebApplicationException with a status code

```java
WebApplicationException status WebApplicationException java.lang.Throwable cause
```

The other two, shown in Example 50.2, “Creating a WebApplicationException with a status code” take the response status as an instance of Response.Status.

Example 50.2. Creating a WebApplicationException with a status code

```java
WebApplicationException status WebApplicationException java.lang.Throwable cause
```

When an exception created by either of these constructors is thrown, the runtime returns a response with an empty entity body and the specified status code.

Providing an entity body

If you want a message to be sent along with the exception, you can use one of the WebApplicationException constructors that takes a Response object. The runtime uses the Response object to create the response sent to the client. The entity stored in the response is mapped to the
entity body of the message and the status field of the response is mapped to the HTTP status of the message.

Example 50.3, “Sending a message with an exception” shows code for returning a text message to a client containing the reason for the exception and sets the HTTP message status to 409 Conflict.

Example 50.3. Sending a message with an exception

```java
import javax.ws.rs.core.Response;
import javax.ws.rs.WebApplicationException;
import org.apache.cxf.jaxrs.impl.ResponseBuilderImpl;

... 
ResponseBuilderImpl builder = new ResponseBuilderImpl();
builder.status(Response.Status.CONFLICT);
builder.entity("The requested resource is conflicted.");
Response response = builder.build();
throw WebApplicationException(response);
```

Extending the generic exception

It is possible to extend the WebApplicationException exception. This would allow you to create custom exceptions and eliminate some boiler plate code.

Example 50.4, “Extending WebApplicationException” shows a new exception that creates a similar response to the code in Example 50.3, “Sending a message with an exception”.

Example 50.4. Extending WebApplicationException

```java
public class ConflicteddException extends WebApplicationException 
{
    public ConflicteddException(String message)
    {
        ResponseBuilderImpl builder = new ResponseBuilderImpl();
        builder.status(Response.Status.CONFLICT);
        builder.entity(message);
        super(builder.build());
    }
}
...
throw ConflicteddException("The requested resource is conflicted.");
```

50.3. JAX-RS 2.0 EXCEPTION TYPES

Overview

JAX-RS 2.0 introduces a number of specific HTTP exception types that you can throw (and catch) in your application code (in addition to the existing WebApplicationException exception type). These exception types can be used to wrap standard HTTP status codes, either for HTTP client errors (HTTP 4xx status codes), or HTTP server errors (HTTP 5xx status codes).
Exception hierarchy

Figure 50.1, “JAX-RS 2.0 Application Exception Hierarchy” shows the hierarchy of application level exceptions supported in JAX-RS 2.0.

**Figure 50.1. JAX-RS 2.0 Application Exception Hierarchy**

```
    WebApplicationException
       /   \
  ClientErrorException  ServerErrorException  RedirectionException
      |        |                        |
  BadRequestException  InternalServerErrorException
      |                                |
  ForbiddenException  ServiceUnavailableException
                    |
  NotAcceptableException
                    |
  NotAllowedException
                    |
  NotAuthorizedException
                    |
  NotFoundException
                    |
  NotSupportedException
```

**WebApplicationException class**

The `javax.ws.rs.WebApplicationException` exception class (which has been available since JAX-RS 1.x) is at the base of the JAX-RS 2.0 exception hierarchy, and is described in detail in Section 50.2, “Using WebApplicationException exceptions to report”.

**ClientErrorException class**

The `javax.ws.rs.ClientErrorException` exception class is used to encapsulate HTTP client errors (HTTP 4xx status codes). In your application code, you can throw this exception or one of its subclasses.

**ServerErrorException class**

The `javax.ws.rs.ServerErrorException` exception class is used to encapsulate HTTP server errors (HTTP 5xx status codes). In your application code, you can throw this exception or one of its subclasses.

**RedirectionException class**

The `javax.ws.rs.RedirectException` exception class is used to encapsulate HTTP request redirection (HTTP 3xx status codes). The constructors of this class take a URI argument, which specifies the redirect location. The redirect URI is accessible through the `getLocation()` method. Normally, HTTP redirection is transparent on the client side.

**Client exception subclasses**
You can raise the following HTTP client exceptions (HTTP 4xx status codes) in a JAX-RS 2.0 application:

**BadRequestException**
Encapsulates the **400 Bad Request** HTTP error status.

**ForbiddenException**
Encapsulates the **403 Forbidden** HTTP error status.

**NotAcceptableException**
Encapsulates the **406 Not Acceptable** HTTP error status.

**NotAllowedException**
Encapsulates the **405 Method Not Allowed** HTTP error status.

**NotAuthorizedException**
Encapsulates the **401 Unauthorized** HTTP error status. This exception could be raised in either of the following cases:

- The client did not send the required credentials (in a HTTP Authorization header), or
- The client presented the credentials, but the credentials were not valid.

**NotFoundException**
Encapsulates the **404 Not Found** HTTP error status.

**NotSupportedException**
Encapsulates the **415 Unsupported Media Type** HTTP error status.

**Server exception subclasses**
You can raise the following HTTP server exceptions (HTTP 5xx status codes) in a JAX-RS 2.0 application:

**InternalServerErrorException**
Encapsulates the **500 Internal Server Error** HTTP error status.

**ServiceUnavailableException**
Encapsulates the **503 Service Unavailable** HTTP error status.

### 50.4. MAPPING EXCEPTIONS TO RESPONSES

#### Overview
There are instances where throwing a WebApplicationException exception is impractical or impossible. For example, you may not want to catch all possible exceptions and then create a WebApplicationException for them. You may also want to use custom exceptions that make working with your application code easier.

To handle these cases the JAX-RS API allows you to implement a custom exception provider that generates a Response object to send to a client. Custom exception providers are created by implementing the ExceptionMapper<E> interface. When registered with the Apache CXF runtime, the custom provider will be used whenever an exception of type E is thrown.

#### How exception mappers are selected
Exception mappers are used in two cases:

- When any exception or one of its subclasses is thrown, the runtime will check for an appropriate exception mapper. An exception mapper is selected if it handles the specific exception thrown. If there is not an exception mapper for the specific exception that was thrown, the exception mapper for the nearest superclass of the exception is selected.

- By default, a WebApplicationException will be handled by the default mapper, `WebApplicationExceptionMapper`. Even if an additional custom mapper is registered, which could potentially handle a WebApplicationException exception (for example, a custom `RuntimeException` mapper), the custom mapper will not be used and the `WebApplicationExceptionMapper` will be used instead. This behaviour can be changed, however, by setting the `default.wae.mapper.least.specific` property to `true` on a `Message` object. When this option is enabled, the default `WebApplicationExceptionMapper` is relegated to the lowest priority, so that it becomes possible to handle a WebApplicationException exception with a custom exception mapper. For example, if this option is enabled, it would be possible to catch a WebApplicationException exception by registering a custom `RuntimeException` mapper. See the section called “Registering an exception mapper for WebApplicationException”.

If an exception mapper is not found for an exception, the exception is wrapped in a ServletException exception and passed onto the container runtime. The container runtime will then determine how to handle the exception.

**Implementing an exception mapper**

Exception mappers are created by implementing the `javax.ws.rs.ext.ExceptionMapper<E>` interface. As shown in Example 50.5, “Exception mapper interface”, the interface has a single method, `toResponse()`, that takes the original exception as a parameter and returns a `Response` object.

```
Example 50.5. Exception mapper interface

public interface ExceptionMapper<E extends java.lang.Throwable> {
    public Response toResponse(E exception);
}
```

The `Response` object created by the exception mapper is processed by the runtime just like any other `Response` object. The resulting response to the consumer will contain the status, headers, and entity body encapsulated in the `Response` object.

Exception mapper implementations are considered providers by the runtime. Therefore they must be decorated with the `@Provider` annotation.

If an exception occurs while the exception mapper is building the `Response` object, the runtime will send a response with a status of `500 Server Error` to the consumer.

Example 50.6, “Mapping an exception to a response” shows an exception mapper that intercepts Spring AccessDeniedException exceptions and generates a response with a `403 Forbidden` status and an empty entity body.

```
Example 50.6. Mapping an exception to a response

import javax.ws.rs.core.Response;
```
import javax.ws.rs.ext.ExceptionMapper;
import org.springframework.security.AccessDeniedException;

@Provider
public class SecurityExceptionMapper implements ExceptionMapper<AccessDeniedException> {
    public Response toResponse(AccessDeniedException exception) {
        return Response.status(Response.Status.FORBIDDEN).build();
    }
}

The runtime will catch any AccessDeniedException exceptions and create a Response object with no entity body and a status of 403. The runtime will then process the Response object as it would for a normal response. The result is that the consumer will receive an HTTP response with a status of 403.

Registering an exception mapper

Before a JAX-RS application can use an exception mapper, the exception mapper must be registered with the runtime. Exception mappers are registered with the runtime using the jaxrs:providers element in the application’s configuration file.

The jaxrs:providers element is a child of the jaxrs:server element and contains a list of bean elements. Each bean element defines one exception mapper.

Example 50.7, “Registering exception mappers with the runtime” shows a JAX-RS server configured to use a custom exception mapper, SecurityExceptionMapper.

Example 50.7. Registering exception mappers with the runtime

<beans ...>
    <jaxrs:server id="customerService" address="/"
        ...
        <jaxrs:providers>
            <bean id="securityException" class="com.bar.providers.SecurityExceptionMapper"/>
        </jaxrs:providers>
    </jaxrs:server>
</beans>

Registering an exception mapper for WebApplicationException

Registering an exception mapper for a WebApplicationException exception is a special case, because this exception type is automatically handled by the default WebApplicationExceptionMapper. Normally, even when you register a custom mapper that you would expect to handle WebApplicationException, it will continue to be handled by the default WebApplicationExceptionMapper. To change this default behaviour, you need to set the default.wae.mapper.least.specific property to true.
For example, the following XML code shows how to enable the `default.wae.mapper.least.specific` property on a JAX-RS endpoint:

```xml
<beans ...
<jaxrs:server id="customerService" address="/"
...>
<jaxrs:providers>
    <bean id="securityException" class="com.bar.providers.SecurityExceptionMapper"/>
</jaxrs:providers>
<jaxrs:properties>
    <entry key="default.wae.mapper.least.specific" value="true"/>
</jaxrs:properties>
</jaxrs:server>
</beans>
```

You can also set the `default.wae.mapper.least.specific` property in an interceptor, as shown in the following example:

```java
// Java
public void handleMessage(Message message)
{
    m.put("default.wae.mapper.least.specific", true);
    ...
```
CHAPTER 51. ENTITY SUPPORT

Abstract

The Apache CXF runtime supports a limited number of mappings between MIME types and Java objects out of the box. Developers can extend the mappings by implementing custom readers and writers. The custom readers and writers are registered with the runtime at start-up.

OVERVIEW

The runtime relies on JAX-RS MessageBodyReader and MessageBodyWriter implementations to serialize and de-serialize data between the HTTP messages and their Java representations. The readers and writers can restrict the MIME types they are capable of processing.

The runtime provides readers and writers for a number of common mappings. If an application requires more advanced mappings, a developer can provide custom implementations of the MessageBodyReader interface and/or the MessageBodyWriter interface. Custom readers and writers are registered with the runtime when the application is started.

NATIVELY SUPPORTED TYPES

Table 51.1, "Natively supported entity mappings" lists the entity mappings provided by Apache CXF out of the box.

Table 51.1. Natively supported entity mappings

## CUSTOM READERS

Custom entity readers are responsible for mapping incoming HTTP requests into a Java type that a service’s implementation can manipulate. They implement the `javax.ws.rs.ext.MessageBodyReader` interface.

The interface, shown in Example 51.1, “Message reader interface”, has two methods that need implementing:

### Example 51.1. Message reader interface

```java
package javax.ws.rs.ext;

public interface MessageBodyReader<T> {
    public boolean isReadable(java.lang.Class<?> type,
                               java.lang.reflect.Type genericType,
                               java.lang.annotation.Annotation[] annotations,
                               javax.ws.rs.core.MediaType mediaType);

    public T readFrom(java.lang.Class<T> type,
                      java.lang.reflect.Type genericType,
                      java.lang.annotation.Annotation[] annotations,
                      javax.ws.rs.core.MediaType mediaType,
                      javax.ws.rs.core.MultivaluedMap<String, String> httpHeaders,
                      java.io.InputStream entityStream)
            throws java.io.IOException, WebApplicationException;
}
```

**isReadable()**

The `isReadable()` method determines if the reader is capable of reading the data stream and creating the proper type of entity representation. If the reader can create the proper type of entity the method returns `true`.

Table 51.2, “Parameters used to determine if a reader can produce an entity” describes the `isReadable()` method’s parameters.

**Table 51.2. Parameters used to determine if a reader can produce an entity**

<table>
<thead>
<tr>
<th>Java Type</th>
<th>MIME Type</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>javax.ws.rs.core.MultivaluedMap&lt;String, String&gt;</code></td>
<td><code>application/x-www-form-urlencoded</code>&lt;sup&gt;[a]&lt;/sup&gt;</td>
</tr>
<tr>
<td><code>javax.ws.rs.core.StreamingOutput</code></td>
<td><code>*/*</code>&lt;sup&gt;[b]&lt;/sup&gt;</td>
</tr>
</tbody>
</table>

[a] This mapping is used for handling HTML form data.

[b] This mapping is only supported for returning data to a consumer.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td>Class&lt;T&gt;</td>
<td>Specifies the actual Java class of the object used to store the entity.</td>
</tr>
<tr>
<td>genericType</td>
<td>Type</td>
<td>Specifies the Java type of the object used to store the entity. For example, if the message body is to be converted into a method parameter, the value will be the type of the method parameter as returned by the <code>Method.getGenericParameterTypes()</code> method.</td>
</tr>
<tr>
<td>annotations</td>
<td>Annotation[]</td>
<td>Specifies the list of annotations on the declaration of the object created to store the entity. For example if the message body is to be converted into a method parameter, this will be the annotations on that parameter returned by the <code>Method.getParameterAnnotations()</code> method.</td>
</tr>
<tr>
<td>mediaType</td>
<td>MediatType</td>
<td>Specifies the MIME type of the HTTP entity.</td>
</tr>
</tbody>
</table>

**readFrom()**

The `readFrom()` method reads the HTTP entity and converts it into the desired Java object. If the reading is successful the method returns the created Java object containing the entity. If an error occurs when reading the input stream the method should throw an IOException exception. If an error occurs that requires an HTTP error response, an WebApplicationException with the HTTP response should be thrown.

*Table 51.3, “Parameters used to read an entity”* describes the `readFrom()` method's parameters.

**Table 51.3. Parameters used to read an entity**

<td>MultivaluedMap&lt;String, String&gt;</td>
<td>Specifies the HTTP message headers associated with the entity.</td>
</tr>
<tr>
<td>entityStream</td>
<td>InputStream</td>
<td>Specifies the input stream containing the HTTP entity.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

This method should not close the input stream.

Before an `MessageBodyReader` implementation can be used as an entity reader, it must be decorated with the `javax.ws.rs.ext.Provider` annotation. The `@Provider` annotation alerts the runtime that the supplied implementation provides additional functionality. The implementation must also be registered with the runtime as described in the section called "Registering readers and writers".

By default a custom entity provider handles all MIME types. You can limit the MIME types that a custom entity reader will handle using the `javax.ws.rs.Consumes` annotation. The `@Consumes` annotation specifies a comma separated list of MIME types that the custom entity provider reads. If an entity is not of a specified MIME type, the entity provider will not be selected as a possible reader.

*Example 51.2, “XML source entity reader”* shows an entity reader the consumes XML entities and stores them in a `Source` object.

**Example 51.2. XML source entity reader**
import java.io.IOException;
import java.io.InputStream;
import java.lang.annotation.Annotation;
import java.lang.reflect.Type;
import javax.ws.rs.Consumes;
import javax.ws.rs.WebApplicationException;
import javax.ws.rs.core.MediaType;
import javax.ws.rs.core.MultivaluedMap;
import javax.ws.rs.ext.MessageBodyReader;
import javax.ws.rs.ext.Provider;
import javax.xml.parsers.DocumentBuilder;
import javax.xml.parsers.DocumentBuilderFactory;
import javax.xml.transform.Source;
import javax.xml.transform.dom.DOMSource;
import javax.xml.transform.stream.StreamSource;
import org.w3c.dom.Document;
import org.apache.cxf.jaxrs.ext.xml.XMLSource;

@Provider
@Consumes({"application/xml", "application/*+xml", "text/xml", "text/html" })
public class SourceProvider implements MessageBodyReader<Object>
{
    public boolean isReadable(Class<?> type,
        Type genericType,
        Annotation[] annotations,
        MediaType mt)
    {
        return Source.class.isAssignableFrom(type) || XMLSource.class.isAssignableFrom(type);
    }

    public Object readFrom(Class<Object> source,
        Type genericType,
        Annotation[] annotations,
        MediaType mediaType,
        MultivaluedMap<String, String> httpHeaders,
        InputStream is)
    throws IOException
    {
        if (DOMSource.class.isAssignableFrom(source))
        {
            Document doc = null;
            DocumentBuilderFactory factory = DocumentBuilderFactory.newInstance();
            DocumentBuilder builder;
            try
            {
                builder = factory.newDocumentBuilder();
                doc = builder.parse(is);
            }
            catch (Exception e)
            {
                IOException ioex = new IOException("Problem creating a Source object");
                ioex.setStackTrace(e.getStackTrace());
                throw ioex;
            }
            return doc;
        }
    }
}
return new DOMSource(doc);
)
else if (StreamSource.class.isAssignableFrom(source) ||
        Source.class.isAssignableFrom(source))
{
    return new StreamSource(is);
} else if (XMLSource.class.isAssignableFrom(source))
{
    return new XMLSource(is);
}
throw new IOException("Unrecognized source");

CUSTOM WRITERS

Custom entity writers are responsible for mapping Java types into HTTP entities. They implement the javax.ws.rs.ext.MessageBodyWriter interface.

The interface, shown in Example 51.3, “Message writer interface”, has three methods that need implementing:

Example 51.3. Message writer interface

package javax.ws.rs.ext;

public interface MessageBodyWriter<T> {
    public boolean isWriteable(java.lang.Class<?> type,
                                java.lang.reflect.Type genericType,
                                java.lang.annotation.Annotation[] annotations,
                                javax.ws.rs.core.MediaType mediaType);

    public long getSize(T t,
                        java.lang.Class<?> type,
                        java.lang.reflect.Type genericType,
                        java.lang.annotation.Annotation[] annotations,
                        javax.ws.rs.core.MediaType mediaType);

    public void writeTo(T t,
                         java.lang.Class<?> type,
                         java.lang.reflect.Type genericType,
                         java.lang.annotation.Annotation[] annotations,
                         javax.ws.rs.core.MediaType mediaType,
                         javax.ws.rs.core.MultivaluedMap<String, Object> httpHeaders,
                         java.io.OutputStream entityStream)
            throws java.io.IOException, WebApplicationException;
}
isWritable()

The `isWritable()` method determines if the entity writer can map the Java type to the proper entity type. If the writer can do the mapping, the method returns `true`. Table 51.4, “Parameters used to read an entity” describes the `isWritable()` method’s parameters.

Table 51.4. Parameters used to read an entity

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>type</td>
<td><code>Class&lt;T&gt;</code></td>
<td>Specifies the Java class of the object being written.</td>
</tr>
<tr>
<td>genericType</td>
<td>Type</td>
<td>Specifies the Java type of object to be written, obtained either by reflection of a resource method return type or via inspection of the returned instance. The <code>GenericEntity</code> class, described in Section 48.4, “Returning entities with generic type information”, provides support for controlling this value.</td>
</tr>
<tr>
<td>annotations</td>
<td><code>Annotation[]</code></td>
<td>Specifies the list of annotations on the method returning the entity.</td>
</tr>
<tr>
<td>mediaType</td>
<td><code>MediaType</code></td>
<td>Specifies the MIME type of the HTTP entity.</td>
</tr>
</tbody>
</table>

getSize()

The `getSize()` method is called before the `writeTo()`. It returns the length, in bytes, of the entity being written. If a positive value is returned the value is written into the HTTP message’s `Content-Length` header. Table 51.5, “Parameters used to read an entity” describes the `getSize()` method’s parameters.

Table 51.5. Parameters used to read an entity

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>t</td>
<td><code>generic</code></td>
<td>Specifies the instance being written.</td>
</tr>
<tr>
<td>type</td>
<td><code>Class&lt;T&gt;</code></td>
<td>Specifies the Java class of the object being written.</td>
</tr>
</tbody>
</table>
writeTo()

The `writeTo()` method converts a Java object into the desired entity type and writes the entity to the output stream. If an error occurs when writing the entity to the output stream the method should throw an `IOException` exception. If an error occurs that requires an HTTP error response, an `WebApplicationException` with the HTTP response should be thrown. Table 51.6, “Parameters used to read an entity” describes the `writeTo()` method’s parameters.

Table 51.6. Parameters used to read an entity

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>t</td>
<td>generic</td>
<td>Specifies the instance being written.</td>
</tr>
<tr>
<td>type</td>
<td><code>Class&lt;T&gt;</code></td>
<td>Specifies the Java class of the object being written.</td>
</tr>
<tr>
<td>genericType</td>
<td>Type</td>
<td>Specifies the Java type of object to be written, obtained either by reflection of a resource method return type or via inspection of the returned instance. The <code>GenericEntity</code> class, described in Section 48.4, “Returning entities with generic type information”, provides support for controlling this value.</td>
</tr>
</tbody>
</table>
Before a MessageBodyWriter implementation can be used as an entity writer, it must be decorated with the `javax.ws.rs.ext.Provider` annotation. The `@Provider` annotation alerts the runtime that the supplied implementation provides additional functionality. The implementation must also be registered with the runtime as described in the section called “Registering readers and writers”.

By default a custom entity provider handles all MIME types. You can limit the MIME types that a custom entity writer will handle using the `javax.ws.rs.Produces` annotation. The `@Produces` annotation specifies a comma separated list of MIME types that the custom entity provider generates. If an entity is not of a specified MIME type, the entity provider will not be selected as a possible writer.

