Red Hat JBoss Enterprise Application Platform 7.4

Migration Guide

Instructions for migrating applications from one major Red Hat JBoss Enterprise Application Platform version to the next.
Instructions for migrating applications from one major Red Hat JBoss Enterprise Application Platform version to the next.
Abstract

This guide provides information about how to migrate your application from previous versions of Red Hat JBoss Enterprise Application Platform.

4.19. CHANGES TO MOD_CLUSTER CONFIGURATION
4.20. VIEWING CONFIGURATION CHANGES

CHAPTER 5. APPLICATION MIGRATION CHANGES

5.1. WEB SERVICES APPLICATION CHANGES
  5.1.1. JAX-RPC support changes
  5.1.2. Apache CXF Spring web services changes
     Apache CXF interceptors
     Apache CXF features
     Apache CXF HTTP transport
  5.1.3. WS-Security changes
  5.1.4. JBoss modules structure change
  5.1.5. Bouncy Castle requirements and changes
  5.1.6. Apache CXF bus selection strategy
  5.1.7. Jakarta XML Web Services 2.2 requirements for WebServiceRef
  5.1.8. IgnoreHttpsHost CN check change
  5.1.9. Server-side configuration and class loading
  5.1.10. Deprecation of Java-endorsed standards override mechanism
  5.1.11. Specification of descriptor in EAR archive

5.2. UPDATE THE REMOTE URL CONNECTOR AND PORT

5.3. MESSAGING APPLICATION CHANGES
  5.3.1. Replace or update Jakarta Messaging deployment descriptors
  5.3.2. Update external Jakarta Messaging clients
  5.3.3. Replace the HornetQ API
  5.3.4. Replace Deprecated Address Setting Attributes
  5.3.5. Messaging Application Changes Required for JBoss EAP 7

5.4. JAX-RS AND RESTEASY APPLICATION CHANGES
  5.4.1. RESTEasy Deprecated Classes
     Interceptor and MessageBody Classes
     Client API
     StringConverter
  5.4.2. Removed or Protected RESTEasy Classes
     ResteasyProviderFactory Add methods
     Additional Classes Removed From RESTEasy 3
  5.4.3. Additional RESTEasy Changes
     SignedInput and SignedOuput
     Security Filters
     Client-side Filters
     Asynchronous HTTP Support
     Server-side Cache
     YAML Provider Setting Changes
     Default Charset UTF-8 in Content-Type Header
     SerializableProvider
     Matching Requests to Resource Methods
     Resource Method Algorithm Switch
  5.4.4. RESTEasy SPI Changes
     SPI Exceptions
     InjectorFactory and Registry
  5.4.5. Jackson Provider Changes
  5.4.6. Spring RESTEasy Integration Changes
  5.4.7. RESTEasy Jettison JSON Provider Changes
  5.4.8. Changes Required in MicroProfile Rest Client Code

5.5. CDI APPLICATION CHANGES
Bean Archives 77
Clarification of Conversation Resolution 78
Observer Resolution 78

5.6. HTTP SESSION ID CHANGE 79

5.7. MIGRATE EXPLICIT MODULE DEPENDENCIES 79
Review Dependencies for Availability 79
Dependencies That Require Annotation Scanning 79

5.8. HIBERNATE AND JAKARTA PERSISTENCE MIGRATION CHANGES 80
5.8.1. Hibernate ORM 3.0 80
5.8.2. Hibernate ORM 4.0 - 4.3 80
5.8.3. Migrating to Hibernate ORM 5 80
 Removed and deprecated classes 80
 Other changes to classes and packages 80
 Type handling 81
 Transaction management 81
 Other Hibernate ORM 5 changes 82
5.8.4. Migrating from Hibernate ORM 5.0 to Hibernate ORM 5.1 82
 Hibernate ORM 5.1 features 82
 Schema management tooling changes 83
 Schema management tooling changes in JBoss EAP 7 83
 Schema management tooling changes in JBoss EAP 7.1 83
5.8.5. Migrating from Hibernate ORM 5.1 to Hibernate ORM 5.3 83
 Hibernate ORM 5.2 features 83
 Hibernate ORM 5.3 features 84
 5.8.5.1. Exception handling changes between Hibernate 5.1 and Hibernate 5.3 85
 5.8.5.2. Compatibility transformer 85
5.9. HIBERNATE SEARCH CHANGES 86
Hibernate search mapping changes 86
 Indexing of ID fields of embedded relations 86
 Number and date index formatting changes 87
 Miscellaneous Hibernate search changes 87
 Hibernate search renamed and repackaged classes 88
 Lucene: Renamed and repackaged classes 88
 Hibernate search deprecated APIs 89
 Hibernate search deprecated interfaces 89
 Hibernate search deprecated classes 89
 Hibernate search deprecated enums 89
 Hibernate search deprecated annotations 89
 Hibernate search deprecated methods 90
 Hibernate search deprecated constructors 90
 Changes impacting advanced integrators 90
5.10. MIGRATE ENTITY BEANS TO JAKARTA PERSISTENCE 91
5.11. JAKARTA PERSISTENCE PROPERTY CHANGES 93
 Jakarta Persistence property changes introduced in JBoss EAP 7.0 93
 Jakarta Persistence property changes introduced in JBoss EAP 7.1 93
5.12. MIGRATE JAKARTA ENTERPRISE BEANS CLIENT CODE 94
 5.12.1. Jakarta Enterprise Beans client changes in JBoss EAP 7 94
 5.12.1.1. Update the default remote connection port 94
 5.12.1.2. Update the default connector 95
 5.12.2. Migrate Remote Naming Client Code 95
 5.12.3. Additional JBoss EJB client changes introduced in JBoss EAP 7.1 95
 5.12.4. EJB client changes required for JBoss EAP 7 99
5.13. MIGRATE CLIENTS TO USE THE WILDFLY CONFIGURATION FILE 100
5.14. MIGRATE DEPLOYMENT PLAN CONFIGURATIONS
5.15. MIGRATE CUSTOM APPLICATION VALVES
   Migrate Valves Configured in Deployments
   Migrate Custom Authenticator Valves
5.16. SECURITY APPLICATION CHANGES
   5.16.1. Migrate Authenticator Valves
   5.16.2. PicketLink Changes
   5.16.3. Other Security Application Changes
5.17. JBOSS LOGGING CHANGES
5.18. JAKARTA SERVER FACES CODE CHANGES
   Dropped support for Jakarta Server Faces 1.2
5.19. MODULE CLASS LOADING CHANGES
5.20. APPLICATION CLUSTERING CHANGES
   5.20.1. Overview of New Clustering Features
   5.20.2. Web Session Clustering Changes
   5.20.3. Overriding the Default Distributable Session Management Behavior
           - Referencing an existing session management profile
           - Using a Deployment-specific Session Management Profile
   5.20.4. Stateful session EJB clustering changes
   5.20.5. Clustering Services Changes
   5.20.6. Migrate Clustering HA Singleton

CHAPTER 6. MISCELLANEOUS CHANGES .......................................................... 110
6.1. CHANGES TO DELIVERY OF JBOSS EAP NATIVES AND APACHE HTTP SERVER
6.2. CHANGES TO DEPLOYMENTS ON AMAZON EC2
6.3. UNDEPLOYING APPLICATIONS THAT INCLUDE SHARED MODULES
6.4. CHANGES TO JBOSS EAP SCRIPTS
6.5. REMOVAL OF OSGI SUPPORT
6.6. CHANGES TO JAVA PLATFORM MODULE SYSTEM NAMES
6.7. CHANGES IN SOAP WITH ATTACHMENTS API FOR JAVA
6.8. MAVEN ARTIFACT CHANGES FOR JAKARTA EE

CHAPTER 7. MIGRATING TO ELYTRON ....................................................... 115
7.1. OVERVIEW OF ELYTRON
7.2. MIGRATE SECURE VAULTS AND PROPERTIES
   7.2.1. Migrate Vaults to Secure Credential Storage
          - Migrating Vault Data Using the WildFly Elytron Tool
          - Migrate a Single Security Vault to a Credential Store
          - Migrate Multiple Security Vaults to a Credential Store in Bulk
   7.2.2. Migrate Security Properties to Elytron
7.3. MIGRATE AUTHENTICATION CONFIGURATION
   7.3.1. Migrate Properties-based Authentication and Authorization to Elytron
          7.3.1.1. Migrate PicketBox Properties-based Configuration to Elytron
                   - Partially Migrate by Exposing the PicketBox Security Domain to Elytron
                   - Fully Migrate Properties-based Authentication to Elytron
          7.3.1.2. Migrate Legacy Properties-based Configuration to Elytron
   7.3.2. Migrate to Filesystem-based Security Realm Using the filesystem-realm Command
   7.3.3. Migrate LDAP Authentication Configuration to Elytron
          7.3.3.1. Migrate the Legacy LDAP Authentication to Elytron
   7.3.4. Migrate Database Authentication Configuration to Elytron
          7.3.4.1. Migrate the Legacy Database Authentication to Elytron
   7.3.5. Migrate Kerberos Authentication to Elytron
          - Migrate Kerberos HTTP Authentication
Migrate the Kerberos HTTP Authentication to Elytron
Migrate Kerberos Remoting SASL Authentication
Migrate the Kerberos Remoting SASL Authentication to Elytron
7.3.6. Migrate Composite Stores to Elytron
PicketBox Composite Store Configuration
Legacy Security Realm Composite Store Configuration
Elytron Aggregate Security Realm Configuration
7.3.7. Migrate Security Domains That Use Caching to Elytron
PicketBox Cached Security Domain Configuration
Elytron Cached Security Domain Configuration
7.3.8. Migrate Jakarta Authorization Security to Elytron
7.4. MIGRATE APPLICATION CLIENTS
7.4.1. Migrate a Naming Client Configuration to Elytron
7.4.1.1. Migrate the Naming Client Using the Configuration File Approach
7.4.1.2. Migrate the Naming Client Using the Programmatic Approach
7.4.2. Migrate a Jakarta Enterprise Beans client to Elytron
7.4.2.1. Migrate the Jakarta Enterprise Beans client using a configuration file
7.4.2.2. Migrate the Jakarta Enterprise Beans client programmatically
7.5. MIGRATE SSL CONFIGURATIONS
7.5.1. Migrate a Simple SSL Configuration to Elytron
7.5.2. Migrate CLIENT-CERT SSL Authentication to Elytron
Legacy truststore Containing Only CA
Realms and Domains
Principal Decoder
HTTP Authentication Factory
CHAPTER 8. MIGRATING FROM OLDER RELEASES OF JBOSS EAP 156
8.1. MIGRATING FROM JBOSS EAP 5 TO JBOSS EAP 7 156
8.2. SUMMARY OF CHANGES MADE TO EACH RELEASE 156
8.3. REVIEW THE CONTENT IN THE MIGRATION GUIDES 157
8.4. JBOSS EAP 5 COMPONENT UPGRADE REFERENCE 157
APPENDIX A. REFERENCE MATERIAL 164
A.1. JACORB SUBSYSTEM MIGRATION OPERATION WARNINGS 164
A.2. MESSAGING SUBSYSTEM MIGRATION OPERATION WARNINGS 165
Replace the Deprecated broadcast-group or discovery-group Attributes 168
A.3. WEB SUBSYSTEM MIGRATION OPERATION WARNINGS 169
Web Subsystem Migration Operation Attribute Warnings
Web SSL Connector Attributes
Web Static Resource Attributes
Web SSO Resource Attributes
Web Access Log Attributes
Web Connector Attributes
A.4. MIGRATE JBOSS WEB SYSTEM PROPERTIES REFERENCE 175
A.5. COMPATIBILITY AND INTEROPERABILITY BETWEEN RELEASES 183
Enterprise beans remoting over IIOP 183
Enterprise beans remoting using Java Naming and Directory Interface 183
Enterprise beans remoting Using @WebService 184
Messaging Standalone Client 184
Messaging MDBs 184
Messaging bridges 185
PROVIDING FEEDBACK ON RED HAT DOCUMENTATION

We appreciate your feedback on our documentation. To provide feedback, you can highlight the text in a document and add comments. Follow the steps in the procedure to learn about submitting feedback on Red Hat documentation.

Prerequisites

- Log in to the Red Hat Customer Portal.
- In the Red Hat Customer Portal, view the document in Multi-page HTML format.

Procedure

1. Click Feedback to see existing reader comments.

   NOTE
   The feedback feature is enabled only in the Multi-page HTML format.

2. Highlight the section of the document where you want to provide feedback.

3. In the prompt menu that displays near the text you selected, click Add Feedback. A text box opens in the feedback section on the right side of the page.

4. Enter your feedback in the text box and click Submit. You have created a documentation issue.

5. To view the issue, click the issue tracker link in the feedback view.
MAKING OPEN SOURCE MORE INCLUSIVE

Red Hat is committed to replacing problematic language in our code, documentation, and web properties. We are beginning with these four terms: master, slave, blacklist, and whitelist. Because of the enormity of this endeavor, these changes will be implemented gradually over several upcoming releases. For more details, see our CTO Chris Wright’s message.
CHAPTER 1. INTRODUCTION

This guide documents the changes required to successfully run and deploy Red Hat JBoss Enterprise Application Platform 6 applications on Red Hat JBoss Enterprise Application Platform 7. It provides information about the new features available in this release, the deprecated and unsupported features, and any application and server configuration updates that might be required to prevent changes in application behavior.

It also provides information about tools that can help with the migration, such as Migration Toolkit for Applications, which simplifies migration of Java applications, and the JBoss Server Migration Tool, which updates the server configuration.

Once the application is successfully deployed and running, plans can be made to upgrade individual components to use the new functions and features of JBoss EAP 7.

If you plan to migrate your JBoss EAP 5 applications directly to JBoss EAP 7, see Migrating from Older Releases of JBoss EAP.

1.1. ABOUT MIGRATIONS AND UPGRADES

Major Upgrades

A major upgrade or migration is required when an application is moved from one major release to another, for example, from JBoss EAP 6.4 to JBoss EAP 7.0. If an application follows the Jakarta EE specifications, does not access deprecated APIs, and does not contain proprietary code, it might be possible to run the application in JBoss EAP 7 without any application code changes. However, the server configuration has changed in JBoss EAP 7 and requires migration. This type of migration is addressed in this guide.

Minor Updates

JBoss EAP periodically provides point releases, which are minor updates that include bug fixes, security fixes, and new features. Information about the changes made in a point release are documented in this guide and in the 7.3.0 Release Notes.

You can use the JBoss Server Migration Tool to automatically upgrade from one point release to another, for example from JBoss EAP 7.0 to JBoss EAP 7.1. For information about how to configure and run the tool, see Using the JBoss Server Migration Tool.

If you prefer, you can perform a manual upgrade of the server configuration. Instructions on how to perform a manual upgrade are documented in Upgrading JBoss EAP in the JBoss EAP Patching and Upgrading Guide.

Cumulative Patches

JBoss EAP also periodically provides cumulative patches that contain bug and security fixes. Cumulative patches increment the release by the last digit, for example from 7.1.0 to 7.1.1. Patch installation is addressed in the JBoss EAP Patching and Upgrading Guide.

1.2. ABOUT THE USE OF EAP_HOME IN THIS DOCUMENT

In this document, the variable EAP_HOME is used to denote the path to the JBoss EAP installation. Replace this variable with the actual path to your JBoss EAP installation.

- If you installed JBoss EAP using the ZIP install method, the install directory is the jboss-eap-7.4 directory where you extracted the ZIP archive.
If you installed JBoss EAP using the RPM install method, the install directory is
/opt/rh/eap7/root/usr/share/wildfly/.

If you used the installer to install JBoss EAP, the default path for EAP_HOME is
${user.home}/EAP-7.4.0:
  - For Red Hat Enterprise Linux and Solaris: /home/USER_NAME/EAP-7.4.0/
  - For Microsoft Windows: C:/Users/USER_NAME/EAP-7.4.0/

If you used the Red Hat CodeReady Studio installer to install and configure the JBoss EAP
server, the default path for EAP_HOME is ${user.home}/devstudio/runtimes/jboss-eap:
  - For Red Hat Enterprise Linux: /home/USER_NAME/devstudio/runtimes/jboss-eap/
  - For Microsoft Windows: C:/Users/USER_NAME/devstudio/runtimes/jboss-eap or
    C:/Documents and Settings/USER_NAME/devstudio/runtimes/jboss-eap

**NOTE**
If you set the Target runtime to 7.4 or a later runtime version in Red Hat CodeReady
Studio, your project is compatible with the Jakarta EE 8 specification.

**NOTE**
EAP_HOME is not an environment variable. JBOSS_HOME is the environment variable
used in scripts.
CHAPTER 2. PREPARATION FOR MIGRATION

NOTE

Oracle donated the Java EE 8 TCKs to Jakarta EE which are used by Jakarta EE 8 implementations (for example, like JBoss EAP) to become Jakarta EE 8 compatible. Jakarta EE 8 APIs are equivalent to Java EE 8 APIs. Jakarta EE 8 Specifications (technologies) are equivalent to Java EE 8 Specifications (technologies).

2.1. PREPARATION OVERVIEW

In JBoss EAP 7, an effort was made to provide backward compatibility for JBoss EAP 6 applications. However, if your application uses features that were deprecated or functionality that was removed from JBoss EAP 7, you might need to make changes to your application code.

In addition, a number of things have changed in this release that might impact deployment of JBoss EAP 7 applications. It is recommended that you do some research and planning before you attempt to migrate your application.

- Become familiar with the features of Jakarta EE 8.
- Review the list of deprecated and unsupported features.
- Review the material in the JBoss EAP 7 Getting Started Guide.
- Take a look at the tools that can help with migration tasks.

Once you are comfortable with the feature changes, the development materials, and the tools that can assist your migration efforts, you can begin to evaluate your applications and your server configuration to determine the changes that are needed to run in JBoss EAP 7.

2.2. REVIEW THE JAKARTA EE 8 FEATURES

Jakarta EE 8 includes many improvements to make it easier to develop and run feature rich applications on private and public clouds. It incorporated new features and the latest standards such as HTML5, WebSocket, JSON, Batch, and Concurrency Utilities. Updates included Jakarta Persistence 2.2, Jakarta RESTful Web Services 2.1, Jakarta Servlet 4.0, Jakarta Expression Language 3.0, Jakarta Messaging 2.0, Jakarta Server Faces 2.3, Jakarta Enterprise Beans 3.2, Contexts and Dependency Injection 2.0, and Jakarta Bean Validation 2.0.

You can find more information about Jakarta EE 8 on Jakarta EE Platform 8.

2.3. REVIEW THE JAVA EE 7 FEATURES

If you are migrating from JBoss EAP 6.4, Java EE 7 includes many improvements to make it easier to develop and run feature rich applications on private and public clouds. It incorporates new features and the latest standards such as HTML5, WebSocket, JSON, Batch, and Concurrency Utilities. Updates include JPA 2.1, JAX–RS 2.0, Servlet 3.1, Expression Language 3.0, JMS 2.0, JSF 2.2, EJB 3.2, CDI 1.2, and Bean Validation 1.1.

You can find more information about Java EE 7, including tutorials, on Oracle’s web site: Java™ EE Documentation.
2.4. REVIEW WHAT’S NEW IN JBOSS EAP 7

JBoss EAP 7 includes some notable upgrades and improvements over previous releases. This section highlights some of the new features and enhancements that have been introduced in the JBoss EAP 7 point releases.

New Features and Enhancements Introduced JBoss EAP 7.0

Jakarta EE 8

JBoss EAP 7 is a certified implementation of Jakarta EE 8, meeting both the Web Profile and the full platform specifications. It also includes support for the latest iterations of Jakarta Contexts and Dependency Injection 2.0 and Jakarta WebSocket 1.1.

Undertow

Undertow is the new lightweight, flexible, and performant web server included in JBoss EAP 7, replacing JBoss Web. Written in Java, it is designed for maximum throughput and scalability. It supports the latest web technologies, such as the new HTTP/2 standard.

Apache ActiveMQ Artemis

Apache ActiveMQ Artemis is the new JBoss EAP 7 built-in messaging provider. Based on a code donation from HornetQ, this Apache subproject provides outstanding performance based on a proven non-blocking architecture.

IronJacamar 1.2

The latest IronJacamar provides a stable and feature rich support for Jakarta Connectors and DataSources.

JBossWS 5

The fifth generation of JBossWS is a major leap forward, bringing new features and performance improvements to JBoss EAP 7 web services.

RESTEasy 3

JBoss EAP 7 includes the latest generation of RESTEasy. It goes beyond the standard Jakarta RESTful Web Services 2.1 by providing a number of useful extensions such as JSON Web Encryption, Jackson, Jakarta JSON Processing 1.1, and Jettison.

OpenJDK ORB

JBoss EAP 7 replaced the JacORB IIOP implementation with a downstream branch of the OpenJDK ORB, leading to better interoperability with the JVM ORB.

Feature Rich Clustering

Clustering support was heavily refactored in JBoss EAP 7 and includes several public APIs for access by applications.

Port Reduction

By utilizing HTTP upgrade, JBoss EAP 7 has moved nearly all of its protocols to be multiplexed over just two HTTP ports: a management port (9990), and an application port (8080).

Enhanced Logging

The management API now supports the ability to list and view the available log files on a server, or even define custom formatters other than the default pattern formatter. Deployment’s logging setup is also greatly enhanced.

For a complete list of new features introduced in JBoss EAP 7.0, see New Features and Enhancements in the JBoss EAP 7.0.0 Release Notes.

New Features and Enhancements Introduced in JBoss EAP 7.1

Elytron
Elytron, based on the WildFly Elytron project, is the new security framework in JBoss EAP 7.1. It is designed to unify security across the entire application server.

Management Console
The management console has been improved to provide the ability to configure more subsystems, provide enhanced transaction subsystem and transaction resource metrics, and manage many additional configurations.

Management CLI
The management CLI provides enhanced support for response and file attachments, module configuration, and debugging support through the echo-command argument.

For the complete list of new features introduced in JBoss EAP 7.1, see New Features and Enhancements in the 7.1.0 Release Notes on the Red Hat Customer Portal.

New Features and Enhancements Introduced in JBoss EAP 7.2

Jakarta EE 8
JBoss EAP 7.2 is a certified implementation of Jakarta EE 8. It includes support for Jakarta Servlet 4.0, Jakarta Persistence 2.2, Contexts and Dependency Injection 2.0, Jakarta Server Faces 2.3, Jakarta JSON Binding 1.0, Jakarta JSON Processing 1.1, and Jakarta RESTful Web Services 2.1, and more. See Jakarta EE Platform 8 for more information about the technologies supported in the Jakarta Enterprise Edition (Jakarta EE) 8 platform.

New Features and Enhancements Introduced in JBoss EAP 7.3

Clustering
The mod_cluster subsystem now defines a new attribute, initial-load. The initial-load attribute helps to gradually increase the load value of a newly joined node to avoid overloading it while joining a cluster.

Eclipse MicroProfile Metrics
The Eclipse MicroProfile Metrics functionality provides monitoring data for JBoss EAP. This release enhances the SmallRye Metrics component to provide the JBoss EAP metrics in the Prometheus format.

Jakarta Enterprise Beans
A message-driven bean (MDB) can now belong to more than one delivery group.

Elytron
The elytron subsystem in this release now provides an implementation of the Servlet profile from the Java Authentication SPI for Containers (JASPI). Elytron now includes enhanced support for JwtValidator. Support is also included for the Jakarta EE Security API (Security 1.0 API) The Jakarta equivalent for this support is defined in the Jakarta Security 1.0 specification.

Jakarta EE 8
JBoss EAP 7.3 is based on the Jakarta EE 8 platform.

Changes to BOMs for Jakarta EE 8
Some JBoss EAP BOMs in the Group ID org.jboss.bom were replaced as a result of the move to Jakarta EE 8 platform in JBoss EAP 7.3. If your applications use the BOMs that were replaced, update the project POMs to contain the Artifact IDs of the new BOMs, when migrating the applications to the JBoss EAP 7.3 release. The following BOMs were replaced:

Table 2.1. BOM Artifacts Replaced in the Group ID org.jboss.bom for Jakarta EE
### Jakarta EE 8 Backwards Compatibility

JBoss EAP 7.3 maintains backwards compatibility with Jakarta EE 8. Jakarta EE 8 remains backwards compatible with other Jakarta EE versions as well. All previous JBoss EAP 7 applications should deploy on JBoss EAP 7.3.

### JBoss EAP Operator

JBoss EAP now offers EAP operator, a JBoss EAP-specific controller, to automate common deployment-related tasks. The EAP operator ensures safe transaction recovery in your application cluster and uses `StatefulSet` for the appropriate handling of Jakarta Enterprise Beans remoting and transaction recovery processing.

### Management Console

External Jakarta Messaging server resources can now be configured from the management console.

### Messaging

The `journal-file-open-timeout` attribute now configures the timeout value for opening message journal files.

In addition to existing support for static HTTP load balancers, load balancers using `mod_cluster` are now supported.

### OpenShift Enhancements

OpenShift now utilizes the JBoss EAP management CLI for S2I builds. OpenShift now allows customization of image footprints using Galleon layers. Jakarta Enterprise Beans remoting and transaction recovery processing also underwent improvements within OpenShift.

### Security

The `server-ssl-sni-context` in this release provides server-side SNI matching. It supplies matching rules to correlate host names to SSL contexts, along with a default in case none of the provided host names are matched.

For the complete list of new features introduced in JBoss EAP 7.3, see New Features and Enhancements in the 7.3.0 Release Notes on the Red Hat Customer Portal.

### 2.5. REVIEW THE LIST OF DEPRECATED AND UNSUPPORTED FEATURES

Before you migrate your application to JBoss EAP 7.4, be aware that some features that were available in previous releases of JBoss EAP might be deprecated or no longer supported. Support for some technologies was removed due to the high maintenance cost, low community interest, and much better alternative solutions.

The following is a short summary of some of the deprecated and unsupported features.

<table>
<thead>
<tr>
<th>Old Artifact ID</th>
<th>New Artifact ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>jboss-eap-javaee8</td>
<td>jboss-eap-jakartaee8</td>
</tr>
<tr>
<td>jboss-eap-javaee8-with-tools</td>
<td>jboss-eap-jakartaee8-with-tools</td>
</tr>
</tbody>
</table>

For information about configuring project dependencies, see Manage Project Dependencies in the Development Guide.
Entity Beans

Entity beans are no longer supported. If your application uses entity beans, you should migrate the code to use Jakarta Persistence, which offers a much more performant and flexible API.

JAX-RPC

Because Jakarta XML Web Services offers a much more accurate and complete solution, code written for Jakarta XML RPC should be migrated to use Jakarta XML Web Services.

Jakarta Deployment

Jakarta Deployment, which defined a contract to enable tools from multiple providers to configure and deploy applications on any Jakarta EE 8 platform product, was not widely adopted. You must use another JBoss EAP supported option for application deployment, such as the management console, the management CLI, deployment scanner, or Maven.

Generic Jakarta Messaging Resource Adapter

The ability to configure a generic Jakarta Messaging resource adapter to connect to a Jakarta Messaging Provider is no longer supported.

IO Subsystem

IO buffer pools are deprecated, but they are still set as the default in the current release. If you want, you can set Undertow byte buffer pools as the default.

Cache Stores

The remote cache store has been deprecated in favor of using the hotrod cache store.

Platforms and Features

A number of platforms and databases that were available in previous releases are deprecated in JBoss EAP 7.4.

For a complete list of deprecated and unsupported features in JBoss EAP 7.0, see Unsupported and Deprecated Functionality in the JBoss EAP 7.0.0 Release Notes on the Red Hat Customer Portal.

For the complete list of deprecated and unsupported features in JBoss EAP 7.1, see Unsupported and Deprecated Functionality in the JBoss EAP 7.1.0 Release Notes on the Red Hat Customer Portal.

For the complete list of deprecated and unsupported features in JBoss EAP 7.2, see Unsupported and Deprecated Functionality in the JBoss EAP 7.2.0 Release Notes on the Red Hat Customer Portal.

For the complete list of deprecated and unsupported features in JBoss EAP 7.3, see Unsupported and Deprecated Functionality in the JBoss EAP 7.3.0 Release Notes on the Red Hat Customer Portal.

2.6. REVIEW THE JBOSS EAP GETTING STARTED MATERIAL

Be sure to review the JBoss EAP Getting Started Guide. It contains the following important information:

- How to download and install JBoss EAP 7
- How to download and install Red Hat CodeReady Studio
- How to configure Maven for your development environment, manage project dependencies, and configure your projects to use the JBoss EAP Bill of Material (BOM) artifacts
- How to download and run the quickstart example applications that ship with the product

2.7. MIGRATION ANALYSIS AND PLANNING

Each application and server configuration is unique, and you must thoroughly understand the
components and architecture of the existing application and server platform before you attempt the migration. Your migration plan should include a detailed road map for testing and rollout to production that takes into account the following information.

**Identify the People Responsible for the Migration**
Identify the stakeholders, project managers, developers, administrators, and others who are responsible for the migration.

**Review the Application Server Platform Configuration and Hardware**
Examine the existing application server and platform configuration to determine how they are impacted by feature changes in JBoss EAP 7. The review should include the following items.

- Operating systems and versions
- Database used by the applications
- Web servers
- Security architecture
- Number and type of processors
- Amount of memory
- Amount of physical disk storage
- Migration of database or messaging data
- Other components that might be impacted by the migration

**Review the Current Production Environment**
You should plan to recreate the production environment as closely as possible for testing and staging the migration process.

- Take into account any clustering configurations. See [Upgrading a Cluster](#) in the JBoss EAP Patching and Upgrading Guide for more information about how to migrate clusters.
- If you are currently running a large managed domain, consider a gradual migration approach.
- Determine whether you need to migrate any database or messaging data.

**Examine and Understand the Existing Application**
Thoroughly examine the existing JBoss EAP 6 application. Be totally familiar with its architecture, functions, features and components, including:

- The JVM version
- Integration with other Red Hat application server middleware components
- Integration with proprietary third-party software
- Use of deprecated features that will require replacement
- Application configuration including deployment descriptors, Java Naming and Directory Interface, persistence, JDBC configuration and pooling, Jakarta Messaging topics and queues, and logging
Identify any code or configuration incompatibilities that will require modification during the migration to JBoss EAP 7.

Create a Detailed Test Plan

- The plan should include regression testing and acceptance criteria requirements.
- It should also include performance testing.
- Set up a staging environment as close to the production environment as possible to test the migration before the rollout to production.
- Be sure to create a backup and backout plan!

Review the Resources Available for the Migration Process

- Assess the skills of the development team and plan for training or additional consulting help.
- Be aware that additional hardware and other resources will be required for staging and testing during the migration process until the effort is completed.
- Determine whether any formal training is needed. If so, add it to the schedule.

Execute the Plan

Gather the necessary resources and implement the migration plan.

IMPORTANT

Before making any modifications to your application, be sure to create a backup copy.

2.8. BACK UP IMPORTANT DATA AND REVIEW SERVER STATE

Before you migrate your application, you need to be aware of the following potential issues.

- The migration might remove temporary folders. Any deployments stored in the `data/content/` directory must be backed up prior to the migration and restored after it completes. Otherwise, the server will fail to start due to the missing content.
- Prior to the migration, handle any open transactions and delete the `data/tx-object-store/` transaction directory.
- The persistent timer data in `data/timer-service-data` must be checked to determine whether it will still be applicable after the upgrade. Before the upgrade, review the `deployment-*` files in that directory to determine which timers are still in use.

Be sure to also back up the current server configuration and applications before you begin.

2.9. MIGRATING AN RPM INSTALLATION
IMPORTANT

It is not supported to have more than one RPM-installed instance of JBoss EAP on a single Red Hat Enterprise Linux Server. As a result, we recommend that you migrate your JBoss EAP installation to a new machine when migrating to JBoss EAP 7.

When migrating a JBoss EAP RPM installation from JBoss EAP 6 to JBoss EAP 7, ensure that JBoss EAP 7 is installed on a machine that does not have an existing JBoss EAP RPM installation.

To install JBoss EAP 7 using RPMs, see the JBoss EAP Installation Guide.

The migration advice in this guide also applies to migrating RPM installations of JBoss EAP, but you might need to alter some steps (such as how to start JBoss EAP) to suit an RPM installation compared to a ZIP or installer installation.

2.10. MIGRATE JBOSS EAP RUNNING AS A SERVICE

If you run JBoss EAP 6 as a service, be sure to review Configuring JBoss EAP to Run as a Service in the JBoss EAP Installation Guide for updated configuration instructions for JBoss EAP 7.
CHAPTER 3. TOOLS TO ASSIST IN MIGRATION

3.1. USE MIGRATION TOOLKIT FOR APPLICATIONS TO ANALYZE APPLICATIONS FOR MIGRATION

Migration Toolkit for Applications (MTA) is an extensible and customizable rule-based set of tools that helps simplify migration of Java applications. It analyzes the APIs, technologies, and architectures used by the applications you plan to migrate and provides detailed migration reports for each application. These reports provide the following information.

- Detailed explanations of the migration changes needed
- Whether the reported change is mandatory or optional
- Whether the reported change is complex or trivial
- Links to the code requiring the migration change
- Hints and links to information about how to make the required changes
- An estimate of the level of effort for each migration issue found and the total estimated effort to migrate the application

You can use MTA to analyze the code and architecture of your JBoss EAP 6 applications before you migrate them to JBoss EAP 7. The MTA rule set for migration from JBoss EAP 6 to JBoss EAP 7 reports on XML descriptors and specific application code and parameters that need to be replaced by an alternative configuration when migrating to JBoss EAP 7.

For more information about how to use Migration Toolkit for Applications to analyze your JBoss EAP 6 applications, see the Migration Toolkit for Applications Getting Started Guide.

3.2. USE THE JBOSS SERVER MIGRATION TOOL TO MIGRATE SERVER CONFIGURATIONS

The JBoss Server Migration Tool is the preferred method to update your server configuration to include the new features and settings in JBoss EAP 7 while keeping your existing configuration. The JBoss Server Migration Tool reads your existing JBoss EAP server configuration files and adds configurations for any new subsystems, updates the existing subsystem configurations with new features, and removes any obsolete subsystem configurations.

You can use the JBoss Server Migration Tool to migrate standalone servers and managed domains for the following configurations.

Migrating to JBoss EAP 7.4

   The JBoss Server Migration Tool ships with JBoss EAP 7.4, so there is no separate download or installation required. This tool supports migration from JBoss EAP 6.4 and later to JBoss EAP 7.4. You run the tool by executing the `jboss-server-migration` script located in the `EAP_HOME/bin` directory. For more information about how to configure and run the tool, see Using the JBoss Server Migration Tool.

   It is recommended that you use this version of the JBoss Server Migration Tool to migrate your server configuration to JBoss EAP 7.4 as this version of the tool is supported.

Migrating from WildFly to JBoss EAP
If you want to migrate from the WildFly server to JBoss EAP, you must download the latest binary distribution of the JBoss Server Migration Tool from the JBoss Server Migration Tool GitHub repository. This open source, standalone version of the tool supports migration from several versions of the WildFly server to JBoss EAP. For information about how to install and run this version of the tool, see the JBoss Server Migration Tool User Guide.

**IMPORTANT**

The binary distribution of the JBoss Server Migration Tool is not supported. If you are migrating from a previous release of JBoss EAP, it is recommended that you use this supported version of the tool to migrate your server configuration to JBoss EAP 7.4 instead.
CHAPTER 4. SERVER CONFIGURATION CHANGES

4.1. RPM INSTALLATION CHANGES

In JBoss EAP 6, the default path for the RPM installation was the /usr/share/jbossas/ directory.

JBoss EAP 7 was built to Software Collections Library conventions. The root directory of Software Collections is normally located in the /opt/ directory to avoid possible conflicts between Software Collections and the base system installation. The use of the /opt/ directory is recommended by the Filesystem Hierarchy Standard (FHS). As a result, the default path for the RPM installation has changed to /opt/rh/eap7/root/usr/share/wildfly/ in JBoss EAP 7.

4.2. SERVER CONFIGURATION MIGRATION OPTIONS

To migrate your server configuration from JBoss EAP 6 to JBoss EAP 7, you can either use the JBoss Server Migration Tool or you can perform a manual migration with the help of the management CLI migrate operation.

JBoss Server Migration Tool
The JBoss Server Migration Tool is the preferred method to update your configuration to include the new features and settings in JBoss EAP 7 while keeping your existing configuration. For information about how to configure and run the tool, see Using the JBoss Server Migration Tool.

Management CLI Migrate Operation
You can use the management CLI migrate operation to update the jacob, messaging, and web subsystems in the JBoss EAP 6 server configuration file to allow them run on the new release, but be aware that the result is not a complete JBoss EAP 7 configuration. For example:

- The operation does not update the original remote protocol and port settings to the new http-remoting and new port settings now used in JBoss EAP 7.
- The configuration does not include the new JBoss EAP subsystems or features such as clustered singleton deployments, or graceful shutdown.
- The configuration does not include the Jakarta EE 8 features such as batch processing.
- The migrate operation does not migrate the ejb3 subsystem configuration. For information about possible Jakarta Enterprise Beans migration issues, see Jakarta Enterprise Beans Server Configuration Changes.

For more information about using the migrate operation to migration the server configuration, see Management CLI Migration Operation.

4.3. MANAGEMENT CLI MIGRATION OPERATION

You can use the management CLI to update your JBoss EAP 6 server configuration files to run on JBoss EAP 7. The management CLI provides a migrate operation to automatically update the jacob, messaging, and web subsystems from the previous release to the new configuration. You can also execute the describe-migration operation for the jacob, messaging, and web subsystems to review the proposed migration configuration changes before you perform the migration. There are no replacements for the cmp, jaxr, or threads subsystems and they must be removed from the server configuration.
**IMPORTANT**

See Server Configuration Migration Options for limitations of the migrate operation. The JBoss Server Migration Tool is the preferred method to update your configuration to include the new features and settings in JBoss EAP 7 while keeping your existing configuration. For information about how to configure and run the tool, see Using the JBoss Server Migration Tool.

### Table 4.1. Subsystem Migration and Management CLI Operation

<table>
<thead>
<tr>
<th>JBoss EAP 6 Subsystem</th>
<th>JBoss EAP 7 Subsystem</th>
<th>Management CLI Operation</th>
</tr>
</thead>
<tbody>
<tr>
<td>cmp</td>
<td>no replacement</td>
<td>remove</td>
</tr>
<tr>
<td>jacobr</td>
<td>iiop-openjdk</td>
<td>migrate</td>
</tr>
<tr>
<td>jaxr</td>
<td>no replacement</td>
<td>remove</td>

<td>migrate</td>
</tr>
<tr>
<td>threads</td>
<td>no replacement</td>
<td>remove</td>
</tr>
<tr>
<td>web</td>
<td>undertow</td>
<td>migrate</td>
</tr>
</tbody>
</table>

### Start the Server and the Management CLI

Follow the steps below to update your JBoss EAP 6 server configuration to run on JBoss EAP 7.

1. Before you begin, review Back Up Important Data and Review Server State. It contains important information about making sure the server is in a good state and the appropriate files are backed up.

2. Start the JBoss EAP 7 server with the JBoss EAP 6 configuration.
   
   a. Back up the JBoss EAP 7 server configuration files.
   
   b. Copy the configuration file from the previous release into the JBoss EAP 7 directory.

   ```bash
   $ cp EAP6_HOME/standalone/configuration/standalone-full.xml EAP7_HOME/standalone/configuration
   ```

   c. Navigate to the JBoss EAP 7 install directory and start the server with the `--start-mode=admin-only` argument.

   ```bash
   $ bin/standalone.sh -c standalone-full.xml --start-mode=admin-only
   ```
NOTE

You will see the following `org.jboss.as.controller.management-operation` ERRORS in the server log when you start the server. These errors are expected and indicate that the legacy subsystem configurations must be removed or migrated to JBoss EAP 7.

- WFLYCTL0402: Subsystems [cmp] provided by legacy extension 'org.jboss.as.cmp' are not supported on servers running this version. Both the subsystem and the extension must be removed or migrated before the server will function.

- WFLYCTL0402: Subsystems [jacob] provided by legacy extension 'org.jboss.as.jacorb' are not supported on servers running this version. Both the subsystem and the extension must be removed or migrated before the server will function.

- WFLYCTL0402: Subsystems [jaxr] provided by legacy extension 'org.jboss.as.jaxr' are not supported on servers running this version. Both the subsystem and the extension must be removed or migrated before the server will function.

- WFLYCTL0402: Subsystems [messaging] provided by legacy extension 'org.jboss.as.messaging' are not supported on servers running this version. Both the subsystem and the extension must be removed or migrated before the server will function.

- WFLYCTL0402: Subsystems [threads] provided by legacy extension 'org.jboss.as.threads' are not supported on servers running this version. Both the subsystem and the extension must be removed or migrated before the server will function.

- WFLYCTL0402: Subsystems [web] provided by legacy extension 'org.jboss.as.web' are not supported on servers running this version. Both the subsystem and the extension must be removed or migrated before the server will function.

3. Open a new terminal, navigate to the JBoss EAP 7 install directory, and start the management CLI using the `--controller=remote://localhost:9990` arguments.

   ```
   $ bin/jboss-cli.sh --connect --controller=remote://localhost:9990
   ```

Migrate the JacORB, Messaging, and Web Subsystems

1. To review the configuration changes that will be made to the subsystem before you perform the migration, execute the `describe-migration` operation.

   The `describe-migration` operation uses the following syntax.

   ```
   /subsystem=SUBSYSTEM_NAME:describe-migration
   ```

   The following example describes the configuration changes that are made to the JBoss EAP 6.4 `standalone-full.xml` configuration file when it is migrated to JBoss EAP 7. Entries were removed from the output to improve readability and to save space.

   **Example: describe-migration Operation**
2. Execute the **migrate** operation to migrate the subsystem configuration to the subsystem that replaces it in JBoss EAP 7. The operation uses the following syntax.

```
/subsystem=SUBSYSTEM_NAME:migrate
```

**NOTE**

The **messaging** subsystem **describe-migration** and **migrate** operations allow you to pass an argument to configure access by legacy clients. For more information about the command syntax, see [Messaging Subsystem Migration and Forward Compatibility](CHAP04.html#Messaging Subsystem Migration and Forward Compatibility).

3. Review the outcome and result of the command. Be sure the operation completed successfully and there are no "migration-warning" entries. This means the migration configuration for the subsystem is complete.

**Example: Successful migrate Operation with No Warnings**

```
/subsystem=messaging:migrate
{
    "outcome" => "success",
    "result" => {"migration-operations" => [}
    { "operation" => "add",
      "address" => {"extension" => "org.wildfly.extension.messaging-activemq"},
      "module" => "org.wildfly.extension.messaging-activemq"
    },
    { "operation" => "add",
      "address" => {["subsystem" => "messaging-activemq"]}
    },
    <!-- *** Entries removed for readability *** -->
    { "operation" => "remove",
      "address" => {["subsystem" => "messaging"]}
    },
    { "operation" => "remove",
      "address" => {["extension" => "org.jboss.as.messaging"]}
    }
  ]
}
```

If you see "migration-warnings" entries in the log, this indicates the migration of the server configuration completed successfully but it was not able to migrate all of elements and
attributes. You must follow the suggestions provided by the "migration-warnings" and run additional management CLI commands to modify those configurations. The following is an example of a migrate operation that returns "migration-warnings".

Example: migrate Operation with Warnings

```json
/subsystem=messaging:migrate
{
    "outcome" => "success",
    "result" => {
        "migration-warnings" => [
            "WFLYMSG0080: Could not migrate attribute group-address from resource [ ("subsystem" => "messaging-activemq"), ("server" => "default"), ("broadcast-group" => "groupB")]. Use instead the socket-binding attribute to configure this broadcast-group.",
            "WFLYMSG0080: Could not migrate attribute group-port from resource [ ("subsystem" => "messaging-activemq"), ("server" => "default"), ("broadcast-group" => "groupB")]. Use instead the socket-binding attribute to configure this broadcast-group.",
            "WFLYMSG0080: Could not migrate attribute local-bind-address from resource [ ("subsystem" => "messaging-activemq"), ("server" => "default"), ("broadcast-group" => "groupA")]. Use instead the socket-binding attribute to configure this broadcast-group.",
            "WFLYMSG0080: Could not migrate attribute local-bind-port from resource [ ("subsystem" => "messaging-activemq"), ("server" => "default"), ("broadcast-group" => "groupA")]. Use instead the socket-binding attribute to configure this broadcast-group.",
            "WFLYMSG0080: Could not migrate attribute group-address from resource [ ("subsystem" => "messaging-activemq"), ("server" => "default"), ("broadcast-group" => "groupA")]. Use instead the socket-binding attribute to configure this broadcast-group.",
            "WFLYMSG0080: Could not migrate attribute group-port from resource [ ("subsystem" => "messaging-activemq"), ("server" => "default"), ("broadcast-group" => "groupA")]. Use instead the socket-binding attribute to configure this broadcast-group.",
        ]
    }
}
```

NOTE

The list of migrate and describe-migration warnings for each subsystem is located in the Reference Material at the end of this guide.

- Jacobr Subsystem Migration Operation Warnings
- Messaging Subsystem Migration Operation Warnings
- Web Subsystem Migration Operation Warnings
4. Review the server configuration file to verify the extension, subsystem, and namespace were updated and the existing subsystem configuration was migrated to JBoss EAP 7.

**NOTE**

You must repeat this process for each of the **jacorb**, **messaging**, and **web** subsystems using the following commands.

/subsystem=jacorb:migrate
/subsystem=messaging:migrate
/subsystem=web:migrate

5. Remove the **cmp**, **jaxr**, and **threads** subsystems and extensions from the server configuration. While still in the management CLI prompt, remove the obsolete **cmp**, **jaxr**, and **threads** subsystems by executing the following commands.

/subsystem=cmp:remove
/subsystem=jacorb:remove
/subsystem=messaging:remove
/subsystem=jaxr:remove
/subsystem=web:remove
/subsystem=threads:remove
/subextension=org.jboss.as.threads:remove

**IMPORTANT**

You must migrate the **messaging**, **jacorb**, and **web** subsystems and remove the **cmp**, **jaxr**, and **threads** extensions and subsystems before you can restart the server for normal operation. If you need to restart the server before you complete this process, be sure to include the **--start-mode=admin-only** argument on the server start command line. This allows you to continue with the configuration changes.

### 4.4. LOGGING CHANGES

#### 4.4.1. Logging Message Prefix Changes

Log messages are prefixed with the project code for the subsystem that reports the message. The prefixes for all log messages have changed in JBoss EAP 7.

For a complete list of the new log message project code prefixes used in JBoss EAP 7, see Project Codes Used in JBoss EAP in the JBoss EAP Development Guide.

#### 4.4.2. Root Logger Console Handler Changes

The JBoss EAP 7.0 root logger included a console log handler for all domain server profiles and for all default standalone profiles except the **standalone-full-ha** profile. As of JBoss EAP 7.1, the root logger no longer includes a console log handler for the managed domain profiles. The host controller and process controller log to the console by default. To achieve the same functionality that was provided in JBoss EAP 7.0, see Configure a Console Log Handler in the Configuration Guide for JBoss EAP.

### 4.5. WEB SERVER CONFIGURATION CHANGES
4.5.1. Replace the Web Subsystem with Undertow

Undertow replaces JBoss Web as the web server in JBoss EAP 7. This means the legacy web subsystem configuration must be migrated to the new JBoss EAP 7 undertow subsystem configuration.

- The urn:jboss:domain:web:2.2 subsystem configuration namespace in the server configuration file has been replaced by the urn:jboss:domain:undertow:10.0 namespace.

- The org.jboss.as.web extension module, located in EAP_HOME/modules/system/layers/base/, has been replaced with the org.wildfly.extension.undertow extension module.

You can use the management CLI migrate operation to migrate the web subsystem to undertow in the server configuration file. However, be aware that this operation is not able to migrate all JBoss Web subsystem configurations. If you see “migration-warning” entries, you must run additional management CLI commands to migrate those configurations to Undertow. For more information about the management CLI migrate operation, see Management CLI Migration Operation.

The following is an example of the default web subsystem configuration in JBoss EAP 6.4.

```xml
<subsystem xmlns="urn:jboss:domain:web:2.2" default-virtual-server="default-host" native="false">
  <connector name="http" protocol="HTTP/1.1" scheme="http" socket-binding="http"/>
  <virtual-server name="default-host" enable-welcome-root="true">
    <alias name="localhost"/>
    <alias name="example.com"/>
  </virtual-server>
</subsystem>
```

The following is an example of the default undertow subsystem configuration in JBoss EAP 7.4.

```xml
<subsystem xmlns="urn:jboss:domain:undertow:10.0" default-server="default-server" default-virtual-host="default-host" default-servlet-container="default" default-security-domain="other">
  <buffer-cache name="default"/>
  <server name="default-server">
    <http-listener name="default" socket-binding="http" redirect-socket="https" enable-http2="true"/>
    <https-listener name="https" socket-binding="https" security-realm="ApplicationRealm" enable-http2="true"/>
    <host name="default-host" alias="localhost">
      <location name="/" handler="welcome-content"/>
      <http-invoker security-realm="ApplicationRealm"/>
    </host>
  </server>
  ... 
</subsystem>
```

4.5.2. Migrate JBoss Web Rewrite Conditions

The management CLI migrate operation is not able to automatically migrate rewrite conditions. They are reported as “migration-warnings”, and you must migrate them manually. You can create the equivalent configuration in JBoss EAP 7 by using Undertow Predicates Attributes and Handlers.

The following is an example of a web subsystem configuration in JBoss EAP 6 that includes rewrite configuration.

```xml
<subsystem xmlns="urn:jboss:domain:web:2.2" default-virtual-server="default" native="false">
```
Follow the Management CLI Migration Operation instructions to start your server and the management CLI, then migrate the web subsystem configuration file using the following command.

/subsystem=web:migrate

The following "migration-warnings" are reported when you run the migrate operation on the above configuration.

/subsystem=web:migrate
{
  "outcome" => "success",
  "result" => {"migration-warnings" => ["WFLYWEB0002: Could not migrate resource {"pattern" => "(.*)",
  "substitution" => "-
  "flags" => "F",
  "operation" => "add",
  "address" => 
    ("subsystem" => "web"),
    ("virtual-server" => "default-host"),
    ("rewrite" => "test2")
  ],
    "WFLYWEB0002: Could not migrate resource {
  "test" => "%{REQUEST_METHOD}",
  "pattern" => "GET",
  "flags" => undefined,
  "operation" => "add",
  "address" => 
    ("subsystem" => "web"),
    ("virtual-server" => "default-host"),
    ("rewrite" => "test2")
  ],
    "WFLYWEB0002: Could not migrate resource {
  "test" => "%{REQUEST_URI}",
  "pattern" => ".*index.html",
  "flags" => "NC",
  "operation" => "add",
  "address" => 
    ("subsystem" => "web"),
    ("virtual-server" => "default-host"),
    ("rewrite" => "test2")
  ],
    "WFLYWEB0002: Could not migrate resource {
  "test" => "%{REQUEST_URI}"
  "pattern" => ".*index.html",
  "flags" => "NC",
  "operation" => "add",
  "address" => 
    ("subsystem" => "web"),
    ("virtual-server" => "default-host"),
    ("rewrite" => "test2")
  ],
    "WFLYWEB0002: Could not migrate resource {
  "test" => "%{REQUEST_URI}"
  "pattern" => ".*index.html",
  "flags" => "NC",
  "operation" => "add",
  "address" => 
    ("subsystem" => "web"),
    ("virtual-server" => "default-host"),
    ("rewrite" => "test2")
  ]
}
}
Review the server configuration file and you see the following configuration for the **undertow** subsystem.

**NOTE**

The rewrite configuration is dropped.

```
<subsystem xmlns="urn:jboss:domain:undertow:10.0" default-server="default-server" default-virtual-host="default-host" default-servlet-container="default" default-security-domain="other">
  <buffer-cache name="default"/>
  <server name="default-server">
    <http-listener name="http" socket-binding="http"/>
    <https-listener name="https" socket-binding="https" security-realm="ApplicationRealm" enable-http2="true"/>
    <host name="default-host" alias="localhost, example.com">
      <location name="/" handler="welcome-content"/>
    </host>
  </server>
</subsystem>
```

Use the management CLI to create the filter to replace the rewrite configuration in the **undertow** subsystem. You should see "{"outcome" ⇒ "success"}" for each command.

```bash
# Create the filters
/subsystem=undertow/configuration=filter/expression-filter="test1":add(expression="path(\(.*\)/toberewritten/(.*)") -> rewrite($1/rewritten/$2")")
/subsystem=undertow/configuration=filter/expression-filter="test2":add(expression="method('GET') and path('.*index.html') -> response-code(403)")
```

# Add the filters to the default server
/subsystem=undertow/server=default-server/host=default-host/filter-ref="test1":add
/subsystem=undertow/server=default-server/host=default-host/filter-ref="test2":add
```
Review the updated server configuration file. The JBoss Web subsystem is now completely migrated and configured in the **undertow** subsystem.

```
<subsystem xmlns="urn:jboss:domain:undertow:10.0" default-server="default-server" default-virtual-host="default-host" default-servlet-container="default" default-security-domain="other">
  <buffer-cache name="default"/>
  <server name="default-server">
    <http-listener name="http" socket-binding="http"/>
    <https-listener name="https" socket-binding="https" security-realm="ApplicationRealm" enable-http2="true"/>
  </server>
```
```
For more information about how to configure filters and handlers using the management CLI, see Configuring the Web Server in the JBoss EAP 7 Configuration Guide.

4.5.3. Migrate JBoss Web System Properties

In the previous release of JBoss EAP, system properties could be used to modify the default JBoss Web behavior. For information about how to configure the same behavior in Undertow, see JBoss Web System Properties Migration Reference

4.5.4. Update the Access Log Header Pattern

When you migrate from JBoss EAP 6.4 to JBoss EAP 7, you might find that the access logs no longer write the expected "Referer" and "User-agent" values. This is because JBoss Web, which was included in JBoss EAP 6.4, used a pattern of %{headername}i in the access-log to log an incoming header.

Example: Access Log Format in JBoss EAP 6.4

```
<access-log pattern="%h %l %u %t &quot;%T sec&quot; &quot;%r&quot; %s %b &quot;%{Referer}i&quot; %{User-agent}i"/>
```

With the change to use Undertow in JBoss EAP 7, the pattern for an incoming header has changed to %i,headername).

Example: Access Format Header in JBoss EAP 7

```
<access-log pattern="%h %l %u %t &quot;%T sec&quot; &quot;%r&quot; %s %b &quot;%i,Referer&quot; &quot;%i,User-Agent&quot;"/>
```

4.5.5. Migrate Global Valves

Previous releases of JBoss EAP supported valves. Valves are custom classes inserted into the request processing pipeline for an application before servlet filters to make changes to the request or perform additional processing.
Global valves are inserted into the request processing pipeline of all deployed applications and are configured in the server configuration file.

Authenticator valves authenticate the credentials of the request.

Custom application valves were created by extending the \texttt{org.apache.catalina.valves.ValveBase} class and configured in the \texttt{<valve>} element of the \texttt{jboss-web.xml} descriptor file. These valves must be migrated manually.

This section describes how to migrate global valves. Migration of custom and authenticator valves are covered in the Migrate Custom Application Valves section of this guide.

Undertow, which replaces JBoss Web in JBoss EAP 7, does not support global valves; however, you should be able to achieve similar functionality by using Undertow handlers. Undertow includes a number of built-in handlers that provide common functionality. It also provides the ability to create custom handlers, which can be used to replace custom valve functionality.

If your application uses valves, you must replace them with the appropriate Undertow handler code to achieve the same functionality when you migrate to JBoss EAP 7.

For more information about how to configure handlers, see Configuring Handlers in the JBoss EAP 7 Configuration Guide.

For more information about how to configure filters, see Configuring Filters in the JBoss EAP 7 Configuration Guide.

\textbf{Migrate JBoss Web Valves}

The following table lists the valves that were provided by JBoss Web in the previous release of JBoss EAP and the corresponding Undertow built-in handler. The JBoss Web valves are located in the \texttt{org.apache.catalina.valves} package.

\begin{table}[h]
\centering
\begin{tabular}{|l|l|}
\hline
Valve & Handler \\
\hline
AccessLogValve & io.undertow.server.handlers.accesslog.AccessLogHandler \\
\hline
CrawlerSessionManagerValve & io.undertow.servlet.handlers.CrawlerSessionManagerHandler \\
\hline
ExtendedAccessLogValve & io.undertow.server.handlers.accesslog.AccessLogHandler \\
\hline
JDBCAccessLogValve & See the JDBCAccessLogValve Manual Migration Procedure below for instructions. \\
\hline
RemoteAddrValve & io.undertow.server.handlers.IPAddressAccessControlHandler \\
\hline
RemoteHostValve & io.undertow.server.handlers.AccessControlListHandler \\
\hline
RemotelpValve & io.undertow.server.handlers.ProxyPeerAddressHandler \\
\hline
RequestDumperValve & io.undertow.server.handlers.RequestDumpingHandler \\
\hline
\end{tabular}
\end{table}
<table>
<thead>
<tr>
<th>Valve</th>
<th>Handler</th>
</tr>
</thead>
<tbody>
<tr>
<td>RewriteValve</td>
<td>See Migrate JBoss Web Rewrite Conditions for instructions to migrate these valves manually.</td>
</tr>
<tr>
<td>StuckThreadDetectionValve</td>
<td>io.undertow.server.handlers.StuckThreadDetectionHandler</td>
</tr>
</tbody>
</table>

You can use the management CLI **migrate** operation to automatically migrate global valves that meet the following criteria:

- They are limited to the valves listed in the previous table that do not require manual processing.
- They must be defined in the **web** subsystem of the server configuration file.

For more information about the management CLI **migrate** operation, see Management CLI Migration Operation.

**JDBCAccessLogValve Manual Migration Procedure**

The **org.apache.catalina.valves.JDBCAccessLogValve** valve is an exception to the rule and can not be automatically migrated to **io.undertow.server.handlers.JDBCLogHandler**. Follow the steps below to migrate the following example valve.

```
<valve name="jdbc" module="org.jboss.as.web" class-name="org.apache.catalina.valves.JDBCAccessLogValve">
  <param param-name="driverName" param-value="com.mysql.jdbc.Driver" />
  <param param-name="connectionName" param-value="root" />
  <param param-name="connectionPassword" param-value="password" />
  <param param-name="connectionURL" param-value="jdbc:mysql://localhost:3306/wildfly?zeroDateTimeBehavior=convertToNull" />
  <param param-name="format" param-value="combined" />
</valve>
```

1. Create a driver module for the database that will store the log entries.

2. Configure the datasource for the database and add the driver to the list of available drivers in the **datasources** subsystem.

```
<datasources>
  <datasource jndi-name="java:jboss/datasources/accessLogDS" pool-name="accessLogDS" enabled="true" use-java-context="true">
    <connection-url>jdbc:mysql://localhost:3306/wildfly?zeroDateTimeBehavior=convertToNull</connection-url>
    <driver>mysql</driver>
    <security>
      <user-name>root</user-name>
      <password>Password1!</password>
    </security>
  </datasource>
  ...
  <drivers>
    <driver name="mysql" module="com.mysql">
      <driver-class>com.mysql.jdbc.Driver</driver-class>
    </driver>
  </drivers>
</datasources>
```
3. Configure an expression-filter in the undertow subsystem with the following expression: `jdbc-access-log(datasource='java:jboss/datasources/accessLogDS')`.

```xml
<filters>
  <expression-filter name="jdbc-access" expression="jdbc-access-log(datasource='java:jboss/datasources/accessLogDS')" />
  ...
</filters>
```

### 4.5.6. Changes to Set-Cookie Behavior

Previous specifications for Set-Cookie HTTP response header syntax, for example RFC2109 and RFC2965, allowed white space and other separator characters in the cookie value when the cookie value was quoted. JBoss Web in JBoss EAP 6.4 conformed to the previous specifications and automatically quoted a cookie value when it contained any separator characters.

The [RFC6265](https://tools.ietf.org/html/rfc6265) specification for Set-Cookie HTTP response header syntax states that cookie values in the Set-Cookie response header must conform to specific grammar constraints. For example, they must be US-ASCII characters, but they cannot include CTRLs (controls), whitespace, double quotes, commas, semicolons, or backslash characters.

In JBoss EAP 7.0, prior to cumulative patch Red Hat JBoss Enterprise Application Platform 7.0 Update 08, Undertow does not restrict these invalid characters and does not quote cookies that contained the excluded characters. If you apply this cumulative patch or a newer cumulative patch you can enable RFC6265 compliant cookie validation by setting the `io.undertow.cookie.DEFAULT_ENABLE_RFC6265_COOKIE_VALIDATION` system property to `true`.

Starting in JBoss EAP 7.1, by default, Undertow does not enable RFC6265 compliant cookie validation. It does quote cookies that contain the excluded characters. Starting in JBoss EAP 7.1, you cannot use the `io.undertow.cookie.DEFAULT_ENABLE_RFC6265_COOKIE_VALIDATION` system property to enable RFC6265 compliant cookie validation. Instead, you enable RFC6265 compliant cookie validation for an HTTP, HTTPS, or AJP listener by setting the `rfc6265-cookie-validation` listener attribute to `true`. The default value for this attribute is `false`. The following example enables RFC6265 compliant cookie validation for the HTTP listener.

```
/subsystem=undertow/server=default-server/http-listener=default:write-attribute(name=rfc6265-cookie-validation,value=true)
```

### 4.5.7. Changes to HTTP Method Call Behavior

JBoss EAP 6.4, which included JBoss Web as the web server, allowed HTTP TRACE method calls by default.

Undertow, which replaces JBoss Web as the web server in JBoss EAP 7, disallows HTTP TRACE method calls by default. This setting is configured using the `disallowed-methods` attribute of the `http-listener` element in the undertow subsystem. This can be confirmed by reviewing the output from the following `read-resource` command. Note that the value for the `disallowed-methods` attribute is `"TRACE"`.

```
/subsystem=undertow/server=default-server/http-listener=default:read-resource
```
To enable HTTP TRACE method calls in JBoss EAP 7 and later, you must remove the "TRACE" entry from the disallowed-methods attribute list by running the following command.

```
/subsystem=undertow/server=default-server/http-listener=default:list-remove(name=disallowed-methods,value="TRACE")
```

When you run the read-resource command again, you will notice the TRACE method call is no longer in the list of disallowed methods.

```
/subsystem=undertow/server=default-server/http-listener=default:read-resource
{
  "outcome" => "success",
  "result" => {
    "allow-encoded-slash" => false,
    "allow-equals-in-cookie-value" => false,
    "allow-unescaped-characters-in-url" => false,
    "always-set-keep-alive" => true,
    "buffer-pipelined-data" => false,
    "buffer-pool" => "default",
    "certificate-forwarding" => false,
    "decode-url" => true,
    "disallowed-methods" => [],
    ...
  }
}
```

For more information about the default behavior of HTTP methods, see Default Behavior of HTTP Methods in the JBoss EAP Configuration Guide.