Example 51.4, “XML source entity writer” shows an entity writer that takes Source objects and produces XML entities.

```java
import java.io.IOException;
import java.io.OutputStream;
import java.lang.annotation.Annotation;
import javax.ws.rs.Produces;
import javax.ws.rs.WebApplicationException;
import javax.ws.rs.core.MediaType;
import javax.ws.rs.core.MultivaluedMap;
import javax.ws.rs.ext.MessageBodyWriter;
import javax.ws.rs.ext.Provider;
import javax.xml.transform.Source;
import javax.xml.transform.Transformer;
import javax.xml.transform.TransformerException;
import javax.xml.transform.TransformerFactory;
import javax.xml.transform.stream.StreamResult;
import org.w3c.dom.Document;
import org.apache.cxf.jaxrs.ext.xml.XMLSource;
```
@Provider
@Produces({"application/xml", "application/"+xml", "text/xml" })
public class SourceProvider implements MessageBodyWriter<Source>
{

    public boolean isWriteable(Class<?> type,
    Type genericType,
    Annotation[] annotations,
    MediaType mt)
    {
        return Source.class.isAssignableFrom(type);
    }

    public void writeTo(Source source,
    Class<?> clazz,
    Type genericType,
    Annotation[] annotations,
    MediaType mediatype,
    MultivaluedMap<String, Object> httpHeaders,
    OutputStream os)
    throws IOException
    {
        StreamResult result = new StreamResult(os);
        TransformerFactory tf = TransformerFactory.newInstance();
        try
        {
            Transformer t = tf.newTransformer();
            t.transform(source, result);
        }
        catch (TransformerException te)
        {
            te.printStackTrace();
            throw new WebApplicationException(te);
        }
    }

    public long getSize(Source source,
    Class<?> type,
    Type genericType,
    Annotation[] annotations,
    MediaType mt)
    {
        return -1;
    }
}

REGISTERING READERS AND WRITERS

Before a JAX-RS application can use any custom entity providers, the custom providers must be registered with the runtime. Providers are registered with the runtime using either the jaxrs:providers element in the application’s configuration file or using the JAXRSServerFactoryBean class.

The jaxrs:providers element is a child of the jaxrs:server element and contains a list of bean elements. Each bean element defines one entity provider.
Example 51.5, "Registering entity providers with the runtime" show a JAX-RS server configured to use a set of custom entity providers.

```xml
<beans ...>
    <jaxrs:server id="customerService" address="/">
        ...
        <jaxrs:providers>
            <bean id="isProvider" class="com.bar.providers.InputStreamProvider"/>
            <bean id="longProvider" class="com.bar.providers.LongProvider"/>
        </jaxrs:providers>
    </jaxrs:server>
</beans>
```

The JAXRSServerFactoryBean class is a Apache CXF extension that provides access to the configuration APIs. It has a `setProvider()` method that allows you to add instantiated entity providers to an application. Example 51.6, “Programmatically registering an entity provider” shows code for registering an entity provider programmatically.

```java
import org.apache.cxf.jaxrs.JAXRSServerFactoryBean;
...
JAXRSServerFactoryBean sf = new JAXRSServerFactoryBean();
...
SourceProvider provider = new SourceProvider();
sf.setProvider(provider);
...
CHAPTER 52. GETTING AND USING CONTEXT INFORMATION

Abstract

Context information includes detailed information about a resource’s URI, the HTTP headers, and other details that are not readily available using the other injection annotations. Apache CXF provides a special class that amalgamates all the possible context information into a single object.

52.1. INTRODUCTION TO CONTEXTS

Context annotation

You specify that context information is to be injected into a field or a resource method parameter using the `javax.ws.rs.core.Context` annotation. Annotating a field or parameter of one of the context types will instruct the runtime to inject the appropriate context information into the annotated field or parameter.

Types of contexts

Table 52.1, “Context types” lists the types of context information that can be injected and the objects that support them.

<table>
<thead>
<tr>
<th>Object</th>
<th>Context information</th>
</tr>
</thead>
<tbody>
<tr>
<td>UriInfo</td>
<td>The full request URI</td>
</tr>
<tr>
<td>HttpHeaders</td>
<td>The HTTP message headers</td>
</tr>
<tr>
<td>Request</td>
<td>Information that can be used to determine the best representation variant or to determine if a set of preconditions have been set</td>
</tr>
<tr>
<td>SecurityContext</td>
<td>Information about the security of the requester including the authentication scheme in use, if the request channel is secure, and the user principle</td>
</tr>
</tbody>
</table>

Where context information can be used

Context information is available to the following parts of a JAX-RS application:

- resource classes
- resource methods
- entity providers
- exception mappers

Scope
All context information injected using the `@Context` annotation is specific to the current request. This is true in all cases including entity providers and exception mappers.

Adding contexts

The JAX-RS framework allows developers to extend the types of information that can be injected using the context mechanism. You add custom contexts by implementing a `Context<T>` object and registering it with the runtime.

52.2. WORKING WITH THE FULL REQUEST URI

Abstract

The request URI contains a significant amount of information. Most of this information can be accessed using method parameters as described in Section 47.2.2, "Injecting data from a request URI", however using parameters forces certain constraints on how the URI is processed. Using parameters to access the segments of a URI also does not provide a resource access to the full request URI.

You can provide access to the complete request URI by injecting the URI context into a resource. The URI is provided as a UriInfo object. The UriInfo interface provides functions for decomposing the URI in a number of ways. It can also provide the URI as a UriBuilder object that allows you to construct URIs to return to clients.

Example

Injecting the URI context into a class field shows a class with a field populated by injecting the URI context.

Injecting the URI context into a class field

```java
import javax.ws.rs.core.Context;
import javax.ws.rs.core.UriInfo;
import javax.ws.rs.Path;
...
@Path("/monstersforhire/")
public class MonsterService
{
    @Context
    UriInfo requestURI;
    ...
}
```

52.2.2. Working with the URI
Overview

One of the main advantages of using the URI context is that it provides access to the base URI of the service and the path segment of the URI for the selected resource. This information can be useful for a number of purposes such as making processing decisions based on the URI or calculating URIs to return as part of the response. For example if the base URI of the request contains a .com extension the service may decide to use US dollars and if the base URI contains a .co.uk extension is may decide to use British Pounds.

The UriInfo interface provides methods for accessing the parts of the URI:

- the base URI
- the resource path
- the full URI

Getting the Base URI

The base URI is the root URI on which the service is published. It does not contain any portion of the URI specified in any of the service’s @Path annotations. For example if a service implementing the resource defined in Example 47.5, “Disabling URI decoding” were published to http://fusesource.org and a request was made on http://fusesource.org/montersforhire/nightstalker?12 the base URI would be http://fusesource.org.

Table 52.2, “Methods for accessing a resource’s base URI” describes the methods that return the base URI.

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>URI.getBaseUri</td>
<td>Returns the service’s base URI as a URI object.</td>
</tr>
<tr>
<td>UriBuilder.getBaseUriBuilder</td>
<td>Returns the base URI as a javax.ws.rs.core.UriBuilder object. The UriBuilder class is useful for creating URIs for other resources implemented by the service.</td>
</tr>
</tbody>
</table>

Getting the path

The path portion of the request URI is the portion of the URI that was used to select the current resource. It does not include the base URI, but does include any URI template variable and matrix parameters included in the URI.

The value of the path depends on the resource selected. For example, the paths for the resources defined in Getting a resource’s path would be:

- **rootPath** — /monstersforhire/
  
- **getterPath** — /monstersforhire/nightstalker
  The GET request was made on /monstersforhire/nightstalker.

- **putterPath** — /monstersforhire/911
  The PUT request was made on /monstersforhire/911.
Getting a resource’s path

```java
@Path("/monstersforhire/")
public class MonsterService {
    @Context
    UriInfo rootUri;

    ...

    @GET
    public List<Monster> getMonsters(@Context UriInfo getUri) {
        String rootPath = rootUri.getPath();
        ...
    }

    @GET
    @Path("/{type}")
    public Monster getMonster(@PathParam("type") String type,
        @Context UriInfo getUri) {
        String getterPath = getUri.getPath();
        ...
    }

    @PUT
    @Path("/{id}")
    public void addMonster(@Encoded @PathParam("type") String type,
        @Context UriInfo putUri) {
        String putterPath = putUri.getPath();
        ...
    }
    ...
}
```

Table 52.3, “Methods for accessing a resource’s path” describes the methods that return the resource path.

### Table 52.3. Methods for accessing a resource’s path

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String getPath</td>
<td>Returns the resource’s path as a decoded URI.</td>
</tr>
<tr>
<td>String getPathBoolean decode</td>
<td>Returns the resource’s path. Specifying <strong>false</strong> disables URI decoding.</td>
</tr>
</tbody>
</table>
List<PathSegment> getPathSegments

Returns the decoded path as a list of javax.ws.rs.core.PathSegment objects. Each portion of the path, including matrix parameters, is placed into a unique entry in the list.

For example the resource path box/round#tall would result in a list with three entries: box, round, and tall.

List<PathSegment> getPathSegments(boolean decode)

Returns the path as a list of javax.ws.rs.core.PathSegment objects. Each portion of the path, including matrix parameters, is placed into a unique entry in the list. Specifying false disables URI decoding.

For example the resource path box#tall/round would result in a list with three entries: box, tall, and round.

Getting the full request URI

Table 52.4, “Methods for accessing the full request URI” describes the methods that return the full request URI. You have the option of returning the request URI or the absolute path of the resource. The difference is that the request URI includes the any query parameters appended to the URI and the absolute path does not include the query parameters.

Table 52.4. Methods for accessing the full request URI

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>URI getRequestUri</td>
<td>Returns the complete request URI, including query parameters and matrix parameters, as a java.net.URI object.</td>
</tr>
<tr>
<td>UriBuilder getRequestUriBuilder</td>
<td>Returns the complete request URI, including query parameters and matrix parameters, as a javax.ws.rs.UriBuilder object. The UriBuilder class is useful for creating URIs for other resources implemented by the service.</td>
</tr>
<tr>
<td>URI getAbsolutePath</td>
<td>Returns the complete request URI, including matrix parameters, as a java.net.URI object. The absolute path does not include query parameters.</td>
</tr>
<tr>
<td>UriBuilder getAbsolutePathBuilder</td>
<td>Returns the complete request URI, including matrix parameters, as a javax.ws.rs.UriBuilder object. The absolute path does not include query parameters.</td>
</tr>
</tbody>
</table>
For a request made using the URI http://fusesource.org/montersforhire/nightstalker?12, the 
getRequestUri() methods would return http://fusesource.org/montersforhire/nightstalker?12. The 
getAbsolutePath() method would return http://fusesource.org/montersforhire/nightstalker.

52.2.3. Getting the value of URI template variables

Overview

As described in the section called “Setting the path”, resource paths can contain variable segments that 
are bound to values dynamically. Often these variable path segments are used as parameters to a 
resource method as described in the section called “Getting data from the URI’s path”. You can, 
however, also access them through the URI context.

Methods for getting the path parameters

The UriInfo interface provides two methods, shown in Example 52.1, “Methods for returning path 
parameters from the URI context”, that return a list of the path parameters.

```
Example 52.1. Methods for returning path parameters from the URI context

MultivaluedMap<java.lang.String, 
java.lang.String> getPathParameters();

MultivaluedMap<java.lang.String, 
java.lang.String> getPathParameters(boolean decode);
```

The getPathParameters() method that does not take any parameters automatically decodes the path 
parameters. If you want to disable URI decoding use getPathParameters(false).

The values are stored in the map using their template identifiers as keys. For example if the URI template 
for the resource is /{color}/box/{note} the returned map will have two entries with the keys color and 
note.

Example

Example 52.2, “Extracting path parameters from the URI context” shows code for retrieving the path 
parameters using the URI context.

```
Example 52.2. Extracting path parameters from the URI context

import javax.ws.rs.Path;
import javax.ws.rs.Get;
import javax.ws.rs.core.Context;
import javax.ws.rs.core.UriInfo;
import javax.ws.rs.core.MultivaluedMap;

@Path("/montersforhire/"")
public class MonsterService
{

    @Path("/{type}/{size}"")
    public Monster getMonster(@Context UriInfo uri)
    {
        MultivaluedMap paramMap = uri.getPathParameters();
        String type = paramMap.getFirst("type");
    
```
String size = paramMap.getFirst("size");
}
Red Hat Fuse 7.8 Apache CXF Development Guide

CHAPTER 53. ANNOTATION INHERITANCE
Abstract
JAX-RS annotations can be inherited by subclasses and classes implementing annotated interfaces. The
inheritance mechanism allows for subclasses and implementation classes to override the annotations
inherited from its parents.

OVERVIEW
Inheritance is one of the more powerful mechanisms in Java because it allows developers to create
generic objects that can then be specialized to meet particular needs. JAX-RS keeps this power by
allowing the annotations used in mapping classes to resources to be inherited from super classes.
JAX-RS’s annotation inheritance also extends to support for interfaces. Implementation classes inherit
the JAX-RS annotations used in the interface they implement.
The JAX-RS inheritance rules do provide a mechanism for overriding inherited annotations. However, it
is not possible to completely remove JAX-RS annotations from a construct that inherits them from a
super class or interface.

INHERITANCE RULES
Resource classes inherit any JAX-RS annotations from the interface(s) it implements. Resource classes
also inherit any JAX-RS annotations from any super classes they extend. Annotations inherited from a
super class take precedence over annotations inherited from am interface.
In the code sample shown in Example 53.1, “Annotation inheritance” , the Kaijin class' getMonster()
method inherits the @Path, @GET, and @PathParam annotations from the Kaiju interface.
Example 53.1. Annotation inheritance
public interface Kaiju
{
@GET
@Path("/{id}")
public Monster getMonster(@PathParam("id") int id);
...
}
@Path("/kaijin")
public class Kaijin implements Kaiju
{
public Monster getMonster(int id)
{
...
}
...
}

OVERRIDING INHERITED ANNOTATIONS
550


CHAPTER 53. ANNOTATION INHERITANCE

Overriding inherited annotations is as easy as providing new annotations. If the subclass, or
implementation class, provides any of its own JAX-RS annotations for a method then all of the JAX-RS
annotations for that method are ignored.
In the code sample shown in Example 53.2, “Overriding annotation inheritance”, the Kaijin class'
getMonster() method does not inherit any of the annotations from the Kaiju interface. The
implementation class overrides the @Produces annotation which causes all of the annotations from the
interface to be ignored.
Example 53.2. Overriding annotation inheritance
public interface Kaiju
{
@GET
@Path("/{id}")
@Produces("text/xml");
public Monster getMonster(@PathParam("id") int id);
...
}
@Path("/kaijin")
public class Kaijin implements Kaiju
{
@GET
@Path("/{id}")
@Produces("application/octect-stream");
public Monster getMonster(@PathParam("id") int id)
{
...
}
...
}

CHAPTER 54. EXTENDING JAX-RS ENDPOINTS WITH OPENAPI SUPPORT

Abstract

The CXF OpenApiFeature (org.apache.cxf.jaxrs.openapi.OpenApiFeature) allows you to generate OpenAPI documents by extending published JAX-RS service endpoints with a simple configuration.

The OpenApiFeature is supported in both Spring Boot and Karaf implementations.

54.1. OPENAPIFEATURE OPTIONS

You can use the following options in OpenApiFeature.

Table 54.1. OpenApiFeature operations

<table>
<thead>
<tr>
<th>Name</th>

### 54.2. KARAF IMPLEMENTATIONS

This section describes how to use the OpenApiFeature in which REST services are defined inside JAR files and deployed to a Fuse on Karaf container.

#### 54.2.1. Quickstart example

You can download Red Hat Fuse quickstarts from the [Fuse Software Downloads](https://fuse.apache.org/downloads/) page.

The Quickstart zip file contains a `/cxf/rest/` directory for a quickstart that demonstrates how to create a RESTful (JAX-RS) web service using CXF and how to enable OpenAPI and annotate the JAX-RS endpoints.

#### 54.2.2. Enabling OpenAPI

Enabling OpenAPI involves:

- Modifying the XML file that defines the CXF service by adding the CXF class (`org.apache.cxf.jaxrs.openapi.OpenApiFeature`) to the `<jaxrs:server>` definition. For an example, see Example 55.4 Example XML file.

- In the REST resource class:
  - Importing the OpenAPI annotations for each annotation required by the service:
    ```java
    import io.swagger.annotations.*
    where * = Api, ApiOperation, ApiParam, ApiResponse, ApiResponses, and so on.
    ```

    For details, go to [https://github.com/swagger-api/swagger-core/wiki/Annotations-1.5.X](https://github.com/swagger-api/swagger-core/wiki/Annotations-1.5.X).

    For an example, see Example 55.5 Example Resource class.

    - Adding OpenAPI annotations to the JAX-RS annotated endpoints (@PATH, @PUT, @POST, @GET, @Produces, @Consumes, @DELETE, @PathParam, and so on).

    For an example, see Example 55.5 Example Resource class.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>useContextBasedConfig</code></td>
<td>If set, the unique Context Id is going to be generated for each OpenApiContext instance (please see Using Multiple Server Endpoints). Also, you may want to set scan property to false.</td>
<td><code>false</code></td>
</tr>
<tr>
<td><code>version</code></td>
<td>The version+</td>
<td><code>null</code></td>
</tr>
</tbody>
</table>

+ The option is defined in the OpenAPI class

++ The option is defined in the SwaggerConfiguration class
Example 55.4 Example XML file

```xml

        </cxf:properties>
    </cxf:bus>

    <bean id="customerSvc" class="org.jboss.fuse.quickstarts.cxf.rest.CustomerService"/>

</blueprint>
```

Example 55.5 Example Resource class

```java
// ...
import javax.ws.rs.Consumes;
import javax.ws.rs.DELETE;
import javax.ws.rs.GET;
import javax.ws.rs.POST;
import javax.ws.rs.PUT;
```
import javax.ws.rs.PathParam;
import javax.ws.rs.Produces;
import javax.ws.rs.core.Context;
import javax.ws.rs.core.Response;
import io.swagger.annotations.Api;
import io.swagger.annotations.ApiOperation;
import io.swagger.annotations.ApiParam;
import io.swagger.annotations.ApiResponse;
import io.swagger.annotations.ApiResponses;

@Path("/customerservice/")
@Api(value = "customerservice", description = "Operations about customerservice")
public class CustomerService {

    private static final Logger LOG =
            LoggerFactory.getLogger(CustomerService.class);

    private MessageContext jaxrsContext;
    private long currentId = 123;
    private Map<Long, Customer> customers = new HashMap<>();
    private Map<Long, Order> orders = new HashMap<>();

    public CustomerService() {
        init();
    }

    @GET
    @Path("/customers/{id}/")
    @Produces("application/xml")
    @ApiOperation(value = "Find Customer by ID", notes = "More notes about this method", response = Customer.class)
    @ApiResponses(value = {
            @ApiResponse(code = 500, message = "Invalid ID supplied"),
            @ApiResponse(code = 204, message = "Customer not found")
        })
    public Customer getCustomer(@ApiParam(value = "ID of Customer to fetch", required = true) @PathParam("id") String id) {
        LOG.info("Invoking getCustomer, Customer id is: {}", id);
        long idNumber = Long.parseLong(id);
        return customers.get(idNumber);
    }

    @PUT
    @Path("/customers/")
    @Consumes({"application/xml", "application/json"})
    @ApiOperation(value = "Update an existing Customer")

        })
    public Customer updateCustomer(@ApiParam(value = "ID of Customer to fetch", required = true) @PathParam("id") String id) {
        LOG.info("Invoking updateCustomer, Customer id is: {}", id);
        long idNumber = Long.parseLong(id);
        return customers.get(idNumber);
    }
}

Red Hat Fuse 7.8 Apache CXF Development Guide
public Response updateCustomer(@ApiParam(value = "Customer object that needs to be updated", required = true) Customer customer) {
    LOG.info("Invoking updateCustomer, Customer name is: {}", customer.getName());
    Customer c = customers.get(customer.getId());
    Response r;
    if (c != null) {
        customers.put(customer.getId(), customer);
        r = Response.ok().build();
    } else {
        r = Response.notModified().build();
    }
    return r;
}

@POST
@Path("/customers/")
@Consumes({ "application/xml", "application/json" })
@ApiOperation(value = "Add a new Customer")
@ApiResponses(value = { @ApiResponse(code = 500, message = "Invalid ID supplied"), })
public Response addCustomer(@ApiParam(value = "Customer object that needs to be updated", required = true) Customer customer) {
    LOG.info("Invoking addCustomer, Customer name is: {}", customer.getName());
    customer.setId(++currentId);
    customers.put(customer.getId(), customer);
    if (jaxrsContext.getHttpHeaders().getMediaType().getSubtype().equals("json")) {
        return Response.ok().type("application/json").entity(customer).build();
    } else {
        return Response.ok().type("application/xml").entity(customer).build();
    }
}

@DELETE
@Path("/customers/{id}/")
@ApiOperation(value = "Delete Customer")
@ApiResponses(value = {
    @ApiResponse(code = 500, message = "Invalid ID supplied"),
    @ApiResponse(code = 204, message = "Customer not found")
})
public Response deleteCustomer(@ApiParam(value = "ID of Customer to delete", required = true) @PathParam("id") String id) {
    LOG.info("Invoking deleteCustomer, Customer id is: {}", id);
    long idNumber = Long.parseLong(id);
    Customer c = customers.get(idNumber);
    Response r;
    if (c != null) {
        r = Response.ok().build();
        customers.remove(idNumber);
    } else {
        r = Response.notModified().build();
    }
}
54.3. SPRING BOOT IMPLEMENTATIONS

This section describes how to use the Swagger2Feature in Spring Boot.

Note that for OpenAPI 3 implementations, use the
OpenApiFeature(\org.apache.cxf.jaxrs.openapi.OpenApiFeature).  

54.3.1. Quickstart example

The Quickstart example (https://github.com/fabric8-quickstarts/spring-boot-cxf-jaxrs) demonstrates how you can use Apache CXF with Spring Boot. The Quickstart uses Spring Boot to configure an application that includes a CXF JAX-RS endpoint with Swagger enabled.

54.3.2. Enabling Swagger

Enabling Swagger involves:

- In the REST application:
  - Importing Swagger2Feature:
    ```java
    import org.apache.cxf.jaxrs.swagger.Swagger2Feature;
    ```
  - Adding Swagger2Feature to a CXF endpoint:
    ```java
    endpoint.setFeatures(Arrays.asList(new Swagger2Feature()));
    ```
    For an example, see Example 55.1 Example REST application.

- In the Java implementation file, importing the Swagger API annotations for each annotation required by the service:
  ```java
  import io.swagger.annotations.*
  ```
  where * = Api,ApiOperation,ApiParam,ApiResponse,ApiResponse, and so on.
  For details, see https://github.com/swagger-api/swagger-core/wiki/Annotations.
  For an example, see Example 55.2 Example Java implementation file.

- In the Java file, adding Swagger annotations to the JAX-RS annotated endpoints (@PATH, @PUT, @POST, @GET, @Produces, @Consumes, @DELETE, @PathParam, and so on).
  For an example, see Example 55.3 Example Java file.
Example 55.1 Example REST application