### 4.5.8. Changes in the Default Web Module Behavior

In JBoss EAP 7.0, the root context of a web application was disabled by default in mod_cluster.

As of JBoss EAP 7.1, this is no longer the case. This can have unexpected consequences if you are expecting the root context to be disabled. For example, requests can be misrouted to undesired nodes or a private application that should not be exposed can be inadvertently accessible through a public proxy. Undertow locations are also now registered with the mod_cluster load balancer automatically unless they are explicitly excluded.
Use the following management CLI command to exclude ROOT from the modcluster subsystem configuration.

```
/subsystem=modcluster/mod-cluster-config=configuration:write-attribute(name=excluded-contexts,value=ROOT)
```

Use the following management CLI command to disable the default welcome web application.

```
/subsystem=undertow/server=default-server/host=default-host/location=/V:remove
/subsystem=undertow/configuration=handler/file=welcome-content:remove
/reload
```

For more information about how to configure the default welcome web application, see Configure the Default Welcome Web Application in the Development Guide for JBoss EAP.

### 4.5.9. Changes in the Undertow Subsystem Default Configuration

Prior to JBoss EAP 7.2, the default undertow subsystem configuration included two response header filters that were appended to each HTTP response by the default-host.

- **Server**, which was set to JBoss-EAP/7.

- **X-Powered-By**, which was set to Undertow/1.

These response header filters were removed from the default JBoss EAP 7.2 configuration to prevent inadvertent disclosure of information about the server in use.

The following is an example of the default undertow subsystem configuration in JBoss EAP 7.1.

```
<subsystem xmlns="urn:jboss:domain:undertow:4.0">
  <buffer-cache name="default"/>
  <server name="default-server">
    <http-listener name="default" socket-binding="http" redirect-socket="https"/>
    <https-listener name="https" socket-binding="https" security-realm="ApplicationRealm" enable-http2="true"/>
    <host name="default-host" alias="localhost">
      <location name="/" handler="welcome-content"/>
      <filter-ref name="server-header"/>
      <filter-ref name="x-powered-by-header"/>
      <http-invoker security-realm="ApplicationRealm"/>
    </host>
  </server>
  <servlet-container name="default">
    <jsp-config/>
    <websockets/>
  </servlet-container>
  <handlers>
    <file name="welcome-content" path="${jboss.home.dir}/welcome-content"/>
  </handlers>
  <filters>
    <response-header name="server-header" header-name="Server" header-value="JBoss-EAP/7"/>
    <response-header name="x-powered-by-header" header-name="X-Powered-By" header-value="Undertow/1"/>
  </filters>
</subsystem>
```
The following is an example of the new default undertow subsystem configuration in JBoss EAP 7.4.

```xml
<subsystem xmlns="urn:jboss:domain:undertow:10.0" default-server="default-server" default-virtual-host="default-host" default-servlet-container="default" default-security-domain="other">
  <buffer-cache name="default"/>
  <server name="default-server">
    <http-listener name="default" socket-binding="http" redirect-socket="https" enable-http2="true"/>
    <https-listener name="https" socket-binding="https" security-realm="ApplicationRealm" enable-http2="true"/>
    <host name="default-host" alias="localhost">
      <location name="/" handler="welcome-content"/>
      <http-invoker security-realm="ApplicationRealm"/>
    </host>
  </server>
  <servlet-container name="default">
    <jsp-config/>
    <websockets/>
  </servlet-container>
  <handlers>
    <file name="welcome-content" path="${jboss.home.dir}/welcome-content"/>
  </handlers>
</subsystem>
```

### 4.6. JGROUPS SERVER CONFIGURATION CHANGES

#### 4.6.1. JGroups Defaults to a Private Network Interface

In the JBoss EAP 6 default configuration, JGroups used the *public* interface defined in the `<interfaces>` section of the server configuration file.

Because it is a recommended practice to use a dedicated network interface, JGroups now defaults to using the new *private* interface that is defined in the `<interfaces>` section of the server configuration file in JBoss EAP 7.

#### 4.6.2. JGroups Channels Changes

JGroups provides group communication support for HA services in the form of JGroups channels. JBoss EAP 7 introduces `<channel>` elements to the `<jgroups>` subsystem in the server configuration file. You can add, remove, or change the configuration of JGroups channels using the management CLI.

For more information about how to configure JGroups, see [Cluster Communication with JGroups](#) in the JBoss EAP Configuration Guide.

### 4.7. INFINISPAN SERVER CONFIGURATION CHANGES

#### 4.7.1. Infinispan Default Cache Configuration Changes

In JBoss EAP 6, the default clustered caches for web session replication and EJB replication were replicated `ASYNC` caches. This has changed in JBoss EAP 7. The default clustered caches are now distributed `ASYNC` caches. The replicated caches are no longer even configured by default. See [Configure the Cache Mode](#) in the JBoss EAP Configuration Guide for information about how to add a replicated cache and make it the default.
This only affects you when you use the new JBoss EAP 7 default configuration. If you migrate the configuration from JBoss EAP 6, the configuration of the infinispan subsystem will be preserved.

### 4.7.2. Infinispan Cache Strategy Changes

The behavior of **ASYNC** cache strategy has changed in JBoss EAP 7.

In JBoss EAP 6, **ASYNC** cache reads were lock free. Although they would never block, they were prone to dirty reads of stale data, for example on failover. This is because it would allow subsequent requests for the same user to start before the previous request completed. This permissiveness is not acceptable when using distributed mode, since cluster topology changes can affect session affinity and easily result in stale data.

In JBoss EAP 7, **ASYNC** cache reads require locks. Since they now block new requests from the same user until the previous replication finishes, dirty reads are prevented.

### 4.7.3. Configuring Custom Stateful Session Bean Cache for Passivation

Be aware of the following restrictions when configuring a custom stateful session bean (SFSB) cache for passivation in JBoss EAP 7.1 and later.

- The `idle-timeout` attribute, which is configured in the **infinispan passivation-store** of the **ejb3** subsystem, is deprecated in JBoss EAP 7.1 and later. JBoss EAP 6.4 supported eager passivation, passing according to the `idle-timeout` value. JBoss EAP 7.1 and later support lazy passivation, passivating when the `max-size` threshold is reached.

- In JBoss EAP 7.1 and later, the cluster name used by the Jakarta Enterprise Beans client is determined by the actual cluster name of the channel, as configured in the **jgroups** subsystem.

- JBoss EAP 7.1 and later still allow you to set the `max-size` attribute to control the passivation threshold.

- You should not configure eviction or expiration in your Jakarta Enterprise Beans cache configuration.
  - You should configure eviction by using the `max-size` attribute of the **passivation-store** in the **ejb3** subsystem.
  - You should configure expiration by using the `@StatefulTimeout` annotation in the SFSB Java source code or by specifying a `stateful-timeout` value in the **ejb-jar.xml** file.

### 4.7.4. Infinispan Cache Container Transport Changes

A change in behavior between JBoss EAP 7.0 and later versions requires that any updates to the cache container transport protocol to be done in batch mode or using a special header. This change in behavior also impacts any tools that are used to manage the JBoss EAP server.

The following is an example of the management CLI commands used to configure the cache container transport protocol in JBoss EAP 7.0.

```
/subsystem=infinispan/cache-container=my:add()
/subsystem=infinispan/cache-container=my/transport=jgroups:add()
/subsystem=infinispan/cache-container=my/invalidation-cache=mycache:add(mode=SYNC)
```

The following is an example of the management CLI commands needed to perform the same configuration in JBoss EAP 7.1. Note that the commands are executed in batch mode.
If you prefer not to use batch mode, you can instead specify the operation header `allow-resource-service-restart=true` when defining the transport. Be aware that this restarts the service so that the operations can take effect, and some services might stop working until the service is restarted.

If you use scripts to update the cache container transport protocol, be sure to review them and add batch mode.

### 4.8. JAKARTA ENTERPRISE BEANS SERVER CONFIGURATION CHANGES

There is no `migrate` operation for the `ejb3` subsystem, so if you use the management CLI `migrate` operations to upgrade your other existing JBoss EAP 6.4 configurations, be aware that the `ejb3` subsystem configuration is not migrated. Because the configuration of the `ejb3` subsystem is slightly different in JBoss EAP 7 than in JBoss EAP 6.4, you might see exceptions in the server log when you deploy your enterprise bean applications.

**IMPORTANT**
If you use the JBoss Server Migration Tool to update your server configuration, the `ejb3` subsystem should be configured correctly and you should not see any issues when you deploy your Jakarta Enterprise Beans applications. For information about how to configure and run the tool, see Using the JBoss Server Migration Tool.

**DuplicateServiceException**
The following `DuplicateServiceException` is caused by caching changes in JBoss EAP 7.

**DuplicateServiceException in Server Log**

```plaintext
ERROR [org.jboss.msc.service.fail] (MSC service thread 1-3) MSC000001: Failed to start service jboss.deployment.unit."mdb-1.0-SNAPSHOT.jar".cache-dependencies-installer: org.jboss.msc.service.StartException in service jboss.deployment.unit."mdb-1.0-SNAPSHOT.jar".cache-dependencies-installer: Failed to start service ...

Caused by: org.jboss.msc.service.DuplicateServiceException: Service jboss.infinispan.ejb."mdb-1.0-SNAPSHOT.jar".config is already registered
```

You must reconfigure the cache to resolve this error.

1. Follow the instructions to **Start the Server and the Management CLI**.

2. Issue the following commands to reconfigure caching in the `ejb3` subsystem.

```plaintext
/subsystem=ejb3/file-passivation-store=file:remove
/subsystem=ejb3/cluster-passivation-store=infinispan:remove
/subsystem=ejb3/passivation-store=infinispan:add(cache-container=ejb, max-size=10000)
/subsystem=ejb3/cache=passivating:remove
```
4.9. MESSAGING SERVER CONFIGURATION CHANGES

In JBoss EAP 7, ActiveMQ Artemis replaces HornetQ as the Jakarta Messaging support provider. This section describes how to migrate the configuration and related messaging data.

4.9.1. Messaging Subsystem Server Configuration Changes

The org.jboss.as.messaging module extension, located in EAP_HOME/modules/system/layers/base/, has been replaced by the org.wildfly.extension.messaging-activemq extension module.

The urn:jboss:domain:messaging:3.0 subsystem configuration namespace has been replaced by the urn:jboss:domain:messaging-activemq:4.0 namespace.

Management Model

In most cases, an effort was made to keep the element and attribute names as similar as possible to those used in previous releases. The following table lists some of the changes.

Table 4.3. Mapping Messaging Attributes

<table>
<thead>
<tr>
<th>HornetQ Name</th>
<th>ActiveMQ Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>hornetq-server</td>
<td>server</td>
</tr>
<tr>
<td>hornetq-serverType</td>
<td>serverType</td>
</tr>
<tr>
<td>connectors</td>
<td>connector</td>
</tr>
<tr>
<td>discovery-group-name</td>
<td>discovery-group</td>
</tr>
</tbody>
</table>

The management operations invoked on the new messaging-activemq subsystem have changed from /subsystem=messaging/hornetq-server= to /subsystem=messaging-activemq/server=.

You can migrate an existing JBoss EAP 6 messaging subsystem configuration to the messaging-activemq subsystem on a JBoss EAP 7 server by invoking its migrate operation.

/subsystem=messaging:migrate

Before you execute the migrate operation, you can invoke the describe-migration operation to review the list of management operations that will be performed to migrate from the existing JBoss EAP 6 messaging subsystem configuration to the messaging-activemq subsystem on the JBoss EAP 7 server.

/subsystem=messaging:describe-migration

The migrate and describe-migration operations also display a list of migration-warnings for resources or attributes that can not be migrated automatically.
Messaging Subsystem Migration and Forward Compatibility

The `describe-migration` and `migrate` operations for the `messaging` subsystem provide an additional configuration argument. If you want to configure messaging to allow legacy JBoss EAP 6 clients to connect to the JBoss EAP 7 server, you can add the boolean `add-legacy-entries` argument to the `describe-migration` or `migrate` operation as follows.

```
/subsystem=messaging:describe-migration(add-legacy-entries=true)
/subsystem=messaging:migrate(add-legacy-entries=true)
```

If the boolean argument `add-legacy-entries` is set to `true`, the `messaging-activemq` subsystem creates the `legacy-connection-factory` resource and adds `legacy-entries` to the `jms-queue` and `jms-topic` resources.

If the boolean argument `add-legacy-entries` is set to `false`, no legacy resources are created in the `messaging-activemq` subsystem and legacy messaging clients will not be able to communicate with the JBoss EAP 7 servers. This is the default value.

For more information about forward and backward compatibility see the Backward and Forward Compatibility in Configuring Messaging for JBoss EAP.

For more information about the management CLI `migrate` and `describe-migration` operations, see Management CLI Migration Operation.

Change in Behavior of `forward-when-no-consumers` Attribute

The behavior of the `forward-when-no-consumers` attribute has changed in JBoss EAP 7.

In JBoss EAP 6, when `forward-when-no-consumers` was set to `false` and there were no consumers in a cluster, messages were redistributed to all nodes in a cluster.

This behavior has changed in JBoss EAP 7. When `forward-when-no-consumers` is set to `false` and there are no consumers in a cluster, messages are not redistributed. Instead, they are kept on the original node to which they were sent.

Change in Default Cluster Load Balancing Policy

The default cluster load balancing policy has changed in JBoss EAP 7.

In JBoss EAP 6, the default cluster load balancing policy was similar to `STRICT`, which is like setting the legacy `forward-when-no-consumers` parameter to `true`. In JBoss EAP 7, the default is now `ON_DEMAND`, which is like setting the legacy `forward-when-no-consumers` parameter to `false`. For more information about these settings, see Cluster Connection Attributes in Configuring Messaging for JBoss EAP.

Messaging Subsystem XML Configuration

The XML configuration has changed significantly with the new `messaging-activemq` subsystem, and now provides an XML scheme more consistent with other JBoss EAP subsystems.

It is strongly advised that you do not attempt to modify the JBoss EAP `messaging` subsystem XML configuration to conform to the new `messaging-activemq` subsystem. Instead, invoke the legacy subsystem `migrate` operation. This operation will write the XML configuration of the new `messaging-activemq` subsystem as a part of its execution.

4.9.2. Migrate Messaging Data

You can use one of the following approaches to migrate messaging data from a previous release to the current release of JBoss EAP.
For file-based messaging systems, you can migrate messaging data to JBoss EAP 7.4 from JBoss EAP 6.4 and previous JBoss EAP 7.x releases using the export and import method. With this method you export the messaging data from the previous release and import it using the management CLI import-journal operation. Be aware that you can use this approach for file-based messaging systems only.

You can migrate messaging data from JBoss EAP 6.4 to JBoss EAP 7.4 by configuring a Jakarta Messaging bridge. You can use this approach for both file-based and JDBC messaging systems.

Due to the change from HornetQ to ActiveMQ Artemis as the Jakarta Messaging support provider, both the format and the location of the messaging data changed in JBoss EAP 7.0 and later. See Mapping Messaging Folder Names for details of the changes to the messaging data folder names and locations between the 6.4 and 7.x releases.

### 4.9.2.1. Migrate Messaging Data Using Export and Import

Using this approach, you export the messaging data from a previous release to an XML file, and then import that file using the import-journal operation.

1. Export the messaging data to an XML file.
   - Export messaging data from JBoss EAP 6.4.
   - Export messaging data from JBoss EAP 7.x.

2. Import the XML formatted messaging data.

   **IMPORTANT**
   
   You cannot use the export and import method to move messaging data between systems that use a JDBC-based journal for storage.

### Export Messaging Data from JBoss EAP 6.4

Due to the change from HornetQ to ActiveMQ Artemis as the messaging support provider, both the format and the location of the messaging data changed in JBoss EAP 7.0 and later.

To export messaging data from JBoss EAP 6.4, you must use the HornetQ exporter utility. The HornetQ exporter utility generates and exports the messaging data from JBoss EAP 6.4 to an XML file. This command requires that you specify the paths to the required HornetQ JARs that shipped with JBoss EAP 6.4, pass the paths to messagingbindings/, messagingjournal/, messagingpaging/, and messaginglargemessages/ folders from the previous release as arguments, and specify an output file in which to write the exported XML data.

The following is the syntax required by the HornetQ exporter utility.

```
$ java -jar -mp MODULE_PATH org.hornetq.exporter MESSAGING_BINDINGS_DIRECTORY
MESSAGING_JOURNAL_DIRECTORY MESSAGING_PAGING_DIRECTORY
MESSAGING_LARGE_MESSAGES_DIRECTORY > OUTPUT_DATA.xml
```

Create a custom module to ensure the correct versions of the HornetQ JARs, including any JARs installed with patches or upgrades, are loaded and made available to the exporter utility. Using your favorite editor, create a new module.xml file in the EAP6_HOME/modules/org/hornetq/exporter/main/ directory and copy the following content:
Follow the steps below to export the data.

1. Stop the JBoss EAP 6.4 server.

2. Create the custom module as described above.

3. Run the following command to export the data.

   ```
   $ java -jar jboss-modules.jar -mp modules/ org.hornetq.exporter
   standalone/data/messagingbindings/ standalone/data/messagingjournal/
   standalone/data/messagingpaging standalone/data/messaginglargemessages/ >
   OUTPUT_DIRECTORY/OldMessagingData.xml
   ```

4. Make sure there are no errors or warning messages in the log at the completion of the command.

5. Use tooling available for your operating system to validate the XML in the generated output file.

### Export Messaging Data from JBoss EAP 7.x

Follow these steps to export messaging data from JBoss EAP 7.x.

1. Open a terminal, navigate to the JBoss EAP 7.x install directory, and start the server in `admin-only` mode.

   ```
   $ EAP_HOME/bin/standalone.sh -c standalone-full.xml --start-mode=admin-only
   ```

2. Open a new terminal, navigate to the JBoss EAP 7.x install directory, and connect to the management CLI.

   ```
   $ EAP_HOME/bin/jboss-cli.sh --connect
   ```

3. Use the following management CLI command to export the messaging journal data.

   ```
   /subsystem=messaging-activemq/server=default:export-journal()
   ```

4. Make sure there are no errors or warning messages in the log at the completion of the command.
5. Use tooling available for your operating system to validate the XML in the generated output file.

Import the XML Formatted Messaging Data
You then import the XML file into JBoss EAP 7.0 or later by using the `import-journal` operation as follows.

**IMPORTANT**
If your target server has already performed some messaging tasks, be sure to back up your messaging folders before you begin the `import-journal` operation to prevent data loss in the event of an import failure. See [Backing Up Messaging Folder Data](#) for more information.

1. If you are migrating your JBoss EAP 6.4 server to JBoss EAP 7.4, make sure you have completed the migration of the server configuration before you begin by using the `management CLI migrate operation` or by running the JBoss Server Migration Tool. For information about how to configure and run the tool, see [Using the JBoss Server Migration Tool](#).

2. Start the JBoss EAP 7.x server in normal mode with no Jakarta Messaging clients connected.

**IMPORTANT**
It is important that you start the server with no Jakarta Messaging clients connected. This is because the `import-journal` operation behaves like a Jakarta Messaging producer. Messages are immediately available when the operation is in progress. If this operation fails in the middle of the import and Jakarta Messaging clients are connected, there is no way to recover because Jakarta Messaging clients might have already consumed some of the messages.

3. Open a new terminal, navigate to the JBoss EAP 7.x install directory, and connect to the management CLI.

   ```sh
   $ EAP_HOME/bin/jboss-cli.sh --connect
   ```

4. Use the following management CLI command to import the messaging data.

   ```sh
   /subsystem=messaging-activemq/server=default:import-journal(file=OUTPUT_DIRECTORY/OldMessagingData.xml)
   ```

**IMPORTANT**
Do not run this command more than one time as doing so will result in duplicate messages!
**WARNING**

If you are using JBoss EAP 7.0, you must apply Red Hat JBoss Enterprise Application Platform 7.0 Update 05 or a newer cumulative patch to your JBoss EAP installation in order to avoid a known issue when reading large messages. For more information, see JBEAP-4407 - Consumer crashes with IndexOutOfBoundsException when reading large messages from imported journal.

This issue does not affect JBoss EAP 7.1 and later.

---

**Recovering from an Import Messaging Data Failure**

If the `import-journal` operation fails, you can attempt to recover by using the following steps.

1. Shut down the JBoss EAP 7.x server.

2. Delete all of the messaging journal folders. See Backing Up Messaging Folder Data for the management CLI commands to determine the correct directory location for the messaging journal folders.

3. If you backed up the target server messaging data prior to the import, copy the messaging folders from the backup location to the messaging journal directory determined in the prior step.

4. Repeat the steps to import the XML formatted messaging data.

**4.9.2.2. Migrate Messaging Data Using a Messaging Bridge**

Using this approach, you configure and deploy a messaging bridge to the JBoss EAP 7.x server. This bridge moves messages from the JBoss EAP 6.4 HornetQ queue to the JBoss EAP 7.x ActiveMQ Artemis queue.

A Jakarta Messaging bridge consumes messages from a source Jakarta Messaging queue or topic and sends them to a target Jakarta Messaging queue or topic, which is typically on a different server. It can be used to bridge messages between any messaging servers, as long as they are JMS 1.1 compliant. The source and destination Jakarta Messaging resources are looked up using Java Naming and Directory Interface, and the client classes for the Java Naming and Directory Interface lookup must be bundled in a module. The module name is then declared in the Jakarta Messaging bridge configuration.

This section describes how to configure the servers and deploy a messaging bridge to move the messaging data from JBoss EAP 6.4 to JBoss EAP 7.x.

1. Configure the source JBoss EAP 6.4 server.

2. Configure the target JBoss EAP 7.x server.

3. Migrate the messaging data.

**Configure the Source JBoss EAP 6.4 Server**

1. Stop the JBoss EAP 6.4 server.
2. Back up the HornetQ journal and configuration files.
   - By default, the HornetQ journal is located in the \texttt{EAP6\_HOME/standalone/data/} directory.
   - See Mapping Messaging Folder Names for default messaging folder locations for each release.

3. Make sure that the \textit{InQueue} JMS queue containing the JMS messages is defined on the JBoss EAP 6.4 server.

4. Make sure that \textit{messaging} subsystem configuration contains an entry for the \texttt{RemoteConnectionFactory} similar to the following.

   
   $$\begin{aligned}
   \text{<connection-factory name="RemoteConnectionFactory">} \\
   \text{<entries>} \\
   \text{<entry name="java:jboss/exported/jms/RemoteConnectionFactory"/>} \\
   \text{</entries>} \\
   \text{...} \\
   \text{</connection-factory>}
   \end{aligned}$$

   If it does not contain the entry, create one using the following management CLI command:

   \text{/subsystem=messaging/hornetq-server=default/connection-factory=RemoteConnectionFactory:add(factory-type=XA\_GENERIC, connector=[netty], entries=[java:jboss/exported/jms/RemoteConnectionFactory],ha=true,block-on-acknowledge=true,retry-interval=1000,retry-interval-multiplier=1.0,reconnect-attempts=-1)}

Configure the Target JBoss EAP 7.x Server

1. The Jakarta Messaging bridge configuration needs the \texttt{org.hornetq} module to connect to the HornetQ server in the previous release. This module and its direct dependencies are not present in JBoss EAP 7.x, so you must copy the following modules from the previous release.

   - Copy the \texttt{org.hornetq} module into the JBoss EAP 7.x \texttt{EAP\_HOME/modules/org/} directory.
     - If you did not apply patches to this module, copy this folder from the JBoss EAP 6.4 server: \texttt{EAP6\_HOME/modules/system/layers/base/org/hornetq/}
     - If you did apply patches to this module, copy this folder from the JBoss EAP 6.4 server: \texttt{EAP6\_HOME/modules/system/layers/base/.overlays/layer-base-jboss-eap-6.4.x.CP/org/hornetq/}
   
   - Remove the \texttt{<resource-root>} for the HornetQ \texttt{lib} path from the JBoss EAP 7.x \texttt{EAP\_HOME/modules/org/hornetq/main/module.xml} file.
     - If you did not apply patches to the JBoss EAP 6.4 \texttt{org.hornetq} module, remove the following line from the file:
       $$<resource-root path="lib"/>$$
     - If you did apply patches to the JBoss EAP 6.4 \texttt{org.hornetq} module, remove the following lines from the file:
       $$<resource-root path="lib"/>$$
       $$<resource-root path="..\..\..\..\\org/hornetq/main/lib"/>$$
FAILURE TO REMOVE THE HORNETQ LIB PATH RESOURCE-ROOT WILL CAUSE THE BRIDGE TO FAIL WITH THE FOLLOWING ERROR IN THE LOG FILE.

   ("subsystem" => "messaging-activemq"),
   ("jms-bridge" => "myBridge")
]) - failure description: "WFLYMSGAMQ0086: Unable to load module org.hornetq"

- Copy the org.jboss.netty module into the JBoss EAP 7.x EAP_HOME/modules/org/jboss/directory.
  - If you did not apply patches to this module, copy this folder from the JBoss EAP 6.4 server: EAP6_HOME/modules/system/layers/base/org/jboss/netty/
  - If you did apply patches to this module, copy this folder from the JBoss EAP 6.4 server: EAP6_HOME/modules/system/layers/base/.overlays/layer-base-jboss-eap-6.4.x.CP/org/jboss/netty

2. Create the Jakarta Messaging queue to contain the messages received from JBoss EAP 6.4 server. The following is an example of a management CLI command that creates the MigratedMessagesQueue Jakarta Messaging queue to receive the message.

   jms-queue add --queue-address=MigratedMessagesQueue --entries=
   [jms/queue/MigratedMessagesQueue
    java:jboss/exported/jms/queue/MigratedMessagesQueue]

   This creates the following jms-queue configuration for the default server in the messaging-activemq subsystem of the JBoss EAP 7.x server.

   <jms-queue name="MigratedMessagesQueue" entries="jms/queue/MigratedMessagesQueue
    java:jboss/exported/jms/queue/MigratedMessagesQueue"/>

3. Make sure that messaging-activemq subsystem default server contains a configuration for the InVmConnectionFactory connection-factory similar to the following:

   <connection-factory name="InVmConnectionFactory" factory-type="XA_GENERIC"
    entries="java:/ConnectionFactory" connectors="in-vm"/>

   If it does not contain the entry, create one using the following management CLI command:

   /subsystem=messaging-activemq/server=default/connection-factory=InVmConnectionFactory:add(factory-type=XA_GENERIC, connectors=[in-vm],
   entries=[java:/ConnectionFactory])
4. Create and deploy a Jakarta Messaging bridge that reads messages from the InQueue JMS queue configured on the JBoss EAP 6.4 server and transfers them to the MigratedMessagesQueue configured on the JBoss EAP 7.x server.

```
```

This creates the following jms-bridge configuration in the messaging-activemq subsystem of the JBoss EAP 7.x server.

```
<jms-bridge name="myBridge" add-messageID-in-header="true" max-batch-time="100" max-batch-size="10" max-retries="-1" failure-retry-interval="1000" quality-of-service="AT_MOST_ONCE" module="org.hornetq">
  <source destination="jms/queue/InQueue" connection-factory="jms/RemoteConnectionFactory">
    <source-context>
      <property name="java.naming.factory.initial" value="org.wildfly.naming.client.WildFlyInitialContextFactory"/>
      <property name="java.naming.provider.url" value="remote://127.0.0.1:4447"/>
    </source-context>
  </source>
  <target destination="jms/queue/MigratedMessagesQueue" connection-factory="java:/ConnectionFactory"/>
</jms-bridge>
```

5. If security is configured for JBoss EAP 6.4, you must also configure the messaging bridge configuration `<source>` element to include a `source-context` that specifies the correct user name and password to use for the Java Naming and Directory Interface lookup when creating the connection.

Migrate the Messaging Data

1. Verify that the information you provided for the following configurations is correct.
   - Any queue and topic names.
   - The `java.naming.provider.url` for Java Naming and Directory Interface lookup.

2. Make sure that you have deployed the target Jakarta Messaging destination to the JBoss EAP 7.x server.

3. Start both the JBoss EAP 6.4 and JBoss EAP 7.x servers.

4.9.2.3. Mapping Messaging Folder Names

The following table shows the messaging directory names used in the previous release and the corresponding names used in the current release of JBoss EAP. The directories are relative to the `jboss.server.data.dir` directory, which defaults to `EAP_HOME/standalone/data/` if it is not specified.
### 4.9.2.4. Backing Up Messaging Folder Data

If your target server has already processed messages, it is a good idea to back up the target message folders to a backup location before you begin. The default location of the messaging folders is `$EAP_HOME/standalone/data/activemq`; however, it is configurable. If you are not sure of the location of your messaging data, you can use the following management CLI commands to find the location of the messaging folders.

```
/subsystem=messaging-activemq/server=default/path=journal-directory:resolve-path
/subsystem=messaging-activemq/server=default/path=paging-directory:resolve-path
/subsystem=messaging-activemq/server=default/path=bindings-directory:resolve-path
/subsystem=messaging-activemq/server=default/path=large-messages-directory:resolve-path
```

Once you know the location of the folders, copy each folder to a safe backup location.

### 4.9.3. Migrate Messaging Destinations

In JBoss EAP 6, messaging destination queues were configured in the `<jms-destinations>` element under the `<hornetq-server>` element in the `messaging` subsystem.

```
<hornetq-server>
...
<jms-destinations>
  <jms-queue name="testQueue">
    <entry name="queue/test"/>
    <entry name="java:jboss/exported/jms/queue/test"/>
  </jms-queue>
</jms-destinations>
...
</hornetq-server>
```

In JBoss EAP 7, the Jakarta Messaging destination queue is configured in the default `<server>` element of the `messaging-activemq` subsystem.

```
<server name="default">
...
```
4.9.4. Migrate Messaging Interceptors

Messaging interceptors have changed significantly in JBoss EAP 7 with the replacement of HornetQ with ActiveMQ Artemis as the Jakarta Messaging provider.

The HornetQ **messaging** subsystem included in the previous release of JBoss EAP required that you install the HornetQ interceptors by adding them to a JAR and then modifying the HornetQ **module.xml** file.

The **messaging-activemq** subsystem included in JBoss EAP 7 does not require modification of a **module.xml** file. User interceptor classes, which now implement the Apache ActiveMQ Artemis **Interceptor** interface, can now be loaded from any server module. You specify the module from which the interceptor should be loaded in the **messaging-activemq** subsystem of the server configuration file.