```java
package io.fabric8.quickstarts.cxf.jaxrs;

import java.util.Arrays;
import org.apache.cxf.Bus;
import org.apache.cxf.endpoint.Server;
import org.apache.cxf.jaxrs.JAXRSServerFactoryBean;
import org.apache.cxf.jaxrs.swagger.Swagger2Feature;
import org.springframework.beans.factory.annotation.Autowired;
import org.springframework.boot.SpringApplication;
import org.springframework.boot.autoconfigure.SpringBootApplication;

@SpringBootApplication
public class SampleRestApplication {

    @Autowired
    private Bus bus;

    public static void main(String[] args) {
        SpringApplication.run(SampleRestApplication.class, args);
    }

    @Bean
    public Server rsServer() {
        // setup CXF-RS
        JAXRSServerFactoryBean endpoint = new JAXRSServerFactoryBean();
        endpoint.setBus(bus);
        endpoint.setServiceBeans(Arrays.<Object>asList(new HelloServiceImpl()));
        endpoint.setAddress(“/”);
        endpoint.setFeatures(Arrays.asList(new Swagger2Feature()));
        return endpoint.create();
    }
}
```

Example 55.2 Example Java implementation file

```java
import io.swagger.annotations.Api;

@Api("/sayHello")
public class HelloServiceImpl implements HelloService {

    public String welcome() {
        return "Welcome to the CXF RS Spring Boot application, append /{name} to call the hello service";
    }

    public String sayHello(String a) {
        return "Hello " + a + ", Welcome to CXF RS Spring Boot World!!!";
    }
}
```
Example 55.3 Example Java file

```java
package io.fabric8.quickstarts.cxf.jaxrs;

import javax.ws.rs.GET;
import javax.ws.rs.Path;
import javax.ws.rs.PathParam;
import javax.ws.rs.Produces;
import javax.ws.rs.core.MediaType;
import org.springframework.stereotype.Service;

@Path("/sayHello")
@Service
public interface HelloService {

    @GET
    @Path(""")
    @Produces(MediaType.TEXT_PLAIN)
    String welcome();

    @GET
    @Path("/{a}")
    @Produces(MediaType.TEXT_PLAIN)
    String sayHello(@PathParam("a") String a);
}
```

54.4. ACCESSING OPENAPI DOCUMENTS

When OpenAPI is enabled by OpenApiFeature, the OpenAPI documents are available at the location URL constructed of the service endpoint location followed by `/openapi.json` or `/openapi.yaml`.

For example, for a JAX-RS endpoint that is published at `http://host:port/context/services/` where `context` is a web application context and `/services` is a servlet URL, its OpenAPI documents are available at `http://host:port/context/services/openapi.json` and `http://host:port/context/services/openapi.yaml`.

If OpenApiFeature is active, the CXF Services page links to OpenAPI documents.

In the above example, you would go to `http://host:port/context/services/services` and then follow a link which returns an OpenAPI JSON document.

If CORS support is needed to access the definition from an OpenAPI UI on another host, you can add the `CrossOriginResourceSharingFilter` from `cxf-rt-rs-security-cors`.

54.5. ACCESSING OPENAPI THROUGH A REVERSE PROXY

If you want to access an OpenAPI JSON document or an OpenAPI UI through a reverse proxy, set the following options:

- Set the `CXFServlet use-x-forwarded-headers` init parameter to `true`.
  - In Spring Boot, prefix the parameter name with `cxf.servlet.init:`
cxf.servlet.init.use-x-forwarded-headers=true

- In Karaf, add the following line to the \installDir/etc/org.apache.cxf.osgi.cfg configuration file:

  cxf.servlet.init.use-x-forwarded-headers=true

  Note: If you do not already have an \org.apache.cxf.osgi.cfg file in your \etc directory, you can create one.

- If you specify a value for the OpenApiFeature \basePath option and you want to prevent OpenAPI from caching the \basePath value, set the OpenApiFeature \usePathBasedConfig option to TRUE:

  <bean class="org.apache.cxf.jaxrs.openapi.OpenApiFeature">
    <property name="usePathBasedConfig" value="TRUE" />
  </bean>
PART VII. DEVELOPING APACHE CXF INTERCEPTORS

This guide describes how to write Apache CXF interceptors that can perform pre and post processing on messages.
CHAPTER 55. INTERCEPTORS IN THE APACHE CXF RUNTIME

Abstract

Most of the functionality in the Apache CXF runtime is implemented by interceptors. Every endpoint created by the Apache CXF runtime has three potential interceptor chains for processing messages. The interceptors in the these chains are responsible for transforming messages between the raw data transported across the wire and the Java objects handled by the endpoint’s implementation code. The interceptors are organized into phases to ensure that processing happens on the proper order.

OVERVIEW

A large part of what Apache CXF does entails processing messages. When a consumer makes an invocation on a remote service the runtime needs to marshal the data into a message the service can consume and place it on the wire. The service provider must unmarshal the message, execute its business logic, and marshal the response into the appropriate message format. The consumer must then unmarshal the response message, correlate it to the proper request, and pass it back to the consumer’s application code. In addition to the basic marshaling and unmarshaling, the Apache CXF runtime may do a number of other things with the message data. For example, if WS-RM is activated, the runtime must process the message chunks and acknowledgement messages before marshaling and unmarshaling the message. If security is activated, the runtime must validate the message’s credentials as part of the message processing sequence.

Figure 55.1, “Apache CXF interceptor chains” shows the basic path that a request message takes when it is received by a service provider.
MESSAGE PROCESSING IN APACHE CXF

When a Apache CXF developed consumer invokes a remote service the following message processing sequence is started:

1. The Apache CXF runtime creates an outbound interceptor chain to process the request.

2. If the invocation starts a two-way message exchange, the runtime creates an inbound interceptor chain and a fault processing interceptor chain.

3. The request message is passed sequentially through the outbound interceptor chain. Each interceptor in the chain performs some processing on the message. For example, the Apache CXF supplied SOAP interceptors package the message in a SOAP envelope.

4. If any of the interceptors on the outbound chain create an error condition the chain is unwound and control is returned to the application level code. An interceptor chain is unwound by calling the fault processing method on all of the previously invoked interceptors.

5. The request is dispatched to the appropriate service provider.

6. When the response is received, it is passed sequentially through the inbound interceptor chain.
NOTE

If the response is an error message, it is passed into the fault processing interceptor chain.

7. If any of the interceptors on the inbound chain create an error condition, the chain is unwound.

8. When the message reaches the end of the inbound interceptor chain, it is passed back to the application code.

When a Apache CXF developed service provider receives a request from a consumer, a similar process takes place:

1. The Apache CXF runtime creates an inbound interceptor chain to process the request message.

2. If the request is part of a two-way message exchange, the runtime also creates an outbound interceptor chain and a fault processing interceptor chain.

3. The request is passed sequentially through the inbound interceptor chain.

4. If any of the interceptors on the inbound chain create an error condition, the chain is unwound and a fault is dispatched to the consumer.
An interceptor chain is unwound by calling the fault processing method on all of the previously invoked interceptors.

5. When the request reaches the end of the inbound interceptor chain, it is passed to the service implementation.

6. When the response is ready it is passed sequentially through the outbound interceptor chain.

NOTE

If the response is an exception, it is passed through the fault processing interceptor chain.

7. If any of the interceptors on the outbound chain create an error condition, the chain is unwound and a fault message is dispatched.

8. Once the request reaches the end of the outbound chain, it is dispatched to the consumer.

INTERCEPTORS

All of the message processing in the Apache CXF runtime is done by interceptors. Interceptors are POJOs that have access to the message data before it is passed to the application layer. They can do a number of things including: transforming the message, stripping headers off of the message, or validating the message data. For example, an interceptor could read the security headers off of a message, validate the credentials against an external security service, and decide if message processing can continue.

The message data available to an interceptor is determined by several factors:

- the interceptor’s chain
- the interceptor’s phase
PHASES

Interceptors are organized into phases. A phase is a logical grouping of interceptors with common functionality. Each phase is responsible for a specific type of message processing. For example, interceptors that process the marshaled Java objects that are passed to the application layer would all occur in the same phase.

INTERCEPTOR CHAINS

Phases are aggregated into interceptor chains. An interceptor chain is a list of interceptor phases that are ordered based on whether messages are inbound or outbound.

Each endpoint created using Apache CXF has three interceptor chains:

- a chain for inbound messages
- a chain for outbound messages
- a chain for error messages

Interceptor chains are primarily constructed based on the choose of binding and transport used by the endpoint. Adding other runtime features, such as security or logging, also add interceptors to the chains. Developers can also add custom interceptors to a chain using configuration.

DEVELOPING INTERCEPTORS

Developing an interceptor, regardless of its functionality, always follows the same basic procedure:

1. Chapter 56, The Interceptor APIs
   Apache CXF provides a number of abstract interceptors to make it easier to develop custom interceptors.

2. Section 57.2, “Specifying an interceptor’s phase”
   Interceptors require certain parts of a message to be available and require the data to be in a certain format. The contents of the message and the format of the data is partially determined by an interceptor’s phase.

3. Section 57.3, “Constraining an interceptors placement in a phase”
   In general, the ordering of interceptors within a phase is not important. However, in certain situations it may be important to ensure that an interceptor is executed before, or after, other interceptors in the same phase.

4. Section 58.2, “Processing messages”

5. Section 58.3, “Unwinding after an error”
   If an error occurs in the active interceptor chain after the interceptor has executed, its fault processing logic is invoked.

6. Chapter 59, Configuring Endpoints to Use Interceptors
Abstract

Interceptors implement the PhaseInterceptor interface which extends the base Interceptor interface. This interface defines a number of methods used by the Apache CXF’s runtime to control interceptor execution and are not appropriate for application developers to implement. To simplify interceptor development, Apache CXF provides a number of abstract interceptor implementations that can be extended.

INTERFACES

All of the interceptors in Apache CXF implement the base Interceptor interface shown in Example 56.1, “Base interceptor interface”.

Example 56.1. Base interceptor interface

```java
package org.apache.cxf.interceptor;

public interface Interceptor<T extends Message> {
    void handleMessage(T message) throws Fault;
    void handleFault(T message);
}
```

The Interceptor interface defines the two methods that a developer needs to implement for a custom interceptor:

handleMessage()

The `handleMessage()` method does most of the work in an interceptor. It is called on each interceptor in a message chain and receives the contents of the message being processed. Developers implement the message processing logic of the interceptor in this method. For detailed information about implementing the `handleMessage()` method, see Section 58.2, “Processing messages”.

handleFault()

The `handleFault()` method is called on an interceptor when normal message processing has been interrupted. The runtime calls the `handleFault()` method of each invoked interceptor in reverse order as it unwinds an interceptor chain. For detailed information about implementing the `handleFault()` method, see Section 58.3, “Unwinding after an error”.

Most interceptors do not directly implement the Interceptor interface. Instead, they implement the PhaseInterceptor interface shown in Example 56.2, “The phase interceptor interface”. The PhaseInterceptor interface adds four methods that allow an interceptor the participate in interceptor chains.

Example 56.2. The phase interceptor interface

```java
package org.apache.cxf.phase;
```
... 

public interface PhaseInterceptor<T extends Message> extends Interceptor<T> 
{
    Set<String> getAfter();
    Set<String> getBefore();
    String getId();
    String getPhase();
}

ABSTRACT INTERCEPTOR CLASS

Instead of directly implementing the PhaseInterceptor interface, developers should extend the AbstractPhaseInterceptor class. This abstract class provides implementations for the phase management methods of the PhaseInterceptor interface. The AbstractPhaseInterceptor class also provides a default implementation of the handleFault() method.

Developers need to provide an implementation of the handleMessage() method. They can also provide a different implementation for the handleFault() method. The developer-provided implementations can manipulate the message data using the methods provided by the generic org.apache.cxf.message.Message interface.

For applications that work with SOAP messages, Apache CXF provides an AbstractSoapInterceptor class. Extending this class provides the handleMessage() method and the handleFault() method with access to the message data as an org.apache.cxf.binding.soap.SoapMessage object. SoapMessage objects have methods for retrieving the SOAP headers, the SOAP envelope, and other SOAP metadata from the message.
CHAPTER 57. DETERMINING WHEN THE INTERCEPTOR IS INVOKED

Abstract

Interceptors are organized into phases. The phase in which an interceptor runs determines what portions of the message data it can access. An interceptor can determine its location in relationship to the other interceptors in the same phase. The interceptor’s phase and its location within the phase are set as part of the interceptor’s constructor logic.

57.1. SPECIFYING THE INTERCEPTOR LOCATION

When developing a custom interceptor, the first thing to consider is where in the message processing chain the interceptor belongs. The developer can control an interceptor’s position in the message processing chain in one of two ways:

- Specifying the interceptor’s phase
- Specifying constraints on the location of the interceptor within the phase

Typically, the code specifying an interceptor’s location is placed in the interceptor’s constructor. This makes it possible for the runtime to instantiate the interceptor and put in the proper place in the interceptor chain without any explicit action in the application level code.

57.2. SPECIFYING AN INTERCEPTOR’S PHASE

Overview

Interceptors are organized into phases. An interceptor’s phase determines when in the message processing sequence it is called. Developers specify an interceptor’s phase its constructor. Phases are specified using constant values provided by the framework.

Phase

Phases are a logical collection of interceptors. As shown in Figure 57.1, “An interceptor phase”, the interceptors within a phase are called sequentially.

Figure 57.1. An interceptor phase
The phases are linked together in an ordered list to form an interceptor chain and provide defined logical steps in the message processing procedure. For example, a group of interceptors in the RECEIVE phase of an inbound interceptor chain processes transport level details using the raw message data picked up from the wire.

There is, however, no enforcement of what can be done in any of the phases. It is recommended that interceptors within a phase adhere to tasks that are in the spirit of the phase.

The complete list of phases defined by Apache CXF can be found in Chapter 62, Apache CXF Message Processing Phases.

Specifying a phase

Apache CXF provides the org.apache.cxf.Phase class to use for specifying a phase. The class is a collection of constants. Each phase defined by Apache CXF has a corresponding constant in the Phase class. For example, the RECEIVE phase is specified by the value Phase.RECEIVE.

Setting the phase

An interceptor’s phase is set in the interceptor’s constructor. The AbstractPhaseInterceptor class defines three constructors for instantiating an interceptor:

- public AbstractPhaseInterceptor(String phase)—sets the phase of the interceptor to the specified phase and automatically sets the interceptor’s id to the interceptor’s class name. This constructor will satisfy most use cases.

- public AbstractPhaseInterceptor(String id, String phase)—sets the interceptor’s id to the string passed in as the first parameter and the interceptor’s phase to the second string.

- public AbstractPhaseInterceptor(String phase, boolean uniqueld)—specifies if the interceptor should use a unique, system generated id. If the uniqueld parameter is true, the interceptor’s id will be calculated by the system. If the uniqueld parameter is false the interceptor’s id is set to the interceptor’s class name.

The recommended way to set a custom interceptor’s phase is to pass the phase to the AbstractPhaseInterceptor constructor using the super() method as shown in Example 57.1, “Setting an interceptor’s phase”.

Example 57.1. Setting an interceptor’s phase

```java
import org.apache.cxf.message.Message;
import org.apache.cxf.phase.AbstractPhaseInterceptor;
import org.apache.cxf.phase.Phase;

class StreamInterceptor extends AbstractPhaseInterceptor<Message>
{
    public StreamInterceptor()
    { super(Phase.PRE_STREAM); }
}
```
The StreamInterceptor interceptor shown in Example 57.1, “Setting an interceptor’s phase” is placed into the PRE_STREAM phase.

57.3. CONSTRAINING AN INTERCEPTORS PLACEMENT IN A PHASE

Overview

Placing an interceptor into a phase may not provide fine enough control over its placement to ensure that the interceptor works properly. For example, if an interceptor needed to inspect the SOAP headers of a message using the SAAJ APIs, it would need to run after the interceptor that converts the message into a SAAJ object. There may also be cases where one interceptor consumes a part of the message needed by another interceptor. In these cases, a developer can supply a list of interceptors that must be executed before their interceptor. A developer can also supply a list of interceptors that must be executed after their interceptor.

IMPORTANT

The runtime can only honor these lists within the interceptor’s phase. If a developer places an interceptor from an earlier phase in the list of interceptors that must execute after the current phase, the runtime will ignore the request.

Add to the chain before

One issue that arises when developing an interceptor is that the data required by the interceptor is not always present. This can occur when one interceptor in the chain consumes message data required by a later interceptor. Developers can control what a custom interceptor consumes and possibly fix the problem by modifying their interceptors. However, this is not always possible because a number of interceptors are used by Apache CXF and a developer cannot modify them.

An alternative solution is to ensure that a custom interceptor is placed before any interceptors that will consume the message data the custom interceptor requires. The easiest way to do that would be to place it in an earlier phase, but that is not always possible. For cases where an interceptor needs to be placed before one or more other interceptors the Apache CXF’s AbstractPhaseInterceptor class provides two addBefore() methods.

As shown in Example 57.2, “Methods for adding an interceptor before other interceptors”, one takes a single interceptor id and the other takes a collection of interceptor ids. You can make multiple calls to continue adding interceptors to the list.

Example 57.2. Methods for adding an interceptor before other interceptors

```java
public addBefore(String i

public addBeforeCollection<String>i
```

As shown in Example 57.3, “Specifying a list of interceptors that must run after the current interceptor”, a developer calls the addBefore() method in the constructor of a custom interceptor.

Example 57.3. Specifying a list of interceptors that must run after the current interceptor

```java
public class MyPhasedOutInterceptor extends AbstractPhaseInterceptor
{
    public MyPhasedOutInterceptor() {
        super(Phase.PRE_LOGICAL);
```
Most interceptors use their class name for an interceptor id.

**Add to the chain after**

Another reason the data required by the interceptor is not present is that the data has not been placed in the message object. For example, an interceptor may want to work with the message data as a SOAP message, but it will not work if it is placed in the chain before the message is turned into a SOAP message. Developers can control what a custom interceptor consumes and possibly fix the problem by modifying their interceptors. However, this is not always possible because a number of interceptors are used by Apache CXF and a developer cannot modify them.

An alternative solution is to ensure that a custom interceptor is placed after the interceptor, or interceptors, that generate the message data the custom interceptor requires. The easiest way to do that would be to place it in a later phase, but that is not always possible. The AbstractPhaseInterceptor class provides two addAfter() methods for cases where an interceptor needs to be placed after one or more other interceptors.

As shown in Example 57.4, “Methods for adding an interceptor after other interceptors”, one method takes a single interceptor id and the other takes a collection of interceptor ids. You can make multiple calls to continue adding interceptors to the list.

**Example 57.4. Methods for adding an interceptor after other interceptors**

```java
public addAfter(String i)
public addAfterCollection<String> i
```

As shown in Example 57.5, “Specifying a list of interceptors that must run before the current interceptor”, a developer calls the addAfter() method in the constructor of a custom interceptor.

**Example 57.5. Specifying a list of interceptors that must run before the current interceptor**

```java
public class MyPhasedOutInterceptor extends AbstractPhaseInterceptor
{
    public MyPhasedOutInterceptor() {
        super(Phase.PRE_LOGICAL);
        addAfter(StartingOutInterceptor.class.getName());
    }
    ...
}
```

Most interceptors use their class name for an interceptor id.
CHAPTER 58. IMPLEMENTING THE INTERCEPTORS PROCESSING LOGIC

Abstract

Interceptors are straightforward to implement. The bulk of their processing logic is in the `handleMessage()` method. This method receives the message data and manipulates it as needed. Developers may also want to add some special logic to handle fault processing cases.

58.1. INTERCEPTOR FLOW

Figure 58.1, “Flow through an interceptor” shows the process flow through an interceptor.

In normal message processing, only the `handleMessage()` method is called. The `handleMessage()` method is where the interceptor’s message processing logic is placed.

If an error occurs in the `handleMessage()` method of the interceptor, or any subsequent interceptor in the interceptor chain, the `handleFault()` method is called. The `handleFault()` method is useful for cleaning up after an interceptor in the event of an error. It can also be used to alter the fault message.

58.2. PROCESSING MESSAGES

Overview

In normal message processing, an interceptor’s `handleMessage()` method is invoked. It receives that message data as a Message object. Along with the actual contents of the message, the Message object may contain a number of properties related to the message or the message processing state. The exact contents of the Message object depends on the interceptors preceding the current interceptor in the chain.

Getting the message contents

The Message interface provides two methods that can be used in extracting the message contents:

- `public<T> T getContent(java.lang.Class<T> format` The `getContent()` method returns the content of the message in an object of the specified class. If the contents are not available as an instance of the specified class, null is returned. The list of available content types is determined by the interceptor’s location on the interceptor chain and the direction of the interceptor chain.
The `getAttachments()` method returns a Java `Collection` object containing any binary attachments associated with the message. The attachments are stored in `org.apache.cxf.message.Attachment` objects. Attachment objects provide methods for managing the binary data.

**IMPORTANT**

Attachments are only available after the attachment processing interceptors have executed.

## Determining the message’s direction

The direction of a message can be determined by querying the message exchange. The message exchange stores the inbound message and the outbound message in separate properties.\[3\]

The message exchange associated with a message is retrieved using the message’s `getExchange()` method. As shown in Example 58.1, “Getting the message exchange”, `getExchange()` does not take any parameters and returns the message exchange as a `org.apache.cxf.message.Exchange` object.

**Example 58.1. Getting the message exchange**

```java
Exchange getExchange()
```

The `Exchange` object has four methods, shown in Example 58.2, “Getting messages from a message exchange”, for getting the messages associated with an exchange. Each method will either return the message as a `org.apache.cxf.Message` object or it will return null if the message does not exist.

**Example 58.2. Getting messages from a message exchange**

```java
Message getInMessage()
Message getInFaultMessage()
Message getOutMessage()
Message getOutFaultMessage()
```

Example 58.3, “Checking the direction of a message chain” shows code for determining if the current message is outbound. The method gets the message exchange and checks to see if the current message is the same as the exchange’s outbound message. It also checks the current message against the exchanges outbound fault message to error messages on the outbound fault interceptor chain.

**Example 58.3. Checking the direction of a message chain**

```java
public static boolean isOutbound() {
    Exchange exchange = message.getExchange();
    return message != null && exchange != null &&
           (message == exchange.getOutMessage() ||
            message == exchange.getOutFaultMessage());
}
```

---

574
Example 58.4, “Example message processing method” shows code for an interceptor that processes zip compressed messages. It checks the direction of the message and then performs the appropriate actions.