Example: Interceptor Configuration

```xml
<subsystem xmlns="urn:jboss:domain:messaging-activemq:4.0">  
  <server name="default">  
    ...  
    <incoming-interceptors>  
      <class name="com.mycompany.incoming.myInterceptor" module="com.mycompany" />  
      <class name="com.othercompany.incoming.myOtherInterceptor" module="com.othercompany" />  
    </incoming-interceptors>  
    <outgoing-interceptors>  
      <class name="com.mycompany.outgoing.myInterceptor" module="com.mycompany" />  
      <class name="com.othercompany.outgoing.myOtherInterceptor" module="com.othercompany" />  
    </outgoing-interceptors>  
  </server>  
</subsystem>
```

4.9.5. Replace Netty Servlet Configuration

In JBoss EAP 6, you could configure a servlet engine to work with the Netty Servlet transport. Because ActiveMQ Artemis replaces HornetQ as the built-in messaging provider in JBoss EAP 7, this configuration is no longer available. You must replace the servlet configuration to use the new built-in messaging HTTP connectors and HTTP acceptors instead.

4.9.6. Configuring a Generic Jakarta Messaging Resource Adapter

The way you configure a generic Jakarta Messaging resource adapter for use with a third-party Jakarta Messaging provider has changed in JBoss EAP 7. For more information, see Deploying a Generic Jakarta Messaging Resource Adapter in Configuring Messaging for JBoss EAP.

4.9.7. Messaging Configuration Changes

In JBoss EAP 7.0, if you configured the **replication-master** policy without specifying the **check-for-live-server** attribute, its default value was `false`. This has changed in JBoss EAP 7.1 and later. The default value for the **check-for-live-server** attribute is now `true`. 
The following is an example of a management CLI command that configures the `replication-master` policy without specifying the `check-for-live-server` attribute.

```
/subsystem=messaging-activemq/server=default/ha-policy=replication-master:add(cluster-name=my-cluster,group-name=group1)
```

When you read the resource using the management CLI, note that the `check-for-live-server` attribute value is set to `true`.

```
/subsystem=messaging-activemq/server=default/ha-policy=replication-master:read-resource(recursive=true)
{
  "outcome" => "success",
  "result" => {
    "check-for-live-server" => true,
    "cluster-name" => "my-cluster",
    "group-name" => "group1",
    "initial-replication-sync-timeout" => 30000L
  },
  "response-headers" => {"process-state" => "reload-required"}
}
```

### 4.9.8. Changes in JMS and Jakarta Messaging Serialization Behavior Between Releases

The `serialVersionUID` of `javax.jms.JMSException` changed between JMS 1.1 and JMS 2.0.0. This means that if an instance of a `JMSException`, or any of its subclasses, is serialized using JMS 1.1, it cannot be deserialized using JMS 2.0.0. The reverse is also true. If an instance of `JMSException` is serialized using JMS 2.0.0, it cannot be deserialized using JMS 1.1. In both of these cases, it throws an exception similar to the following:

```
javax.jms.JMSException: javax.jms.JMSException; local class incompatible: stream classdesc serialVersionUID = 8951994251593378324, local class serialVersionUID = 2368476267211489441
```

This issue is fixed in the Jakarta Messaging 2.0.1 maintenance release.

**NOTE**

The JMS 2.0.1 specification is compatible with the Jakarta Messaging 2.0.3 specification.

The following table details implementations for each JBoss EAP release.

**Table 4.4. Implementations for Each JBoss EAP Release**

<table>
<thead>
<tr>
<th>JBoss EAP Version</th>
<th>Implementation</th>
<th>Version</th>
</tr>
</thead>
<tbody>
<tr>
<td>6.4</td>
<td>HornetQ</td>
<td>JMS 1.1</td>
</tr>
<tr>
<td>7.0</td>
<td>Apache ActiveMQ Artemis</td>
<td>JMS 2.0.0</td>
</tr>
<tr>
<td>7.1 and later</td>
<td>Apache ActiveMQ Artemis</td>
<td>Jakarta Messaging 2.0.3 or later</td>
</tr>
</tbody>
</table>
Be aware that the `serialVersionUID` incompatibility can result in a migration issue in the following situations:

- If you send a message that contains a `JMSException` using a JBoss EAP 6.4 client, migrate your messaging data to JBoss EAP 7.0, and then attempt to deserialize that message using a JBoss EAP 7.0 client, the deserialization will fail and it will throw an exception. This is because the `serialVersionUID` in JMS 1.1 is not compatible with the one in JMS 2.0.0.

- If you send a message that contains a `JMSException` using a JBoss EAP 7.0 client, migrate your messaging data to JBoss EAP 7.1 or later, and then attempt to deserialize that message using a JBoss EAP 7.1 or later client, the deserialization will fail and it will throw an exception. This is because the `serialVersionUID` in JMS 2.0.0 is not compatible with the one in Jakarta Messaging 2.0.3 or later.

Note that if you send a message that contains a `JMSException` using a JBoss EAP 6.4 client, migrate your messaging data to JBoss EAP 7.1 or later, and then attempt to deserialize that message using a JBoss EAP 7.1 or later client, the deserialization will succeed because the `serialVersionUID` in JMS 1.1 is compatible with the one in Jakarta Messaging 2.0.3 or later.

**IMPORTANT**

Red Hat recommends that you do the following before you migrate your messaging data:

- Be sure to consume all JMS 1.1 messages that contain JMSExceptions before migrating messaging data from JBoss EAP 6.4 to JBoss EAP 7.0.

- Be sure to consume all Jakarta Messaging 2.0.3 messages that contain Jakarta Messaging Exceptions before migrating messaging data from JBoss EAP 7.0 to JBoss EAP 7.1 or later.

### 4.10. JMX MANAGEMENT AND JAKARTA MANAGEMENT CHANGES

The HornetQ component in JBoss EAP 6 provided its own JMX management; however, it was not recommended and is now deprecated and no longer supported. If you relied on this feature in JBoss EAP 6, you must migrate your management tooling to use either the JBoss EAP management CLI or the Jakarta Management management provided with JBoss EAP 7.

You must also upgrade your client libraries to use the `jboss-client.jar` that ships with JBoss EAP 7.

The following is an example of HornetQ JMX management code that was used in JBoss EAP 6.

```java
JMXConnector connector = null;
try {
    HashMap environment = new HashMap();
    String[] credentials = new String[]{'"admin", "Password123!"'};
    environment.put(JMXConnector.CREDENTIALS, credentials);

    // HornetQ used the protocol "remoting-jmx" and port "9999"
    JMXServiceURL beanServerUrl = new JMXServiceURL("service:jmx:remoting-jmx://127.0.0.1:9990");

    connector = JMXConnectorFactory.connect(beanServerUrl, environment);
    MBeanServerConnection mbeanServer = connector.getMBeanServerConnection();

    // The JMX object name pointed to the HornetQ JMX management
```
The following is an example of the equivalent code needed for ActiveMQ Artemis in JBoss EAP 7.

```java
ObjectName objectName = new ObjectName("org.hornetq:type=Server,module=JMS");

// The invoked method name was "listConnectionIDs"
String[] connections = (String[]) mbeanServer.invoke(objectName, "listConnectionIDs", new Object[][], new String[]{});
for (String connection : connections) {
    System.out.println(connection);
}
finally {
    if (connector != null) {
        connector.close();
    }
}
```

Notice that the method names and parameters have changed in the new implementation. You can find the new method names in the JConsole by following these steps.

1. Connect to the JConsole using the following command.

   ```
   $ EAP_HOME/bin/jconsole.sh
   ```

2. Connect to JBoss EAP local process. Note that it should start with "jboss-modules.jar".
3. In the **MBeans** tab, choose **jboss.as → messaging-activemq → default → Operations** to display the list of method names and attributes.

### 4.11. ORB SERVER CONFIGURATION CHANGES

The JacORB implementation has been replaced with a downstream branch of the OpenJDK ORB in JBoss EAP 7.

The **org.jboss.as.jacorb** extension module, located in **EAP_HOME/modules/system/layers/base/**, has been replaced by the **org.wildfly.iiop-openjdk** extension module.

The **urn:jboss:domain:jacorb:1.4** subsystem configuration namespace in the server configuration file has been replaced by the **urn:jboss:domain:iiop-openjdk:2.1** namespace.

The following is an example of the default **jacorb** system configuration in JBoss EAP 6.

```
<subsystem xmlns="urn:jboss:domain:jacorb:1.4">
  <orb socket-binding="jacorb" ssl-socket-binding="jacorb-ssl">
    <initializers security="identity" transactions="spec"/>
  </orb>
</subsystem>
```

The following is an example of the default **iiop-openjdk** subsystem configuration in JBoss EAP 7.

```
<subsystem xmlns="urn:jboss:domain:iiop-openjdk:2.1">
  <orb socket-binding="jacorb" ssl-socket-binding="jacorb-ssl"/>
  <initializers security="identity" transactions="spec"/>
</subsystem>
```

The new **iiop-openjdk** subsystem configuration accepts only a subset of the legacy elements and attributes. The following is an example of a **jacorb** subsystem configuration in the previous release of JBoss EAP that contains all valid elements and attributes:

```
<subsystem xmlns="urn:jboss:domain:jacorb:1.4">
  <orb name="JBoss" print-version="off" use-imr="off" use-bom="off" cache-typecodes="off" cache-poa-names="off" giop-minor-version="2" socket-binding="jacorb" ssl-socket-binding="jacorb-ssl">
    <connection retries="5" retry-interval="500" client-timeout="0" server-timeout="0">
      <max-server-connections="500" max-managed-buf-size="24" outbuf-size="2048" outbuf-cache-timeout="-1"/>
    </connection>
    <initializers security="off" transactions="spec"/>
  </orb>
  <poa monitoring="off" queue-wait="on" queue-min="10" queue-max="100">
    <request-processors pool-size="10" max-threads="32"/>
  </poa>
  <naming root-context="JBoss/Naming/root" export-corbaloc="on"/>
  <interop sun="on" comet="off" iona="off" chunk-custom-rmi-valuetypes="on" lax-boolean-encoding="off" indirection-encoding-disable="off" strict-check-on-tc-creation="off"/>
  <security support-ssl="off" add-component-via-interceptor="on" client-supports="MutualAuth" client-queue="None" server-supports="MutualAuth" server-requires="None"/>
  <properties>
    <property name="some_property" value="some_value"/>
  </properties>
</subsystem>
```
The following element attributes are no longer supported and must be removed.

Table 4.5. Attributes to Remove

<table>
<thead>
<tr>
<th>Element</th>
<th>Unsupported Attributes</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;orb&gt;</td>
<td>• client-timeout</td>
</tr>
<tr>
<td></td>
<td>• max-managed-buf-size</td>
</tr>
<tr>
<td></td>
<td>• max-server-connections</td>
</tr>
<tr>
<td></td>
<td>• outbuf-cache-timeout</td>
</tr>
<tr>
<td></td>
<td>• outbuf-size</td>
</tr>
<tr>
<td></td>
<td>• connection retries</td>
</tr>
<tr>
<td></td>
<td>• retry-interval</td>
</tr>
<tr>
<td></td>
<td>• name</td>
</tr>
<tr>
<td></td>
<td>• server-timeout</td>
</tr>
<tr>
<td>&lt;poa&gt;</td>
<td>• queue-min</td>
</tr>
<tr>
<td></td>
<td>• queue-max</td>
</tr>
<tr>
<td></td>
<td>• pool-size</td>
</tr>
<tr>
<td></td>
<td>• max-threads</td>
</tr>
</tbody>
</table>

The following on/off attributes are no longer supported and will not be migrated when you run the management CLI `migrate` operation. If they are set to on, you will get a migration warning. Other on/off attributes that are not mentioned in this table, for example `<security support-ssl="on|off">`, are still supported and will be migrated successfully. The only difference is that their values will be changed from on/off to true/false.

Table 4.6. Attributes to Turn Off or Remove

<table>
<thead>
<tr>
<th>Element</th>
<th>Attributes to Set to Off</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;orb&gt;</td>
<td>• cache-poa-names</td>
</tr>
<tr>
<td></td>
<td>• cache-typecodes</td>
</tr>
<tr>
<td></td>
<td>• print-version</td>
</tr>
<tr>
<td></td>
<td>• use-bom</td>
</tr>
<tr>
<td></td>
<td>• use-imr</td>
</tr>
</tbody>
</table>
4.12. MIGRATE THE THREADS SUBSYSTEM CONFIGURATION

The JBoss EAP 6 server configuration included a threads subsystem that was used to manage thread pools across the various subsystems in the server.

The threads subsystem is no longer available in JBoss EAP 7. Instead, each subsystem is responsible for managing its own thread pools.

For information about how to configure thread pools for the infinispan subsystem, see Configure Infinispan Thread Pools in the JBoss EAP Configuration Guide.

For information about how to configure thread pools for the jgroups subsystem, see Configure JGroups Thread Pools in the JBoss EAP Configuration Guide.

In JBoss EAP 6, you configured thread pools for connectors and listeners for the web subsystem by referencing an executor that was defined in the threads subsystem. In JBoss EAP 7, you now configure thread pools for the undertow subsystem by referencing a worker that is defined in the io subsystem. For more information, see Configuring the IO Subsystem in the JBoss EAP Configuration Guide.

For information about about changes to thread pool configuration in the remoting subsystem, see Migrate the Remoting Subsystem Configuration in this guide, and Configuring the Endpoint in the JBoss EAP Configuration Guide.

4.13. MIGRATE THE REMOTING SUBSYSTEM CONFIGURATION

In JBoss EAP 6, you configured the thread pool for the remoting subsystem by setting various worker-* attributes. The worker thread pool is no longer configured in the remoting subsystem in JBoss EAP 7 and if you attempt to modify the existing configuration, you will see the following message.

WFLYRMT0022: Worker configuration is no longer used, please use endpoint worker configuration
In JBoss EAP 7, the worker thread pool is replaced by an endpoint configuration that references a worker defined in the io subsystem.

For information about how to configure the endpoint, see Configuring the Endpoint in the JBoss EAP Configuration Guide.

### 4.14. WEBSOCKET SERVER CONFIGURATION CHANGES

To use WebSockets in JBoss EAP 6, you had to enable the non-blocking NIO2 connector protocol for the http connector in the web subsystem of the JBoss EAP server configuration file using a command similar to the following.

```
```

To use WebSockets in an application, you also had to create a `<enable-websockets>` element in the application WEB-INF/jboss-web.xml file and set it to `true`.

In JBoss EAP 7, you no longer need to configure the server for default WebSocket support or configure the application to use it. WebSockets are a requirement of the Jakarta EE 8 specification and the required protocols are configured by default. More complex WebSocket configuration is done in the servlet-container of the undertow subsystem of the JBoss EAP server configuration file. You can view the available settings using the following command.

```
/subsystem=undertow/servlet-container=default/setting=websockets:read-resource(recursive=true)
```

For more information about WebSocket development, see Creating WebSocket Applications in the JBoss EAP Development Guide.

WebSocket code examples can also be found in the quickstarts that ship with JBoss EAP.

### 4.15. SINGLE SIGN-ON SERVER CHANGES

The infinispan subsystem still provides distributed caching support for HA services in the form of Infinispan caches in JBoss EAP 7; however the caching and distribution of authentication information is handled differently than in previous releases.

In JBoss EAP 6, if single sign-on (SSO) was not provided an Infinispan cache, the cache was not distributed.

In JBoss EAP 7, SSO is distributed automatically when you select the HA profile. When running the HA profile, each host has its own Infinispan cache, which is based on the default cache of the web cache container. This cache stores the relevant session and SSO cookie information for the host. JBoss EAP handles propagation of individual cache information to all hosts. There is no way to specifically assign an Infinispan cache to SSO in JBoss EAP 7.

In JBoss EAP 7, SSO is configured in the undertow subsystem of the server configuration file.
There are no application code changes required for SSO when migrating to JBoss EAP 7.

4.16. DATASOURCE CONFIGURATION CHANGES

4.16.1. JDBC Datasource Driver Name

When you configured a datasource in the previous release of JBoss EAP, the value specified for the driver name depended on the number of classes listed in the `META-INF/services/java.sql.Driver` file contained in the JDBC driver JAR.

**Driver Containing a Single Class**

If the `META-INF/services/java.sql.Driver` file specified only one class, the driver name value was simply the name of the JDBC driver JAR. This has not changed in JBoss EAP 7.

**Driver Containing Multiple Classes**

In JBoss EAP 6, if there was more than one class listed in `META-INF/services/java.sql.Driver` file, you specified which class was the driver class by appending its name to the JAR name, along with the major and minor version, in the following format.

```
JAR_NAME + DRIVER_CLASS_NAME + "_" + MAJOR_VERSION + "_" + MINOR_VERSION
```

In JBoss EAP 7, this has changed. You now specify the driver name using the following format.

```
JAR_NAME + "+ DRIVER_CLASS_NAME + "+ MAJOR_VERSION + "+ MINOR_VERSION
```

**NOTE**

An underscore has been added between the `JAR_NAME` and the `DRIVER_CLASS_NAME`.

The MySQL 5.1.31 JDBC driver is an example of a driver that contains two classes. The driver class name is `com.mysql.jdbc.Driver`. The following examples demonstrate the differences between how you specify the driver name in the previous and current release of JBoss EAP.

**Example: JBoss EAP 6 Driver Name**

```
mysql-connector-java-5.1.31-bin.jarcom.mysql.jdbc.Driver_5_1
```

**Example: JBoss EAP 7 Driver Name**

```
mysql-connector-java-5.1.31-bin.jar_com.mysql.jdbc.Driver_5_1
```

4.17. SECURITY SERVER CONFIGURATION CHANGES

If you migrate to JBoss EAP 7 and plan to run with the Java Security Manager enabled, you should be aware that changes were made in the way policies are defined and that additional configuration changes might be needed. Also be aware that custom security managers are not supported in JBoss EAP 7.

For information about Java Security Manager server configuration changes, see Considerations Moving from Previous Versions in How to Configure Server Security for JBoss EAP.
4.17.1. Changes in Legacy Security Behavior between JBoss EAP 7.0 and JBoss EAP 7.1

4.17.1.1. HTTP Status Change for Unreachable LDAP Realms

If no LDAP realm was reachable by the server in JBoss EAP 7.0, the security subsystem returned an HTTP status code of "401 Unauthorized".

The legacy security subsystem in JBoss EAP 7.1 and later instead return an HTTP status code of "500 Internal Error" to more accurately describe that an unexpected condition occurred that prevented the server from successfully processing the request.

4.17.1.2. Enabling the LDAP Security Realm to Parse Roles from a DN

In JBoss EAP 7.0, the org.jboss.as.domain.management.security.parseGroupNameFromLdapDN system property was used to enable the LDAP security realm to parse for roles from a DN. When this property was set to true, roles were parsed from a DN. Otherwise, a normal LDAP search was used to search for roles.

In JBoss EAP 7.1 and later, this system property is deprecated. Instead, you configure this option by setting the newly introduced parse-group-name-from-dn attribute to true in the core service path using the following management CLI command:

```
/core-service=management/security-realm=REALM_NAME/authorization=ldap/group-search=principal-to-group:add(parse-group-name-from-dn=true)
```

4.17.1.3. Changes in Sending the JBoss EAP SSL Certificate to an LDAP Server

In JBoss EAP 7.0, when the management interface is configured to use the ldapSSL security realm, mutual authentication between the server and LDAP can fail, resulting in an authentication failure in the management interface. This is because two different LDAP connections are made, each by a different thread, and they do not share the SSL sessions.

JBoss EAP 7.1 introduced a new boolean always-send-client-cert management attribute on the LDAP outbound-connection. This option allows configuration of outbound LDAP connections to support LDAP servers that are configured to always require a client certificate.

LDAP authentication happens in two steps:

1. It searches for the account.
2. It verifies the credentials.

By default, the always-send-client-cert attribute is set to false, meaning the client SSL certificate is sent only with the first search account request. When this attribute is set to true, the JBoss EAP LDAP client sends the client certificate to the LDAP server with both the search and verification requests.

You can set this attribute to true using the following management CLI command.

```
/core-service=management/ldap-connection=my-ldap-connection:write-attribute(name=always-send-client-cert,value=true)
```

This results in the following LDAP outbound connection in the server configuration file.
4.17.2. FIPS Mode Changes

If you are running in FIPS mode, be aware that the default behavior has changed between JBoss EAP 7.0 and JBoss EAP 7.1.

When using legacy security realms, JBoss EAP 7.1 and later provide the automatic generation of a self-signed certificate for development purposes. This feature, which was not available in JBoss EAP 7.0, is enabled by default. This means that if you are running in FIPS mode, you must configure the server to disable automatic self-signed certificate creation. Otherwise, you might see the following error when you start the server.

```
ERROR [org.xnio.listener] (default I/O-6) XNIO001007: A channel event listener threw an exception: java.lang.RuntimeException: WFLYDM0114: Failed to lazily initialize SSL context
... 
Caused by: java.lang.RuntimeException: WFLYDM0112: Failed to generate self signed certificate
... 
Caused by: java.security.KeyStoreException: Cannot get key bytes, not PKCS#8 encoded
```

For information about automatic self-signed certificate creation, see Automatic Self-signed Certificate Creation for Applications in How to Configure Server Security for JBoss EAP.

4.18. TRANSACTIONS SUBSYSTEM CHANGES

Some Transaction Manager configuration attributes that were available in the transactions subsystem in JBoss EAP 6 have changed in JBoss EAP 7.

**Removed Transactions Subsystem Attributes**
The following table lists the JBoss EAP 6 attributes that were removed from the transactions subsystem in JBoss EAP 7 and the equivalent replacement attributes.

<table>
<thead>
<tr>
<th>Attribute in JBoss EAP 6</th>
<th>Replacement in JBoss EAP 7</th>
</tr>
</thead>
<tbody>
<tr>
<td>path</td>
<td>object-store-path</td>
</tr>
<tr>
<td>relative-to</td>
<td>object-store-relative-to</td>
</tr>
</tbody>
</table>

**Deprecated Transactions Subsystem Attributes**
The following attributes that were available in the transactions subsystem in JBoss EAP 6 are deprecated in JBoss EAP 7. The deprecated attributes might be removed in a future release of the product. The following table lists the equivalent replacement attributes.
### Attribute in JBoss EAP 6 | Replacement in JBoss EAP 7
---|---
use-hornetq-store | use-journal-store
hornetq-store-enable-async-io | journal-store-enable-async-io
enable-statistics | statistics-enabled

#### 4.19. CHANGES TO MOD_CLUSTER CONFIGURATION

The configuration for static proxy lists in mod_cluster has changed in JBoss EAP 7.

In JBoss EAP 6, you configured the **proxy-list** attribute, which was a comma-separated list of httpd proxy addresses specified in the format of *hostname:port*.

The **proxy-list** attribute is deprecated in JBoss EAP 7. It has been replaced by the **proxies** attribute, which is a list of outbound socket binding names.

This change impacts how you define a static proxy list, for example, when disabling advertising for mod_cluster. For information about how to disable advertising for mod_cluster, see [Disable Advertising for mod_cluster](#) in the JBoss EAP Configuration Guide.

For more information about mod_cluster attributes, see [ModCluster Subsystem Attributes](#) in the JBoss EAP Configuration Guide.

#### 4.20. VIEWING CONFIGURATION CHANGES

JBoss EAP 7 provides the ability to track configuration changes made to the running server. This allows administrators to view a history of configuration changes made by authorized users.

In JBoss EAP 7.0, you must use the **core-service** management CLI command to configure options and to list recent configuration changes.

**Example: List Configuration Changes in JBoss EAP 7.0**

```
/core-service=management/service=configuration-changes:add(max-history=10)
/core-service=management/service=configuration-changes:list-changes
```

JBoss EAP 7.1 introduced a new **core-management** subsystem that can be configured to track configuration changes made to the running server. This is the preferred method of configuring and viewing configuration changes in JBoss EAP 7.1 and later.

**Example: List Configuration Changes in JBoss EAP 7.1 and Later**

```
/subsystem=core-management/service=configuration-changes:add(max-history=20)
/subsystem=core-management/service=configuration-changes:list-changes
```

For more information about using the new **core-management** subsystem introduced in JBoss EAP 7.1, see [View Configuration Changes](#) in the JBoss EAP Configuration Guide.
CHAPTER 5. APPLICATION MIGRATION CHANGES

5.1. WEB SERVICES APPLICATION CHANGES

JBossWS 5 brings new features and performance improvements to JBoss EAP 7 web services, mainly through upgrades of the Apache CXF, Apache WSS4J, and Apache Santuario components.

5.1.1. JAX-RPC support changes

The Java API for XML-based RPC (JAX-RPC) was deprecated in Java EE 6 and was optional in Java EE 7. It is no longer available or supported in JBoss EAP 7. Applications that use JAX-RPC must be migrated to use Jakarta XML Web Services, which is the current Jakarta EE standard web services framework.

Use of JAX-RPC web services can be identified in any of the following ways:

- The presence of a JAX-RPC mapping file, which is an XML file with the root element `<java-wsdl-mapping>`.
- The presence of a `webservices.xml` XML descriptor file that contains a `<webservice-description>` element, which includes a `<jaxrpc-mapping-file>` child element. The following is an example of `webservices.xml` descriptor file that defines a JAX-RPC web service.

```
<webservices xmlns="http://java.sun.com/xml/ns/j2ee"
     xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
     xsi:schemaLocation="http://java.sun.com/xml/ns/j2ee
http://www.ibm.com/webservices/xsd/j2ee_web_services_1_1.xsd" version="1.1">
  <webservice-description>
    <webservice-description-name>HelloService</webservice-description-name>
    <wsdl-file>WEB-INF/wsdl/HelloService.wsdl</wsdl-file>
    <jaxrpc-mapping-file>WEB-INF/mapping.xml</jaxrpc-mapping-file>
    <port-component>
      <port-component-name>Hello</port-component-name>
      <wsdl-port>HelloPort</wsdl-port>
      <service-endpoint-interface>org.jboss.chap12.hello.Hello</service-endpoint-interface>
      <service-impl-bean>
        <servlet-link>HelloWorldServlet</servlet-link>
      </service-impl-bean>
    </port-component>
  </webservice-description>
</webservices>
```

- The presence of an `ejb-jar.xml` file, which contains a `<service-ref>` that references a JAX-RPC mapping file.

5.1.2. Apache CXF Spring web services changes

In previous releases of JBoss EAP, you could customize the JBossWS and Apache CXF integration by including a `jbossws-cxf.xml` configuration file with the endpoint deployment archive. One use case for this was to configure interceptor chains for web service client and server endpoints on the Apache CXF bus. This integration required Spring to be deployed in the JBoss EAP server.

Spring integration is no longer supported in JBoss EAP 7. Any application that contains a `jbossws-cxf.xml` descriptor configuration file must be modified to replace the custom configuration defined in
that file. While it is still possible to directly access the Apache CXF API, be aware that the application will not be portable.

The suggested approach is to replace Spring custom configurations with the new JBossWS descriptor configuration options where possible. The JBossWS descriptor-based approach provides similar functionality without requiring modification of the client endpoint code. In some cases, you can replace Spring with Context Dependency Injection (CDI).

**Apache CXF interceptors**

The JBossWS descriptor provides new configuration options that allow you to declare the interceptors without modifying the client endpoint code. Instead you declare interceptors within predefined client and endpoint configurations by specifying a list of interceptor class names for the `cxf.interceptors.in` and `cxf.interceptors.out` properties.

The following is an example of a `jaxws-endpoint-config.xml` file that declares interceptors using these properties.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<jaxws-config xmlns="urn:jboss:jbossws-jaxws-config:4.0"
xmlns:javaee="http://java.sun.com/xml/ns/javaee"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="urn:jboss:jbossws-jaxws-config:4.0 schema/jbossws-jaxws-config_4_0.xsd">
  <endpoint-config>
    <config-name>org.jboss.test.ws.jaxws.cxf.interceptors.EndpointImpl</config-name>
    <property>
      <property-name>cxf.interceptors.in</property-name>
      <property-value>org.jboss.test.ws.jaxws.cxf.interceptors.EndpointInterceptor,org.jboss.test.ws.jaxws.cxf.interceptors.FooInterceptor</property-value>
    </property>
    <property>
      <property-name>cxf.interceptors.out</property-name>
      <property-value>org.jboss.test.ws.jaxws.cxf.interceptors.EndpointCounterInterceptor</property-value>
    </property>
  </endpoint-config>
</jaxws-config>
```

**Apache CXF features**

The JBossWS descriptor allows you to declare features within predefined client and endpoint configurations by specifying a list of feature class names for the `cxf.features` property.

The following is an example of a `jaxws-endpoint-config.xml` file that declares a feature using this property.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<jaxws-config xmlns="urn:jboss:jbossws-jaxws-config:4.0"
xmlns:javaee="http://java.sun.com/xml/ns/javaee"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="urn:jboss:jbossws-jaxws-config:4.0 schema/jbossws-jaxws-config_4_0.xsd">
  <endpoint-config>
    <config-name>Custom FI Config</config-name>
    <property>
      <property-name>cxf.features</property-name>
      <property-value>org.apache.cxf.feature.FastInfosetFeature</property-value>
    </property>
  </endpoint-config>
</jaxws-config>
```
Apache CXF HTTP transport
In Apache CXF, HTTP transport configuration is achieved by specifying
org.apache.cxf.transport.http.HTTPConduit options. JBossWS integration allows conduits to be
modified programatically using the Apache CXF API as follows.

```java
import org.apache.cxf.frontend.ClientProxy;
import org.apache.cxf.transport.http.HTTPConduit;
import org.apache.cxf.transports.http.configuration.HTTPClientPolicy;

// Set chunking threshold before using a JAX-WS port client
...
HTTPConduit conduit = (HTTPConduit)ClientProxy.getClient(port).getConduit();
HTTPClientPolicy client = conduit.getClient();
client.setChunkingThreshold(8192);
...
```

You can also control and override the Apache CXF HTTPConduit default values by setting system
properties.

<table>
<thead>
<tr>
<th>Property</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cxf.client.allowChunking</td>
<td>Boolean</td>
<td>Specifies whether to send requests using chunking.</td>
</tr>
<tr>
<td>cxf.client.chunkingThreshold</td>
<td>Integer</td>
<td>Sets the threshold at which switching from non-chunking to chunking mode.</td>
</tr>
<tr>
<td>cxf.client.connectionTimeout</td>
<td>Long</td>
<td>Sets the number of milliseconds for the connection timeout.</td>
</tr>
<tr>
<td>cxf.client.receiveTimeout</td>
<td>Long</td>
<td>Sets the number of milliseconds for the receive timeout.</td>
</tr>
<tr>
<td>cxf.client.connection</td>
<td>String</td>
<td>Specifies whether to use the Keep-Alive or close connection type.</td>
</tr>
<tr>
<td>cxf.tls-client.disableCNCheck</td>
<td>Boolean</td>
<td>Specifies whether to disable the CN host name check.</td>
</tr>
</tbody>
</table>

5.1.3. WS-Security changes

- If your application contains a custom callback handler that accesses the
  org.apache.ws.security.WSPasswordCallback class, be aware that this class has moved to
  package org.apache.wss4j.common.ext.

- Most of the SAML bean objects from the org.apache.ws.security.saml.ext package have
  been moved to the org.apache.wss4j.common.saml package.

- Use the RSA v1.5 key transport and all related algorithms are disallowed by default.
The Security Token Service (STS) previously only validated onBehalfOf tokens. It now also validates ActAs tokens. As a consequence, a valid username and password must be specified in the UsernameToken that is provided for the ActAs token.

SAML Bearer tokens are now required to have an internal signature. The org.apache.wss4j.dom.validate.SamlAssertionValidator class now has a setRequireBearerSignature() method to enable or disable the signature verification.