```java
import java.io.IOException;
import java.io.InputStream;
import java.util.zip.GZIPInputStream;
import org.apache.cxf.message.Message;
import org.apache.cxf.phase.AbstractPhaseInterceptor;
import org.apache.cxf.phase.Phase;

public class StreamInterceptor extends AbstractPhaseInterceptor<Message>
{
    ...

    public void handleMessage(Message message)
    {
        boolean isOutbound = false;
        isOutbound = message == message.getExchange().getOutMessage()
                     || message == message.getExchange().getOutFaultMessage();

        if (!isOutbound)
        {
            try
            {
                InputStream is = message.getContent(InputStream.class);
                GZIPInputStream zipInput = new GZIPInputStream(is);
                message.setContent(InputStream.class, zipInput);
            }
            catch (IOException ioe)
            {
                ioe.printStackTrace();
            }
        }
        else
        {
            // zip the outbound message
        }
    }
}
```

58.3. UNWINDING AFTER AN ERROR

Overview
When an error occurs during the execution of an interceptor chain, the runtime stops traversing the interceptor chain and unwinds the chain by calling the `handleFault()` method of any interceptors in the chain that have already been executed.

The `handleFault()` method can be used to clean up any resources used by an interceptor during normal message processing. It can also be used to rollback any actions that should only stand if message processing completes successfully. In cases where the fault message will be passed on to an outbound fault processing interceptor chain, the `handleFault()` method can also be used to add information to the fault message.

**Getting the message payload**

The `handleFault()` method receives the same `Message` object as the `handleMessage()` method used in normal message processing. Getting the message contents from the `Message` object is described in the section called "Getting the message contents".

**Example**

Example 58.5, “Handling an unwinding interceptor chain” shows code used to ensure that the original XML stream is placed back into the message when the interceptor chain is unwound.

```java
@ Override
public void handleFault(SoapMessage message)
{
    super.handleFault(message);
    XMLStreamWriter writer = (XMLStreamWriter) message.get(ORIGINAL_XML_WRITER);
    if (writer != null)
    {
        message.setContent(XMLStreamWriter.class, writer);
    }
}
```

[3] It also stores inbound and outbound faults separately.
CHAPTER 59. CONFIGURING ENDPOINTS TO USE INTERCEPTORS

Abstract

Interceptors are added to an endpoint when it is included in a message exchange. The endpoint’s interceptor chains are constructed from the interceptor chains of a number of components in the Apache CXF runtime. Interceptors are specified in either the endpoint’s configuration or the configuration of one of the runtime components. Interceptors can be added using either the configuration file or the interceptor API.

59.1. DECIDING WHERE TO ATTACH INTERCEPTORS

Overview

There are a number of runtime objects that host interceptor chains. These include:

- the endpoint object
- the service object
- the proxy object
- the factory object used to create the endpoint or the proxy
- the binding
- the central Bus object

A developer can attach their own interceptors to any of these objects. The most common objects to attach interceptors are the bus and the individual endpoints. Choosing the correct object requires understanding how these runtime objects are combined to make an endpoint. As per the design, each cxf related bundle has its own cxf bus. Hence, if the interceptors are configured in the bus and the service at the same Blueprint context is imported or created into another bundle, the interceptor won’t be processed. Instead you can configure the interceptors directly into the JAXWS client or endpoint in the imported service.

Endpoints and proxies

Attaching interceptors to either the endpoint or the proxy is the most fine grained way to place an interceptor. Any interceptors attached directly to an endpoint or a proxy only effect the specific endpoint or proxy. This is a good place to attach interceptors that are specific to a particular incarnation of a service. For example, if a developer wants to expose one instance of a service that converts units from metric to imperial they could attach the interceptors directly to one endpoint.

Factories

Using the Spring configuration to attach interceptors to the factories used to create an endpoint or a proxy has the same effect as attaching the interceptors directly to the endpoint or proxy. However, when interceptors are attached to a factory programmatically the interceptors attached to the factory are propagated to every endpoint or proxy created by the factory.

Bindings
Attaching interceptors to the binding allows the developer to specify a set of interceptors that are applied to all endpoints that use the binding. For example, if a developer wants to force all endpoints that use the raw XML binding to include a special ID element, they could attach the interceptor responsible for adding the element to the XML binding.

**Buses**

The most general place to attach interceptors is the bus. When interceptors are attached to the bus, the interceptors are propagated to all of the endpoints managed by that bus. Attaching interceptors to the bus is useful in applications that create multiple endpoints that share a similar set of interceptors.

**Combining attachment points**

Because an endpoint’s final set of interceptor chains is an amalgamation of the interceptor chains contributed by the listed objects, several of the listed object can be combined in a single endpoint’s configuration. For example, if an application spawned multiple endpoints that all required an interceptor that checked for a validation token, that interceptor would be attached to the application’s bus. If one of those endpoints also required an interceptor that converted Euros into dollars, the conversion interceptor would be attached directly to the specific endpoint.

### 59.2. ADDING INTERCEPTORS USING CONFIGURATION

**Overview**

The easiest way to attach interceptors to an endpoint is using the configuration file. Each interceptor to be attached to an endpoint is configured using a standard Spring bean. The interceptor’s bean can then be added to the proper interceptor chain using Apache CXF configuration elements.

Each runtime component that has an associated interceptor chain is configurable using specialized Spring elements. Each of the component’s elements have a standard set of children for specifying their interceptor chains. There is one child for each interceptor chain associated with the component. The children list the beans for the interceptors to be added to the chain.

**Configuration elements**

Table 59.1, “Interceptor chain configuration elements” describes the four configuration elements for attaching interceptors to a runtime component.

**Table 59.1. Interceptor chain configuration elements**

<table>
<thead>
<tr>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>inInterceptors</td>
<td>Contains a list of beans configuring interceptors to add to an endpoint’s inbound interceptor chain.</td>
</tr>
<tr>
<td>outInterceptors</td>
<td>Contains a list of beans configuring interceptors to add to an endpoint’s outbound interceptor chain.</td>
</tr>
<tr>
<td>inFaultInterceptors</td>
<td>Contains a list of beans configuring interceptors to add to an endpoint’s inbound fault processing interceptor chain.</td>
</tr>
</tbody>
</table>
All of the interceptor chain configuration elements take a `list` child element. The `list` element has one child for each of the interceptors being attached to the chain. Interceptors can be specified using either a `bean` element directly configuring the interceptor or a `ref` element that refers to a `bean` element that configures the interceptor.

### Examples

**Example 59.1, “Attaching interceptors to the bus”** shows configuration for attaching interceptors to a bus’ inbound interceptor chain.

```xml
&lt;beans xmlns="http://www.springframework.org/schema/beans"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xmlns:cxf="http://cxf.apache.org/core"
    xmlns:http="http://cxf.apache.org/transports/http/configuration"
    xsi:schemaLocation="
        http://cxf.apache.org/transports/http/configuration
        http://cxf.apache.org/schemas/configuration/http-conf.xsd
        http://www.springframework.org/schema/beans
        http://www.springframework.org/schema/beans/spring-beans.xsd"
    ...>
    &lt;bean id="GZIPStream" class="demo.stream.interceptor.StreamInterceptor"/&gt;

    &lt;cxf:bus&gt;
        *&lt;cxf:inInterceptors&gt;
            &lt;list&gt;
                &lt;ref bean="GZIPStream"/&gt;
            &lt;/list&gt;
        &lt;/cxf:inInterceptors&gt;
    &lt;/cxf:bus&gt;
&lt;/beans&gt;
```

**Example 59.2, “Attaching interceptors to a JAX-WS service provider”** shows configuration for attaching an interceptor to a JAX-WS service’s outbound interceptor chain.

```xml
&lt;beans xmlns="http://www.springframework.org/schema/beans"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xmlns:jaxws="http://cxf.apache.org/jaxws"
    xmlns:wsa="http://cxf.apache.org/ws/addressing"
    ...>
    &lt;bean id="GZIPStream" class="demo.stream.interceptor.StreamInterceptor"/&gt;

    &lt;jaxws:service&gt;
        *&lt;jaxws:portTypeInterceptors&gt;
            &lt;list&gt;
                &lt;ref bean="GZIPStream"/&gt;
            &lt;/list&gt;
        &lt;/jaxws:portTypeInterceptors&gt;
    &lt;/jaxws:service&gt;
&lt;/beans&gt;
```
More information

For more information about configuring endpoints using the Spring configuration see Part IV, “Configuring Web Service Endpoints”.

59.3. ADDING INTERCEPTORS PROGRAMMATICALLY

59.3.1. Approaches to Adding Interceptors

Interceptors can be attached to endpoints programmatically using either one of two approaches:

- the InterceptorProvider API
- Java annotations

Using the InterceptorProvider API allows the developer to attach interceptors to any of the runtime components that have interceptor chains, but it requires working with the underlying Apache CXF classes. The Java annotations can only be added to service interfaces or service implementations, but they allow developers to stay within the JAX-WS API or the JAX-RS API.

59.3.2. Using the interceptor provider API

Overview

Interceptors can be registered with any component that implements the InterceptorProvider interface shown in The interceptor provider interface.

The interceptor provider interface

```java
package org.apache.cxf.interceptor;

import java.util.List;

public interface InterceptorProvider {
    List<Interceptor<? extends Message>> getInInterceptors();
    List<Interceptor<? extends Message>> getOutInterceptors();
}
```
The four methods in the interface allow you to retrieve each of an endpoint’s interceptor chains as a Java `List` object. Using the methods offered by the Java `List` object, developers can add and remove interceptors to any of the chains.

**Procedure**

To use the `InterceptorProvider` API to attach an interceptor to a runtime component’s interceptor chain, you must:

1. Get access to the runtime component with the chain to which the interceptor is being attached. Developers must use Apache CXF specific APIs to access the runtime components from standard Java application code. The runtime components are usually accessible by casting the JAX-WS or JAX-RS artifacts into the underlying Apache CXF objects.

2. Create an instance of the interceptor.

3. Use the proper get method to retrieve the desired interceptor chain.

4. Use the `List` object’s `add()` method to attach the interceptor to the interceptor chain. This step is usually combined with retrieving the interceptor chain.

**Attaching an interceptor to a consumer**

**Attaching an interceptor to a consumer programmatically** shows code for attaching an interceptor to the inbound interceptor chain of a JAX-WS consumer.

**Attaching an interceptor to a consumer programmatically**

```java
package com.fusesource.demo;

import java.io.File;
import java.net.URL;
import javax.xml.namespace.QName;
import javax.xml.ws.Service;
import org.apache.cxf.endpoint.Client;

import org.apache.cxf.endpoint.Client;

public class Client
{
    public static void main(String args[])
    {
        QName serviceName = new QName("http://demo.eric.org", "stockQuoteReporter");
        Service s = Service.create(serviceName);

        QName portName = new QName("http://demo.eric.org", "stockQuoteReporterPort");
        s.addPort(portName, "http://schemas.xmlsoap.org/soap/", "http://localhost:9000/EricStockQuote");

        quoteReporter proxy = s.getPort(portName, quoteReporter.class);

        Client cxfClient = (Client) proxy;
    }
}
```
The code in **Attaching an interceptor to a consumer programmatically** does the following:

- Creates a JAX-WS **Service** object for the consumer.
- Adds a port to the **Service** object that provides the consumer’s target address.
- Creates the proxy used to invoke methods on the service provider.
- Casts the proxy to the **org.apache.cxf.endpoint.Client** type.
- Creates an instance of the interceptor.
- Attaches the interceptor to the inbound interceptor chain.

### Attaching an interceptor to a service provider

The code in **Attaching an interceptor to a service provider programmatically** shows code for attaching an interceptor to a service provider’s outbound interceptor chain.

The code in **Attaching an interceptor to a service provider programmatically** does the following:

- Creates a **ServerFactoryBean** object that will provide access to the underlying Apache CXF objects.
- Gets the **Server** object that Apache CXF uses to represent the endpoint.
Gets the Apache CXF `EndpointImpl` object for the service provider.

Creates an instance of the interceptor.

Attaches the interceptor to the endpoint's outbound interceptor chain.

**Attaching an interceptor to a bus**

*Attaching an interceptor to a bus* shows code for attaching an interceptor to a bus' inbound interceptor chain.

```java
import org.apache.cxf.BusFactory;
org.apache.cxf.Bus;
...

Bus bus = BusFactory.getDefaultBus();

WatchInterceptor watchInterceptor = new WatchInterceptor();
bus.getInInterceptor().add(watchInterceptor);
...
```

The code in *Attaching an interceptor to a bus* does the following:

- Gets the default bus for the runtime instance.
- Creates an instance of the interceptor.
- Attaches the interceptor to the inbound interceptor chain.

The `WatchInterceptor` will be attached to the inbound interceptor chain of all endpoints created by the runtime instance.

**59.3.3. Using Java annotations**

**Overview**

Apache CXF provides four Java annotations that allow a developer to specify the interceptor chains used by an endpoint. Unlike the other means of attaching interceptors to endpoints, the annotations are attached to application-level artifacts. The artifact that is used determines the scope of the annotation’s effect.

**Where to place the annotations**

The annotations can be placed on the following artifacts:

- the service endpoint interface(SEI) defining the endpoint
  If the annotations are placed on an SEI, all of the service providers that implement the interface and all of the consumers that use the SEI to create proxies will be affected.

- a service implementation class
If the annotations are placed on an implementation class, all of the service providers using the implementation class will be affected.

The annotations

The annotations are all in the `org.apache.cxf.interceptor` package and are described in Table 59.2, “Interceptor chain annotations”.

Table 59.2. Interceptor chain annotations

<table>
<thead>
<tr>
<th>Annotation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>InInterceptors</code></td>
<td>Specifies the interceptors for the inbound interceptor chain.</td>
</tr>
<tr>
<td><code>OutInterceptors</code></td>
<td>Specifies the interceptors for the outbound interceptor chain.</td>
</tr>
<tr>
<td><code>InFaultInterceptors</code></td>
<td>Specifies the interceptors for the inbound fault interceptor chain.</td>
</tr>
<tr>
<td><code>OutFaultInterceptors</code></td>
<td>Specifies the interceptors for the outbound fault interceptor chain.</td>
</tr>
</tbody>
</table>

Listing the interceptors

The list of interceptors is specified as a list of fully qualified class names using the syntax shown in Syntax for listing interceptors in a chain annotation.

Syntax for listing interceptors in a chain annotation

```java
interceptors={"interceptor1", "interceptor2", ..., "interceptorN"}
```

Example

`Attaching interceptors to a service implementation` shows annotations that attach two interceptors to the inbound interceptor chain of endpoints that use the logic provided by `SayHiImpl`.

`Attaching interceptors to a service implementation`

```java
import org.apache.cxf.interceptor.InInterceptors;

@InInterceptors(interceptors={"com.sayhi.interceptors.FirstLast", "com.sayhi.interceptors.LogName"})
public class SayHiImpl implements SayHi {
    ...
}
```
CHAPTER 60. MANIPULATING INTERCEPTOR CHAINS ON THE FLY

Abstract

Interceptors can reconfigure an endpoint’s interceptor chain as part of its message processing logic. It can add new interceptors, remove interceptors, reorder interceptors, and even suspend the interceptor chain. Any on-the-fly manipulation is invocation-specific, so the original chain is used each time an endpoint is involved in a message exchange.

OVERVIEW

Interceptor chains only live as long as the message exchange that sparked their creation. Each message contains a reference to the interceptor chain responsible for processing it. Developers can use this reference to alter the message’s interceptor chain. Because the chain is per-exchange, any changes made to a message’s interceptor chain will not effect other message exchanges.

CHAIN LIFE-CYCLE

Interceptor chains and the interceptors in the chain are instantiated on a per-invocation basis. When an endpoint is invoked to participate in a message exchange, the required interceptor chains are instantiated along with instances of its interceptors. When the message exchange that caused the creation of the interceptor chain is completed, the chain and its interceptor instances are destroyed.

This means that any changes you make to the interceptor chain or to the fields of an interceptor do not persist across message exchanges. So, if an interceptor places another interceptor in the active chain only the active chain is effected. Any future message exchanges will be created from a pristine state as determined by the endpoint’s configuration. It also means that a developer cannot set flags in an interceptor that will alter future message processing.

If an interceptor needs to pass information along to future instances, it can set a property in the message context. The context does persist across message exchanges.

GETTING THE INTERCEPTOR CHAIN

The first step in changing a message’s interceptor chain is getting the interceptor chain. This is done using the `Message.getInterceptorChain()` method shown in Example 60.1, “Method for getting an interceptor chain”. The interceptor chain is returned as an `org.apache.cxf.interceptor.InterceptorChain` object.

Example 60.1. Method for getting an interceptor chain

`InterceptorChain getInterceptorChain`

ADDING INTERCEPTORS

The `InterceptorChain` object has two methods, shown in Example 60.2, “Methods for adding interceptors to an interceptor chain”, for adding interceptors to an interceptor chain. One allows you to add a single interceptor and the other allows you to add multiple interceptors.

Example 60.2. Methods for adding interceptors to an interceptor chain
Example 60.3, "Adding an interceptor to an interceptor chain on-the-fly" shows code for adding a single interceptor to a message's interceptor chain.

```java
void handleMessage(Message message) {
    ...
    AddledIntereptor addled = new AddledIntereptor();
    InterceptorChain chain = message.getInterceptorChain();
    chain.add(addled);
    ...
}
```

The code in Example 60.3, "Adding an interceptor to an interceptor chain on-the-fly" does the following:

- Instantiates a copy of the interceptor to be added to the chain.
- Gets the interceptor chain for the current message.
- Adds the new interceptor to the chain.

### REMOVING INTERCEPTORS

The InterceptorChain object has one method, shown in Example 60.4, "Methods for removing interceptors from an interceptor chain", for removing an interceptor from an interceptor chain.

```java
removeInterceptor<? extends Message>?
```

Example 60.5, "Removing an interceptor from an interceptor chain on-the-fly" shows code for removing an interceptor from a message's interceptor chain.

```java
void handleMessage(Message message) {
    ...
    Iterator<Interceptor<? extends Message>> iterator =
        message.getInterceptorChain().iterator();
    Interceptor<? extends Message> removeInterceptor = null;
    for (; iterator.hasNext(); ) {
```
Interceptor<?> interceptor = iterator.next();
if (interceptor.getClass().getName().equals("InterceptorClassName")) {
    removeInterceptor = interceptor;
    break;
}
if (removeInterceptor != null) {
    log.debug("Removing interceptor {}", removeInterceptor.getClass().getName());
    message.getInterceptorChain().remove(removeInterceptor);
}

Where **InterceptorClassName** is the class name of the interceptor you want to remove from the chain.
CHAPTER 61. JAX-RS 2.0 FILTERS AND INTERCEPTORS

Abstract

JAX-RS 2.0 defines standard APIs and semantics for installing filters and interceptors in the processing pipeline for REST invocations. Filters and interceptors are typically used to provide such capabilities as logging, authentication, authorization, message compression, message encryption, and so on.

61.1. INTRODUCTION TO JAX-RS FILTERS AND INTERCEPTORS

Overview

This section provides an overview of the processing pipeline for JAX-RS filters and interceptors, highlighting the extension points where it is possible to install a filter chain or an interceptor chain.

Filters

A JAX-RS 2.0 filter is a type of plug-in that gives a developer access to all of the JAX-RS messages passing through a CXF client or server. A filter is suitable for processing the metadata associated with a message: HTTP headers, query parameters, media type, and other metadata. Filters have the capability to abort a message invocation (useful for security plug-ins, for example).

If you like, you can install multiple filters at each extension point, in which case the filters are executed in a chain (the order of execution is undefined, however, unless you specify a priority value for each installed filter).

Interceptors

A JAX-RS 2.0 interceptor is a type of plug-in that gives a developer access to a message body as it is being read or written. Interceptors are wrapped around either the MessageBodyReader.readFrom method invocation (for reader interceptors) or the MessageBodyWriter.writeTo method invocation (for writer interceptors).

If you like, you can install multiple interceptors at each extension point, in which case the interceptors are executed in a chain (the order of execution is undefined, however, unless you specify a priority value for each installed interceptor).

Server processing pipeline

Figure 61.1, “Server-Side Filter and Interceptor Extension Points” shows an outline of the processing pipeline for JAX-RS filters and interceptors installed on the server side.

Figure 61.1. Server-Side Filter and Interceptor Extension Points

[Diagram showing the server processing pipeline with extension points for filters and interceptors in the request and response flows, including priority order notation.]
Server extension points

In the server processing pipeline, you can add a filter (or interceptor) at any of the following extension points:

1. `PreMatchContainerRequest` filter
2. `ContainerRequest` filter
3. `ReadInterceptor`
4. `ContainerResponse` filter
5. `WriteInterceptor`

Note that the `PreMatchContainerRequest` extension point is reached before resource matching has occurred, so some of the context metadata will not be available at this point.

Client processing pipeline

Figure 61.2, “Client-Side Filter and Interceptor Extension Points” shows an outline of the processing pipeline for JAX-RS filters and interceptors installed on the client side.

Figure 61.2. Client-Side Filter and Interceptor Extension Points

Client extension points

In the client processing pipeline, you can add a filter (or interceptor) at any of the following extension points:

1. `ClientRequest` filter
2. `WriteInterceptor`
3. `ClientResponse` filter
4. `ReadInterceptor`

Filter and interceptor order
If you install multiple filters or interceptors at the same extension point, the execution order of the filters depends on the priority assigned to them (using the @Priority annotation in the Java source). A priority is represented as an integer value. In general, a filter with a higher priority number is placed closer to the resource method invocation on the server side; while a filter with a lower priority number is placed closer to the client invocation. In other words, the filters and interceptors acting on a request message are executed in ascending order of priority number; while the filters and interceptors acting on a response message are executed in descending order of priority number.

Filter classes

The following Java interfaces can be implemented in order to create custom REST message filters:

- javax.ws.rs.container.ContainerRequestFilter
- javax.ws.rs.container.ContainerResponseFilter
- javax.ws.rs.client.ClientRequestFilter
- javax.ws.rs.client.ClientResponseFilter

Interceptor classes

The following Java interfaces can be implemented in order to create custom REST message interceptors:

- javax.ws.rs.ext.ReaderInterceptor
- javax.ws.rs.ext.WriterInterceptor

61.2. CONTAINER REQUEST FILTER

Overview

This section explains how to implement and register a container request filter, which is used to intercept an incoming request message on the server (container) side. Container request filters are often used to process headers on the server side and can be used for any kind of generic request processing (that is, processing that is independent of the particular resource method called).

Moreover, the container request filter is something of a special case, because it can be installed at two distinct extension points: PreMatchContainerRequest (before the resource matching step); and ContainerRequest (after the resource matching step).

ContainerRequestFilter interface

The javax.ws.rs.container.ContainerRequestFilter interface is defined as follows:

```java
// Java
...
package javax.ws.rs.container;

import java.io.IOException;
```
By implementing the `ContainerRequestFilter` interface, you can create a filter for either of the following extension points on the server side:

- **PreMatchContainerRequest**
- **ContainerRequest**

**ContainerRequestContext interface**

The `filter` method of `ContainerRequestFilter` receives a single argument of type `javax.ws.rs.container.ContainerRequestContext`, which can be used to access the incoming request message and its related metadata. The `ContainerRequestContext` interface is defined as follows:

```java
// Java
... package javax.ws.rs.container;

import java.io.InputStream;
import java.net.URI;
import java.util.Collection;
import java.util.Date;
import java.util.List;
import java.util.Locale;
import java.util.Map;
import javax.ws.rs.core.Cookie;
import javax.ws.rs.core.MediaType;
import javax.ws.rs.core.MultivaluedMap;
import javax.ws.rs.core.Request;
import javax.ws.rs.core.Response;
import javax.ws.rs.core.SecurityContext;
import javax.ws.rs.core.UriInfo;

public interface ContainerRequestContext {
    public Object getProperty(String name);
    public Collection getPropertyNames();
    public void setProperty(String name, Object object);
    public void removeProperty(String name);
    public UriInfo getUriInfo();
    public void setRequestUri(URI requestUri);
    public void setRequestUri(URI baseUri, URI requestUri);
    public Request getRequest();
}
```
Sample implementation for PreMatchContainerRequest filter

To implement a container request filter for the PreMatchContainerRequest extension point (that is, where the filter is executed prior to resource matching), define a class that implements the ContainerRequestFilter interface, making sure to annotate the class with the @PreMatching annotation (to select the PreMatchContainerRequest extension point).

For example, the following code shows an example of a simple container request filter that gets installed in the PreMatchContainerRequest extension point, with a priority of 20:

```java
// Java
package org.jboss.fuse.example;
import javax.ws.rs.container.ContainerRequestContext;
import javax.ws.rs.container.ContainerRequestFilter;
import javax.ws.rs.container.PreMatching;
import javax.annotation.Priority;
import javax.ws.rs.ext.Provider;
@PreMatching
```
Sample implementation for ContainerRequest filter

To implement a container request filter for the `ContainerRequest` extension point (that is, where the filter is executed after resource matching), define a class that implements the `ContainerRequestFilter` interface, without the `@PreMatching` annotation.

For example, the following code shows an example of a simple container request filter that gets installed in the `ContainerRequest` extension point, with a priority of 30:

```java
// Java
package org.jboss.fuse.example;

import javax.ws.rs.container.ContainerRequestContext;
import javax.ws.rs.container.ContainerRequestFilter;
import javax.ws.rs.ext.Provider;
import javax.annotation.Priority;

@Provider
@Priority(value = 30)
public class SampleContainerRequestFilter implements ContainerRequestFilter {

    public SampleContainerRequestFilter() {
        System.out.println("SampleContainerRequestFilter starting up");
    }

    @Override
    public void filter(ContainerRequestContext requestContext) {
        System.out.println("SampleContainerRequestFilter.filter() invoked");
    }
}
```

Injecting ResourceInfo

At the `ContainerRequest` extension point (that is, after resource matching has occurred), it is possible to access the matched resource class and resource method by injecting the `ResourceInfo` class. For example, the following code shows how to inject the `ResourceInfo` class as a field of the `ContainerRequestFilter` class:

```java
// Java
```
package org.jboss.fuse.example;

import javax.ws.rs.container.ContainerRequestContext;
import javax.ws.rs.container.ContainerRequestFilter;
import javax.ws.rs.container.ResourceInfo;
import javax.ws.rs.ext.Provider;
import javax.annotation.Priority;
import javax.ws.rs.core.Context;
@Provider
@Priority(value = 30)
public class SampleContainerRequestFilter implements ContainerRequestFilter {

    @Context
    private ResourceInfo resinfo;

    public SampleContainerRequestFilter() {
        ...
    }

    @Override
    public void filter(ContainerRequestContext requestContext) {
        String resourceClass = resinfo.getResourceClass().getName();
        String methodName = resinfo.getResourceMethod().getName();
        System.out.println("REST invocation bound to resource class: " + resourceClass);
        System.out.println("REST invocation bound to resource method: " + methodName);
    }
}

Aborting the invocation

It is possible to abort a server-side invocation by creating a suitable implementation of a container request filter. Typically, this is useful for implementing security features on the server side: for example, to implement an authentication feature or an authorization feature. If an incoming request fails to authenticate successfully, you could abort the invocation from within the container request filter.

For example, the following pre-matching feature attempts to extract a username and password from the URI's query parameters and calls an authenticate method to check the username and password credentials. If the authentication fails, the invocation is aborted by calling `abortWith` on the `ContainerRequestContext` object, passing the error response that is to be returned to the client.

// Java
package org.jboss.fuse.example;

import javax.annotation.Priority;
import javax.ws.rs.container.ContainerRequestContext;
import javax.ws.rs.container.ContainerRequestFilter;
import javax.ws.rs.container.PreMatching;
import javax.ws.rs.core.Response;
import javax.ws.rs.core.Response.ResponseBuilder;
import javax.ws.rs.core.Response.Status;
import javax.ws.rs.ext.Provider;

@PreMatching
@Priority(value = 20)
public class SampleAuthenticationRequestFilter implements ContainerRequestFilter {

    public SampleAuthenticationRequestFilter() {
        System.out.println("SampleAuthenticationRequestFilter starting up");
    }

    @Override
    public void filter(ContainerRequestContext requestContext) {
        ResponseBuilder responseBuilder = null;
        Response response = null;

        String userName = requestContext.getUriInfo().getQueryParameters().getFirst("UserName");
        String password = requestContext.getUriInfo().getQueryParameters().getFirst("Password");
        if (authenticate(userName, password) == false) {
            responseBuilder = Response.serverError();
            response = responseBuilder.status(Status.BAD_REQUEST).build();
            requestContext.abortWith(response);
        }
    }

    public boolean authenticate(String userName, String password) {
        // Perform authentication of 'user'
        ...
    }
}

Binding the server request filter

To bind a server request filter (that is, to install it into the Apache CXF runtime), perform the following steps:

1. Add the @Provider annotation to the container request filter class, as shown in the following code fragment:

    // Java
    package org.jboss.fuse.example;
    import javax.ws.rs.container.ContainerRequestContext;
    import javax.ws.rs.container.ContainerRequestFilter;
    import javax.ws.rs.ext.Provider;
    import javax.annotation.Priority;
    @Provider
    @Priority(value = 30)
    public class SampleContainerRequestFilter implements ContainerRequestFilter {
        ...
    }

When the container request filter implementation is loaded into the Apache CXF runtime, the REST implementation automatically scans the loaded classes to search for the classes marked with the @Provider annotation (the scanning phase).
2. When defining a JAX-RS server endpoint in XML (for example, see Section 18.1, “Configuring JAX-RS Server Endpoints”), add the server request filter to the list of providers in the \texttt{jaxrs:providers} element.

\begin{verbatim}
<blueprint xmlns="http://www.osgi.org/xmlns/blueprint/v1.0.0"
   xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
   xmlns:jaxrs="http://cxf.apache.org/blueprint/jaxrs"
   xmlns:cxf="http://cxf.apache.org/blueprint/core"
   ...>
  ...
  <jaxrs:server id="customerService" address="/customers">
    ...
    <jaxrs:providers>
      <ref bean="filterProvider" />
    </jaxrs:providers>
  </jaxrs:server>
</blueprint>
\end{verbatim}

\textbf{NOTE}

This step is a non-standard requirement of Apache CXF. Strictly speaking, according to the JAX-RS standard, the \texttt{@Provider} annotation should be all that is required to bind the filter. But in practice, the standard approach is somewhat inflexible and can lead to clashing providers when many libraries are included in a large project.

### 61.3. CONTAINER RESPONSE FILTER

**Overview**

This section explains how to implement and register a container response filter, which is used to intercept an outgoing response message on the server side. Container response filters can be used to populate headers automatically in a response message and, in general, can be used for any kind of generic response processing.

**ContainerResponseFilter interface**

The \texttt{javax.ws.rs.container.ContainerResponseFilter} interface is defined as follows:

\begin{verbatim}
// Java
... package javax.ws.rs.container;
import java.io.IOException;
import java.io.IOException;
public interface ContainerResponseFilter {
  public void filter(ContainerRequestContext requestContext, ContainerResponseContext ...
\end{verbatim}
By implementing the `ContainerResponseFilter`, you can create a filter for the `ContainerResponse` extension point on the server side, which filters the response message after the invocation has executed.

**NOTE**

The container response filter gives you access both to the request message (through the `requestContext` argument) and the response message (through the `responseContext` message), but only the response can be modified at this stage.

**ContainerResponseContext interface**

The `filter` method of `ContainerResponseFilter` receives two arguments: an argument of type `javax.ws.rs.container.ContainerRequestContext` (see the section called “ContainerRequestContext interface”); and an argument of type `javax.ws.rs.container.ContainerResponseContext`, which can be used to access the outgoing response message and its related metadata.

The `ContainerResponseContext` interface is defined as follows:

```java
public interface ContainerResponseContext {
    public int getStatus();
    public void setStatus(int code);
    public Response.StatusType getStatusInfo();
    public void setStatusInfo(Response.StatusType statusInfo);
    public MultivaluedMap<String, Object> getHeaders();
}
```

```java
// Java
...
package javax.ws.rs.container;

import java.io.OutputStream;
import java.lang.annotation.Annotation;
import java.lang.reflect.Type;
import java.net.URI;
import java.util.Date;
import java.util.Locale;
import java.util.Map;
import java.util.Set;
import javax.ws.rs.core.EntityTag;
import javax.ws.rs.core.Link;
import javax.ws.rs.core.MediaType;
import javax.ws.rs.core.MultivaluedMap;
import javax.ws.rs.core.NewCookie;
import javax.ws.rs.core.Response;
import javax.ws.rs.ext.MessageBodyWriter;
```
public abstract MultivaluedMap<String, String> getStringHeaders();

public String getHeaderString(String name);

public Set<String> getAllowedMethods();

public Date getDate();

public Locale getLanguage();

public int getLength();

public MediaType getMediaType();

public Map<String, NewCookie> getCookies();

public EntityTag getEntityTag();

public Date getLastModified();

public URI getLocation();

public Set<Link> getLinks();

boolean hasLink(String relation);

public Link getLink(String relation);

public Link.Builder getLinkBuilder(String relation);

public boolean hasEntity();

public Object getEntity();

public Class<?> getEntityClass();

public Type getEntityType();

public void setEntity(final Object entity);

public void setEntity(final Object entity,
        final Annotation[] annotations,
        final MediaType mediaType);

public Annotation[] getEntityAnnotations();

public OutputStream getEntityStream();

public void setEntityStream(OutputStream outputStream);
To implement a container response filter for the `ContainerResponse` extension point (that is, where the filter is executed after the invocation has been executed on the server side), define a class that implements the `ContainerResponseFilter` interface.

For example, the following code shows an example of a simple container response filter that gets installed in the `ContainerResponse` extension point, with a priority of 10:

```java
// Java
package org.jboss.fuse.example;

import javax.annotation.Priority;
import javax.ws.rs.container.ContainerRequestContext;
import javax.ws.rs.container.ContainerResponseContext;
import javax.ws.rs.container.ContainerResponseFilter;
import javax.ws.rs.ext.Provider;

@Provider
@Priority(value = 10)
public class SampleContainerResponseFilter implements ContainerResponseFilter {

    public SampleContainerResponseFilter() {
        System.out.println("SampleContainerResponseFilter starting up");
    }

    @Override
    public void filter(ContainerRequestContext requestContext,
                       ContainerResponseContext responseContext)
    {
        // This filter replaces the response message body with a fixed string
        if (responseContext.hasEntity()) {
            responseContext.setEntity("New message body!");
        }
    }
}
```

### Binding the server response filter

To bind a server response filter (that is, to install it into the Apache CXF runtime), perform the following steps:

1. Add the `@Provider` annotation to the container response filter class, as shown in the following code fragment:

```java
// Java
package org.jboss.fuse.example;

import javax.annotation.Priority;
import javax.ws.rs.container.ContainerRequestContext;
import javax.ws.rs.container.ContainerResponseContext;
import javax.ws.rs.container.ContainerResponseFilter;
import javax.ws.rs.ext.Provider;

@Provider
```
When the container response filter implementation is loaded into the Apache CXF runtime, the REST implementation automatically scans the loaded classes to search for the classes marked with the `@Provider` annotation (the *scanning phase*).

2. When defining a JAX-RS server endpoint in XML (for example, see Section 18.1, "Configuring JAX-RS Server Endpoints"), add the server response filter to the list of providers in the `<jaxrs:providers>` element.

```xml
<blueprint xmlns="http://www.osgi.org/xmlns/blueprint/v1.0.0"
           xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
           xmlns:jaxrs="http://cxf.apache.org/blueprint/jaxrs"
           xmlns:cxf="http://cxf.apache.org/blueprint/core"
           ...
   >
   ...
   <jaxrs:server id="customerService" address="/customers">
      ...
      <jaxrs:providers>
         <ref bean="filterProvider" />
      </jaxrs:providers>
      <bean id="filterProvider"
            class="org.jboss.fuse.example.SampleContainerResponseFilter"/>
   </jaxrs:server>
</blueprint>
```

**NOTE**

This step is a non-standard requirement of Apache CXF. Strictly speaking, according to the JAX-RS standard, the `@Provider` annotation should be all that is required to bind the filter. But in practice, the standard approach is somewhat inflexible and can lead to clashing providers when many libraries are included in a large project.

### 61.4. CLIENT REQUEST FILTER

**Overview**

This section explains how to implement and register a *client request filter*, which is used to intercept an outgoing request message on the client side. Client request filters are often used to process headers and can be used for any kind of generic request processing.

**ClientRequestFilter interface**

The `javax.ws.rs.client.ClientRequestFilter` interface is defined as follows:

```java
// Java
```
By implementing the `ClientRequestFilter`, you can create a filter for the `ClientRequest` extension point on the client side, which filters the request message before sending the message to the server.

### ClientRequestContext interface

The `filter` method of `ClientRequestFilter` receives a single argument of type `javax.ws.rs.client.ClientRequestContext`, which can be used to access the outgoing request message and its related metadata. The `ClientRequestContext` interface is defined as follows:

```java
public interface ClientRequestContext {
    public Object getProperty(String name);
    public Collection<String> getPropertyNames();
    public void setProperty(String name, Object object);
    public void removeProperty(String name);
    public URI getUri();
    public void setUri(URI uri);
    public String getMethod();
}
```
public void setMethod(String method);

public MultivaluedMap<String, Object> getHeaders();

public abstract MultivaluedMap<String, String> getStringHeaders();

public String getHeaderString(String name);

public Date getDate();

public Locale getLanguage();

public MediaType getMediaType();

public List<MediaType> getAcceptableMediaTypes();

public List<Locale> getAcceptableLanguages();

public Map<String, Cookie> getCookies();

public boolean hasEntity();

public Object getEntity();

public Class<?> getEntityClass();

public Type getEntityType();

public void setEntity(final Object entity);

public void setEntity(
        final Object entity,
        final Annotation[] annotations,
        final MediaType mediaType);

public Annotation[] getEntityAnnotations();

public OutputStream getEntityStream();

public void setEntityStream(OutputStream outputStream);

public Client getClient();

public Configuration getConfiguration();

public void abortWith(Response response);}

Sample implementation

To implement a client request filter for the ClientRequest extension point (that is, where the filter is executed prior to sending the request message), define a class that implements the ClientRequestFilter interface.

For example, the following code shows an example of a simple client request filter that gets installed in the ClientRequest extension point, with a priority of 20:
Aborting the invocation

It is possible to abort a client-side invocation by implementing a suitable client request filter. For example, you might implement a client-side filter to check whether a request is correctly formatted and, if necessary, abort the request.

The following test code always aborts the request, returning the **BAD_REQUEST** HTTP status to the client calling code:

```java
// Java
package org.jboss.fuse.example;

import javax.ws.rs.client.ClientRequestContext;
import javax.ws.rs.client.ClientRequestFilter;
import javax.ws.rs.core.Response;
import javax.ws.rs.core.Response.Status;
import javax.annotation.Priority;

@Priority(value = 10)
public class TestAbortClientRequestFilter implements ClientRequestFilter {

    public TestAbortClientRequestFilter() {
        System.out.println("TestAbortClientRequestFilter starting up");
    }

    @Override
    public void filter(ClientRequestContext requestContext) {
        // Test filter: aborts with BAD_REQUEST status
        requestContext.abortWith(Response.status(Status.BAD_REQUEST).build());
    }
}
```

**Registering the client request filter**
Using the JAX-RS 2.0 client API, you can register a client request filter directly on a `javax.ws.rs.client.Client` object or on a `javax.ws.rs.client.WebTarget` object. Effectively, this means that the client request filter can optionally be applied to different scopes, so that only certain URI paths are affected by the filter.

For example, the following code shows how to register the `SampleClientRequestFilter` filter so that it applies to all invocations made using the `client` object; and how to register the `TestAbortClientRequestFilter` filter, so that it applies only to sub-paths of `rest/TestAbortClientRequest`.