5.1.4. JBoss modules structure change
The cxf-api and cxf-rt-core JARs have been merged into one cxf-core JAR. As a consequence, the org.apache.cxf module in JBoss EAP now contains the cxf-core JAR and exposes more classes than in the previous release.

5.1.5. Bouncy Castle requirements and changes
If you want to use AES encryption with Galois/Counter Mode (GCM) for symmetric encryption in XML/WS-Security, you need the BouncyCastle Security Provider.

JBoss EAP 7 ships with the org.bouncycastle module and JBossWS is now able to rely on its class loader to get and use the BouncyCastle Security Provider. Therefore it is no longer necessary to statically install BouncyCastle in the current JVM. For applications running outside of the container, the security provider can be made available to JBossWS by adding a BouncyCastle library to the class path.

You can disable this behavior by setting the org.jboss.ws.cxf.noLocalBC property value to true in the jaxws-endpoint-config.xml deployment descriptor file for the server or the jaxws-client-config.xml descriptor file for clients.

If you want to use a different version than the one that ships with JBoss EAP, you can still statically install BouncyCastle to the JVM. In that case, the statically installed BouncyCastle Security Provider is chosen over the provider present in the class path. To avoid any issues, you must use BouncyCastle 1.49, 1.51, or greater.

5.1.6. Apache CXF bus selection strategy
The default bus selection strategy for clients running in-container has changed from THREAD_BUS to TCCL_BUS. For clients running out-of container, the default strategy is still THREAD_BUS. You can restore the behavior to that of the previous release by using either of the following methods.

- Boot the JBoss EAP server with the system property org.jboss.ws.cxf.jaxws-client.bus.strategy value set to THREAD_BUS.
- Explicitly set the selection strategy in the client code.

5.1.7. Jakarta XML Web Services 2.2 requirements for WebServiceRef
Containers must use Jakarta XML Web Services 2.2 style constructors, which include the WebServiceFeature class as an argument in the constructor, to build clients that are injected into web service references. JBoss EAP 6.4, which ships with JBossWS 4, hides that requirement. JBoss EAP 7 ships with JBossWS 5, which no longer hides this requirement. This means that user provided service classes injected by the container must implement Jakarta XML Web Services 2.2 or later by updating the existing code to use the javax.xml.ws.Service constructor that includes one or more WebServiceFeature arguments.
5.1.8. IgnoreHttpsHost CN check change

In previous releases, you could disable the HTTPS URL hostname check against a service’s Common Name (CN) given in its certificate by setting the system property `org.jboss.security.ignoreHttpsHost` to `true`. This system property name has been replaced with `cxf.tls-client.disableCNCheck`.

5.1.9. Server-side configuration and class loading

As a consequence of enabling injections into service endpoint and service client handlers, it is no longer possible to automatically load handler classes from the `org.jboss.as.webservices.server.integration` JBoss module. If your application depends on a given predefined configuration, you might need to explicitly define new module dependencies for your deployment. For more information, see Migrate Explicit Module Dependencies.

5.1.10. Deprecation of Java-endorsed standards override mechanism

The Java-endorsed standards override mechanism was deprecated in JDK 1.8_40 with intent to remove it in JDK 9. This mechanism allowed developers to make libraries available to all deployed applications by placing JARs into an endorsed directory within the JRE.

If your application uses the JBossWS implementation of Apache CXF, JBoss EAP 7 ensures the required dependencies are added in the correct order and you should not be impacted by this change. If your application accesses Apache CXF directly, you must now provide the Apache CXF dependencies after the JBossWS dependencies as part of your application deployment.

5.1.11. Specification of descriptor in EAR archive

In previous releases of JBoss EAP, you could configure the `jboss-webservices.xml` deployment descriptor file for Jakarta Enterprise Beans web service deployments in the `META-INF/` directory of JAR archives or in the `WEB-INF/` directory for POJO web service deployments and Jakarta Enterprise Beans web service endpoints bundled in WAR archives.

In JBoss EAP 7, you can now configure the `jboss-webservices.xml` deployment descriptor file in the `META-INF/` directory of an EAR archive. If a `jboss-webservices.xml` file is found both in the EAR archive and the JAR or WAR archive, the configuration data in the `jboss-webservices.xml` file for the JAR or WAR overrides the corresponding data in the EAR descriptor file.

5.2. UPDATE THE REMOTE URL CONNECTOR AND PORT

In JBoss EAP 7, the default connector has changed from `remote` to `http-remoting` and the default remote connection port has changed from `4447` to `8080`. The JNDI provider URL for the default configuration has changed from `remote://localhost:4447` to `http-remoting://localhost:8080`.

If you use the JBoss EAP 7 `migrate` operation to update your configuration, you do not need to modify the remote connector, remote port, or JNDI provider URLs because the migration operation preserves the JBoss EAP 6 remoting connector and `4447` port configuration settings in the subsystem configuration. For more information about the `migrate` operation, see Management CLI Migration Operation.
If you do not use the **migrate** operation and instead run with the new JBoss EAP 7 default configuration, you must change the remote connector, remote port, and JNDI provider URL to use the new settings as described above.

## 5.3. MESSAGING APPLICATION CHANGES

### 5.3.1. Replace or update Jakarta Messaging deployment descriptors

The proprietary HornetQ messaging resource deployment descriptor files identified by the naming pattern `-jms.xml` no longer work in JBoss EAP 7. The following is an example of a Jakarta Messaging resource deployment descriptor file in JBoss EAP 6:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<messaging-deployment xmlns="urn:jboss:messaging-deployment:1.0">
  <hornetq-server>
    <jms-destinations>
      <jms-queue name="testQueue">
        <entry name="queue/test"/>
        <entry name="java:jboss/exported/jms/queue/test"/>
      </jms-queue>
      <jms-topic name="testTopic">
        <entry name="topic/test"/>
        <entry name="java:jboss/exported/jms/topic/test"/>
      </jms-topic>
    </jms-destinations>
  </hornetq-server>
</messaging-deployment>
```

If you used `-jms.xml` Jakarta Messaging deployment descriptors in your application in the previous release, you can either convert your application to use the standard deployment descriptor as specified in section EE.5.18 of *Jakarta EE Platform*, or you can update the deployment descriptor to use the `messaging-activemq-deployment` schema instead. If you choose to update the descriptor, you need to make the following modifications:

- Change the namespace from "urn:jboss:messaging-deployment:1.0" to "urn:jboss:messaging-activemq-deployment:1.0".
- Change the `<hornetq-server>` element name to `<server>`.

The modified file should look like the following example.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<messaging-deployment xmlns="urn:jboss:messaging-activemq-deployment:1.0">
  <server>
    <jms-destinations>
      <jms-queue name="testQueue">
        <entry name="queue/test"/>
        <entry name="java:jboss/exported/jms/queue/test"/>
      </jms-queue>
      <jms-topic name="testTopic">
        <entry name="topic/test"/>
        <entry name="java:jboss/exported/jms/topic/test"/>
      </jms-topic>
    </jms-destinations>
  </server>
</messaging-deployment>
```
For information about server configuration changes related to messaging, see Messaging Server Configuration Changes.

### 5.3.2. Update external Jakarta Messaging clients

JBoss EAP 7 still supports the Jakarta Messaging 1.1 API, so you do not need to modify your code.

The default remote connector and port has changed in JBoss EAP 7. For details about this change, see Update the Remote URL Connector and Port.

If you migrate your server configuration using the `migrate` operation, the old settings are preserved and you do not need to update your `PROVIDER_URL`. However, if you run with the new JBoss EAP 7 default configuration, you must change the `PROVIDER_URL` in the client code to use the new `http-remoting://localhost:8080` setting. For more information, see Migrate Remote Naming Client Code.

If you plan to migrate your code to use the Jakarta Messaging 2.0 API, see the `helloworld-jms` quickstart for a working example.

### 5.3.3. Replace the HornetQ API

JBoss EAP 6 included the `org.hornetq` module, which allowed you to use the HornetQ API in your application source code.

Apache ActiveMQ Artemis replaces HornetQ in JBoss EAP 7, so you must migrate any code that used the HornetQ API to use the Apache ActiveMQ Artemis API. The libraries for this API are included in the `org.apache.activemq.artemis` module.

ActiveMQ Artemis is an evolution of HornetQ, so many of the concepts still apply.

### 5.3.4. Replace Deprecated Address Setting Attributes

The ability to auto-create and auto-delete topics and queues using the `auto-create-jms-queues`, `auto-delete-jms-queues`, `auto-create-jms-topics`, and `auto-delete-jms-topics` attributes was only partially implemented and not fully configurable in JBoss EAP 7. These attributes, which are deprecated, were provided as a technology preview feature only and were not supported.

You must replace any usage of these deprecated attributes with the following replacement attributes.

**NOTE**

The deprecated attributes no longer configure this functionality in JBoss EAP 7.4 and do not take effect. The replacement attributes are not supported either. They are provided only as a way to migrate on the best effort basis.

<table>
<thead>
<tr>
<th>Deprecated Attribute</th>
<th>Replacement Attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>auto-create-jms-queues</td>
<td>auto-create-queues</td>
</tr>
<tr>
<td>auto-delete-jms-queues</td>
<td>auto-delete-queues</td>
</tr>
</tbody>
</table>
### 5.3.5. Messaging Application Changes Required for JBoss EAP 7

Starting with JBoss EAP 7.2, if a client application directly depends on Artemis client JARs, for example, `artemis-jms-client`, `artemis-commons`, `artemis-core-client`, or `artemis-selector`, then you must add the following dependency in your `pom.xml` file for `wildfly-client-properties`.

```xml
<dependency>
    <groupId>org.jboss.eap</groupId>
    <artifactId>wildfly-client-properties</artifactId>
</dependency>
```

This is to avoid a `JMSRuntimeException` when calling `message.getJMSReplyTo()` from an older JBoss EAP 7 client as described in JBEAP-15889.

### 5.4. JAX-RS AND RESTEASY APPLICATION CHANGES

JBoss EAP 6 bundled RESTEasy 2, which was an implementation of JAX-RS 1.x.

JBoss EAP 7.0 and JBoss EAP 7.1 included RESTEasy 3.0.x, which is an implementation of JAX-RS 2.0 as defined by the JSR 339: JAX-RS 2.0: The Java™ API for RESTful Web Services specification. For more information about the Java API for RESTful Web Services, see the JAX-RS 2.0 API Specification.

JBoss EAP 7.4 includes RESTEasy 3.9.0, which is an implementation of Jakarta RESTful Web Services 2.1. This release also adds support for JDK 11. While providing some of the RESTEasy 4 key features, this release is based on RESTEasy 3.0, ensuring full backward compatibility. As a result, you should encounter few issues when migrating from RESTEasy 3.0.x to 3.9.0. For more information about the Java API for RESTEasy 3.9.0, see RESTEasy JAX-RS 3.9.0.Final API.

If you are migrating from JBoss EAP 6.4, be aware that the version of Jackson included in JBoss EAP has changed. JBoss EAP 6.4 included Jackson 1.9.9. JBoss EAP 7 and later now include Jackson 2.6.3 or greater.

This section describes how these changes might impact applications that use RESTEasy or JAX-RS.

#### 5.4.1. RESTEasy Deprecated Classes

**Interceptor and MessageBody Classes**

JSR 311: JAX-RS: The Java™ API for RESTful Web Services did not include an interceptor framework, so RESTEasy 2 provided one. JSR 339: JAX-RS 2.0: The Java API for RESTful Web Services introduced

<table>
<thead>
<tr>
<th>Deprecated Attribute</th>
<th>Replacement Attribute</th>
</tr>
</thead>
<tbody>
<tr>
<td>auto-create-jms-topics</td>
<td>auto-create-addresses</td>
</tr>
<tr>
<td>auto-delete-jms-topics</td>
<td>auto-delete-addresses</td>
</tr>
</tbody>
</table>
an official interceptor and filter framework, so the interceptor framework included in RESTEasy 2 is now deprecated, and was replaced by the JAX-RS compliant interceptor facility in RESTEasy 3.x. The relevant interfaces are defined in the `javax.ws.rs.ext` package of the `jaxrs-api` module.

- The following interceptor interfaces are deprecated in RESTEasy 3.x.
  - `org.jboss.resteasy.spi.interception.PreProcessInterceptor`
  - `org.jboss.resteasy.spi.interception.PostProcessInterceptor`
  - `org.jboss.resteasy.spi.interception.ClientExecutionInterceptor`
  - `org.jboss.resteasy.spi.interception.ClientExecutionContext`
  - `org.jboss.resteasy.spi.interception.AcceptedByMethod`

- The `org.jboss.resteasy.spi.interception.PreProcessInterceptor` interface was replaced by the `javax.ws.rs.container.ContainerRequestFilter` interface in RESTEasy 3.x.

- The following interfaces and classes are also deprecated in RESTEasy 3.x.
  - `org.jboss.resteasy.spi.interception.MessageBodyReaderInterceptor`
  - `org.jboss.resteasy.spi.interception.MessageBodyWriterInterceptor`
  - `org.jboss.resteasy.spi.interception.MessageBodyWriterContext`
  - `org.jboss.resteasy.spi.interception.MessageBodyReaderContext`
  - `org.jboss.resteasy.core.interception.InterceptorRegistry`
  - `org.jboss.resteasy.core.interception.InterceptorRegistryListener`
  - `org.jboss.resteasy.core.interception.ClientExecutionContextImpl`

- The `org.jboss.resteasy.spi.interception.MessageBodyWriterInterceptor` interface was replaced by the `javax.ws.rs.ext.WriterInterceptor` interface.

- In addition, some changes to the `javax.ws.rs.ext.MessageBodyWriter` interface might not be backward compatible with respect to JAX-RS 1.x. If your application used JAX-RS 1.x, review your application code to make sure you define `@Produces` or `@Consumes` for your endpoints. Failure to do so might result in an error similar to the following.

  org.jboss.resteasy.core.NoMessageBodyWriterFoundFailure: Could not find MessageBodyWriter for response object of type: <OBJECT> of media type:

The following is an example of a REST endpoint that can cause this error.

```java
@Path("dates")
public class DateService {

  @GET
  @Path("daysuntil/{targetdate}")
  public long showDaysUntil(@PathParam("targetdate") String targetDate) {
    DateLogger.LOGGER.logDaysUntilRequest(targetDate);
    final long days;
```
try {
    final LocalDate date = LocalDate.parse(targetDate, DateTimeFormatter.ISO_DATE);
    days = ChronoUnit.DAYS.between(LocalDate.now(), date);
} catch (DateTimeParseException ex) {
    // ** DISCLAIMER **. This example is contrived.
    throw new WebApplicationException(Response.status(400).entity(ex.getLocalizedMessage()).type(MediaType.TEXT_PLAIN)
        .build());
}
return days;
}

To fix the issue, add the import for `javax.ws.rs.Produces` and the `@Produces` annotation as follows.

```java
import javax.ws.rs.Produces;
...

@Path("dates")
public class DateService {

    @GET
    @Path("daysuntil/{targetdate}")
    @Produces(MediaType.TEXT_PLAIN)
    public long showDaysUntil(@PathParam("targetdate") String targetDate) {
        DateLogger.LOGGER.logDaysUntilRequest(targetDate);
        final long days;
        try {
            final LocalDate date = LocalDate.parse(targetDate, DateTimeFormatter.ISO_DATE);
            days = ChronoUnit.DAYS.between(LocalDate.now(), date);
        } catch (DateTimeParseException ex) {
            // ** DISCLAIMER **. This example is contrived.
            throw new WebApplicationException(Response.status(400).entity(ex.getLocalizedMessage()).type(MediaType.TEXT_PLAIN)
                .build());
        }
        return days;
    }
}

NOTE

All interceptors from the previous release of RESTEasy can run in parallel with the new JAX-RS filter and interceptor interfaces.

For more information about interceptors, see RESTEasy Interceptors in Developing Web Services Applications for JBoss EAP.

For more information about the new replacement API, see the RESTEasy JAX-RS 3.9.0.Final API.
Client API
The RESTEasy client framework in resteasy-jaxrs was replaced by the JAX-RS 2.0 compliant resteasy-client module in JBoss EAP 7.0. As a result, some RESTEasy client API classes and methods are deprecated.

- The following classes are deprecated.
  - org.jboss.resteasy.client.ClientRequest
  - org.jboss.resteasy.client.ClientRequestFactory
  - org.jboss.resteasy.client.ClientResponse
  - org.jboss.resteasy.client.ProxyBuilder
  - org.jboss.resteasy.client.ProxyConfig
  - org.jboss.resteasy.client.ProxyFactory
  - org.jboss.resteasy.client.ClientResponseFailure
  - org.jboss.resteasy.client.ClientExecutor
  - org.jboss.resteasy.client.EntityTypeFactory
  

  The following is an example of how to send a link header with the RESTEasy client in RESTEasy 2.3.x.

  ```java
  ClientRequest request = new ClientRequest(generateURL("/linkheader/str"));
  request.addLink("previous chapter", "previous", "http://example.com/TheBook/chapter2", null);
  ClientResponse response = request.post();
  LinkHeader header = response.getLinkHeader();
  ```

  The following is an example of how to accomplish the same task with the RESTEasy client in RESTEasy 3.

  ```java
  ResteasyClient client = new ResteasyClientBuilder().build();
  Response response = client.target(generateURL("/linkheader/str")).request()
  .header("Link", "<http://example.com/TheBook/chapter2>; rel="previous");
  .post(Entity.text(new String()));
  javax.ws.rs.core.Link link = response.getLink("previous");
  ```

  See the resteasy-jaxrs-client quickstart for an example of an external JAX-RS RESTEasy client that interacts with a JAX-RS Web service.

  - The classes and interfaces in the org.jboss.resteasy.client.cache package are also deprecated. They are replaced by equivalent classes and interfaces in the org.jboss.resteasy.client.jaxrs.cache package.

NOTE
For more information about the org.jboss.resteasy.client.jaxrs API classes, see the RESTEasy JAX-RS JavaDoc.
StringConverter
The `org.jboss.resteasy.spi.StringConverter` class is deprecated in RESTEasy 3.x. This functionality can be replaced using the JAX-RS `javax.ws.rs.ext.ParamConverterProvider` class.

5.4.2. Removed or Protected RESTEasy Classes

ResteasyProviderFactory Add methods
Most of the `org.jboss.resteasy.spi.ResteasyProviderFactory` `add()` methods have been removed or made protected in RESTEasy 3.0. For example, the `addBuiltInMessageBodyReader()` and `addBuiltInMessageBodyWriter()` methods have been removed and the `addMessageBodyReader()` and `addMessageBodyWriter()` methods have been made protected.

You should now use the `registerProvider()` and `registerProviderInstance()` methods.

Additional Classes Removed From RESTEasy 3
The `@org.jboss.resteasy.annotations.cache.ServerCached` annotation, which specified the response to the JAX-RS method should be cached on the server, was removed from RESTEasy 3 and must be removed from the application code.

5.4.3. Additional RESTEasy Changes

SignedInput and SignedOuput

- `SignedInput` and `SignedOutput` for `resteasy-crypto` must have the `Content-Type` set to `multipartSigned` in either the `Request` or `Response` object, or by using the `@Consumes` or `@Produces` annotation.

- `SignedOutput` and `SignedInput` can be used to return the `application/pkcs7-signature` MIME type format in binary form by setting that type in the `@Produces` or `@Consumes` annotations.

- If the `@Produces` or `@Consumes` is `text/plain` MIME type, `SignedOutput` will be base64 encoded and sent as a String.

Security Filters
The security filters for `@RolesAllowed`, `@PermitAll`, and `@DenyAll` now return "403 Forbidden" instead of "401 Unauthorized".

Client-side Filters
The client-side filters that were introduced in JAX-RS 2.0 will not be bound and run when you are using the RESTEasy client API from a release prior to RESTEasy 3.0.

Asynchronous HTTP Support
Because the JAX-RS 2.0 specification added asynchronous HTTP support using the `@Suspended` annotation and the `AsyncResponse` interface, the RESTEasy proprietary API for asynchronous HTTP was deprecated and might be removed in a future RESTEasy release. The asynchronous Tomcat and asynchronous JBoss Web modules have also been removed from the server installation. If you are not using the Servlet 3.0 container or higher, asynchronous HTTP server-side processing will be simulated and run synchronously in same request thread.

Server-side Cache
Server-side cache setup has changed. Please see the RESTEasy Documentation for more information.

YAML Provider Setting Changes
In previous releases of JBoss EAP, the RESTEasy YAML provider setting was enabled by default. This has changed in JBoss EAP 7. The YAML provider is now disabled by default. Its use is not supported due to a security issue in the SnakeYAML library used by RESTEasy for unmarshalling and it must be
explicitly enabled in the application. For information about how to enable the YAML provider in your application and add the Maven dependencies, see YAML Provider in Developing Web Services Applications for JBoss EAP.

Default Charset UTF-8 in Content-Type Header

As of JBoss EAP 7.1, the resteasy.add.charset parameter is set to true by default. You can set the resteasy.add.charset parameter to false if you do not want RESTEasy to add charset=UTF-8 to the returned content-type header when the resource method returns a text/* or application/xml* media type without an explicit charset.

For more information about text media types and character sets, see Text Media Types and Character Sets in Developing Web Services Applications for JBoss EAP.

SerializableProvider

Deserializing Java objects from untrusted sources is not safe. For this reason, in JBoss EAP 7, the org.jboss.resteasy.plugins.providers.SerializableProvider class is disabled by default, and it is not recommended to use this provider.

Matching Requests to Resource Methods

In RESTEasy 3, improvements and corrections were made to the implementation of matching rules, as defined in the JAX-RS specification. In particular, a change was made to how an ambiguous URI on a sub-resource method and a sub-resource locator is handled.

In RESTEasy 2, it was possible for a sub-resource locator to execute successfully even when there was another sub-resource with the same URI. This behavior was incorrect according to the specification.

In RESTEasy 3, when there is an ambiguous URI for a sub-resource and a sub-resource locator, calling the sub-resource will be successful; however, calling the sub-resource locator will result in an HTTP status 405 Method Not Allowed error.

The following example contains an ambiguous @Path annotation on a sub-resource method and a sub-resource locator. Notice that the URI to both endpoints, anotherResource and anotherResourceLocator, is the same. The difference between the two endpoints is that the anotherResource method is associated with the REST verb, POST. The anotherResourceLocator method is not associated with any REST verb. According to the specification, the endpoint with the REST verb, in this case the anotherResource method, will always be selected.

```java
@Path("myResource")
public class ExampleSubResources {
    @POST
    @Path("items")
    @Produces("text/plain")
    public Response anotherResource(String text) {
        return Response.ok("ok").build();
    }

    @Path("items")
    @Produces("text/plain")
    public SubResource anotherResourceLocator() {
        return new SubResource();
    }
}
```

Resource Method Algorithm Switch

A bug discovered in the resource method matching algorithm used in RESTEasy 3.0.x versions prior to 3.0.25. Final caused RESTEasy to return too many resource methods when responding to requests.
There are three stages in the matching algorithm:

1. Use the request path to choose possible resource classes.
2. Use the request path to choose possible resource methods.
3. Use the HTTP verb and media types, coming and going, to choose a final resource method.

According to the JAX-RS 2.0 specification, after the set of potential resource methods is sorted, only the maximal elements should be passed on to step 3. However, RESTEasy 3.0.x implementations prior to RESTEasy 3.0.25 passed all methods to step 3. RESTEasy 3.0.24, which was included in JBoss EAP 7.1.0, exhibits this incorrect behavior.

RESTEasy 3.0.25, which is included in JBoss EAP 7.1.1, provides the fix to limit the methods passed to step 3 to be compliant with the JAX-RS 2.0 specification. Because the looser behavior might be preferable, RESTEasy 3.0.25 also introduces a context-param configuration option, resteasy.loose.step2.request.matching, which defaults to false, that can be configured to enable the old behavior.

If you update your JBoss EAP server from 7.1.0 to 7.1.1 and you want to keep the old behavior and pass all potential resource methods to step 3, set the resteasy.loose.step2.request.matching option to true.

The matching algorithm was changed in the JAX-RS 2.1 specification to pass all matching resource methods to step 3. RESTEasy 3.9.0, which is included in JBoss EAP 7.4, provides a jaxrs.2.0.request.matching option to retain the stricter behavior as defined in the JAX-RS 2.0 specification.

If you migrate your application from JBoss EAP from 7.1.0 to 7.2.x, you should not see a change in the behavior of the resource method matching algorithm. If you migrate your application from JBoss EAP from 7.1.1 to 7.2.x or higher and want to retain the stricter behavior as defined in the JAX-RS 2.0 specification, set the jaxrs.2.0.request.matching option to true.

### 5.4.4. RESTEasy SPI Changes

#### SPI Exceptions

All SPI failure exceptions were deprecated and are no longer used internally. They have been replaced with the corresponding JAX-RS exception.

<table>
<thead>
<tr>
<th>Deprecated Exception</th>
<th>Replacement Exception in jaxrs-api module</th>
</tr>
</thead>
<tbody>
<tr>
<td>org.jboss.resteasy.spi.ForbiddenException</td>
<td>javax.ws.rs.ForbiddenException</td>
</tr>
<tr>
<td>org.jboss.resteasy.spi.MethodNotAllowedException</td>
<td>javax.ws.rs.NotAllowedException</td>
</tr>
<tr>
<td>org.jboss.resteasy.spi.NotAcceptableException</td>
<td>javax.ws.rs.NotAcceptableException</td>
</tr>
<tr>
<td>org.jboss.resteasy.spi.NotFoundException</td>
<td>javax.ws.rs.NotFoundException</td>
</tr>
<tr>
<td>org.jboss.resteasy.spi.UnauthorizedException</td>
<td>javax.ws.rs.NotAuthorizedException</td>
</tr>
<tr>
<td>org.jboss.resteasy.spi.UnsupportedMediaTypeException</td>
<td>javax.ws.rs.NotSupportedException</td>
</tr>
</tbody>
</table>
InjectorFactory and Registry

The InjectorFactory and Registry SPIs have changed. This should not be an issue if you use RESTEasy as documented and supported.

5.4.5. Jackson Provider Changes

The version of Jackson included in JBoss EAP has changed. The previous version of JBoss EAP included Jackson 1.9.9. JBoss EAP 7 now includes Jackson 2.6.3 or greater. As a result, the Jackson provider has changed from resteasy-jackson-provider to resteasy-jackson2-provider.

The upgrade to the resteasy-jackson2-provider requires some package changes. For example, the Jackson annotation package has changed from org.codehaus.jackson.annotate to com.fasterxml.jackson.annotation.

To switch your application to use the default provider that was included in the previous release of JBoss EAP, see Switching the Default Jackson Provider in Developing Web Services Applications for JBoss EAP.

5.4.6. Spring RESTEasy Integration Changes

The Spring 4.0 framework introduced support for Java 8. If you plan to use the RESTEasy 3.x integration with Spring, be sure to specify 4.2.x as the minimum Spring version in your deployment as this is the earliest stable version supported by JBoss EAP 7.

5.4.7. RESTEasy Jettison JSON Provider Changes

The RESTEasy Jettison JSON provider is deprecated in JBoss EAP 7 and is no longer added to deployments by default. You are encouraged to switch to the recommended RESTEasy Jackson provider. If you prefer to continue to use the Jettison provider, you must define an explicit dependency for it in the jboss-deployment-descriptor.xml file as demonstrated in the following example.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<jboss-deployment-structure>
  <deployment>
    <exclusions>
      <module name="org.jboss.resteasy.resteasy-jackson2-provider"/>
      <module name="org.jboss.resteasy.resteasy-jackson-provider"/>
    </exclusions>
    <dependencies>
      <module name="org.jboss.resteasy.resteasy-jettison-provider" services="import"/>
    </dependencies>
  </deployment>
</jboss-deployment-structure>
```

For more information about how to define explicit dependencies, see Add an Explicit Module Dependency to a Deployment in the JBoss EAP Development Guide.

5.4.8. Changes Required in MicroProfile Rest Client Code

JBoss EAP 7.3 supports version 1.3.x of the MicroProfile REST client. If you were using the previous version of the MicroProfile REST client, you need to make some updates in your code.
IMPORTANT

MicroProfile REST client is provided as Technology Preview only. Technology Preview features are not supported with Red Hat production service level agreements (SLAs), might not be functionally complete, and Red Hat does not recommend to use them for production. These features provide early access to upcoming product features, enabling customers to test functionality and provide feedback during the development process.

See Technology Preview Features Support Scope on the Red Hat Customer Portal for information about the support scope for Technology Preview features.

The org.jboss.resteasy.client.microprofile.MicroprofileClientBuilderResolver class is replaced by org.eclipse.microprofile.rest.client.RestClientBuilder. For example:

```java
@Path("resource")
public interface TestResourceIntf {
    @Path("test")
    @GET
    public String test();
}

TestResourceIntf service = RestClientBuilder.newBuilder()
    .baseUrl("http://localhost:8081/")
    .build(TestResourceIntf.class);
String s = service.test();
```

For more information about the MicroProfile REST client, see MicroProfile REST Client in the JBoss EAP Developing Web Services Applications guide.

5.5. CDI APPLICATION CHANGES

JBoss EAP 7.4 includes support for CDI 2.0. As a result, applications written using CDI 1.0 or CDI 1.2 might see some changes in behavior when migrating to JBoss EAP 7.4. This section summarizes only few of the changes made in CDI 1.2 and CDI 2.0.

You can find more information about Weld and CDI 2.0 in the following references:

- Jakarta Context Dependency Injection 2.0
- CDI 2.0 Javadoc
- Weld 3.0.5.Final - CDI Reference Implementation

Bean Archives

Bean classes of enabled beans must be deployed in bean archives to ensure they are scanned by CDI to find and process the bean classes.

In CDI 1.0, an archive was defined as an explicit bean archive if it contained a beans.xml file in the META-INF/ directory for an application client, EJB, or library JAR, or if it contained a beans.xml file in the WEB-INF/ directory for a WAR.

CDI 1.1 introduced implicit bean archives, which are archives that contain one or more bean classes with a bean defining annotation, or one or more session beans. Implicit bean archives are scanned by CDI and, during type discovery, only classes with bean defining annotations are discovered. For more information,
see Type and Bean Discovery in JSR 365, Contexts and Dependency Injection for Java 2.0. The Jakarta equivalents for bean defining annotations are defined in the Jakarta Context Dependency Injection 2.0 specification.

A bean archive has a bean discovery mode of **all**, **annotated** or **none**. A bean archive that contains a beans.xml file with no version has a default bean discovery mode of **all**. A bean archive that contains a beans.xml file with version 1.1 or later must specify the bean-discovery-mode attribute. The default value for the attribute is **annotated**.

An archive is not a bean archive in the following cases:

- It contains a beans.xml file with a bean-discovery-mode of none.
- It contains a CDI extension with no beans.xml file.

An archive is an explicit bean archive in the following cases:

- The archive contains a beans.xml file with a version number of 1.1 or later and a bean-discovery-mode of all.
- The archive contains a beans.xml file with no version number.
- The archive contains an empty beans.xml file.

An archive is an implicit bean archive in the following cases:

- The archive contains one or more bean classes with a bean defining annotation, or one or more session beans, even if it does not contain a beans.xml file.
- The archive contains a beans.xml file with a bean-discovery-mode of annotated.

CDI 1.2 limited bean defining annotations to the following:

- @ApplicationScoped, @SessionScoped, @ConversationScoped, and @RequestScoped annotations
- All other normal scope types
- @Interceptor and @Decorator annotations
- All stereotype annotations, which are annotations annotated with @Stereotype
- @Dependent scope annotation

For more information about bean archives, see Bean Archives in JSR 365: Contexts and Dependency Injection for Java 2.0. The Jakarta equivalents for bean archives are defined in the Jakarta Context Dependency Injection 2.0 specification.

Clarification of Conversation Resolution

The conversation context lifecycle was changed in CDI 1.2 to prevent conflicts with the Servlet specification as described in CDI Specification Issue CDI-411. The conversation scope is active during all servlet requests and should not prevent other servlets or servlet filters from setting the request body or character encoding. For more information, see Conversation context lifecycle in Jakarta EE.

Observer Resolution

Event resolution was partly rewritten in CDI 1.2. In CDI 1.0, an event is delivered to an observer method if the observer method has all the event qualifiers. In CDI 1.2, an event is delivered to an observer method
if the observer method has no event qualifiers or has a subset of the event qualifiers. For more information, see the Observer resolution.

5.6. HTTP SESSION ID CHANGE

The string returned by the `request.getSession().getId()` call to get the unique identifier assigned to an HTTP session has changed between JBoss EAP 6.4 and JBoss EAP 7.

JBoss EAP 6.4 returned both the session ID and the instance ID in the `session-id.instance-id` format.

JBoss EAP 7 returns only the session ID.

This change can create issues with routeless cookies for some upgrades from JBoss EAP 6 to JBoss EAP 7. If your application recreates JSESSIONID cookies based upon the return value from this method call, you might need to update the application code to provide the desired behavior.

5.7. MIGRATE EXPLICIT MODULE DEPENDENCIES

The introduction of the modular class loading system and JBoss Modules in the previous release of JBoss EAP allowed for fine-grained control of the classes available to applications. This feature allowed you to configure explicit module dependencies using the application’s `MANIFEST.MF` file or the `jboss-deployment-structure.xml` deployment descriptor file.

If you defined explicit module dependencies in your application, you should be aware of the following changes in JBoss EAP 7.

Review Dependencies for Availability

The modules that are included in JBoss EAP have changed. When you migrate your application to JBoss EAP 7, review your `MANIFEST.MF` and `jboss-deployment-structure.xml` file entries to make sure they do not refer to any modules that were removed from this release of the product.

Dependencies That Require Annotation Scanning

In the previous release of JBoss EAP, if your dependency contained annotations that needed to be processed during annotation scanning, such as when declaring EJB Interceptors, you were required to generate and include a Jandex index in a new JAR file and then set a flag in the `MANIFEST.MF` or `jboss-deployment-structure.xml` deployment descriptor file.

JBoss EAP 7 now provides automatic runtime generation of annotation indexes for static modules, so you no longer need to generate them manually. However, you still need to add the `annotations` flag to the application’s `MANIFEST.MF` file or the `jboss-deployment-structure.xml` deployment descriptor file as demonstrated below.

Example: Annotation Flag in the `MANIFEST.MF` File

```
Dependencies: com.company.my-ejb annotations, com.company.other
```

Example: Annotation Flag in the `jboss-deployment-structure.xml` File

```
<jboss-deployment-structure>
  <deployment>
    <dependencies>
      <module name="com.company.my-ejb" annotations="true"/>
      <module name="com.company.other"/>
    </dependencies>
  </deployment>
</jboss-deployment-structure>
```
5.8. HIBERNATE AND JAKARTA PERSISTENCE MIGRATION CHANGES

5.8.1. Hibernate ORM 3.0

The integration classes that made it easier to use Hibernate ORM 3 in JBoss EAP 6.4 were removed from JBoss EAP 7. If your application still uses Hibernate ORM 3 libraries, it is strongly recommended that you migrate your application to use Hibernate ORM 5 as Hibernate ORM 3 will no longer work in JBoss EAP without a lot of effort. If you can not migrate to Hibernate ORM 5, you must define a custom JBoss Module for the Hibernate ORM 3 JARs and exclude the Hibernate ORM 5 classes from your application.

5.8.2. Hibernate ORM 4.0 - 4.3

If your application needs second-level cache enabled, be aware that Infinispan 8.x was integrated with Hibernate ORM 5.0. Support for using Infinispan as a Hibernate 2nd-level cache provider was then moved to the Infinispan project in Hibernate ORM 5.3, and as a result, the hibernate-infinispan module was dropped from that release.

Applications written with Hibernate ORM 4.x can still use Hibernate ORM 4.x. You must define a custom JBoss module for the Hibernate ORM 4.x JARs and exclude the Hibernate ORM 5 classes from your application. However, it is strongly recommended that you rewrite your application code to use Hibernate ORM 5. For information about migrating to Hibernate ORM 5, see Migrating to Hibernate ORM 5.

5.8.3. Migrating to Hibernate ORM 5

JBoss EAP 7.0 included Hibernate ORM 5.0. This section highlights the changes you need to make when migrating from Hibernate ORM version 4.3 to version 5. For more information about the changes implemented between Hibernate ORM 4 and Hibernate ORM 5, see the Hibernate ORM 5.0 Migration Guide.

Removed and deprecated classes
The following deprecated classes were removed from Hibernate ORM 5:

- org.hibernate.cfg.AnnotationConfiguration
- org.hibernate.id.TableGenerator
- org.hibernate.id.TableHiLoGenerator
- org.hibernate.id.SequenceGenerator

Other changes to classes and packages

- The org.hibernate.integrator.spi.Integrator interface changed to account for bootstrap redesign.
- A new package org.hibernate.engine.jdbc.env.spi was created. It contains the org.hibernate.engine.jdbc.env.spi.JdbcEnvironment interface, which was extracted from the org.hibernate.engine.jdbc.spi.JdbcServices interface.
A new org.hibernate.boot.model.relational.ExportableProducer interface was introduced that will affect org.hibernate.id.PersistentIdentifierGenerator implementations.

The signature of org.hibernate.id.Configurable was changed to accept org.hibernate.service.ServiceRegistry rather than just org.hibernate.dialect.Dialect.

The org.hibernate.metamodel.spi.TypeContributor interface has migrated to org.hibernate.boot.model.TypeContributor.

The org.hibernate.metamodel.spi.TypeContributions interface has migrated to org.hibernate.boot.model.TypeContributions.

Type handling

Built-in org.hibernate.type.descriptor.sql.SqlTypeDescriptor implementations no longer auto-register themselves with org.hibernate.type.descriptor.sql.SqlTypeDescriptorRegistry. Applications using custom SqlTypeDescriptor implementations that extend the built-in implementations and rely on that behavior must be updated to call SqlTypeDescriptorRegistry.addDescriptor() themselves.

For IDs defined as generated UUIDs, some databases require you to explicitly set the @Column(length=16) in order to generate BINARY(16) so that comparisons work properly.

For EnumType mappings defined in the hbm.xml, where you want javax.persistence.EnumType.STRING name-mapping, this configuration must be explicitly stated by using either the useNamed(true) setting or by specifying a VARCHAR value of 12.

Transaction management

The transaction SPI underwent a major redesign in Hibernate ORM 5. In Hibernate ORM 4.3, you used the org.hibernate.Transaction API to directly access different back-end transaction strategies. Hibernate ORM 5 introduced a level of indirection. On the back end, the org.hibernate.Transaction implementation now talks to a org.hibernate.resource.transaction.TransactionCoordinator, which represents the transactional context for a given session according to the back-end strategy. While this does not have a direct impact on developers, it could affect the bootstrap configuration. Previously applications would specify hibernate.transaction.factory_class property, which is now deprecated, and refer to a org.hibernate.engine.transaction.spi.TransactionFactory FQN (fully qualified name). With Hibernate ORM 5, you specify the hibernate.transaction.coordinator_class setting and refer to a org.hibernate.resource.transaction.TransactionCoordinatorBuilder. See org.hibernate.cfg.AvailableSettings.TRANSACTION_COORDINATOR_STRATEGY for additional details.

The following short names are now recognized:

- jdbc: Manage transactions using the JDBC java.sql.Connection. This is the default for non-Jakarta Persistence transactions.
- jta: Manage transactions using Jakarta Transactions.
IMPORTANT

If a Jakarta Persistence application does not provide a setting for the `hibernate.transaction.coordinator_class` property, Hibernate will automatically build the proper transaction coordinator based on the transaction type for the persistence unit.

If a non-Jakarta Persistence application does not provide a setting for the `hibernate.transaction.coordinator_class` property, Hibernate will default to `jdbc` to manage the transactions. This default will cause problems if the application actually uses Jakarta Transactions. A non-Jakarta Persistence application that uses Jakarta Transactions should explicitly set the `hibernate.transaction.coordinator_class` property value to `jta` or provide a custom `org.hibernate.resource.transaction.TransactionCoordinatorBuilder` that builds a `org.hibernate.resource.transaction.TransactionCoordinator` that properly coordinates with Jakarta Transactions.

Other Hibernate ORM 5 changes

- The `cfg.xml` files are again fully parsed and integrated with events, security, and other functions.

- The properties loaded from the `cfg.xml` using the `EntityManagerFactory` did not previously prefix names with `hibernate`. This has now been made consistent.

- The configuration is no longer serializable.

- The `org.hibernate.dialect.Dialect.getQuerySequencesString()` method now retrieves catalog, schema, and increment values.

- The `AuditConfiguration` modifier was removed from `org.hibernate.envers.boot.internal.EnversService`.

- The `AuditStrategy` method parameters were changed to remove the obsolete `AuditConfiguration` and use the new `EnversService`.

- Various classes and interfaces in the `org.hibernate.hql.spi` package and subpackages have been moved to the new `org.hibernate.hql.spi.id` package. This includes the `MultiTableBulkIdStrategy` class and the `AbstractTableBasedBulkIdHandler`, `TableBasedDeleteHandlerImpl`, and `TableBasedUpdateHandlerImpl` interfaces and their subclasses.

- There was a complete redesign of property access contracts.

- Valid `hibernate.cache.default_cache_concurrency_strategy` setting values are now defined using the `org.hibernate.cache.spi.access.AccessType.getExternalName()` method rather than the `org.hibernate.cache.spi.access.AccessType` enum constants. This is more consistent with other Hibernate settings.

5.8.4. Migrating from Hibernate ORM 5.0 to Hibernate ORM 5.1

JBoss EAP 7.1 included Hibernate ORM 5.1. This section highlights the differences and the changes needed when migrating from Hibernate ORM version 5.0 to version 5.1.

Hibernate ORM 5.1 features
This release of Hibernate includes many performance improvements and bug fixes, which are detailed in Hibernate ORM 5.1 Features in the JBoss EAP 7.10 Release Notes. For additional information about the changes implemented between Hibernate ORM 5.0 and Hibernate ORM 5.1, see the Hibernate ORM 5.1 Migration Guide.

Schema management tooling changes
Schema management tooling changes in JBoss EAP 7
Schema management tooling changes in Hibernate ORM 5.1 are mainly focused in the following areas:

- Unifying the handling of hbm2ddl.auto and Hibernate’s Jakarta Persistence schema-generation support.
- Removing JDBC concerns from the SPI to facilitate true replacement for Hibernate OGM, a persistence engine that provides Jakarta Persistence support for NoSQL data stores.

The schema management tooling changes should only be a migration concern for applications that directly use any of the following classes:

- org.hibernate.tool.hbm2ddl.SchemaExport
- org.hibernate.tool.hbm2ddl.SchemaUpdate
- org.hibernate.tool.hbm2ddl.SchemaValidator
- org.hibernate.tool.schema.spi.SchemaManagementTool, or any of its delegates

Schema management tooling changes in JBoss EAP 7.1
Hibernate ORM 5.1.10 which is included in JBoss EAP 7.1, introduced a new strategy for retrieving database tables that improves SchemaMigrator and SchemaValidator performance. This strategy executes a single java.sql.DatabaseMetaData#getTables(String, String, String, String[]) call to determine if each javax.persistence.Entity has a mapped database table. This is the default strategy, and it uses the hibernate.hbm2ddl.jdbc_metadata_extraction_strategy=grouped property setting. This strategy might require hibernate.default_schema and/or hibernate.default_catalog to be provided.

To use the old strategy, which executes a java.sql.DatabaseMetaData#getTables(String, String, String, String[]) call for each javax.persistence.Entity, use the hibernate.hbm2ddl.jdbc_metadata_extraction_strategy=individually property setting.

5.8.5. Migrating from Hibernate ORM 5.1 to Hibernate ORM 5.3

JBoss EAP 7.4 includes Hibernate ORM 5.3. This section highlights some the changes needed when migrating from Hibernate ORM 5.1 to Hibernate ORM 5.3.

Hibernate ORM 5.2 features
Hibernate ORM 5.2 is built using the Java 8 JDK and requires the Java 8 JRE at runtime. The following is a list of some of the changes made in this release:

- The hibernate-java8 module was merged into hibernate-core, and the Java 8 date/time datatypes are now natively supported.
- The hibernate-entitymanager module was merged into hibernate-core. HibernateEntityManager and HibernateEntityManagerFactory are deprecated.
- The Session, StatelessSession, and SessionFactory class hierarchies were refactored to remove deprecated classes and to better align with the Jakarta Persistence Metamodel API.
- The SPIs in the `org.hibernate.persister` and `org.hibernate.tuple` packages have changed. Any custom classes using those SPIs will need to be reviewed and updated.

- `LimitHandler` changes introduced a new `hibernate.legacy_limit_handler` setting, which is set to `false` by default, that is designed to allow you to enable the legacy Hibernate 4.3 limit handler behavior. This impacts a limited list of dialects.

- A new strategy for retrieving database tables was introduced that improves `SchemaMigrator` and `SchemaValidator` performance.

- This release changes how `CLOB` values for `String`, `character[]`, and `Character[]` attributes that are annotated with `@Lob` are processed when using `PostgreSQL81Dialect` and its subclasses.

- The scope of `@TableGenerator` and `@SequenceGenerator` names has changed from global to local.

For the complete list of changes implemented in Hibernate 5.2, see the Hibernate ORM 5.2 Migration Guide.

**Hibernate ORM 5.3 features**

Hibernate ORM 5.3 adds support for the Jakarta Persistence 2.2 specification. This release contains changes to comply with this specification along with other improvements. The following is a list of some of these changes:

- Changes to positional query parameter handling has resulted in the following changes:
  - Removal of support for JDBC-style parameter declarations in HQL/Jakarta Persistence query language queries.
  - Jakarta Persistence positional parameters behave more like named parameters.
  - JDBC-style parameter declarations in native queries use one-based instead of zero-based parameter binding to be consistent with Jakarta Persistence. You can revert back to zero-based binding by setting the `hibernate.query.sql.jdbc_style_params_base` property to `true`.

- To comply with the Jakarta Persistence specification, the sequence value stored by the `@TableGenerator` stored value is that last generated value. Previously, Hibernate stored the next sequence value. You can use the `hibernate.id.generator.stored_last_used` property to enable the legacy Hibernate behavior. Existing applications that use `@TableGenerator` and migrate to Hibernate 5.3 must set the `hibernate.id.generator.stored_last_used` configuration property to `false`.

- The `getType()` method in the `org.hibernate.query.QueryParameter` class was renamed to `getHibernateType()`.

- Hibernate’s second-level cache SPI was redesigned to better meet the requirements of the various caching providers. Details can be found in `HHH-11356`.

- Changes for `HHH-11356` also required changes in consumers, which impacts the Hibernate Statistics system.

- Some methods were temporarily added to the `org.hibernate.Query` class to make it easier to migrate native applications from Hibernate ORM 5.1 to 5.3 and maintain the Hibernate 5.1 pagination behavior. These methods are deprecated, and to be portable with future versions of Hibernate, applications should be updated to use the Jakarta Persistence methods.
• Support for using Infinispan as a Hibernate 2nd-level cache provider has been moved to the Infinispan project. As a result, the hibernate-infinispan module has been dropped.

• The API of the org.hibernate.tool.enhance.EnhancementTask Ant task was changed. The addFileset() method was dropped in favor of the setBase() and the setDir() methods. Details can be found in HHH-11795.

• A bug introduced in Hibernate 4.3 caused many-to-one associations in embeddable collection elements and composite IDs to be eagerly fetched, even when explicitly mapped as lazy. In Hibernate 5.3.2, this bug was fixed. As a result, these associations are fetched as specified by their mappings. Details can be found in HHH-12687.

• Jakarta Persistence and native implementations of Hibernate event listeners were unified in this release. As a result, the JpaIntegrator class is obsolete. Classes that extend org.hibernate.jpa.event.spi.JpaIntegrator must be modified to have to change these classes to implement the org.hibernate.integrator.spi.Integrator interface. Details can be found in HHH-11264.

• The SPIs in the org.hibernate.persister package have changed. Any custom classes using those SPIs will need to be reviewed and updated.

For the complete list of these and other changes implemented in Hibernate 5.3, see the Hibernate ORM 5.3 Migration Guide.

5.8.5.1. Exception handling changes between Hibernate 5.1 and Hibernate 5.3

In Hibernate 5.2 and 5.3, exception handling for a SessionFactory that is built using Hibernate’s native bootstrapping, wraps or converts HibernateException according to the Jakarta Persistence specification. The only exception to this behavior is when the operation is Hibernate-specific, for example Session.save() or Session.saveOrUpdate().

In Hibernate 5.3.3, the hibernate.native_exception_handling_51_compliance property was added. This property indicates whether exception handling for a SessionFactory built using Hibernate’s native bootstrapping should behave the same as native exception handling in Hibernate ORM 5.1. When set to true, HibernateException is not wrapped or converted according to the Jakarta Persistence specification. This setting is ignored for a SessionFactory built using Jakarta Persistence bootstrapping.

5.8.5.2. Compatibility transformer

JBoss EAP 7.4 includes a compatibility transformer that addresses Hibernate ORM 5.3 API methods that are no longer compatible with Hibernate ORM 5.1. The transformer is a temporary measure to allow applications built using Hibernate ORM 5.1 to exhibit the same behavior with Hibernate 5.3 in JBoss EAP 7.4. This is a temporary solution and you should replace these method calls with the recommended Jakarta Persistence method calls.

You can enable the transformer in one of the following ways:

• You can enable the transformer globally for all applications by setting the Hibernate51CompatibilityTransformer system property to true.

• You can use the jboss-deployment-structure.xml file to enable the transformer at the application level.

```xml
<jboss-deployment-structure>
  <deployment>
```

For the complete list of these and other changes implemented in Hibernate 5.3, see the Hibernate ORM 5.3 Migration Guide.
The following table lists the Hibernate 5.1 methods that are transformed and the Hibernate 5.3 method it is converted to:

<table>
<thead>
<tr>
<th>Hibernate 5.1 Reference or Method</th>
<th>Transformed to Hibernate 5.3 Reference or Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>org.hibernate.BasicQueryContract.getFlushMode()</td>
<td>org.hibernate.BasicQueryContract.getHibernateFlushMode()</td>
</tr>
<tr>
<td>org.hibernate.Session.getFlushMode()</td>
<td>org.hibernate.Session.getHibernateFlushMode()</td>
</tr>
<tr>
<td>Enum org.hibernate.FlushMode.NEVER (0)</td>
<td>Enum org.hibernate.FlushMode.MANUAL (0)</td>
</tr>
<tr>
<td>org.hibernate.Query.getMaxResults()</td>
<td>org.hibernate.Query.getHibernateMaxResults()</td>
</tr>
<tr>
<td>org.hibernate.Query.setMaxResults(int)</td>
<td>org.hibernate.Query.setHibernateMaxResults(int)</td>
</tr>
<tr>
<td>org.hibernate.Query.getFirstResult(int)</td>
<td>org.hibernate.Query.getHibernateFirstResult()</td>
</tr>
<tr>
<td>org.hibernate.Query.setFirstResult(int)</td>
<td>org.hibernate.Query.setHibernateFirstResult(int)</td>
</tr>
</tbody>
</table>

5.9. HIBERNATE SEARCH CHANGES

The version of Hibernate Search that ships with JBoss EAP 7 has changed. The previous release of JBoss EAP shipped with Hibernate Search 4.6.x. JBoss EAP 7 ships with Hibernate Search 5.5.x.

Hibernate Search 5.5 is built upon Apache Lucene 5.3.1. If you use any native Lucene APIs, be sure to align with this version. The Hibernate Search 5.5 API wraps and hides the complexity of many of the Lucene API changes made between version 3 and version 5; however, some classes are now deprecated, renamed, or repackaged. This section describes how these changes might impact your application code.

Hibernate search mapping changes

Indexing of ID fields of embedded relations
When using an @IndexedEmbedded annotation to include fields from a related entity, the id of the related entity is no longer included. You can enable the inclusion of the id by using the includeEmbeddedObjectId attribute of the @IndexedEmbedded annotation.

Example: @IndexedEmbedded Annotation

@IndexedEmbedded(includeEmbeddedObjectId=true)
Number and date index formatting changes

Numbers and dates are now indexed as numeric fields by default. Properties of type `int`, `long`, `float`, `double`, and their corresponding wrapper classes are no longer indexed as strings. Instead, they are now indexed using Lucene’s appropriate numeric encoding. The `id` fields are an exception to this rule. Even when they are represented by a numeric type, they are still indexed as a string keyword by default. The use of `@NumericField` is now obsolete unless you want to specify a custom precision for the numeric encoding. You can keep the old string-based index format by explicitly specifying a string encoding field bridge. In the case of integers, this is the `org.hibernate.search.bridge.builtin.IntegerBridge`. Check the `org.hibernate.search.bridge.builtin` package for other publicly available field bridges.

Date and `Calendar` are no longer indexed as strings. Instead, instances are encoded as long values representing the number of milliseconds since January 1, 1970, 00:00:00 GMT. You can switch the indexing format by using the new `EncodingType` enum. For example:

Example: `@DateBridge` and `@CalendarBridge` annotation

```java
@DateBridge(encoding=EncodingType.STRING)
@CalendarBridge(encoding=EncodingType.STRING)
```

The encoding change for numbers and dates is important and can have a big impact on application behavior. If you have a query that targets a field that was previously string-encoded, but is now encoded numerically, you must update the query. Numeric fields must be searched with a `NumericRangeQuery`. You must also make sure that all fields targeted by faceting are string encoded. If you use the Search query DSL, the correct query should be created automatically for you.

Miscellaneous Hibernate search changes

- Sorting options have improved and field encoding specified incorrectly for sorting options now results in runtime exceptions. Lucene also offers more performant sorting if the fields used in the sort are known up front. Hibernate Search 5.5 provides the new `@SortableField` annotation and its multi-valued companion `@SortableFields`. See the Migration Guide from Hibernate Search 5.4 to 5.5 for more information.

- The Lucene `SortField` API requires the following application code change.

  In the previous release of JBoss EAP, you set the type of the sort field in the query as follows:

  ```java
  fulltextQuery.setSort(new Sort(new SortField("title", SortField.STRING)));
  ```

  The following is an example of how you set it in JBoss EAP 7:

  ```java
  fulltextQuery.setSort(new Sort(new SortField("title", SortField.Type.STRING)));
  ```

- Since `SearchFactory` should only be used by ORM integration, it was moved from the `hibernate-search-engine` module to the `hibernate-search-orm` module. Other integrators should depend exclusively on `SearchIntegrator`, which replaces the deprecated `SearchFactoryIntegrator`.

- The enum value `SpatialMode.GRID` was renamed to `SpatialMode.HASH`.

- `FullTextIndexEventListener` is now a final class. If you currently extend this class, you must find an alternate solution to achieve the same functionality.

- The `hibernate-search-analyzers` module was removed. The recommended approach is to directly use the appropriate Lucene artifact, for example `org.apache.lucene:lucene-analyzers-common`.
The Jakarta Messaging controller API has changed. The Jakarta Messaging back-end dependency on Hibernate ORM was removed so that it could be used in other non-ORM environments. A consequence is that implementors of `org.hibernate.search.backend.impl.jms.AbstractJMSHibernateSearchController` must adjust to the new signature. This class is an internal class and it is recommended to use it as an example instead of extending it.

The `org.hibernate.search.spi.ServiceProvider` SPI was refactored. If you were integrating with the old service contract, refer to the Hibernate Search 5.5 Javadoc of `ServiceManager, Service, Startable` and `Stoppable` for details about the new contract.

If you have kept indexes generated by Lucene 3.x and have not rebuilt them with Hibernate Search 5.0 or later, you will get an `IndexFormatTooOldException`. It is recommended that you rebuild the indexes with the mass indexer. If you are not able to do that, try to use Lucene’s `IndexUpgrader`. You must carefully update the Hibernate Search mappings in case the default behavior has changed. For more information, see the Apache Lucene Migration Guide.

Apache Lucene was upgraded from 3.6 to 5.3 in JBoss EAP 7. If your code imports Lucene code directly, see the Apache Lucene Migration Guide for details of the changes. Additional information can also be found in the Lucene Change Log.

When using `@Field(indexNullAs=)` to encode a null marker value in the index, the type of the marker must be compatible with all other values that are indexed in that same field. For example, it was previously possible to encode a null value for numeric fields using a string "null". This is no longer allowed. Instead, you must choose a number to represent the null value, such as -1.

Significant improvements were made to the faceting engine. Most of the changes do not affect the API. The one notable exception is that you must now annotate any fields you intend to use for faceting with the `@Facet` or `@Facets` annotation.

### Hibernate search renamed and repackaged classes

The following is a list of Hibernate Search classes that were repackaged or renamed:

<table>
<thead>
<tr>
<th>Previous Package and Class</th>
<th>New Package and Class</th>
</tr>
</thead>
<tbody>
<tr>
<td>org.hibernate.search.SearchException</td>
<td>org.hibernate.search.exception.SearchException</td>
</tr>
</tbody>
</table>

### Lucene: Renamed and repackaged classes

Query parsers were moved to a new module, resulting in a packaging change from `org.apache.lucene.queryParser.QueryParser` to `org.apache.lucene.queryparser.classic.QueryParser`.

Many of the Lucene analyzers were refactored, resulting in packaging changes. See the Apache Lucene Documentation to find the replacement packages.
Some Apache Solr utility classes, for example **TokenizerFactory** or **TokenFilterFactory**, were moved into Apache Lucene. If your application uses those utilities or custom analyzers, you must find the new package name in Apache Lucene.

See the [Apache Lucene Migration Guide](#) for more information.

### Hibernate search deprecated APIs

For the complete list of Hibernate Search deprecated interfaces, classes, enums, annotation types, methods, constructors, and enum constants, see the [Hibernate Search Deprecated API](#) document.

#### Hibernate search deprecated interfaces

<table>
<thead>
<tr>
<th>Interface</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>org.hibernate.search.store.IndexShardingStrategy</td>
<td>Deprecated as of Hibernate Search 4.4. Might be removed in Search 5. Use <strong>ShardIdentifierProvider</strong> instead.</td>
</tr>
<tr>
<td>org.hibernate.search.store.Workspace</td>
<td>This interface will be moved and should be considered non-public API. For more information, see HSEARCH-1915.</td>
</tr>
</tbody>
</table>

#### Hibernate search deprecated classes

<table>
<thead>
<tr>
<th>Class</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>org.hibernate.search.filter.FilterKey</td>
<td>Custom filter keys are deprecated and are scheduled for removal in Hibernate Search 6. As of Hibernate Search 5.1, keys for caching Lucene filters are calculated automatically based on the given filter parameters.</td>
</tr>
<tr>
<td>org.hibernate.search.filter.StandardFilterKey</td>
<td>Custom filter keys are deprecated and are scheduled for removal in Hibernate Search 6. As of Hibernate Search 5.1, keys for caching Lucene filters are calculated automatically based on the given filter parameters.</td>
</tr>
</tbody>
</table>

#### Hibernate search deprecated enums

<table>
<thead>
<tr>
<th>Enum</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>org.hibernate.search.annotations.FieldCacheType</td>
<td>Remove the <strong>CacheFromIndex</strong> annotation as it is deprecated. See <a href="#">Hibernate Search Deprecated Annotations</a>.</td>
</tr>
</tbody>
</table>

#### Hibernate search deprecated annotations

<table>
<thead>
<tr>
<th>Annotation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>org.hibernate.search.annotations.CacheFromIndex</td>
<td>Remove the annotation. No alternative replacement is necessary.</td>
</tr>
</tbody>
</table>
Custom filter cache keys are a deprecated feature and are scheduled to be removed in Hibernate Search 6. As of Hibernate Search 5.1, the filter cache keys are determined automatically based on the filter parameters so it is no longer required to provide a key object.

### Hibernate search deprecated methods

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>org.hibernate.search.FullTextSharedSessionBuilder.autoClose()</td>
<td>No replacement</td>
</tr>
<tr>
<td>org.hibernate.search.FullTextSharedSessionBuilder.autoClose(boolean)</td>
<td>No replacement</td>
</tr>
<tr>
<td>org.hibernate.search.cfg.IndexedMapping.cacheFromIndex(FieldCacheType...)</td>
<td>This will be removed with no replacement.</td>
</tr>
<tr>
<td>org.hibernate.search.cfg.EntityDescriptor.getCachedNameMemory()</td>
<td>This will be removed with no replacement.</td>
</tr>
<tr>
<td>org.hibernate.search.cfg.IndexedMapping.cacheInMemory()</td>
<td>This will be removed with no replacement.</td>
</tr>
<tr>
<td>org.hibernate.search.cfg.ContainedInMapping.numericField()</td>
<td>Invoke <code>field().numericField()</code> instead.</td>
</tr>
<tr>
<td>org.hibernate.search.cfg.EntityDescriptor.setCacheInMemory(Map&lt;String, Object&gt;)</td>
<td>This will be removed with no replacement.</td>
</tr>
<tr>
<td>org.hibernate.search.MassIndexer.threadsForSubsequentFetching(int)</td>
<td>This method will be removed.</td>
</tr>
<tr>
<td>org.hibernate.search.query.dsl.FuzzyContext.withThreshold(float)</td>
<td>Use <code>FuzzyContext.withEditDistanceUpTo(int)</code>.</td>
</tr>
</tbody>
</table>

### Hibernate search deprecated constructors

<table>
<thead>
<tr>
<th>Constructor</th>
<th>Description</th>
</tr>
</thead>
</table>

### Changes impacting advanced integrators

This section describes changes that are not part of the public API. They should not impact the average developer as these artifacts should only be accessed by integrators who extend the Hibernate Search framework.
• The `IndexWriterSetting.MAX_THREAD_STATES` and `IndexWriterSetting.TERM_INDEX_INTERVAL` enum constants are deprecated. They affect which properties are read from the configuration, so the fact they are missing means that configuration properties such as `hibernate.search.Animals.2.indexwriter.term_index_interval = default` are now ignored. The only side effect is that the property is not applied.

• The `SearchFactoryIntegrator` interface is now deprecated. You should immediately migrate all code to use `SearchIntegrator`.

• The `SearchFactoryBuilder` class is now deprecated. Use `SearchIntegrationBuilder` instead.

• The `HSQuery.getExtendedSearchIntegrator()` method has been deprecated. It might be possible to use `SearchIntegrator`, but it is preferable to remove it altogether.

• The `DocumentBuilderIndexedEntity.getFieldCacheOption()` method has been deprecated. There is no replacement.

• The `BuildContext.getIndexingStrategy()` method is deprecated. Use `BuildContext.getIndexingMode()` instead.