```java
// Java
...
import javax.ws.rs.client.Client;
import javax.ws.rs.client.ClientBuilder;
import javax.ws.rs.client.Invocation;
import javax.ws.rs.core.Response;
...
Client client = ClientBuilder.newClient();
client.register(new SampleClientRequestFilter());
WebTarget target = client.target("http://localhost:8001/rest/TestAbortClientRequest");
target.register(new TestAbortClientRequestFilter());
```

### 61.5. CLIENT RESPONSE FILTER

#### Overview

This section explains how to implement and register a client response filter, which is used to intercept an incoming response message on the client side. Client response filters can be used for any kind of generic response processing on the client side.

#### ClientResponseFilter interface

The `javax.ws.rs.client.ClientResponseFilter` interface is defined as follows:

```java
// Java
package javax.ws.rs.client;
...
import java.io.IOException;

public interface ClientResponseFilter {
    void filter(ClientRequestContext requestContext, ClientResponseContext responseContext)
        throws IOException;
}
```

By implementing the `ClientResponseFilter`, you can create a filter for the `ClientResponse` extension point on the client side, which filters the response message after it is received from the server.

#### ClientResponseContext interface

The `filter` method of `ClientResponseFilter` receives two arguments: an argument of type `javax.ws.rs.client.ClientRequestContext` (see the section called "ClientRequestContext interface");
and an argument of type `javax.ws.rs.client.ClientResponseContext`, which can be used to access the outgoing response message and its related metadata.

The `ClientResponseContext` interface is defined as follows:

```java
// Java
...
package javax.ws.rs.client;

import java.io.InputStream;
import java.net.URI;
import java.util.Date;
import java.util.Locale;
import java.util.Map;
import java.util.Set;
import javax.ws.rs.core.EntityTag;
import javax.ws.rs.core.Link;
import javax.ws.rs.core.MediaType;
import javax.ws.rs.core.MultivaluedMap;
import javax.ws.rs.core.NewCookie;
import javax.ws.rs.core.Response;

public interface ClientResponseContext {
    public int getStatus();
    public void setStatus(int code);
    public Response.StatusType getStatusInfo();
    public void setStatusInfo(Response.StatusType statusInfo);
    public MultivaluedMap<String, String> getHeaders();
    public String getHeaderString(String name);
    public Set<String> getAllowedMethods();
    public Date getDate();
    public Locale getLanguage();
    public int getLength();
    public MediaType getMediaType();
    public Map<String, NewCookie> getCookies();
    public EntityTag getEntityTag();
    public Date getLastModified();
    public URI getLocation();
    public Set<Link> getLinks();
}
```
boolean hasLink(String relation);

public Link getLink(String relation);

public Link.Builder getLinkBuilder(String relation);

public boolean hasEntity();

public InputStream getEntityStream();

public void setEntityStream(InputStream input);
}

Sample implementation

To implement a client response filter for the ClientResponse extension point (that is, where the filter is executed after receiving a response message from the server), define a class that implements the ClientResponseFilter interface.

For example, the following code shows an example of a simple client response filter that gets installed in the ClientResponse extension point, with a priority of 20:

```
// Java
package org.jboss.fuse.example;

import javax.ws.rs.client.ClientRequestContext;
import javax.ws.rs.client.ClientResponseContext;
import javax.ws.rs.client.ClientResponseFilter;
import javax.annotation.Priority;

@Priority(value = 20)
public class SampleClientResponseFilter implements ClientResponseFilter {

    public SampleClientResponseFilter() {
        System.out.println("SampleClientResponseFilter starting up");
    }

    @Override
    public void filter(
            ClientRequestContext requestContext,
            ClientResponseContext responseContext
    ) {
        // Add an extra header on the response
        responseContext.getHeaders().putSingle("MyCustomHeader", "my custom data");
    }
}
```

Registering the client response filter

Using the JAX-RS 2.0 client API, you can register a client response filter directly on a javax.ws.rs.client.Client object or on a javax.ws.rs.client.WebTarget object. Effectively, this means that the client request filter can optionally be applied to different scopes, so that only certain URI paths are affected by the filter.
For example, the following code shows how to register the SampleClientResponseFilter filter so that it applies to all invocations made using the client object:

```java
// Java
...
import javax.ws.rs.client.Client;
import javax.ws.rs.client.ClientBuilder;
import javax.ws.rs.client.Invocation;
import javax.ws.rs.client.WebTarget;
import javax.ws.rs.core.Response;
...
Client client = ClientBuilder.newClient();
client.register(new SampleClientResponseFilter());
```

### 61.6. ENTITY READER INTERCEPTOR

#### Overview

This section explains how to implement and register an entity reader interceptor, which enables you to intercept the input stream when reading a message body either on the client side or on the server side. This is typically useful for generic transformations of the request body, such as encryption and decryption, or compressing and decompressing.

#### ReaderInterceptor interface

The `javax.ws.rs.ext.ReaderInterceptor` interface is defined as follows:

```java
// Java
...
package javax.ws.rs.ext;

class ReaderInterceptor {
    public Object aroundReadFrom(ReaderInterceptorContext context)
        throws java.io.IOException, javax.ws.rs.WebApplicationException;
}
```

By implementing the `ReaderInterceptor` interface, you can intercept the message body (`Entity` object) as it is being read either on the server side or the client side. You can use an entity reader interceptor in either of the following contexts:

- **Server side**—if bound as a server-side interceptor, the entity reader interceptor intercepts the request message body when it is accessed by the application code (in the matched resource). Depending on the semantics of the REST request, the message body might not be accessed by the matched resource, in which case the reader interceptor is not called.

- **Client side**—if bound as a client-side interceptor, the entity reader interceptor intercepts the response message body when it is accessed by the client code. If the client code does not explicitly access the response message (for example, by calling the `Response.getEntity` method), the reader interceptor is not called.

#### ReaderInterceptorContext interface
The `aroundReadFrom` method of `ReaderInterceptor` receives one argument of type `javax.ws.rs.ext.ReaderInterceptorContext`, which can be used to access both the message body (`Entity` object) and message metadata.

The `ReaderInterceptorContext` interface is defined as follows:

```java
// Java
...
package javax.ws.rs.ext;

import java.io.IOException;
import java.io.InputStream;
import javax.ws.rs.WebApplicationException;
import javax.ws.rs.core.MultivaluedMap;

public interface ReaderInterceptorContext extends InterceptorContext {
    public Object proceed() throws IOException, WebApplicationException;
    public InputStream getInputStream();
    public void setInputStream(InputStream is);
    public MultivaluedMap<String, String> getHeaders();
}
```

InterceptorContext interface

The `ReaderInterceptorContext` interface also supports the methods inherited from the base `InterceptorContext` interface.

The `InterceptorContext` interface is defined as follows:

```java
// Java
...
package javax.ws.rs.ext;

import java.lang.annotation.Annotation;
import java.lang.reflect.Type;
import java.util.Collection;
import javax.ws.rs.core.MediaType;

public interface InterceptorContext {
    public Object getProperty(String name);
    public Collection<String> getPropertyNames();
    public void setProperty(String name, Object object);
    public void removeProperty(String name);
    public Annotation[] getAnnotations();
}
public void setAnnotations(Annotation[] annotations);

Class<?> getType();

public void setType(Class<?> type);

Type getGenericType();

public void setGenericType(Type genericType);

public MediaType getMediaType();

public void setMediaType(MediaType mediaType);

Sample implementation on the client side

To implement an entity reader interceptor for the client side, define a class that implements the
ReaderInterceptor interface.

For example, the following code shows an example of an entity reader interceptor for the client side
(with a priority of 10), which replaces all instances of COMPANY_NAME by Red Hat in the message
body of the incoming response:

// Java
package org.jboss.fuse.example;

import java.io.ByteArrayInputStream;
import java.io.IOException;
import java.io.InputStream;
import javax.annotation.Priority;
import javax.ws.rs.WebApplicationException;
import javax.ws.rs.ext.ReaderInterceptor;
import javax.ws.rs.ext.ReaderInterceptorContext;

@Priority(value = 10)
public class SampleClientReaderInterceptor implements ReaderInterceptor {

    @Override
    public Object aroundReadFrom(ReaderInterceptorContext interceptorContext)
            throws IOException, WebApplicationException {
        InputStream inputStream = interceptorContext.getInputStream();
        byte[] bytes = new byte[inputStream.available()];
        inputStream.read(bytes);
        String responseContent = new String(bytes);
        responseContent = responseContent.replaceAll("COMPANY_NAME", "Red Hat");
        interceptorContext.setInputStream(new ByteArrayInputStream(responseContent.getBytes()));

        return interceptorContext.proceed();
    }
}
Sample implementation on the server side

To implement an entity reader interceptor for the server side, define a class that implements the
\texttt{ReaderInterceptor} interface and annotate it with the \texttt{@Provider} annotation.

For example, the following code shows an example of an entity reader interceptor for the server side
(with a priority of 10), which replaces all instances of \texttt{COMPANY\_NAME} by \texttt{Red Hat} in the message
body of the incoming request:

\begin{verbatim}
// Java
package org.jboss.fuse.example;

import java.io.ByteArrayInputStream;
import java.io.IOException;
import java.io.InputStream;

import javax.annotation.Priority;
import javax.ws.rs.WebApplicationException;
import javax.ws.rs.ext.Provider;
import javax.ws.rs.ext.ReaderInterceptor;
import javax.ws.rs.ext.ReaderInterceptorContext;

@Priority(value = 10)
@Provider
public class SampleServerReaderInterceptor implements ReaderInterceptor {
    @Override
    public Object aroundReadFrom(ReaderInterceptorContext interceptorContext)
        throws IOException, WebApplicationException {
        InputStream inputStream = interceptorContext.getInputStream();
        byte[] bytes = new byte[inputStream.available()];
        inputStream.read(bytes);
        String requestContent = new String(bytes);
        requestContent = requestContent.replaceAll("COMPANY\_NAME", "Red Hat");
        interceptorContext.setInputStream(new ByteArrayInputStream(requestContent.getBytes()));

        return interceptorContext.proceed();
    }
}
\end{verbatim}

Binding a reader interceptor on the client side

Using the JAX-RS 2.0 client API, you can register an entity reader interceptor directly on a
\texttt{javax.ws.rs.client.Client} object or on a \texttt{javax.ws.rs.client.WebTarget} object. Effectively, this means
that the reader interceptor can optionally be applied to different scopes, so that only certain URI paths
are affected by the interceptor.

For example, the following code shows how to register the \texttt{SampleClientReaderInterceptor} interceptor
so that it applies to all invocations made using the \texttt{client} object:

\begin{verbatim}
// Java
...
import javax.ws.rs.client.Client;
import javax.ws.rs.client.ClientBuilder;
import javax.ws.rs.client.Invocation;
\end{verbatim}
import javax.ws.rs.client.WebTarget;
import javax.ws.rs.core.Response;
...
Client client = ClientBuilder.newClient();
client.register(SampleClientReaderInterceptor.class);

For more details about registering interceptors with a JAX-RS 2.0 client, see Section 49.5, “Configuring the Client Endpoint”.

**Binding a reader interceptor on the server side**

To bind a reader interceptor on the server side (that is, to install it into the Apache CXF runtime), perform the following steps:

1. Add the `@Provider` annotation to the reader interceptor class, as shown in the following code fragment:

   ```java
   // Java
   package org.jboss.fuse.example;
   ...
   import javax.annotation.Priority;
   import javax.ws.rs.WebApplicationException;
   import javax.ws.rs.core.Response;
   import javax.ws.rs.ext.Provider;
   import javax.ws.rs.ext.ReaderInterceptor;
   import javax.ws.rs.ext.ReaderInterceptorContext;

   @Priority(value = 10)
   @Provider
   public class SampleServerReaderInterceptor implements ReaderInterceptor {
      ...
   }
   ```

   When the reader interceptor implementation is loaded into the Apache CXF runtime, the REST implementation automatically scans the loaded classes to search for the classes marked with the `@Provider` annotation (the scanning phase).

2. When defining a JAX-WS server endpoint in XML (for example, see Section 18.1, “Configuring JAX-WS Server Endpoints”), add the reader interceptor to the list of providers in the `jaxrs:providers` element.

   ```xml
   <blueprint xmlns="http://www.osgi.org/xmlns/blueprint/v1.0.0"
      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xmlns:jaxrs="http://cxf.apache.org/blueprint/jaxrs"
      xmlns:cxf="http://cxf.apache.org/blueprint/core"
      ...
      >
      ...
      <jaxrs:server id="customerService" address="/customers">
         ...
         <jaxrs:providers>
            <ref bean="interceptorProvider" />
         </jaxrs:providers>
      </jaxrs:server>
      ...
      <bean id="interceptorProvider" class="org.jboss.fuse.example.SampleServerReaderInterceptor"/>
   ```
NOTE

This step is a non-standard requirement of Apache CXF. Strictly speaking, according to the JAX-RS standard, the @Provider annotation should be all that is required to bind the interceptor. But in practice, the standard approach is somewhat inflexible and can lead to clashing providers when many libraries are included in a large project.

61.7. ENTITY WRITER INTERCEPTOR

Overview

This section explains how to implement and register an entity writer interceptor, which enables you to intercept the output stream when writing a message body either on the client side or on the server side. This is typically useful for generic transformations of the request body, such as encryption and decryption, or compressing and decompressing.

WriterInterceptor interface

The javax.ws.rs.ext.WriterInterceptor interface is defined as follows:

```java
// Java
...
package javax.ws.rs.ext;

public interface WriterInterceptor {
    void aroundWriteTo(WriterInterceptorContext context)
        throws java.io.IOException, javax.ws.rs.WebApplicationException;
}
```

By implementing the WriterInterceptor interface, you can intercept the message body (Entity object) as it is being written either on the server side or the client side. You can use an entity writer interceptor in either of the following contexts:

- **Server side**—if bound as a server-side interceptor, the entity writer interceptor intercepts the response message body just before it is marshalled and sent back to the client.

- **Client side**—if bound as a client-side interceptor, the entity writer interceptor intercepts the request message body just before it is marshalled and sent out to the server.

WriterInterceptorContext interface

The aroundWriteTo method of WriterInterceptor receives one argument of type javax.ws.rs.ext.WriterInterceptorContext, which can be used to access both the message body (Entity object) and message metadata.

The WriterInterceptorContext interface is defined as follows:

```java
// Java
```
package javax.ws.rs.ext;
import java.io.IOException;
import java.io.OutputStream;
import javax.ws.rs.WebApplicationException;
import javax.ws.rs.core.MultivaluedMap;

public interface WriterInterceptorContext extends InterceptorContext {
    void proceed() throws IOException, WebApplicationException;
    Object getEntity();
    void setEntity(Object entity);
    OutputStream getOutputStream();
    public void setOutputStream(OutputStream os);
    MultivaluedMap<String, Object> getHeaders();
}

InterceptorContext interface

The WriterInterceptorContext interface also supports the methods inherited from the base InterceptorContext interface. For the definition of InterceptorContext, see the section called “InterceptorContext interface”.

Sample implementation on the client side

To implement an entity writer interceptor for the client side, define a class that implements the WriterInterceptor interface.

For example, the following code shows an example of an entity writer interceptor for the client side (with a priority of 10), which appends an extra line of text to the message body of the outgoing request:

```
// Java
package org.jboss.fuse.example;
import java.io.IOException;
import java.io.OutputStream;
import javax.ws.rs.WebApplicationException;
import javax.ws.rs.ext.WriterInterceptor;
import javax.ws.rs.ext.WriterInterceptorContext;
import javax.annotation.Priority;

@Priority(value = 10)
public class SampleClientWriterInterceptor implements WriterInterceptor {

    @Override
    public void aroundWriteTo(WriterInterceptorContext interceptorContext)
        throws IOException, WebApplicationException {
```
Sample implementation on the server side

To implement an entity writer interceptor for the server side, define a class that implements the `WriterInterceptor` interface and annotate it with the `@Provider` annotation.

For example, the following code shows an example of an entity writer interceptor for the server side (with a priority of 10), which appends an extra line of text to the message body of the outgoing request:

```java
// Java
package org.jboss.fuse.example;

import java.io.IOException;
import java.io.OutputStream;
import javax.ws.rs.WebApplicationException;
import javax.ws.rs.ext.Provider;
import javax.ws.rs.ext.WriterInterceptor;
import javax.ws.rs.ext.WriterInterceptorContext;
import javax.annotation.Priority;

@Priority(value = 10)
@Provider
public class SampleServerWriterInterceptor implements WriterInterceptor {

    @Override
    public void aroundWriteTo(WriterInterceptorContext interceptorContext) throws IOException, WebApplicationException {
        OutputStream outputStream = interceptorContext.getOutputStream();
        String appendedContent = "\nInterceptors always get the last word in.";
        outputStream.write(appendedContent.getBytes());
        interceptorContext.setOutputStream(outputStream);
        interceptorContext.proceed();
    }
}
```

Binding a writer interceptor on the client side

Using the JAX-RS 2.0 client API, you can register an entity writer interceptor directly on a `javax.ws.rs.client.Client` object or on a `javax.ws.rs.client.WebTarget` object. Effectively, this means that the writer interceptor can optionally be applied to different scopes, so that only certain URI paths are affected by the interceptor.

For example, the following code shows how to register the `SampleClientReaderInterceptor` interceptor so that it applies to all invocations made using the `client` object:
For more details about registering interceptors with a JAX-RS 2.0 client, see Section 49.5, “Configuring the Client Endpoint”.

**Binding a writer interceptor on the server side**

To bind a writer interceptor on the server side (that is, to install it into the Apache CXF runtime), perform the following steps:

1. Add the @Provider annotation to the writer interceptor class, as shown in the following code fragment:

```java
package org.jboss.fuse.example;
...
import javax.ws.rs.WebApplicationException;
import javax.ws.rs.ext.Provider;
import javax.ws.rs.ext.WriterInterceptor;
import javax.ws.rs.ext.WriterInterceptorContext;
import javax.annotation.Priority;
@Priority(value = 10)
@Provider
public class SampleServerWriterInterceptor implements WriterInterceptor {
    ...
}
```

When the writer interceptor implementation is loaded into the Apache CXF runtime, the REST implementation automatically scans the loaded classes to search for the classes marked with the @Provider annotation (the scanning phase).

2. When defining a JAX-RS server endpoint in XML (for example, see Section 18.1, “Configuring JAX-RS Server Endpoints”), add the writer interceptor to the list of providers in the `jaxrs:providers` element.
NOTE

This step is a non-standard requirement of Apache CXF. Strictly speaking, according to the JAX-RS standard, the @Provider annotation should be all that is required to bind the interceptor. But in practice, the standard approach is somewhat inflexible and can lead to clashing providers when many libraries are included in a large project.

61.8. DYNAMIC BINDING

Overview

The standard approach to binding container filters and container interceptors to resources is to annotate the filters and interceptors with the @Provider annotation. This ensures that the binding is global: that is, the filters and interceptors are bound to every resource class and resource method on the server side.

Dynamic binding is an alternative approach to binding on the server side, which enables you to pick and choose which resource methods your interceptors and filters are applied to. To enable dynamic binding for your filters and interceptors, you must implement a custom DynamicFeature interface, as described here.

DynamicFeature interface

The DynamicFeature interface is defined in the javax.ws.rs.container package, as follows:

```java
// Java
package javax.ws.rs.container;
import javax.ws.rs.core.FeatureContext;
import javax.ws.rs.ext.ReaderInterceptor;
import javax.ws.rs.ext.WriterInterceptor;

public interface DynamicFeature {
    public void configure(ResourceInfo resourceInfo, FeatureContext context);
}
```

Implementing a dynamic feature

You implement a dynamic feature, as follows:

1. Implement one or more container filters or container interceptors, as described previously. But do not annotate them with the @Provider annotation (otherwise, they would be bound globally, making the dynamic feature effectively irrelevant).
2. Create your own dynamic feature by implementing the `DynamicFeature` class, overriding the `configure` method.

3. In the `configure` method, you can use the `ResourceInfo` argument to discover which resource class and which resource method this feature is being called for. You can use this information as the basis for deciding whether or not to register some of the filters or interceptors.

4. If you decide to register a filter or an interceptor with the current resource method, you can do so by invoking one of the `context.register` methods.

5. Remember to annotate your dynamic feature class with the `@Provider` annotation, to ensure that it gets picked up during the scanning phase of deployment.

Example dynamic feature

The following example shows you how to define a dynamic feature that registers the `LoggingFilter` filter for any method of the `MyResource` class (or subclass) that is annotated with `@GET`:

```java
// Java
...
import javax.ws.rs.container.DynamicFeature;
import javax.ws.rs.container.ResourceInfo;
import javax.ws.rs.core.FeatureContext;
import javax.ws.rs.ext.Provider;

@Provider
public class DynamicLoggingFilterFeature implements DynamicFeature {
  @Override
  void configure(ResourceInfo resourceInfo, FeatureContext context) {
    if (MyResource.class.isAssignableFrom(resourceInfo.getResourceClass())
       && resourceInfo.getResourceMethod().isAnnotationPresent(GET.class)) {
      context.register(new LoggingFilter());
    }
  }
}
```

Dynamic binding process

The JAX-RS standard requires that the `DynamicFeature.configure` method is called exactly once for each resource method. This means that every resource method could potentially have filters or interceptors installed by the dynamic feature, but it is up to the dynamic feature to decide whether to register the filters or interceptors in each case. In other words, the granularity of binding supported by the dynamic feature is at the level of individual resource methods.

FeatureContext interface

The `FeatureContext` interface (which enables you to register filters and interceptors in the `configure` method) is defined as a sub-interface of `Configurable<>`, as follows:

```java
// Java
package javax.ws.rs.core;

public interface FeatureContext extends Configurable<FeatureContext> {
  }
```
The `Configurable<>` interface defines a variety of methods for registering filters and interceptors on a single resource method, as follows:

```java
// Java

package javax.ws.rs.core;

import java.util.Map;

public interface Configurable<C extends Configurable> {
    public Configuration getConfiguration();
    public C property(String name, Object value);
    public C register(Class<?> componentClass);
    public C register(Class<?> componentClass, int priority);
    public C register(Class<?> componentClass, Class<?>... contracts);
    public C register(Class<?> componentClass, Map<Class<?>, Integer> contracts);
    public C register(Object component);
    public C register(Object component, int priority);
    public C register(Object component, Class<?>... contracts);
    public C register(Object component, Map<Class<?>, Integer> contracts);
}
```
CHAPTER 62. APACHE CXF MESSAGE PROCESSING PHASES

INBOUND PHASES

Table 62.1, “Inbound message processing phases” lists the phases available in inbound interceptor chains.

Table 62.1. Inbound message processing phases

<table>
<thead>
<tr>
<th>Phase</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RECEIVE</td>
<td>Performs transport specific processing, such as determining MIME boundaries for binary attachments.</td>
</tr>
<tr>
<td>PRE_STREAM</td>
<td>Processes the raw data stream received by the transport.</td>
</tr>
<tr>
<td>USER_STREAM</td>
<td></td>
</tr>
<tr>
<td>POST_STREAM</td>
<td></td>
</tr>
<tr>
<td>READ</td>
<td>Determines if a request is a SOAP or XML message and builds adds the proper interceptors. SOAP message headers are also processed in this phase.</td>
</tr>
<tr>
<td>PRE_PROTOCOL</td>
<td>Performs protocol level processing. This includes processing of WS-* headers and processing of the SOAP message properties.</td>
</tr>
<tr>
<td>USER_PROTOCOL</td>
<td></td>
</tr>
<tr>
<td>POST_PROTOCOL</td>
<td></td>
</tr>
<tr>
<td>UNMARSHAL</td>
<td>Unmarshals the message data into the objects used by the application level code.</td>
</tr>
<tr>
<td>PRE_LOGICAL</td>
<td>Processes the unmarshalled message data.</td>
</tr>
<tr>
<td>USER_LOGICAL</td>
<td></td>
</tr>
<tr>
<td>POST_LOGICAL</td>
<td></td>
</tr>
<tr>
<td>PRE_INVOKE</td>
<td></td>
</tr>
<tr>
<td>INVOKE</td>
<td>Passes the message to the application code. On the server side, the service implementation is invoked in this phase. On the client side, the response is handed back to the application.</td>
</tr>
</tbody>
</table>
POST_INVOKE

Invokes the outbound interceptor chain.

## OUTBOUND PHASES

Table 62.2, “Inbound message processing phases” lists the phases available in inbound interceptor chains.