• The `DirectoryHelper.getVerifiedIndexDir(String, Properties, boolean)` method is deprecated. Use `DirectoryHelper.getVerifiedIndexPath(java.lang.String, java.util.Properties, boolean)` instead.

• The following is a list of Hibernate search classes that were repackaged or renamed:

<table>
<thead>
<tr>
<th>Previous Package and Class</th>
<th>New Package and Class</th>
</tr>
</thead>
<tbody>
<tr>
<td>org.hibernate.search.indexes.impl.DirectoryBasedIndexManager</td>
<td>org.hibernate.search.indexes.spi.DirectoryBasedIndexManager</td>
</tr>
<tr>
<td>org.hibernate.search.spi.SearchFactoryBuilder</td>
<td>org.hibernate.search.spi.SearchIntegrationBuilder</td>
</tr>
<tr>
<td>org.hibernate.search.spi.SearchFactoryIntegrator</td>
<td>org.hibernate.search.spi.SearchIntegrator</td>
</tr>
</tbody>
</table>

5.10. MIGRATE ENTITY BEANS TO JAKARTA PERSISTENCE

Support for EJB entity beans is optional in Jakarta EE 8 and they are not supported in JBoss EAP 7.

In previous releases of JBoss EAP, entity beans were created in application source code by extending the `javax.ejb.EntityBean` class and implementing the required methods. They were then configured in the `ejb-jar.xml` file. A CMP entity bean was specified using an `<entity>` element that contained a `<persistence-type>` child element with a value of `Container`. A BMP entity bean was specified using an `<entity>` element that contained a `<persistence-type>` child element with a value of `Bean`. 
In JBoss EAP 7, you must replace any CMP and BMP entity beans in your code with Jakarta Persistence entities. Jakarta Persistence entities are created using the `javax.persistence.*` classes and are defined in the `persistence.xml` file.

The following is an example of a Jakarta Persistence entity class:

```java
import javax.persistence.Column;
import javax.persistence.Entity;
import javax.persistence.GeneratedValue;
import javax.persistence.Id;
import javax.persistence.Table;

@Entity
// User is a keyword in some SQL dialects!
@Table(name = "MyUsers")
public class MyUser {
    @Id
    @GeneratedValue
    private Long id;

    @Column(unique = true)
    private String username;
    private String firstName;
    private String lastName;

    public Long getId() {
        return id;
    }
    public String getUsername() {
        return username;
    }
    public void setUsername(String username) {
        this.username = username;
    }
    public String getFirstName() {
        return firstName;
    }
    public void setFirstName(String firstName) {
        this.firstName = firstName;
    }
    public String getLastName() {
        return lastName;
    }
    public void setLastName(String lastName) {
        this.lastName = lastName;
    }
}
```

The following is an example of a `persistence.xml` file.

```xml
<persistence version="2.1"
    xmlns="http://xmlns.jcp.org/xml/ns/persistence"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="
        http://xmlns.jcp.org/xml/ns/persistence
        http://xmlns.jcp.org/xml/ns/persistence/persistence_2_1.xsd">
    <persistence-unit name="my-unique-persistence-unit-name">
```

Red Hat JBoss Enterprise Application Platform 7.4 Migration Guide
For working examples of Jakarta Persistence entities, see the bmt, cmt, and hibernate5 quickstarts that ship with JBoss EAP 7.

### 5.11. JAKARTA PERSISTENCE PROPERTY CHANGES

Jakarta Persistence property changes introduced in JBoss EAP 7.0

A new persistence property, `jboss.as.jpa.deferdetach`, was added to provide compatibility with the persistence behavior in previous releases of JBoss EAP.

The `jboss.as.jpa.deferdetach` property controls whether the transaction-scoped persistence context used in a non-Jakarta Transactions thread detaches loaded entities after each `EntityManager` invocation or whether it waits until the persistence context is closed, for example, when the session bean invocation ends. The property value defaults to `false`, meaning entities are detached or cleared after each `EntityManager` invocation. If the property value is set to `true`, the entities are not detached until the persistence context is closed.

In JBoss EAP 5, persistence behaved as if the `jboss.as.jpa.deferdetach` property was set to `true`. To get this same behavior when migrating your application from JBoss EAP 5 to JBoss EAP 7, you must set the `jboss.as.jpa.deferdetach` property value to `true` in your `persistence.xml` as shown in the following example.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<persistence xmlns="http://java.sun.com/xml/ns/persistence" version="1.0">
  <persistence-unit name="EAP5_COMPAT_PU">
    <jta-data-source>java:jboss/datasources/ExampleDS</jta-data-source>
    <properties>
      <property name="jboss.as.jpa.deferdetach" value="true"/>
    </properties>
  </persistence-unit>
</persistence>
```

In JBoss EAP 6, persistence behaved as if the `jboss.as.jpa.deferdetach` property was set to `false`. This is the same behavior as seen in JBoss EAP 7, so no changes are necessary when you migrate your application.

### Jakarta Persistence property changes introduced in JBoss EAP 7.1

In JBoss EAP 7.0, unsynchronized persistence context error checking was not as strict as it should have been in the following areas:

- A synchronized container-managed persistence context was allowed to use an unsynchronized extended persistence context that was associated with a Jakarta Transactions. Instead, it should have thrown an `IllegalStateException` to prevent the unsynchronized persistence context from being used.

- An unsynchronized persistence context specified in a deployment descriptor was treated as synchronized.
In addition, PersistenceProperty hints in the @PersistenceContext were mistakenly ignored in JBoss EAP 7.0.

These issues were addressed and fixed in JBoss EAP 7.1 and later. Because these updates can result in an unwanted change in application behavior, two new persistence unit properties were introduced in JBoss EAP 7.1 to provide backward compatibility and preserve the previous behavior.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>wildfly.jpa.skipmixedsynctypechecking</td>
<td>This property disables the error checking. It should only be used as a temporary measure for backward compatibility in situations where applications worked in JBoss EAP 7.0 and fail in JBoss EAP 7.1 and later. Because this property might be deprecated in a future release, it is recommended that you correct your application code as soon as you are able to do so.</td>
</tr>
<tr>
<td>wildfly.jpa.allowjoinedunsync</td>
<td>This property is an alternative to wildfly.jpa.skipmixedsynctypechecking. It allows the application to treat unsynchronized persistence contexts that are associated with a Jakarta Transactions as if they are synchronized persistence contexts.</td>
</tr>
</tbody>
</table>

## 5.12. MIGRATE JAKARTA ENTERPRISE BEANS CLIENT CODE

**NOTE**

Enterprise entity beans are not supported in JBoss EAP 7. For information about how to migrate entity beans to Jakarta Persistence, see Migrate Entity Beans to Jakarta Persistence.

### 5.12.1. Jakarta Enterprise Beans client changes in JBoss EAP 7

The default remote connector and port have changed in JBoss EAP 7. For details about this change, see Update the Remote URL Connector and Port.

If you used the **migrate** operation to migrate your server configuration, the old settings are preserved and you do not need to make the changes detailed here. However, if you use the new JBoss EAP 7 default configuration, you must make the following changes.

#### 5.12.1.1. Update the default remote connection port

Change the remote connection port value from 4447 to 8080 in the **jboss-ejb-client.properties** file. The following are examples of a **jboss-ejb-client.properties** file in the previous and the current release:

**Example: JBoss EAP 6 jboss-ejb-client.properties file**

```properties
remote.connectionprovider.create.options.org.xnio.Options.SSL_ENABLED=false
remote.connections=default
remote.connection.default.host=localhost
```
remote.connection.default.port=4447
remote.connection.default.connect.options.org.xnio.Options.SASL_POLICY_NOANONYMOUS=false

Example: JBoss EAP 7 jboss-ejb-client.properties file

remote.connectionprovider.create.options.org.xnio.Options.SSL_ENABLED=false
remote.connections=default
remote.connection.default.host=localhost
remote.connection.default.port=8080
remote.connection.default.connect.options.org.xnio.Options.SASL_POLICY_NOANONYMOUS=false

5.12.1.2. Update the default connector
If you use the new JBoss EAP 7 configuration, the default connector has changed from remote to http-remoting. This change impacts clients using libraries from one release of JBoss EAP to connect to a server in a different release.

- If a client application uses the Jakarta Enterprise Beans client library from JBoss EAP 6 and wants to connect to JBoss EAP 7 server, the server must be configured to expose a remote connector on a port other than 8080. The client must then connect using that newly configured connector.

- A client application that uses the Jakarta Enterprise Beans client library from JBoss EAP 7 and wants to connect to JBoss EAP 6 server must be aware that the server instance does not use the http-remoting connector and instead uses a remote connector. This is achieved by defining a new client-side connection property.

Example: remote connection property

remote.connection.default.protocol=remote

5.12.2. Migrate Remote Naming Client Code
If you are running with the new default JBoss EAP 7 configuration, you must modify your client code to use the new default remote port and connector.

The following is an example of how remote naming properties were specified in the client code in JBoss EAP 6.

```java
java.naming.factory.initial=org.jboss.naming.remote.client.InitialContextFactory
java.naming.provider.url=remote://localhost:4447
```

The following is an example of how to specify the remote naming properties in the client code in JBoss EAP 7.

```java
java.naming.factory.initial=org.wildfly.naming.client.WildFlyInitialContextFactory
java.naming.provider.url=http-remoting://localhost:8080
```

5.12.3. Additional JBoss EJB client changes introduced in JBoss EAP 7.1
While JBoss EAP 7.0 shipped with JBoss EJB client 2.1.4, JBoss EAP 7.1 and later ship with JBoss EJB client 4.0.x, which includes a number of changes to the API.
NOTE

Enterprise entity beans are not supported in JBoss EAP 7. For information about how to migrate entity beans to Jakarta Persistence, see [Migrate Entity Beans to Jakarta Persistence](#).

- The `org.ejb.client.EJBClientInvocationContext` class has added the following new methods:

<table>
<thead>
<tr>
<th>Method</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>isBlockingCaller()</td>
<td>boolean</td>
<td>Determine whether this invocation is currently blocking the calling thread.</td>
</tr>
<tr>
<td>isClientAsync()</td>
<td>boolean</td>
<td>Determine whether the method is marked client-asynchronous, meaning that invocation should be asynchronous regardless of whether the server-side method is asynchronous.</td>
</tr>
<tr>
<td>isIdempotent()</td>
<td>boolean</td>
<td>Determine whether the method is marked idempotent, meaning that the method may be invoked more than one time with no additional effect.</td>
</tr>
<tr>
<td>setBlockingCaller(Bool ean)</td>
<td>void</td>
<td>Establish whether this invocation is currently blocking the calling thread.</td>
</tr>
<tr>
<td>setLocator(EJBLocator &lt;T&gt;)</td>
<td>&lt;T&gt; void</td>
<td>Set the locator for the invocation target.</td>
</tr>
</tbody>
</table>

- The `org.ejb.client.EJBLocator` class has added the following new methods:

<table>
<thead>
<tr>
<th>Method</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>asStateful()</td>
<td>StatefulEJBLocator&lt;T&gt;</td>
<td>Return this locator as a stateful locator, if it is one.</td>
</tr>
<tr>
<td>asStateless()</td>
<td>StatelessEJBLocator&lt;T&gt;</td>
<td>Return this locator as a stateless locator, if it is one.</td>
</tr>
<tr>
<td>isEntity()</td>
<td>boolean</td>
<td>Determine if this is an entity locator.</td>
</tr>
<tr>
<td>isHome()</td>
<td>boolean</td>
<td>Determine if this is a home locator.</td>
</tr>
<tr>
<td>isStateful()</td>
<td>boolean</td>
<td>Determine if this is a stateful locator.</td>
</tr>
<tr>
<td>isStateless()</td>
<td>boolean</td>
<td>Determine if this is a stateless locator.</td>
</tr>
<tr>
<td>withNewAffinity(Affinity)</td>
<td>abstract EJBLocator&lt;T&gt;</td>
<td>Create a copy of this locator, but with the new given affinity.</td>
</tr>
</tbody>
</table>
A new `org.ejb.client.EJBClientPermission` class, which is a subclass of `java.security.Permission`, has been introduced for controlling access to privileged EJB operations. It provides the following constructors:

- `EJBClientPermission(String name)`
- `EJBClientPermission(String name, String actions)`

It provides the following methods:

<table>
<thead>
<tr>
<th>Method</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>equals(EJBClientPermission obj)</code></td>
<td>boolean</td>
<td>Checks two <code>EJBClientPermission</code> objects for equality.</td>
</tr>
<tr>
<td><code>equals(Object obj)</code></td>
<td>boolean</td>
<td>Checks two <code>Permission</code> objects for equality.</td>
</tr>
<tr>
<td><code>equals(Permission obj)</code></td>
<td>boolean</td>
<td>Checks two <code>Permission</code> objects for equality.</td>
</tr>
<tr>
<td><code>getActions()</code></td>
<td>String</td>
<td>Returns the actions as a string.</td>
</tr>
<tr>
<td><code>hashCode()</code></td>
<td>int</td>
<td>Returns the hash code value for this <code>Permission</code> object.</td>
</tr>
<tr>
<td><code>implies(EJBClientPermission permission)</code></td>
<td>boolean</td>
<td>Checks if the specified permission’s actions are implied by this object’s actions.</td>
</tr>
<tr>
<td><code>implies(Permission permission)</code></td>
<td>boolean</td>
<td>Checks if the specified permission’s actions are implied by this <code>Permission</code> object’s actions.</td>
</tr>
</tbody>
</table>

A new `org.ejb.client.EJBMethodLocator` class has been introduced for locating a specific EJB method. It provides the following constructor:

- `EJBMethodLocator(String methodName, String… parameterTypeNames)`

It provides the following methods:

<table>
<thead>
<tr>
<th>Method</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>equals(EJBMethodLocator other)</code></td>
<td>boolean</td>
<td>Determine whether this object is equal to another.</td>
</tr>
<tr>
<td><code>equals(Object other)</code></td>
<td>boolean</td>
<td>Determine whether this object is equal to another.</td>
</tr>
<tr>
<td><code>forMethod(Method method)</code></td>
<td>static</td>
<td>Get a method locator for the given reflection method.</td>
</tr>
<tr>
<td><code>getMethodName()</code></td>
<td>String</td>
<td>Get the method name.</td>
</tr>
</tbody>
</table>
- A new `org.jboss.ejb.client.EJBReceiverInvocationContext.ResultProducer.Failed` class has been introduced for failure cases. It provides the following constructor:
  - `Failed(Exception cause)`

- It provides the following methods:

<table>
<thead>
<tr>
<th>Method</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>discardResult()</td>
<td>void</td>
<td>Discard the result, indicating that it will not be used.</td>
</tr>
<tr>
<td>getResult()</td>
<td>Object</td>
<td>Get the result.</td>
</tr>
</tbody>
</table>

- A new `org.jboss.ejb.client.EJBReceiverInvocationContext.ResultProducer.Immediate` class has been introduced for immediate results. It provides the following constructor:
  - `Failed(Exception cause)`

- It provides the following methods:

<table>
<thead>
<tr>
<th>Method</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>discardResult()</td>
<td>void</td>
<td>Discard the result, indicating that it will not be used.</td>
</tr>
<tr>
<td>getResult()</td>
<td>Object</td>
<td>Get the result.</td>
</tr>
</tbody>
</table>

- A new `org.jboss.ejb.client.URIAffinity` class, which is a subclass of `org.jboss.ejb.client.Affinity` has been introduced for URI affinity specification. It is created using `Affinity.forUri(URI)`.

- It provides the following methods:

<table>
<thead>
<tr>
<th>Method</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>equals(Affinity other)</td>
<td>boolean</td>
<td>Indicates whether another object is equal to this one.</td>
</tr>
<tr>
<td>equals(Object other)</td>
<td>boolean</td>
<td>Indicates whether another object is equal to this one.</td>
</tr>
</tbody>
</table>
The **org.jboss.ejb.client.EJBMetaDataImpl** class has deprecated the following methods:

- `toAbstractEJBMetaData()`
- `EJBMetaDataImpl(AbstractEJBMetaData<?,?>)`

### 5.12.4. EJB client changes required for JBoss EAP 7

The upgrade of the **org.apache.santuario.xmlsec** module from 2.0.8 to 2.1.1 in JBoss EAP 7.2 has caused a regression with remoting in **PicketLinkSTS**. The issue manifests itself as the following runtime exception:

```
java.lang.IllegalArgumentException: ELY05131: Invalid ASCII control "0xA"
```

This is caused by a change in the formatting in the generated `SignatureValue` in the assertion. In the previous release, the generated value looked similar to the following example:

```
<dsig:SignatureValue
xmlns:dsig="http://www.w3.org/2000/09/xmldsig#">cUNpFJIZILYrBDZtQSTDrq2K6PbnAHyg2qbxD5F
uB4XMjdQ5oxQikMejLyelnA7s4GFusoLhahiqtTOT8UrOyxrR4yYAmJ/e5s+f4gs926+1biraT/3/wG8wM/L
vcjvk5Ap69zOdUyRyppsWfA4jr7TTBxVPGy8g4KUnFviUtufTc2Ghgp53AmUuLis/THyP28jE7+28//q8bi/bQ7fW
HC6iWX67+NK1duFcoQ6IPKeVrePZz55lvgl+WWdkF6uYCz5ldMzurhzmeQ3K8DAMlxz/
MG67VWJIOonuGNWF5nmdy8zd9AFcRsr1XadvZJCbGNfu89AL5inCg==</dsig:SignatureValue>
```

In JBoss EAP 7.2, the generated string value now contains instances of invalid hidden ASCII 0xD carriage return and 0xA line feed control characters.

```
<dsig:SignatureValue
xmlns:dsig="http://www.w3.org/2000/09/xmldsig#">cUNpFJIZILYrBDZtQSTDrq2K6PbnAHyg2qbxD5F
uB4XMjdQ5oxQikMejLyelnA7s4GFusoLhahi& #13;
qTOT8UrOyxrR4yYAmJ/e5s+f4gs926+1biraT/3/wG8wM/Lvcjvk5Ap69zOdUyRyppsWfA4jr1& #13;
7TTBxVPGy8g4KUnFviUtufTc2Ghgp53AmUuLis/THyP28jE7+28//q8bi/bQ7fWHC6iWX67+N& #13;
K1duFcoQ6IPKeVrePZz55lvgl+WWdkF6uYCz5ldMzurhzmeQ3K8DAMlxz/MG67VWJIOonuGNWF7&
#13;
nmdy5zd9AFcRsr1XadvZJCbGNfu89AL5inCg==</dsig:SignatureValue>
```

If you experience the described runtime exception, update your client code to remove occurrences of the hidden ASCII characters from the returned assertion string. For example, assume your current code looks similar to the following example:
You must add a line of code to remove the occurrences of the invalid hidden ASCII \x0D carriage return and \x0A line feed characters; for example:

```java
WSTrustClient client = new WSTrustClient("PicketLinkSTS", "PicketLinkSTSPort", 
"http://localhost:8080/picketlink-sts/PicketLinkSTS", new 
WSTrustClient.SecurityInfo(username, password));
Element assertion = client.issueToken(SAMLUtil.SAML2_TOKEN_TYPE);

// Return the assertion as a string
String assertionString = DocumentUtil.getNodeAsString(assertion);
...
properties.put("remote.connection.main.password", assertionString);
```

```
WSTrustClient client = new WSTrustClient("PicketLinkSTS", "PicketLinkSTSPort", 
"http://localhost:8080/picketlink-sts/PicketLinkSTS", new 
WSTrustClient.SecurityInfo(username, password));
Element assertion = client.issueToken(SAMLUtil.SAML2_TOKEN_TYPE);

// Return the assertion as a string, stripping the invalid hidden ASCII characters
String assertionString = DocumentUtil.getNodeAsString(assertion).replace(String.valueOf((char) 0xA), "").replace(String.valueOf((char) 0xD), "");
...
properties.put("remote.connection.main.password", assertionString);
```

### 5.13. MIGRATE CLIENTS TO USE THE WILDFLY CONFIGURATION FILE

Prior to release 7.1, JBoss EAP client libraries, such as EJB and naming, used different configuration strategies. JBoss EAP 7.1 introduced the `wildfly-config.xml` file with the purpose of unifying all client configurations into one single configuration file, in a similar manner to the way the server configuration is handled.

For example, prior to JBoss EAP 7.1, you might create a new `InitialContext` for an EJB client using a `jboss-ejb-client.properties` file, or by programatically setting the properties using a `Properties` class.

**Example: jboss-ejb-client.properties properties file**

```properties
remote.connectionprovider.create.options.org.xnio.Options.SSL_ENABLED=false
remote.connections=one
remote.connection.one.port=8080
remote.connection.one.host=127.0.0.1
remote.connection.one.username=quickuser
remote.connection.one.password=quick-123
```

In JBoss EAP 7.1 and later, you create a `wildfly-config.xml` file in the `META-INF` directory of the client archive. This is the equivalent configuration using a `wildfly-config.xml` file.

**Example: Equivalent configuration using the wildfly-config.xml file**

```xml
<configuration>
  <authentication-client xmlns="urn:elytron:client:1.2">
    <authentication-rules>
      <rule use-configuration="ejb"/>
    </authentication-rules>
  </authentication-client>
</configuration>
```
Additional resources

- For information about how to configure client authentication for the Elytron Client using the `wildfly-config.xml` file, see Configure Client Authentication with Elytron Client in How to Configure Identity Management for JBoss EAP.

- For information about the types of client configurations that can be done using the `wildfly-config.xml` file, see Client Configuration Using the `wildfly-config.xml` File in the JBoss EAP Development Guide. For information about how to configure client authentication for the Elytron Client using the `wildfly-config.xml` file, see Configure Client Authentication with Elytron Client in How to Configure Identity Management for JBoss EAP.

### 5.14. MIGRATE DEPLOYMENT PLAN CONFIGURATIONS

The Java EE Application Deployment specification (JSR-88) was intended to define a standard contract to enable tools from multiple providers to configure and deploy applications on any Java EE platform product. The contract required Java EE Product Providers to implement the `DeploymentManager` and other `javax.enterprise.deploy.spi` interfaces to be accessed by the Tool Providers. In case of JBoss EAP 6, a deployment plan is identified by an XML descriptor named `deployment-plan.xml` that is bundled in a ZIP or JAR archive.

This specification saw very little adoption because most application server products provide their own more “feature rich” deployment solutions. For this reason, JSR-88 support was dropped from Java EE 7 and, in turn, from JBoss EAP 7.

If you used JSR-88 to deploy your application, you must now use another method to deploy the application. The JBoss EAP management CLI `deploy` command provides a standard way to deploy archives to standalone servers or to server groups in a managed domain. For more information about the management CLI, see the Management CLI Guide.

### 5.15. MIGRATE CUSTOM APPLICATION VALVES

You must manually migrate custom valves or any valves that are defined in the `jboss-web.xml` XML file. This includes valves created by extending the `org.apache.catalina.valves.ValveBase` class and configured in the `<valve>` element of the `jboss-web.xml` descriptor file.
IMPORTANT

Custom valves and valves that are defined in the `jboss-web.xml` file must be rewritten or replaced by the corresponding Undertow built-in handler. For information about mapping valves to Undertow handlers, see Migrate JBoss Web Valves.

Authentication valves must be replaced manually using Undertow built-in authentication mechanisms.

Migrate Valves Configured in Deployments

In JBoss EAP 6, you could define custom valves at the application level by configuring them in the `jboss-web.xml` web application descriptor file. In JBoss EAP 7, it is possible to do this with Undertow handlers as well.

The following is an example of a valve configured in the `jboss-web.xml` file in JBoss EAP 6.

```
<jboss-web>
  <valve>
    <class-name>org.jboss.examples.MyValve</class-name>
    <param>
      <param-name>myParam</param-name>
      <param-value>foobar</param-value>
    </param>
  </valve>
</jboss-web>
```

For more information about how to create and configure custom handlers in JBoss EAP, see Creating Custom Handlers in the JBoss EAP Development Guide.

Migrate Custom Authenticator Valves

For information about how to migrate authenticator valves, see Migrate Authenticator Valves in this guide.

5.16. SECURITY APPLICATION CHANGES

The replacement of JBoss Web with Undertow requires changes to security configuration in JBoss EAP 7.

5.16.1. Migrate Authenticator Valves

If you created a custom authenticator valve that extended `AuthenticatorBase` in JBoss EAP 6.4, you must manually replace it with a custom HTTP authentication implementation in JBoss EAP 7. The HTTP authentication mechanism is created in the `elytron` subsystem and then registered with the `undertow` subsystem. For information about how to implement a custom HTTP authentication mechanism, see Developing a Custom HTTP Mechanism in the Development Guide for JBoss EAP.

5.16.2. PicketLink Changes

For information about the changes required for SSO with SAML v2 configuration, see Changes from Previous Versions of JBoss EAP in How To Set Up SSO with SAML v2 for JBoss EAP.

5.16.3. Other Security Application Changes
For information about the differences in SSO configuration with Kerberos, see Differences from Configuring Previous Versions JBoss EAP in How to Set Up SSO with Kerberos for JBoss EAP.

5.17. JBOSS LOGGING CHANGES

If your application uses JBoss Logging, be aware that the annotations in the `org.jboss.logging` package are now deprecated in JBoss EAP 7. They have been moved to the `org.jboss.logging.annotations` package, so you must update your source code to import the new package.

The annotations have also moved to a separate Maven `groupId:artifactId:version` (GAV) ID so you need to add a new project dependency for `org.jboss.logging:jboss-logging-annotations` in your project `pom.xml` file.

**NOTE**

Only the logging annotations have moved. The `org.jboss.logging.BasicLogger` and `org.jboss.logging.Logger` still exist in the `org.jboss.logging` package.

The following table lists the deprecated annotation classes and corresponding replacements.

<table>
<thead>
<tr>
<th>Deprecated Class</th>
<th>Replacement Class</th>
</tr>
</thead>
<tbody>
<tr>
<td>org.jboss.logging.Cause</td>
<td>org.jboss.logging.annotations.Cause</td>
</tr>
<tr>
<td>org.jboss.logging.Field</td>
<td>org.jboss.logging.annotations.Field</td>
</tr>
<tr>
<td>org.jboss.logging.FormatWith</td>
<td>org.jboss.logging.annotations.FormatWith</td>
</tr>
<tr>
<td>org.jboss.logging.LoggingClass</td>
<td>org.jboss.logging.annotations.LoggingClass</td>
</tr>
<tr>
<td>org.jboss.logging.MessageBundle</td>
<td>org.jboss.logging.annotations.MessageBundle</td>
</tr>
<tr>
<td>org.jboss.logging.Param</td>
<td>org.jboss.logging.annotations.Param</td>
</tr>
<tr>
<td>org.jboss.logging.Property</td>
<td>org.jboss.logging.annotations.Property</td>
</tr>
</tbody>
</table>

5.18. JAKARTA SERVER FACES CODE CHANGES

Dropped support for Jakarta Server Faces 1.2
NOTE

Jakarta Server Faces is the new name for JavaServer Faces.

With JBoss EAP 6.4, you could continue to use Jakarta Server Faces 1.2 with your application deployment by creating a `jboss-deployment-structure.xml` file. JBoss EAP 7.4 includes Jakarta Server Faces 2.3 and no longer supports the Jakarta Server Faces 1.2 API. If your application uses Jakarta Server Faces 1.2, you must rewrite it to use Jakarta Server Faces 2.3.

5.19. MODULE CLASS LOADING CHANGES

In JBoss EAP 7, the class loading behavior has changed in cases where multiple modules contain the same classes or packages.

Assume there are two modules, `MODULE_A` and `MODULE_B`, that depend upon each other and contain some of the same packages. In JBoss EAP 6, the classes or packages that were loaded from the dependencies took precedence over those specified in the `resource-root` of the `module.xml` file. This meant `MODULE_A` saw the packages for `MODULE_B` and `MODULE_B` saw the packages for `MODULE_A`. This behavior was confusing and could cause conflicts. This behavior has changed in JBoss EAP 7. Now the classes or packages specified by the `resource-root` in the `module.xml` file take precedence over those specified by the dependency. This means `MODULE_A` sees the packages for `MODULE_A` and `MODULE_B` sees the packages for `MODULE_B`. This prevents conflicts and provides a more appropriate behavior.

If you have defined custom modules that include `resource-root` libraries or packages that contain classes that are duplicated in their module dependencies, you might see `ClassNotFoundException`, `LinkageError`, class loading errors, or other changes in behavior when you migrate to JBoss EAP 7. To resolve these issues, you must configure your `module.xml` file to ensure only one version of a class is used. This can be accomplished by using either of the following approaches.

- You can avoid specifying a `resource-root` that duplicates classes in the module dependency.
- You can use the `include` and `exclude` sub-elements of the `imports` and `exports` elements to control class loading in the `module.xml` file. The following is an export element that excludes classes is in the specified package.

```xml
<exports>
  <exclude path="com/mycompany/duplicateclassespath"/>
</exports>
```

If you prefer to preserve your existing behavior, you must filter the dependency packages from the dependent `resource-root` in the `module.xml` file using the `filter` element. This allows you to retain the existing behavior without the odd looping that you would see under JBoss EAP 6. The following is an example of a `root-resource` that filters classes in a specified package.

```xml
<resource-root path="mycompany.jar">
  <filter>
    <exclude path="com/mycompany/duplicateclassespath"/>
  </filter>
</resource-root>
```

For more information about modules and class loading, see Class Loading and Modules in the JBoss EAP Development Guide.
5.20. APPLICATION CLUSTERING CHANGES

5.20.1. Overview of New Clustering Features

The following list describes some of the new clustering features to be aware of when migrating your application from JBoss EAP 6 to JBoss EAP 7.

- JBoss EAP 7 introduces a new public API for building singleton services that significantly simplifies the process. For information on singleton services, see HA Singleton Service in the JBoss EAP Development Guide.

- A singleton deployment can be configured to deploy and start on only a single node in the cluster at a time. For more information, see HA Singleton Deployments in the JBoss EAP Development Guide.

- You can now define clustered singleton MDBs. For more information, see Clustered Singleton MDBs in Developing Jakarta Enterprise Beans Applications for JBoss EAP.

- JBoss EAP 7 includes the Undertow mod_cluster implementation. This offers a pure Java load balancing solution that does not require an httpd web server. For more information, see Configuring JBoss EAP as a Front-end Load Balancer in the JBoss EAP Configuration Guide.

The remainder of this section describes how clustering changes might impact the migration of your applications to JBoss EAP 7.

5.20.2. Web Session Clustering Changes

JBoss EAP 7 introduces a new web session clustering implementation. It replaces the previous implementation, which was tightly coupled to the legacy JBoss Web subsystem source code.

The new web session clustering implementation impacts how the application is configured in the jboss-web.xml JBoss EAP proprietary web application XML descriptor file. The following are the only clustering configuration elements that remain in this file.