### Table 62.2. Inbound message processing phases

<table>
<thead>
<tr>
<th>Phase</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SETUP</td>
<td>Performs any set up that is required by later phases in the chain.</td>
</tr>
<tr>
<td>PRE_LOGICAL</td>
<td>Performs processing on the unmarshalled data passed from the application level.</td>
</tr>
<tr>
<td>USER_LOGICAL</td>
<td></td>
</tr>
<tr>
<td>POST_LOGICAL</td>
<td></td>
</tr>
<tr>
<td>PREPARE_SEND</td>
<td>Opens the connection for writing the message on the wire.</td>
</tr>
<tr>
<td>PRE_STREAM</td>
<td>Performs processing required to prepare the message for entry into a data stream.</td>
</tr>
<tr>
<td>PRE_PROTOCOL</td>
<td>Begins processing protocol specific information.</td>
</tr>
<tr>
<td>WRITE</td>
<td>Writes the protocol message.</td>
</tr>
<tr>
<td>PRE_MARSHAL</td>
<td>Marshals the message.</td>
</tr>
<tr>
<td>MARSHAL</td>
<td></td>
</tr>
<tr>
<td>POST_MARSHAL</td>
<td></td>
</tr>
<tr>
<td>USER_PROTOCOL</td>
<td>Process the protocol message.</td>
</tr>
<tr>
<td>POST_PROTOCOL</td>
<td></td>
</tr>
<tr>
<td>USER_STREAM</td>
<td>Process the byte-level message.</td>
</tr>
<tr>
<td>POST_STREAM</td>
<td></td>
</tr>
<tr>
<td>Phase</td>
<td>Description</td>
</tr>
<tr>
<td>-------</td>
<td>-------------</td>
</tr>
<tr>
<td>SEND</td>
<td>Sends the message and closes the transport stream.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

Outbound interceptor chains have a mirror set of ending phases whose names are appended with `_ENDING`. The ending phases are used interceptors that require some terminal action to occur before data is written on the wire.
CHAPTER 63. APACHE CXF PROVIDED INTERCEPTORS

63.1. CORE APACHE CXF INTERCEPTORS

Inbound

Table 63.1, “Core inbound interceptors” lists the core inbound interceptors that are added to all Apache CXF endpoints.

Table 63.1. Core inbound interceptors

<table>
<thead>
<tr>
<th>Class</th>
<th>Phase</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ServiceInvokerInterceptor</td>
<td>INVOKE</td>
<td>Invokes the proper method on the service.</td>
</tr>
</tbody>
</table>

Outbound

The Apache CXF does not add any core interceptors to the outbound interceptor chain by default. The contents of an endpoint’s outbound interceptor chain depend on the features in use.

63.2. FRONT-ENDS

JAX-WS

Table 63.2, “Inbound JAX-WS interceptors” lists the interceptors added to a JAX-WS endpoint’s inbound message chain.

Table 63.2. Inbound JAX-WS interceptors

<table>
<thead>
<tr>
<th>Class</th>
<th>Phase</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HolderInInterceptor</td>
<td>PRE_INVOKE</td>
<td>Creates holder objects for any out or in/out parameters in the message.</td>
</tr>
<tr>
<td>WrapperClassInInterceptor</td>
<td>POST_LOGICAL</td>
<td>Unwraps the parts of a wrapped doc/literal message into the appropriate array of objects.</td>
</tr>
<tr>
<td>LogicalHandlerInInterceptor</td>
<td>PRE_PROTOCOL</td>
<td>Passes message processing to the JAX-WS logical handlers used by the endpoint. When the JAX-WS handlers complete, the message is passed along to the next interceptor on the inbound chain.</td>
</tr>
</tbody>
</table>
Table 63.3, “Outbound JAX-WS interceptors” lists the interceptors added to a JAX-WS endpoint’s outbound message chain.

**Table 63.3. Outbound JAX-WS interceptors**

<table>
<thead>
<tr>
<th>Class</th>
<th>Phase</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HolderOutInterceptor</td>
<td>PRE_LOGICAL</td>
<td>Removes the values of any out and in/out parameters from their holder objects and adds the values to the message’s parameter list.</td>
</tr>
<tr>
<td>WebFaultOutInterceptor</td>
<td>PRE_PROTOCOL</td>
<td>Processes outbound fault messages.</td>
</tr>
<tr>
<td>WrapperClassOutInterceptor</td>
<td>PRE_LOGICAL</td>
<td>Makes sure that wrapped doc/literal messages and rpc/literal messages are properly wrapped before being added to the message.</td>
</tr>
<tr>
<td>LogicalHandlerOutInterceptor</td>
<td>PRE_MARSHAL</td>
<td>Passes message processing to the JAX-WS logical handlers used by the endpoint. When the JAX-WS handlers complete, the message is passed along to the next interceptor on the outbound chain.</td>
</tr>
<tr>
<td>SOAPHandlerInterceptor</td>
<td>PRE_PROTOCOL</td>
<td>Passes message processing to the JAX-WS SOAP handlers used by the endpoint. When the SOAP handlers finish processing the message, it is passed along to the next interceptor in the chain.</td>
</tr>
<tr>
<td>MessageSenderInterceptor</td>
<td>PREPARE_SEND</td>
<td>Calls back to the Destination object to have it setup the output streams, headers, etc. to prepare the outgoing transport.</td>
</tr>
</tbody>
</table>
JAX-RS

Table 63.4, “Inbound JAX-RS interceptors” lists the interceptors added to a JAX-RS endpoint’s inbound message chain.

Table 63.4. Inbound JAX-RS interceptors

<table>
<thead>
<tr>
<th>Class</th>
<th>Phase</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>JAXRSInInterceptor</td>
<td>PRE_STREAM</td>
<td>Selects the root resource class, invokes any configured JAX-RS request filters, and determines the method to invoke on the root resource.</td>
</tr>
</tbody>
</table>

**IMPORTANT**

The inbound chain for a JAX-RS endpoint skips straight to the ServiceInvokerInInterceptor interceptor. No other interceptors will be invoked after the JAXRSInInterceptor.

Table 63.5, “Outbound JAX-RS interceptors” lists the interceptors added to a JAX-RS endpoint’s outbound message chain.

Table 63.5. Outbound JAX-RS interceptors

<table>
<thead>
<tr>
<th>Class</th>
<th>Phase</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>JAXRSOutInterceptor</td>
<td>MARSHAL</td>
<td>Marshals the response into the proper format for transmission.</td>
</tr>
</tbody>
</table>

63.3. MESSAGE BINDINGS

SOAP

Table 63.6, “Inbound SOAP interceptors” lists the interceptors added to a endpoint’s inbound message chain when using the SOAP Binding.

Table 63.6. Inbound SOAP interceptors

<table>
<thead>
<tr>
<th>Class</th>
<th>Phase</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CheckFaultInterceptor</td>
<td>POST_PROTOCOL</td>
<td>Checks if the message is a fault message. If the message is a fault message, normal processing is aborted and fault processing is started.</td>
</tr>
<tr>
<td>MustUnderstandInterceptor</td>
<td>PRE_PROTOCOL</td>
<td>Processes the must understand headers.</td>
</tr>
</tbody>
</table>
### Table 63.7. Outbound SOAP interceptors

<table>
<thead>
<tr>
<th>Class</th>
<th>Phase</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RPCInInterceptor</td>
<td>UNMARSHAL</td>
<td>Unmarshals rpc/literal messages. If the message is bare, the message is passed to a <strong>BareInInterceptor</strong> object to deserialize the message parts.</td>
</tr>
<tr>
<td>ReadsHeadersInterceptor</td>
<td>READ</td>
<td>Parses the SOAP headers and stores them in the message object.</td>
</tr>
<tr>
<td>SoapActionInInterceptor</td>
<td>READ</td>
<td>Parses the SOAP action header and attempts to find a unique operation for the action.</td>
</tr>
<tr>
<td>SoapHeaderInterceptor</td>
<td>UNMARSHAL</td>
<td>Binds the SOAP headers that map to operation parameters to the appropriate objects.</td>
</tr>
<tr>
<td>AttachmentInInterceptor</td>
<td>RECEIVE</td>
<td>Parses the mime headers for mime boundaries, finds the root part and resets the input stream to it, and stores the other parts in a collection of <strong>Attachment</strong> objects.</td>
</tr>
<tr>
<td>DocLiteralInInterceptor</td>
<td>UNMARSHAL</td>
<td>Examines the first element in the SOAP body to determine the appropriate operation and calls the data binding to read in the data.</td>
</tr>
<tr>
<td>StaxInInterceptor</td>
<td>POST_STREAM</td>
<td>Creates an <strong>XMLStreamReader</strong> object from the message.</td>
</tr>
<tr>
<td>URIMappingInterceptor</td>
<td>UNMARSHAL</td>
<td>Handles the processing of HTTP GET methods.</td>
</tr>
<tr>
<td>SwAInInterceptor</td>
<td>PRE_INVOKE</td>
<td>Creates the required MIME handlers for binary SOAP attachments and adds the data to the parameter list.</td>
</tr>
</tbody>
</table>

Table 63.7, "Outbound SOAP interceptors" lists the interceptors added to a endpoint’s outbound message chain when using the SOAP Binding.

Table 63.7. Outbound SOAP interceptors
<table>
<thead>
<tr>
<th>Class</th>
<th>Phase</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RPCOutInterceptor</td>
<td>MARSHAL</td>
<td>Marshals rpc style messages for transmission.</td>
</tr>
<tr>
<td>SoapHeaderOutFilterInterceptor</td>
<td>PRE_LOGICAL</td>
<td>Removes all SOAP headers that are marked as inbound only.</td>
</tr>
<tr>
<td>SoapPreProtocolOutInterceptor</td>
<td>POST_LOGICAL</td>
<td>Sets up the SOAP version and the SOAP action header.</td>
</tr>
<tr>
<td>AttachmentOutInterceptor</td>
<td>PRE_STREAM</td>
<td>Sets up the attachment marshalers and the mime stuff required to process any attachments that might be in the message.</td>
</tr>
<tr>
<td>BareOutInterceptor</td>

<td>Deserializes the message parts.</td>
</tr>
<tr>
<td>CorbaStreamOutInterceptor</td>
<td>PRE_STREAM</td>
<td>Serializes the message.</td>
</tr>
<tr>
<td>BareOutInterceptor</td>
<td>MARSHAL</td>
<td>Writes the message parts.</td>
</tr>
<tr>
<td>CorbaStreamOutEndingInterceptor</td>
<td>USER_STREAM</td>
<td>Creates a streamable object for the message and stores it in the message context.</td>
</tr>
</tbody>
</table>

63.4. OTHER FEATURES

Logging

Table 63.12, “Inbound logging interceptors” lists the interceptors added to a endpoint’s inbound message chain to support logging.

Table 63.12. Inbound logging interceptors

<table>
<thead>
<tr>
<th>Class</th>
<th>Phase</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>LoggingInInterceptor</td>
<td>RECEIVE</td>
<td>Writes the raw message data to the logging system.</td>
</tr>
</tbody>
</table>

Table 63.13, “Outbound logging interceptors” lists the interceptors added to a endpoint’s outbound message chain to support logging.

Table 63.13. Outbound logging interceptors

<table>
<thead>

</thead>
<tbody>
<tr>
<td>LoggingOutInterceptor</td>
<td>PRE_STREAM</td>
<td>Writes the outbound message to the logging system.</td>
</tr>
</tbody>
</table>

For more information about logging see Chapter 19, Apache CXF Logging.
WS-Addressing

Table 63.14, “Inbound WS-Addressing interceptors” lists the interceptors added to an endpoint’s inbound message chain when using WS-Addressing.

Table 63.14. Inbound WS-Addressing interceptors

<table>
<thead>
<tr>
<th>Class</th>
<th>Phase</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MAPCodec</td>
<td>PRE_PROTOCOL</td>
<td>Decodes the message addressing properties.</td>
</tr>
</tbody>
</table>

Table 63.15, “Outbound WS-Addressing interceptors” lists the interceptors added to an endpoint’s outbound message chain when using WS-Addressing.

Table 63.15. Outbound WS-Addressing interceptors

<table>
<thead>
<tr>
<th>Class</th>
<th>Phase</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MAPAggregator</td>
<td>PRE_LOGICAL</td>
<td>Aggregates the message addressing properties for a message.</td>
</tr>
<tr>
<td>MAPCodec</td>
<td>PRE_PROTOCOL</td>
<td>Encodes the message addressing properties.</td>
</tr>
</tbody>
</table>

For more information about WS-Addressing see Chapter 20, Deploying WS-Addressing.

WS-RM

IMPORTANT

WS-RM relies on WS-Addressing so all of the WS-Addressing interceptors will also be added to the interceptor chains.

Table 63.16, “Inbound WS-RM interceptors” lists the interceptors added to an endpoint’s inbound message chain when using WS-RM.

Table 63.16. Inbound WS-RM interceptors

<table>
<thead>
<tr>
<th>Class</th>
<th>Phase</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RMInInterceptor</td>
<td>PRE_LOGICAL</td>
<td>Handles the aggregation of message parts and acknowledgement messages.</td>
</tr>
<tr>
<td>RMSSoapInterceptor</td>
<td>PRE_PROTOCOL</td>
<td>Encodes and decodes the WS-RM properties from messages.</td>
</tr>
</tbody>
</table>
Table 63.17, “Outbound WS-RM interceptors” lists the interceptors added to a endpoint’s outbound message chain when using WS-RM.

Table 63.17. Outbound WS-RM interceptors

<table>
<thead>
<tr>
<th>Class</th>
<th>Phase</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RMOutInterceptor</td>
<td>PRE_LOGICAL</td>
<td>Handles the chunking of messages and the transmission of the chunks. Also handles the processing of acknowledgements and resend requests.</td>
</tr>
<tr>
<td>RMSapInterceptor</td>
<td>PRE_PROTOCOL</td>
<td>Encodes and decodes the WS-RM properties from messages.</td>
</tr>
</tbody>
</table>

For more information about WS-RM see Chapter 21, *Enabling Reliable Messaging*. 
CHAPTER 64. INTERCEPTOR PROVIDERS

OVERVIEW

Interceptor providers are objects in the Apache CXF runtime that have interceptor chains attached to them. They all implement the `org.apache.cxf.interceptor.InterceptorProvider` interface. Developers can attach their own interceptors to any interceptor provider.

LIST OF PROVIDERS

The following objects are interceptor providers:

- `AddressingPolicyInterceptorProvider`
- `ClientFactoryBean`
- `ClientImpl`
- `ClientProxyFactoryBean`
- `CorbaBinding`
- `CXFBusImpl`
- `org.apache.cxf.jaxws.EndpointImpl`
- `org.apache.cxf.endpoint.EndpointImpl`
- `ExtensionManagerBus`
- `JAXRSClientFactoryBean`
- `JAXRSServerFactoryBean`
- `JAXRSServiceImpl`
- `JaxWsClientEndpointImpl`
- `JaxWsClientFactoryBean`
- `JaxWsEndpointImpl`
- `JaxWsProxyFactoryBean`
- `JaxWsServerFactoryBean`
- `JaxwsServiceBuilder`
- `MTOMPolicyInterceptorProvider`
- `NoOpPolicyInterceptorProvider`
- `ObjectBinding`
- `RMPolicyInterceptorProvider`
- ServerFactoryBean
-ServiceImpl
- SimpleServiceBuilder
- SoapBinding
- WrappedEndpoint
- WrappedService
- XMLBinding
PART VIII. APACHE CXF FEATURES

This guide describes how to enable various advanced features of Apache CXF.
CHAPTER 65. BEAN VALIDATION

Abstract

Bean validation is a Java standard that enables you to define runtime constraints by adding Java annotations to service classes or interfaces. Apache CXF uses interceptors to integrate this feature with Web service method invocations.

65.1. INTRODUCTION

Overview

Bean Validation 1.1 (JSR-349)—which is an evolution of the original Bean Validation 1.0 (JSR-303) standard—enables you to declare constraints that can be checked at run time, using Java annotations. You can use annotations to define constraints on the following parts of the Java code:

- Fields in a bean class.
- Method and constructor parameters.
- Method return values.

Example of annotated class

The following example shows a Java class annotated with some standard bean validation constraints:

```java
// Java
import javax.validation.constraints.NotNull;
import javax.validation.constraints.Max;
import javax.validation.Valid;
...
public class Person {
    @NotNull private String firstName;
    @NotNull private String lastName;
    @Valid @NotNull private Person boss;

    public @NotNull String saveItem( @Valid @NotNull Person person, @Max( 23 ) BigDecimal age )
    {
        // ...
    }
}
```

Bean validation or schema validation?

In some respects, bean validation and schema validation are quite similar. Configuring an endpoint with an XML schema is a well established way to validate messages at run time on a Web services endpoint. An XML schema can check many of the same constraints as bean validation on incoming and outgoing messages. Nevertheless, bean validation can sometimes be a useful alternative for one or more of the following reasons:

- Bean validation enables you to define constraints independently of the XML schema (which is useful, for example, in the case of code-first service development).
• If your current XML schema is too lax, you can use bean validation to define stricter constraints.

• Bean validation lets you define custom constraints, which might be impossible to define using XML schema language.

Dependencies

The Bean Validation 1.1 (JSR-349) standard defines just the API, not the implementation. Dependencies must therefore be provided in two parts:

• **Core dependencies**—provide the bean validation 1.1 API, Java unified expression language API, and implementation.

• **Hibernate Validator dependencies**—provides the implementation of bean validation 1.1.

Core dependencies

To use bean validation, you must add the following core dependencies to your project’s Maven `pom.xml` file:

```xml
<dependency>
  <groupId>javax.validation</groupId>
  <artifactId>validation-api</artifactId>
  <version>1.1.0.Final</version>
</dependency>
<dependency>
  <groupId>javax.el</groupId>
  <artifactId>javax.el-api</artifactId>
  <!-- use 3.0-b02 version for Java 6 -->
  <version>3.0.0</version>
</dependency>
<dependency>
  <groupId>org.glassfish</groupId>
  <artifactId>javax.el</artifactId>
  <!-- use 3.0-b01 version for Java 6 -->
  <version>3.0.0</version>
</dependency>
```

**NOTE**

The `javax.el/javax.el-api` and `org.glassfish/javax.el` dependencies provide the API and implementation of Java’s unified expression language. This expression language is used internally by bean validation, but is not important at the application programming level.

Hibernate Validator dependencies

To use the Hibernate Validator implementation of bean validation, you must add the following additional dependencies to your project’s Maven `pom.xml` file:

```xml
<dependency>
  <groupId>org.hibernate</groupId>
  <artifactId>hibernate-validator</artifactId>
  <version>5.0.3.Final</version>
</dependency>
```
Resolving the validation provider in an OSGi environment

The default mechanism for resolving a validation provider involves scanning the classpath to find the provider resource. In the case of an OSGi (Apache Karaf) environment, however, this mechanism does not work, because the validation provider (for example, the Hibernate validator) is packaged in a separate bundle and is thus not automatically available in your application classpath. In the context of OSGi, the Hibernate validator needs to be wired to your application bundle, and OSGi needs a bit of help to do this successfully.

Configuring the validation provider explicitly in OSGi

In the context of OSGi, you need to configure the validation provider explicitly, instead of relying on automatic discovery. For example, if you are using the common validation feature (see the section called “Bean validation feature”) to enable bean validation, you must configure it with a validation provider, as follows:

```xml
<bean id="commonValidationFeature" class="org.apache.cxf.validation.BeanValidationFeature">
  <property name="provider" ref="beanValidationProvider"/>
</bean>

<bean id="beanValidationProvider" class="org.apache.cxf.validation.BeanValidationProvider">
  <constructor-arg ref="validationProviderResolver"/>
</bean>

<bean id="validationProviderResolver" class="org.example.HibernateValidationProviderResolver"/>
```

Where the `HibernateValidationProviderResolver` is a custom class that wraps the Hibernate validation provider.

Example HibernateValidationProviderResolver class

The following code example shows how to define a custom `HibernateValidationProviderResolver`, which resolves the Hibernate validator:

```java
// Java
package org.example;

import static java.util.Collections.singletonList;
import org.hibernate.validator.HibernateValidator;
import javax.validation.ValidationProviderResolver;
import java.util.List;

/**
 * OSGi-friendly implementation of [@code javax.validation.ValidationProviderResolver] returning
 *
 */
public class HibernateValidationProviderResolver implements ValidationProviderResolver {

    @Override
    public List getValidationProviders() {
        return singletonList(new HibernateValidator());
    }
}
```
When you build the preceding class in a Maven build system, which is configured to use the Maven bundle plug-in, your application will be wired to the Hibernate validator bundle at deploy time (assuming you have already deployed the Hibernate validator bundle to the OSGi container).

65.2. DEVELOPING SERVICES WITH BEAN VALIDATION

65.2.1. Annotating a Service Bean

Overview

The first step in developing a service with bean validation is to apply the relevant validation annotations to the Java classes or interfaces that represent your services. The validation annotations enable you to apply constraints to method parameters, return values, and class fields, which are then checked at run time, every time the service is invoked.

Validating simple input parameters

To validate the parameters of a service method—where the parameters are simple Java types—you can apply any of the constraint annotations from the bean validation API (javax.validation.constraints package). For example, the following code example tests both parameters for nullness (@NotNull annotation), whether the id string matches the \d+ regular expression (@Pattern annotation), and whether the length of the name string lies in the range 1 to 50:

```java
import javax.validation.constraints.NotNull;
import javax.validation.constraints.Pattern;
import javax.validation.constraints.Size;
...
@POST
@Path("/books")
public Response addBook(  
    @NotNull @Pattern(regexp = "\d+") @FormParam("id") String id,
    @NotNull @Size(min = 1, max = 50) @FormParam("name") String name) {
    // do some work
    return Response.created().build();
}
```

Validating complex input parameters

To validate complex input parameters (object instances), apply the @Valid annotation to the parameter, as shown in the following example:

```java
import javax.validation.Valid;
...
@POST
@Path("/books")
public Response addBook( @Valid Book book ) {
    // do some work
    return Response.created().build();
}
```

The @Valid annotation does not specify any constraints by itself. When you annotate the Book parameter with @Valid, you are effectively telling the validation engine to look inside the definition of the Book class (recursively) to look for validation constraints. In this example, the Book class is defined
with validation constraints on its **id** and **name** fields, as follows:

```java
import javax.validation.constraints.NotNull;
import javax.validation.constraints.Pattern;
import javax.validation.constraints.Size;
...
public class Book {
    @NotNull @Pattern(regexp = \"\d+\") private String id;
    @NotNull @Size(min = 1, max = 50) private String name;

    // ...
}
```

**Validating return values (non-Response)**

To apply validation to regular method return values (non-Response), add the annotations in front of the method signature. For example, to test the return value for nullness (**@NotNull** annotation) and to test validation constraints recursively (**@Valid** annotation), annotate the `getBook` method as follows:

```java
import javax.validation.constraints.NotNull;
import javax.validation.Valid;
...
@GET
@Path("/books/{bookId}\")
@Override
@NotNull @Valid
public Book getBook(@PathParam("bookId") String id) {
    return new Book( id );
}
```

**Validating return values (Response)**

To apply validation to a method that returns a `javax.ws.rs.core.Response` object, you can use the same annotations as in the non-Response case. For example:

```java
import javax.validation.constraints.NotNull;
import javax.validation.Valid;
import javax.ws.rs.core.Response;
...
@GET
@Path("/books/{bookId}\")
@Valid @NotNull
public Response getBookResponse(@PathParam("bookId") String id) {
    return Response.ok( new Book( id ) ).build();
}
```

### 65.2.2. Standard Annotations

**Bean validation constraints**

Table 65.1, "Standard Annotations for Bean Validation" shows the standard annotations defined in the Bean Validation specification, which can be used to define constraints on fields and on method return values and parameters (none of the standard annotations can be applied at the class level).
<table>
<thead>
<tr>
<th>Annotation</th>
<th>Applicable to</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@AssertFalse</td>
<td>Boolean, boolean</td>
<td>Checks that the annotated element is <strong>false</strong>.</td>
</tr>
<tr>
<td>@AssertTrue</td>
<td>Boolean, boolean</td>
<td>Checks that the annotated element is <strong>true</strong>.</td>
</tr>
<tr>
<td>@DecimalMax(value=, inclusive=)</td>
<td>BigDecimal, BigInteger, CharSequence, byte, short, int, long and primitive type wrappers</td>
<td>When <strong>inclusive=false</strong>, checks that the annotated value is less than the specified maximum. Otherwise, checks that the value is less than or equal to the specified maximum. The <strong>value</strong> parameter specifies the maximum in <strong>BigDecimal</strong> string format.</td>
</tr>
<tr>
<td>@DecimalMin(value=, inclusive=)</td>
<td>BigDecimal, BigInteger, CharSequence, byte, short, int, long and primitive type wrappers</td>
<td>When <strong>inclusive=false</strong>, checks that the annotated value is greater than the specified minimum. Otherwise, checks that the value is greater than or equal to the specified minimum. The <strong>value</strong> parameter specifies the minimum in <strong>BigDecimal</strong> string format.</td>
</tr>
<tr>
<td>@Digits(integer=, fraction=)</td>
<td>BigDecimal, BigInteger, CharSequence, byte, short, int, long and primitive type wrappers</td>
<td>Checks whether the annotated value is a number having up to <strong>integer</strong> digits and <strong>fraction</strong> fractional digits.</td>
</tr>
<tr>
<td>@Future</td>
<td>java.util.Date, java.util.Calendar</td>
<td>Checks whether the annotated date is in the future.</td>
</tr>
<tr>
<td>@Max(value=)</td>
<td>BigDecimal, BigInteger, CharSequence, byte, short, int, long and primitive type wrappers</td>
<td>Checks whether the annotated value is less than or equal to the specified maximum.</td>
</tr>
<tr>
<td>@Min(value=)</td>
<td>BigDecimal, BigInteger, CharSequence, byte, short, int, long and primitive type wrappers</td>
<td>Checks whether the annotated value is greater than or equal to the specified minimum.</td>
</tr>
<tr>
<td>@NotNull</td>
<td>Any type</td>
<td>Checks that the annotated value is not <strong>null</strong>.</td>
</tr>
<tr>
<td>@Null</td>
<td>Any type</td>
<td>Checks that the annotated value is <strong>null</strong>.</td>
</tr>
<tr>
<td>Annotation</td>
<td>Applicable to</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>--------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>@Past</td>
<td>java.util.Date, java.util.Calendar</td>
<td>Checks whether the annotated date is in the past.</td>
</tr>
<tr>
<td>@Pattern(regex=, flag=)</td>
<td>CharSequence</td>
<td>Checks whether the annotated string matches the regular expression regex considering the given flag match.</td>
</tr>
<tr>
<td>@Size(min=, max=)</td>
<td>CharSequence, Collection, Map and arrays</td>
<td>Checks whether the size of the annotated collection, map, or array lies between min and max (inclusive).</td>
</tr>
<tr>
<td>@Valid</td>
<td>Any non-primitive type</td>
<td>Performs validation recursively on the annotated object. If the object is a collection or an array, the elements are validated recursively. If the object is a map, the value elements are validated recursively.</td>
</tr>
</tbody>
</table>

### 65.2.3. Custom Annotations

#### Defining custom constraints in Hibernate

It is possible to define your own custom constraints annotations with the bean validation API. For details of how to do this in the Hibernate validator implementation, see the Creating custom constraints chapter of the Hibernate Validator Reference Guide.

### 65.3. CONFIGURING BEAN VALIDATION

#### 65.3.1. JAX-WS Configuration

#### Overview

This section describes how to enable bean validation on a JAX-WS service endpoint, which is defined either in Blueprint XML or in Spring XML. The interceptors used to perform bean validation are common to both JAX-WS endpoints and JAX-RS 1.1 endpoints (JAX-RS 2.0 endpoints use different interceptor classes, however).

#### Namespaces

In the XML examples shown in this section, you must remember to map the jaxws namespace prefix to the appropriate namespace, either for Blueprint or Spring, as shown in the following table:
Bean validation feature

The simplest way to enable bean validation on a JAX-WS endpoint is to add the bean validation feature to the endpoint. The bean validation feature is implemented by the following class:

`org.apache.cxf.validation.BeanValidationFeature`

By adding an instance of this feature class to the JAX-WS endpoint (either through the Java API or through the `jaxws:features` child element of `jaxws:endpoint` in XML), you can enable bean validation on the endpoint. This feature installs two interceptors: an In interceptor that validates incoming message data; and an Out interceptor that validates return values (where the interceptors are created with default configuration parameters).

Sample JAX-WS configuration with bean validation feature

The following XML example shows how to enable bean validation functionality in a JAX-WS endpoint, by adding the `commonValidationFeature` bean to the endpoint as a JAX-WS feature:

```xml
<jaxws:endpoint xmlns:s="http://bookworld.com"  
    serviceName="s:BookWorld"  
    endpointName="s:BookWorldPort"  
    implementor="#bookWorldValidation"  
    address="/bwsoap">
    <jaxws:features>
        <ref bean="commonValidationFeature" />
    </jaxws:features>
</jaxws:endpoint>

<bean id="bookWorldValidation"  
    class="org.apache.cxf.systest.jaxrs.validation.spring.BookWorldImpl"/>

<bean id="commonValidationFeature" class="org.apache.cxf.validation.BeanValidationFeature">  
    <property name="provider" ref="beanValidationProvider"/>
</bean>

<bean id="beanValidationProvider" class="org.apache.cxf.validation.BeanValidationProvider">  
    <constructor-arg ref="validationProviderResolver"/>
</bean>

<bean id="validationProviderResolver" class="org.example.HibernateValidationProviderResolver"/>
```

For a sample implementation of the `HibernateValidationProviderResolver` class, see the section called “Example HibernateValidationProviderResolver class”. It is only necessary to configure the `beanValidationProvider` in the context of an OSGi environment (Apache Karaf).
NOTE

Remember to map the jaxws prefix to the appropriate XML namespace for either Blueprint or Spring, depending on the context.

Common bean validation 1.1 interceptors

If you want to have more fine-grained control over the configuration of the bean validation, you can install the interceptors individually, instead of using the bean validation feature. In place of the bean validation feature, you can configure one or both of the following interceptors:

**org.apache.cxf.validation.BeanValidationInInterceptor**

When installed in a JAX-WS (or JAX-RS 1.1) endpoint, validates resource method parameters against validation constraints. If validation fails, raises the javax.validation.ConstraintViolationException exception. To install this interceptor, add it to the endpoint through the jaxws:inInterceptors child element in XML (or the jaxrs:inInterceptors child element in XML).

**org.apache.cxf.validation.BeanValidationOutInterceptor**

When installed in a JAX-WS (or JAX-RS 1.1) endpoint, validates response values against validation constraints. If validation fails, raises the javax.validation.ConstraintViolationException exception. To install this interceptor, add it to the endpoint through the jaxws:outInterceptors child element in XML (or the jaxrs:outInterceptors child element in XML).

Sample JAX-WS configuration with bean validation interceptors

The following XML example shows how to enable bean validation functionality in a JAX-WS endpoint, by explicitly adding the relevant **In** interceptor bean and **Out** interceptor bean to the endpoint:

```xml
<jaxws:endpoint xmlns:s="http://bookworld.com"
 serviceName="s:BookWorld"
 endpointName="s:BookWorldPort"
 implementor="#bookWorldValidation"
 address="/bwsoap">
  <jaxws:inInterceptors>
    <ref bean="validationInInterceptor" />
  </jaxws:inInterceptors>

  <jaxws:outInterceptors>
    <ref bean="validationOutInterceptor" />
  </jaxws:outInterceptors>
</jaxws:endpoint>

<bean id="bookWorldValidation"
 class="org.apache.cxf.systest.jaxrs.validation.spring.BookWorldImpl"/>

<bean id="validationInInterceptor" class="org.apache.cxf.validation.BeanValidationInInterceptor">
  <property name="provider" ref="#beanValidationProvider"/>
</bean>

<bean id="validationOutInterceptor" class="org.apache.cxf.validation.BeanValidationOutInterceptor">
  <property name="provider" ref="#beanValidationProvider"/>
</bean>

<bean id="beanValidationProvider" class="org.apache.cxf.validation.BeanValidationProvider">
  <constructor-arg ref="validationProviderResolver"/>
</bean>
```
For a sample implementation of the `HibernateValidationProviderResolver` class, see the section called “Example HibernateValidationProviderResolver class”. It is only necessary to configure the `beanValidationProvider` in the context of an OSGi environment (Apache Karaf).

### Configuring a `BeanValidationProvider`

The `org.apache.cxf.validation.BeanValidationProvider` is a simple wrapper class that wraps the bean validation implementation (`validation provider`). By overriding the default `BeanValidationProvider` class, you can customize the implementation of bean validation. The `BeanValidationProvider` bean enables you to override one or more of the following provider classes:

- **javax.validation.ParameterNameProvider**
  Provides names for method and constructor parameters. Note that this class is needed, because the Java reflection API does not give you access to the names of method parameters or constructor parameters.

- **javax.validation.spi.ValidationProvider<T>**
  Provides an implementation of bean validation for the specified type, `T`. By implementing your own `ValidationProvider` class, you can define custom validation rules for your own classes. This mechanism effectively enables you to extend the bean validation framework.

- **javax.validation.ValidationProviderResolver**
  Implements a mechanism for discovering `ValidationProvider` classes and returns a list of the discovered classes. The default resolver looks for a `META-INF/services/javax.validation.spi.ValidationProvider` file on the classpath, which should contain a list of `ValidationProvider` classes.

- **javax.validation.ValidatorFactory**
  A factory that returns `javax.validation.Validator` instances.

- **org.apache.cxf.validation.ValidationConfiguration**
  A CXF wrapper class that enables you override more classes from the validation provider layer.

To customize the `BeanValidationProvider`, pass a custom `BeanValidationProvider` instance to the constructor of the validation `In` interceptor and to the constructor of the validation `Out` interceptor. For example:

```xml
<bean id="validationProvider" class="org.apache.cxf.validation.BeanValidationProvider" />

<bean id="validationInInterceptor" class="org.apache.cxf.validation.BeanValidationInInterceptor">
  <property name="provider" ref="validationProvider" />
</bean>

<bean id="validationOutInterceptor" class="org.apache.cxf.validation.BeanValidationOutInterceptor">
  <property name="provider" ref="validationProvider" />
</bean>
```

### 65.3.2. JAX-RS Configuration

#### Overview
This section describes how to enable bean validation on a JAX-RS service endpoint, which is defined either in Blueprint XML or in Spring XML. The interceptors used to perform bean validation are common to both JAX-WS endpoints and JAX-RS 1.1 endpoints (JAX-RS 2.0 endpoints use different interceptor classes, however).

**Namespaces**

In the XML examples shown in this section, you must remember to map the `jaxws` namespace prefix to the appropriate namespace, either for Blueprint or Spring, as shown in the following table:

<table>
<thead>
<tr>
<th>XML Language</th>
<th>Namespace</th>
</tr>
</thead>
<tbody>
<tr>
<td>Blueprint</td>
<td><code>http://cxf.apache.org/blueprint/jaxws</code></td>
</tr>
<tr>
<td>Spring</td>
<td><code>http://cxf.apache.org/jaxws</code></td>
</tr>
</tbody>
</table>

**Bean validation feature**

The simplest way to enable bean validation on a JAX-RS endpoint is to add the bean validation feature to the endpoint. The bean validation feature is implemented by the following class:

`org.apache.cxf.validation.BeanValidationFeature`

By adding an instance of this feature class to the JAX-RS endpoint (either through the Java API or through the `jaxrs:features` child element of `jaxrs:server` in XML), you can enable bean validation on the endpoint. This feature installs two interceptors: an In interceptor that validates incoming message data; and an Out interceptor that validates return values (where the interceptors are created with default configuration parameters).

**Validation exception mapper**

A JAX-RS endpoint also requires you to configure a validation exception mapper, which is responsible for mapping validation exceptions to HTTP error responses. The following class implements validation exception mapping for JAX-RS:

`org.apache.cxf.jaxrs.validation.ValidationExceptionMapper`

Implements validation exception mapping in accordance with the JAX-RS 2.0 specification: any input parameter validation violations are mapped to HTTP status code 400 Bad Request; and any return value validation violation (or internal validation violation) is mapped to HTTP status code 500 Internal Server Error.

**Sample JAX-RS configuration**

The following XML example shows how to enable bean validation functionality in a JAX-RS endpoint, by adding the `commonValidationFeature` bean as a JAX-RS feature and by adding the `exceptionMapper` bean as a JAX-RS provider:

```xml
<jaxrs:server address="/bwrest">
  <jaxrs:serviceBeans>
    <ref bean="bookWorldValidation"/>
  </jaxrs:serviceBeans>
  <jaxrs:providers>
    <ref bean="exceptionMapper"/>
  </jaxrs:providers>
</jaxrs:server>
```
For a sample implementation of the `HibernateValidationProviderResolver` class, see the section called "Example HibernateValidationProviderResolver class". It is only necessary to configure the `beanValidationProvider` in the context of an OSGi environment (Apache Karaf).

**NOTE**

Remember to map the `jaxrs` prefix to the appropriate XML namespace for either Blueprint or Spring, depending on the context.

**Common bean validation 1.1 interceptors**

Instead of using the bean validation feature, you can optionally install bean validation interceptors to get more fine-grained control over the validation implementation. JAX-RS uses the same interceptors as JAX-WS for this purpose—see the section called "Common bean validation 1.1 interceptors".

**Sample JAX-RS configuration with bean validation interceptors**

The following XML example shows how to enable bean validation functionality in a JAX-RS endpoint, by explicitly adding the relevant `In` interceptor bean and `Out` interceptor bean to the server endpoint:

```xml
<jaxrs:server address="/"
  <jaxrs:inInterceptors>
    <ref bean="validationInInterceptor" />
  </jaxrs:inInterceptors>

  <jaxrs:outInterceptors>
    <ref bean="validationOutInterceptor" />
  </jaxrs:outInterceptors>

  <jaxrs:serviceBeans>
    ...
  </jaxrs:serviceBeans>

  <jaxrs:providers>
    <ref bean="exceptionMapper"/>
  </jaxrs:providers>
```
Configuring a BeanValidationProvider

You can inject a custom BeanValidationProvider instance into the validation interceptors, as described in the section called "Configuring a BeanValidationProvider".

65.3.3. JAX-RS 2.0 Configuration

Overview

Unlike JAX-RS 1.1 (which shares common validation interceptors with JAX-WS), the JAX-RS 2.0 configuration relies on dedicated validation interceptor classes that are specific to JAX-RS 2.0.

Bean validation feature

For JAX-RS 2.0, there is a dedicated bean validation feature, which is implemented by the following class:

org.apache.cxf.validation.JAXRSBeanValidationFeature

By adding an instance of this feature class to the JAX-RS endpoint (either through the Java API or through the jaxrs:features child element of jaxrs:server in XML), you can enable bean validation on a JAX-RS 2.0 server endpoint. This feature installs two interceptors: an In interceptor that validates incoming message data; and an Out interceptor that validates return values (where the interceptors are created with default configuration parameters).

Validation exception mapper

JAX-RS 2.0 uses the same validation exception mapper class as JAX-RS 1.x:

org.apache.cxf.jaxrs.validation/validationExceptionMapper

Implements validation exception mapping in accordance with the JAX-RS 2.0 specification: any input parameter validation violations are mapped to HTTP status code 400 Bad Request; and any return
value validation violation (or internal validation violation) is mapped to HTTP status code 500 Internal Server Error.

Bean validation invoker

If you configure the JAX-RS service with a non-default lifecycle policy (for example, using Spring lifecycle management), you should also register a org.apache.cxf.jaxrs.validation.JAXRSBeanValidationInvoker instance—using the jaxrs:invoker element in the endpoint configuration—with the service endpoint, to ensure that bean validation is invoked correctly.

For more details about JAX-RS service lifecycle management, see the section called “Lifecycle management in Spring XML”.

Sample JAX-RS 2.0 configuration with bean validation feature

The following XML example shows how to enable bean validation functionality in a JAX-RS 2.0 endpoint, by adding the jaxrsValidationFeature bean as a JAX-RS feature and by adding the exceptionMapper bean as a JAX-RS provider:

```xml
<jaxrs:server address="/"
   
   <jaxrs:serviceBeans>
   ...
   </jaxrs:serviceBeans>
   
   <jaxrs:providers>
   
   <ref bean="exceptionMapper"/>
   </jaxrs:providers>
   
   <jaxrs:features>
   
   <ref bean="jaxrsValidationFeature"/>
   </jaxrs:features>
   </jaxrs:server>

<bean id="exceptionMapper" class="org.apache.cxf.jaxrs.validation.ValidationExceptionMapper"/>
<bean id="jaxrsValidationFeature" class="org.apache.cxf.validation.JAXRSBeanValidationFeature">
   <property name="provider" ref="beanValidationProvider"/>
</bean>

<bean id="beanValidationProvider" class="org.apache.cxf.validation.BeanValidationProvider">
   <constructor-arg ref="validationProviderResolver"/>
</bean>

<bean id="validationProviderResolver" class="org.example.HibernateValidationProviderResolver"/>

For a sample implementation of the HibernateValidationProviderResolver class, see the section called “Example HibernateValidationProviderResolver class”. It is only necessary to configure the beanValidationProvider in the context of an OSGi environment (Apache Karaf).

NOTE

Remember to map the jaxrs prefix to the appropriate XML namespace for either Blueprint or Spring, depending on the context.

Common bean validation 1.1 interceptors
If you want to have more fine-grained control over the configuration of the bean validation, you can install the JAX-RS interceptors individually, instead of using the bean validation feature. Configure one or both of the following JAX-RS interceptors:

**org.apache.cxf.validation.JAXRSBeanValidationInInterceptor**

When installed in a JAX-RS 2.0 server endpoint, validates resource method parameters against validation constraints. If validation fails, raises the `javax.validation.ConstraintViolationException` exception. To install this interceptor, add it to the endpoint through the `jaxrs:inInterceptors` child element in XML.

**org.apache.cxf.validation.JAXRSBeanValidationOutInterceptor**

When installed in a JAX-RS 2.0 endpoint, validates response values against validation constraints. If validation fails, raises the `javax.validation.ConstraintViolationException` exception. To install this interceptor, add it to the endpoint through the `jaxrs:outInterceptors` child element in XML.

**Sample JAX-RS 2.0 configuration with bean validation interceptors**

The following XML example shows how to enable bean validation functionality in a JAX-RS 2.0 endpoint, by explicitly adding the relevant In interceptor bean and Out interceptor bean to the server endpoint:

```xml
<jaxrs:server address="/">
  <jaxrs:inInterceptors>
    <ref bean="validationInInterceptor" />
  </jaxrs:inInterceptors>

  <jaxrs:outInterceptors>
    <ref bean="validationOutInterceptor" />
  </jaxrs:outInterceptors>

  <jaxrs:serviceBeans>
    ...
  </jaxrs:serviceBeans>

  <jaxrs:providers>
    <ref bean="exceptionMapper"/>
  </jaxrs:providers>
</jaxrs:server>

<bean id="exceptionMapper" class="org.apache.cxf.jaxrs.validation.ValidationExceptionMapper"/>

<bean id="validationInInterceptor" class="org.apache.cxf.jaxrs.validation.JAXRSBeanValidationInInterceptor">
  <property name="provider" ref="beanValidationProvider" />
</bean>

<bean id="validationOutInterceptor" class="org.apache.cxf.jaxrs.validation.JAXRSBeanValidationOutInterceptor">
  <property name="provider" ref="beanValidationProvider" />
</bean>

<bean id="beanValidationProvider" class="org.apache.cxf.validation.BeanValidationProvider">
  <constructor-arg ref="validationProviderResolver"/>
</bean>

<bean id="validationProviderResolver" class="org.example.HibernateValidationProviderResolver"/>
```
For a sample implementation of the `HibernateValidationProviderResolver` class, see the section called “Example HibernateValidationProviderResolver class”. It is only necessary to configure the `beanValidationProvider` in the context of an OSGi environment (Apache Karaf).

**Configuring a BeanValidationProvider**

You can inject a custom `BeanValidationProvider` instance into the validation interceptors, as described in the section called “Configuring a BeanValidationProvider”.

**Configuring a JAXRSPParameterNameProvider**

The `org.apache.cxf.jaxrs.validation.JAXRSPParameterNameProvider` class is an implementation of the `javax.validation.ParameterNameProvider` interface, which can be used to provide the names for method and constructor parameters in the context of JAX-RS 2.0 endpoints.