```xml
<jboss-web>
  ...
  <max-active-sessions>...</max-active-sessions>
  ...
  <replication-config>
    <replication-granularity>...</replication-granularity>
    <cache-name>...</cache-name>
  </replication-config>
  ...
</jboss-web>
```

The distributable-web subsystem deprecates the <replication-config> element of jboss-web.xml. It enhances the usage of <replication-config> by generating an ad hoc distributable web session profile.

You can override the default distributable session management behavior by referencing a session management profile by name or by providing a deployment-specific session management configuration. For more information, see Override Default Distributable Session Management Behavior.

The following table describes how to achieve similar behavior for elements in the jboss-web.xml file that are now obsolete.
<table>
<thead>
<tr>
<th>Configuration Element</th>
<th>Description of Change</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;max-active-sessions/&gt;</code></td>
<td>Previously, the session creation would fail if it caused the number of active sessions to exceed the value specified by <code>&lt;max-active-sessions/&gt;</code>. In the new implementation, <code>&lt;max-active-sessions/&gt;</code> is used to enable session passivation. If session creation will cause the number of active sessions to exceed the <code>&lt;max-active-sessions/&gt;</code>, then the oldest session known to the session manager will passivate to make room for the new session.</td>
</tr>
<tr>
<td><code>&lt;passivation-config/&gt;</code></td>
<td>This configuration element and its sub-elements are no longer used in JBoss EAP 7.</td>
</tr>
<tr>
<td><code>&lt;use-session-passivation/&gt;</code></td>
<td>Previously, passivation was enabled using this attribute. In the new implementation, passivation is enabled by specifying a non-negative value for <code>&lt;max-active-sessions/&gt;</code>.</td>
</tr>
<tr>
<td><code>&lt;passivation-min-idle-time/&gt;</code></td>
<td>Previously, sessions needed to be active for a minimum amount of time before becoming a candidate for passivation. This could cause session creation to fail, even when passivation was enabled. The new implementation does not support this logic and thus avoids this Denial of Service (DoS) vulnerability.</td>
</tr>
<tr>
<td><code>&lt;passivation-max-idle-time/&gt;</code></td>
<td>Previously, a session would be passivated after it was idle for a specific amount of time. The new implementation only supports lazy passivation. It does not support eager passivation. Sessions are only passivated when necessary to comply with <code>&lt;max-active-sessions/&gt;</code>.</td>
</tr>
<tr>
<td><code>&lt;replication-config/&gt;</code></td>
<td>The distributable-web subsystem deprecates this element. For more information, see The distributable-web subsystem for Distributable Web Session Configurations and Overiding Default Distributable Session Management Behavior.</td>
</tr>
<tr>
<td><code>&lt;replication-trigger/&gt;</code></td>
<td>Previously, this element was used to determine when session replication was triggered. The new implementation replaces this configuration option with a single, robust strategy. For more information, see Immutable Session Attributes in the JBoss EAP Development Guide.</td>
</tr>
<tr>
<td><code>&lt;use-jk/&gt;</code></td>
<td>Previously, the <code>instance-id</code> of the node handling a given request was appended to the <code>jsessionid</code>, for use by load balancers such as mod_jk, mod_proxy_balancer, mod_cluster, depending on the value specified for <code>&lt;use-jk/&gt;</code>. In the new implementation, the <code>instance-id</code>, if defined, is always appended to the <code>jsessionid</code>.</td>
</tr>
</tbody>
</table>

Red Hat JBoss Enterprise Application Platform 7.4 Migration Guide

106
Previously, this configuration option was intended as an optimization to prevent the replication of a session’s timestamp if no session attribute was changed. While this sounds nice, in practice it does not prevent any RPCs, since session access requires cache transaction RPCs regardless of whether any session attributes changed.

In the new implementation, the timestamp of a session is replicated on every request. This prevents stale session metadata following a failover.

Previously, one could configure `<snapshot-mode/>` as `INSTANT` or `INTERVAL`. Infinispan’s asynchronous replication makes this configuration option obsolete.

This was only relevant for `<snapshot-mode>INTERVAL</snapshot-mode>`. Since `<snapshot-mode/>` is obsolete, this option is now obsolete as well.

Previously, the value specified by this attribute defined a policy for triggering session events.

In the new implementation, this behavior is specification-driven and not configurable.

This new implementation also supports write-through cache stores as well as passivation-only cache stores. Typically, a write-through cache store is used in conjunction with an invalidation cache. The web session clustering implementation in JBoss EAP 6 did not operate correctly when used with an invalidation cache.

### 5.20.3. Overriding the Default Distributable Session Management Behavior

You can override the default distributable session management behavior in one of the following ways:

- Referencing a session management profile by name
- Providing a deployment-specific session management configuration

#### Referencing an existing session management profile

- To use an existing distributed session management profile, include a `distributable-web.xml` deployment descriptor located in the application’s `/WEB-INF` directory. For example:

```
<?xml version="1.0" encoding="UTF-8"?>
<distributable-web xmlns="urn:jboss:distributable-web:1.0">
    <session-management name="foo"/>
</distributable-web>
```

- Alternatively, define the target distributed session management profile within an existing `jboss-all.xml` deployment descriptor:
Using a Deployment-specific Session Management Profile

If only a single web application uses the custom session management configuration, you can define the configuration within the deployment descriptor itself. Ad hoc configuration looks identical to the configuration used by the `distributable-web` subsystem.

- Define the custom session management configuration within the deployment descriptor. For example:

  ```xml
  <?xml version="1.0" encoding="UTF-8"?>
  <distributable-web xmlns="urn:jboss:distributable-web:1.0">
    <infinispan-session-management cache-container="foo" cache="bar" granularity="SESSION">
      <primary-owner-affinity/>
    </infinispan-session-management>
  </distributable-web>
  </jboss>
  ```

- Alternatively, define the session management configuration within an existing `jboss-all.xml` deployment descriptor:

  ```xml
  <?xml version="1.0" encoding="UTF-8"?>
  <distributable-web xmlns="urn:jboss:distributable-web:1.0">
    <infinispan-session-management cache-container="foo" cache="bar" granularity="ATTRIBUTE">
      <local-affinity/>
    </infinispan-session-management>
  </distributable-web>
  </jboss>
  ```

### 5.20.4. Stateful session EJB clustering changes

In JBoss EAP 6, you were required to enabled the clustering behavior for stateful session beans (SFSBs) in one of the following ways:

- You could add the `org.jboss.ejb3.annotation.Clustered` annotation in the session bean.

```java
@Stateful
@Clustered
public class MyBean implements MySessionInt {
  public void myMethod() {
    //
  }
}
```
You could add the `<clustered>` element to the `jboss-ejb3.xml` file.

```xml
<c:clustering>
  <ejb-name>DDBasedClusteredSFSB</ejb-name>
  <c:clustered>true</c:clustered>
</c:clustering>
```

JBoss EAP 7 no longer requires you to enable the clustering behavior. By default, if the server is started using an HA profile, the state of SFSBs will be replicated automatically. You can disable this default behavior in one of the following ways:

- You can disable the default behavior for a single stateful session bean by using `@Stateful(passivationCapable=false)`, which is new to the EJB 3.2 specification.
- You can disable this behavior globally in the configuration of the `ejb3` subsystem in the server configuration.

**NOTE**

If the `@Clustered` annotation is not removed from the application, it is simply ignored and does not affect the deployment of the application.

### 5.20.5. Clustering Services Changes

In JBoss EAP 6, the APIs for clustering services were in private modules and were not supported.

JBoss EAP 7 introduces a public clustering services API for use by applications. The new services are designed to be lightweight, easily injectable, and require no external dependencies.

- The new `org.wildfly.clustering.group.Group` interface provides access to the current cluster status and allows listening for cluster membership changes.
- The new `org.wildfly.clustering.dispatcher.CommandDispatcher` interface allows running code in the cluster, on all or a selected subset of nodes.

These services replace similar APIs that were available in previous releases, namely `HAPartition` from JBoss EAP 5 and `GroupCommunicationService`, `GroupMembershipNotifier`, and `GroupRpcDispatcher` in JBoss EAP 6.

For more information, see Public API for Clustering Services in the JBoss EAP Development Guide.

### 5.20.6. Migrate Clustering HA Singleton

In JBoss EAP 6, there was no public API available for the cluster-wide HA singleton service. If you used the private `org.jboss.as.clustering.singleton.*` classes, you must change your code to use the new public `org.wildfly.clustering.singleton.*` packages when you migrate your application to JBoss EAP 7.

For more information about HA singleton services, see HA Singleton Service in the Development Guide for JBoss EAP. For information about HA singleton deployments, see HA Singleton Deployments in the Development Guide for JBoss EAP.
CHAPTER 6. MISCELLANEOUS CHANGES

6.1. CHANGES TO DELIVERY OF JBOSS EAP NATIVES AND APACHE HTTP SERVER

JBoss EAP 7 natives are delivered differently in this release than in the past. Some now ship with the new Red Hat JBoss Core Services product, which is a set of supplementary software that is common to many of the Red Hat JBoss middleware products. The new product allows for faster distribution of updates and a more consistent update experience. The JBoss Core Services product is available for download in a different location on the Red Hat Customer Portal.

- The following table lists the differences in the delivery methods between the releases.

<table>
<thead>
<tr>
<th>Package</th>
<th>JBoss EAP 6</th>
<th>JBoss EAP 7</th>
</tr>
</thead>
<tbody>
<tr>
<td>AIO Natives for Messaging</td>
<td>Delivered with the product in a separate “Native Utilities” download</td>
<td>Included within the JBoss EAP distribution. No additional download is required.</td>
</tr>
<tr>
<td>Apache HTTP Server</td>
<td>Delivered with the product in a separate “Apache HTTP Server” download</td>
<td>Delivered with the new JBoss Core Services product</td>
</tr>
<tr>
<td>mod_cluster, mod_jk, isapi, and nsapi connectors</td>
<td>Delivered with the product in a separate “Webserver Connector Natives” download</td>
<td>Delivered with the new JBoss Core Services product</td>
</tr>
<tr>
<td>JSVC</td>
<td>Delivered with the product in a separate “Native Utilities” download</td>
<td>Delivered with the new JBoss Core Services product</td>
</tr>
<tr>
<td>OpenSSL</td>
<td>Delivered with the product in a separate “Native Utilities” download</td>
<td>Delivered with the new JBoss Core Services product</td>
</tr>
<tr>
<td>tcnatives</td>
<td>Delivered with the product in a separate “Native Components” download</td>
<td>This was dropped in JBoss EAP 7</td>
</tr>
</tbody>
</table>

- You should also be aware of the following changes:
  - Support was dropped for mod_cluster and mod_jk connectors used with Apache HTTP Server from Red Hat Enterprise Linux RPM channels. If you run Apache HTTP Server from Red Hat Enterprise Linux RPM channels and need to configure load balancing for JBoss EAP 7 servers, you can do one of the following:
    - Use the Apache HTTP Server provided by JBoss Core Services.
    - You can configure JBoss EAP 7 to act as a front-end load balancer. For more information, see Configuring JBoss EAP as a Front-end Load Balancer in the JBoss EAP Configuration Guide.
You can deploy Apache HTTP Server on a machine that is supported and certified and then run the load balancer on that machine. For the list of supported configurations, see Overview of HTTP Connectors in the JBoss EAP 7 Configuration Guide.

- You can find more information about JBoss Core Services in the Apache HTTP Server Installation Guide.

### 6.2. CHANGES TO DEPLOYMENTS ON AMAZON EC2

A number of changes have been made to the Amazon Machine Images (AMI) in JBoss EAP 7. This section briefly summarizes some of those changes.

- The way you launch non-clustered and clustered JBoss EAP instances and domains in Amazon EC2 has changed significantly.

- JBoss EAP 6 used the User Data: field for JBoss EAP configuration. The AMI scripts that parsed the configuration in the User Data: field and started the servers automatically on instance startup have been removed from JBoss EAP 7.

- Red Hat JBoss Operations Network agent was installed in the previous release of JBoss EAP. In JBoss EAP 7, you must install it separately.

For details on deploying JBoss EAP 7 on Amazon EC2, see Deploying JBoss EAP on Amazon Web Services.

### 6.3. UNDEPLOYING APPLICATIONS THAT INCLUDE SHARED MODULES

Changes in the JBoss EAP 7.1 server and the Maven plug-in can result in the following failure when you attempt to undeploy your application. This error can occur if your application contains modules that interact with or depend on each other.

```
WFLYCTL0184:    New missing/unsatisfied dependencies
```

For example, assume you have an application that contains two Maven WAR project modules, application-A and application-B, that share data managed by the data-sharing module.

When you deploy this application, you must deploy the shared data-sharing module first, and then deploy the modules that depend on it. The deployment order is specified in the <modules> element of the parent pom.xml file. This is true in JBoss EAP 6.4 through JBoss EAP 7.4.

In releases prior to JBoss EAP 7.1, you could undeploy all of the archives for this application from the root of the parent project using the following command.

```
$ mvn wildfly:undeploy
```

In JBoss EAP 7.1 and later, you must first undeploy the archives that use the shared modules, and then undeploy the shared modules. Since there is no way to specify the order of undeployment in the project pom.xml file, you must undeploy the modules manually. You can accomplish this by running the following commands from the root of the parent directory.

```
$ mvn wildfly:undeploy -pl application-A,application-B
$ mvn wildfly:undeploy -pl data-shared
```
This new undeploy behavior is more correct and ensures that you do not end up in an unstable deployment state.

6.4. CHANGES TO JBOSS EAP SCRIPTS

The `add-user` script behavior has changed in JBoss EAP 7 due to a change in password policy. JBoss EAP 6 had a strict password policy. As a result, the `add-user` script rejected weak passwords that did not satisfy the minimum requirements. In JBoss EAP 7, weak passwords are accepted and a warning is issued. For more information, see Setting Add-User Utility Password Restrictions in the JBoss EAP Configuration Guide.

6.5. REMOVAL OF OSGI SUPPORT

When JBoss EAP 6.0 GA was first released, JBoss OSGi, an implementation of the OSGi specification, was included as a Technology Preview feature. With the release of JBoss EAP 6.1.0, JBoss OSGi was demoted from Technology Preview to Unsupported.

In JBoss EAP 6.1.0, the `configadmin` and `osgi` extension modules and subsystem configuration for a standalone server were moved to a separate `EAP_HOME/standalone/configuration/standalone-osgi.xml` configuration file. Because you should not migrate this unsupported configuration file, the removal of JBoss OSGi support should not impact the migration of a standalone server configuration. If you modified any of the other standalone configuration files to configure `osgi` or `configadmin`, those configurations must be removed.

For a managed domain, the `osgi` extension and subsystem configuration were removed from the `EAP_HOME/domain/configuration/domain.xml` file in the JBoss EAP 6.1.0 release. However, the `configadmin` module extension and subsystem configuration remain in the `EAP_HOME/domain/configuration/domain.xml` file. This configuration is no longer supported in JBoss EAP 7 and must be removed.

6.6. CHANGES TO JAVA PLATFORM MODULE SYSTEM NAMES

Standalone Java applications that use the JPMS architecture require code updates due to Java Platform Module System (JPMS) name changes in JBoss EAP 7.3.

Update your standalone application code with the new JPMS module names to work properly with JBoss EAP 7.3. The change in JPMS module names only affects standalone applications, therefore no code updates are required to the JBoss EAP applications deployed on the server.

<table>
<thead>
<tr>
<th>GroupID</th>
<th>JBoss EAP 7.2</th>
<th>JBoss EAP 7.3</th>
</tr>
</thead>
<tbody>
<tr>
<td>org.jboss.spec.javax.ws.rs:jboss-jaxrs-api_2.1_spec</td>
<td>beta.jboss.jaxrs.api_2_1</td>
<td>java.ws.rs</td>
</tr>
<tr>
<td>org.jboss.spec.javax.security.jacc:jboss-jacc-api_1.5_spec</td>
<td>beta.jboss.jacc.api_1_5</td>
<td>java.security.jacc</td>
</tr>
<tr>
<td>org.jboss.spec.javax.security.auth.message:jboss-jaspi-api_1.1_spec</td>
<td>beta.jboss.jaspi.api_1_1</td>
<td>java.security.auth.message</td>
</tr>
</tbody>
</table>
6.7. CHANGES IN SOAP WITH ATTACHMENTS API FOR JAVA

Update the user-defined SOAP handlers to comply with the SAAJ 1.4 specification when migrating to JBoss EAP 7.3.

As JBoss EAP 7.3 ships with SAAJ 1.4, SOAP handlers written for the previous release of JBoss EAP, which shipped with SAAJ 1.3, might not work correctly due to the differences in SAAJ 1.4 and 1.3 specifications. For information about SAAJ 1.4, see SOAP with Attachments.

While updating the SOAP handlers, SAAJ 1.3 can be used in JBoss EAP 7.3 by setting the system property `-Djboss.saaj.api.version=1.3`. After the SOAP handlers are updated, remove the system property to restore the default functionality.

6.8. MAVEN ARTIFACT CHANGES FOR JAKARTA EE

Some `javax` Maven artifacts have been replaced with `jakarta` Maven artifacts for JBoss EAP 7.3.

You must update your project dependencies with the new `jakarta` Maven artifacts when building your projects for JBoss EAP 7.3. Not updating project dependencies will cause build failures when building the projects for JBoss EAP 7.3. For information about managing project dependencies, see Manage Project Dependencies in the Development Guide.

The following table lists the `javax` artifacts and the `jakarta` artifacts that replaced them in JBoss EAP 7.3.

Table 6.2. `javax` artifacts and `jakarta` artifacts replacing them

<table>
<thead>
<tr>
<th><code>javax</code> artifact</th>
<th><code>jakarta</code> artifact</th>

</tbody>
</table>

**NOTE**

`com.sun.mail:jakarta.mail` brings in Jakarta Mail 1.6.4 library. For information about Jakarta Mail compatibility, see [Compatibility Notes](https://www.eclipse.org/jmc/notes) maintained by Eclipse.
CHAPTER 7. MIGRATING TO ELYTRON

7.1. OVERVIEW OF ELYTRON

JBoss EAP 7.1 introduced Elytron, which provides a single unified framework that can manage and configure access for both standalone servers and managed domains. It can also be used to configure security access for applications deployed to JBoss EAP servers.

IMPORTANT

The architectures of Elytron and the legacy security subsystem that is based on PicketBox are very different. With Elytron, an attempt was made to create a solution that allows you to operate in the same security environments in which you currently operate; however, this does not mean that every PicketBox configuration option has an equivalent configuration option in Elytron.

If you are not able to find information in the documentation to help you achieve similar functionality using Elytron that you had when using the legacy security implementation, you can find help in one of the following ways.

- If you have a Red Hat Development subscription, you have access to Support Cases, Solutions, and Knowledge Articles on the Red Hat Customer Portal. You can also open a case with Technical Support and get help from the WildFly community as described below.

- If you do not have a Red Hat Development subscription, you can still access Knowledge Articles on the Red Hat Customer Portal. You can also join the user forums and live chat to ask questions of the WildFly community. The WildFly community offerings are actively monitored by the Elytron engineering team.

Your JBoss EAP 7.0 server configuration and deployments that use the legacy security subsystem, which is based on PicketBox, should run without changes on JBoss EAP 7.1 and later. PicketBox continues to support security domains, which allows applications to continue to use existing login modules. Security realms, which are used by the management layer for security, are also carried over and emulated by Elytron. This allows you to define authentication in both the elytron and legacy security subsystems and use them in parallel. For more information about how to configure your application to use Elytron and legacy security, see Configure Web Applications to Use Elytron or Legacy Security for Authentication in How to Configure Identity Management for JBoss EAP.

Even though PicketBox authentication continues to be supported, you are encouraged to switch to Elytron when you are ready to migrate your applications. One of the advantages for using Elytron security is that it provides a consistent security solution across the server and your applications. For information on how to migrate PicketBox authentication and authorization to use Elytron, see Migrate Authentication Configuration in this guide.

For an overview of the new resources that are available in the elytron subsystem, see Resources in the Elytron Subsystem in the JBoss EAP Security Architecture guide.
IMPORTANT

Be aware that if you do choose to use both the legacy security subsystem and Elytron in your deployments, invocations between deployments using different security architectures is not supported.

For more information about using these subsystems in parallel, see Using Elytron and Legacy Security Subsystems in Parallel in How to Configure Identity Management for JBoss EAP.

7.2. MIGRATE SECURE VAULTS AND PROPERTIES

7.2.1. Migrate Vaults to Secure Credential Storage

The vault that was used to store plain text string encryption in the legacy security subsystem in JBoss EAP 7.0 is not compatible with Elytron in JBoss EAP 7.1 or later, which uses a newly designed credential store to store strings. Credential stores safely encrypt credentials in a storage file outside of the JBoss EAP configuration files. You can use the implementation provided by Elytron or you can customize the configuration using the credential store APIs and SPIs. Each JBoss EAP server can contain multiple credential stores.

NOTE

If you previously used vault expressions to parameterize nonsensitive data, it is recommended that you replace the data with Elytron security properties.

If you continue to use the legacy security subsystem, you should not need to modify or update your vault data. However, if you plan to migrate your application to use Elytron, you must convert your existing vaults to credential stores so that they can be processed by the elytron subsystem. For more information about credential stores, see Credential Stores in How to Configure Server Security for JBoss EAP.

Migrating Vault Data Using the WildFly Elytron Tool
The WildFly Elytron Tool that ships with JBoss EAP provides a vault command to help you migrate vault content to credential stores. You execute the tool by running the elytron-tool script, which is located in the $EAP_HOME/bin directory.

$ EAP_HOME/bin/elytron-tool.sh vault VAULT_ARGUMENTS

If you prefer, you can execute the tool by running the java -jar command.

$ java -jar EAP_HOME/bin/wildfly-elytron-tool.jar vault VAULT_ARGUMENTS

You can use the following command to get a description of all of the available arguments.

$ EAP_HOME/bin/elytron-tool.sh vault --help
The WildFly Elytron Tool cannot handle the first version of the security vault data files.

You can enter the `--keystore-password` argument in masked format, as shown in the below example to migrate a single vault, or in clear text.

The `--salt` and `--iteration` arguments are provided to supply information to decrypt the masked password or to generate a masked password in the output. If the `--salt` and `--iteration` arguments are omitted, default values are used.

The `--summary` argument produces formatted management CLI commands that can be used to add the converted credential stores to the JBoss EAP configuration. Plain text passwords are masked in the summary output.

Be aware that credential stores can only be used for securing passwords. They do not support the vault expression feature that could be used anywhere in the management model.

Choose one of the following migration options:

- Migrate a Single Security Vault to a Credential Store
- Migrate Multiple Security Vaults to a Credential Store in Bulk

**Migrate a Single Security Vault to a Credential Store**

The following is an example of the command used to convert a single security vault to a credential store.

```bash
$ EAP_HOME/bin/elytron-tool.sh vault --enc-dir vault_data/ --keystore vault-jceks.keystore --keystore-password MASK-2hKo56F1a3jYGnJwhPmiF5 --iteration 34 --salt 12345678 --alias test --location cs-v1.store --summary
```

This command converts the security vault to a credential store and prints the summary of the management CLI commands that were used to convert it in the output.

```
Vault (enc-dir="vault_data/";keystore="vault-jceks.keystore") converted to credential store "cs-v1.store"
Vault Conversion summary:
--------------------------------------
Vault Conversion Successful
CLI command to add new credential store:
/subsystem=elytron/credential-store=test:add(relative-to=jboss.server.data.dir,create=true,modifiable=true,location="cs-v1.store",implementation-properties={"keyStoreType"=>"JCEKS"},credential-reference={clear-text="MASK-2hKo56F1a3jYGnJwhPmiF5;12345678;34"})
```

**Migrate Multiple Security Vaults to a Credential Store in Bulk**

You can convert multiple vaults to a credential store using the `--bulk-convert` argument and pointing to a bulk conversion descriptor file.

The examples in this section use the following bulk conversion descriptor file.
Example: bulk-vault-conversion-descriptor.txt File

```plaintext
different vault vault-v1-more
keystore: vault-v1-more/vault-jceks.keystore
keystore-password: MASK-2hKo56F1a3jY GnJwhPmiF5
enc-dir: vault-v1-more/vault_data/
salt: 12345678
iteration: 34
location: v1-cs-more.store
alias: test
```

A new conversion starts when each new `keystore: ` line is encountered. All options are mandatory except for `salt`, `iteration`, and `properties`.

To perform the bulk conversion and generate output that formats the management CLI commands, execute the following command.

```
$ EAP_HOME/bin/elytron-tool.sh vault --bulk-convert path/to/bulk-vault-conversion-descriptor.txt --summary
```

This command converts all of the security vaults specified in the file to a credential store and prints the summary of the management CLI commands that were used to convert them in the output.

```plaintext
Vault (enc-dir="vault-v1/vault_data/"; keystore="vault-v1/vault-jceks.keystore") converted to credential store "v1-cs-1.store"
Vault Conversion summary:
--------------------------------------
Vault Conversion Successful
CLI command to add new credential store:
/subsystem=elytron/credential-store=test:add(relative-to=jboss.server.data.dir,create=true,modifiable=true,location="v1-cs-1.store",implementation-properties={"keyStoreType"=>"JCEKS"},credential-reference={clear-text="MASK-2hKo56F1a3jY GnJwhPmiF5;12345678;34")
--------------------------------------
Vault (enc-dir="vault-v1/vault_data/"; keystore="vault-v1/vault-jceks.keystore") converted to credential store "v1-cs-2.store"
Vault Conversion summary:
--------------------------------------
Vault Conversion Successful
CLI command to add new credential store:
```

118
7.2.2. Migrate Security Properties to Elytron

The examples in this section assume that the group.name and encoding.algorithm security properties are defined as security-properties in the legacy security subsystem as follows.

Example: Security Properties Defined in the security Subsystem

```xml
<subsystem xmlns="urn:jboss:domain:security:2.0"> ...
  <security-properties>
    <property name="group.name" value="engineering-group" />
    <property name="encoding.algorithm" value="BASE64" />
  </security-properties>
</subsystem>
```

To define the same security properties in the elytron subsystem, set the security-properties attribute of the elytron subsystem using the following management CLI command.

```
/subsystem=elytron:write-attribute(name=security-properties, value={ group.name = "engineering-group", encoding.algorithm = "BASE64" })
```

This configures the following security-properties in the elytron subsystem in the server configuration file.

```xml
<subsystem xmlns="urn:wildfly:elytron:4.0" final-providers="combined-providers" disallowed-providers="OracleUcrypto"> ...
  <security-properties>
    <security-property name="group.name" value="engineering-group"/>
    <security-property name="encoding.algorithm" value="BASE64"/>
  </security-properties>
</subsystem>
```

The write-attribute operation used in the previous command overwrites the existing properties. To add or change a security property without impacting other security properties, use the map operation in the management CLI command.
In a similar manner, you can remove a specific security property by using the `map-remove` operation.

7.3. MIGRATE AUTHENTICATION CONFIGURATION

7.3.1. Migrate Properties-based Authentication and Authorization to Elytron

7.3.1.1. Migrate PicketBox Properties-based Configuration to Elytron

This section describes how to migrate PicketBox properties-based authentication to Elytron. You can choose to partially migrate properties-based authentication by only exposing the PicketBox security domain to Elytron or you can fully migrate the properties-based authentication configurations to use Elytron.

The following procedures assume that the deployed web application you plan to migrate is configured to require form-based authentication. The application is referencing a PicketBox security domain and is using the `UsersRolesLoginModule` to load user information from the `example-users.properties` and `example-roles.properties` files. These examples also assume that the security domain is defined in the legacy `security` subsystem using the following management CLI commands.

**Example: PicketBox Properties-based Configuration Commands**

```
/subsystem=security/security-domain=application-security:add
/subsystem=security/security-domain=application-security/authentication=classic:add(login-modules=[
{code=UsersRoles, flag=Required, module-options=
{usersProperties=file://${jboss.server.config.dir}/example-users.properties,
rolesProperties=file://${jboss.server.config.dir}/example-roles.properties}])
```

This results in the following server configuration.

**Example: PicketBox Properties-based Security Domain Configuration**

```
<security-domain name="application-security">
  <authentication>
    <login-module code="UsersRoles" flag="required">
      <module-option name="usersProperties" value="file://${jboss.server.config.dir}/example-users.properties"/>
      <module-option name="rolesProperties" value="file://${jboss.server.config.dir}/example-roles.properties"/>
    </login-module>
  </authentication>
</security-domain>
```

Choose one of the following migration options:

- Partially Migrate by Exposing the PicketBox Security Domain to Elytron
- Fully Migrate Properties-based Authentication to Elytron

**Partially Migrate by Exposing the PicketBox Security Domain to Elytron**
You can expose a PicketBox security domain as an Elytron security realm so that it can be wired into an Elytron configuration; however, doing so creates a dependency on the legacy security subsystem. If you are only migrating properties-based authentication, it is recommended that you fully migrate the application to Elytron to avoid the unnecessary dependency on the legacy security subsystem. However, a partial migration can be an intermediate solution when it is not possible to fully migrate the application to use Elytron.

Follow this procedure to add an existing PicketBox security realm configuration as an Elytron security realm.

1. Add a mapping to the Elytron security realm within the legacy security subsystem.

```
/subsystem=security/elytron-realm=application-security:add(legacy-jaas-config=application-security)
```

This configures the following Elytron security realm in the security subsystem of the server configuration file.

```
<subsystem xmlns="urn:jboss:domain:security:2.0">
... 
<elytron-integration>
  <security-realms>
    <elytron-realm name="application-security" legacy-jaas-config="application-security"/>
  </security-realms>
  </elytron-integration>
... 
</subsystem>
```

2. Define a security domain in the elytron subsystem that references the exported security realm.

```
/subsystem=elytron/security-domain=application-security:add(realms= [{realm=application-security}], default-realm=application-security, permission-mapper=default-permission-mapper)
```

This results in the following elytron subsystem configuration in the server configuration file.

```
<subsystem xmlns="urn:wildfly:elytron:4.0" final-providers="combined-providers" disallowed-providers="OracleUcrypto">
... 
<security-domains>
... 
<security-domain name="application-security" default-realm="application-security" permission-mapper="default-permission-mapper">
  <realm name="application-security"/>
</security-domain>
</security-domains>
... 
</subsystem>
```

3. In the undertow subsystem, map the application security domain referenced by the deployment to the newly defined security domain.

```
/subsystem=undertow/application-security-domain=application-security:add(security-domain=application-security)
```
This results in the following `undertow` subsystem configuration in the server configuration file.

```xml
<subsystem xmlns="urn:wildfly:elytron:4.0">
  ...
  <application-security-domains>
    <application-security-domain name="application-security" security-domain="application-security"/>
  </application-security-domains>
  ...
</subsystem>
```

**NOTE**

- If the application was already deployed prior to this configuration, you must reload the server or redeploy the application for the new application security domain mapping to take effect.
- In current web service-Elytron integration, the name of the security domain specified to secure a web service endpoint and the Elytron security domain name must be the same.

4. Verify the mapping was applied to the deployment using the following management CLI command. The deployment used in this example is `HelloWorld.war`. The output from the this command shows this deployment is referencing the Elytron mapping.

```
/subsystem=undertow/application-security-domain=application-security:read-resource(include-runtime=true)
{
  "outcome" => "success",
  "result" => {
    "enable-jacc" => false,
    "http-authentication-factory" => undefined,
    "override-deployment-config" => false,
    "referencing-deployments" => ["HelloWorld.war"],
    "security-domain" => "application-security",
    "setting" => undefined
  }
}
```

At this stage, the previously defined security domain is used for its `LoginModule` configuration, but it is wrapped by Elytron components, which take over authentication.

**Fully Migrate Properties-based Authentication to Elytron**

Follow these steps to fully migrate the PicketBox properties-based authentication to Elytron. This procedure assumes you are starting with the legacy configuration described in the introduction to this section and have not migrated to the partially migrated solution. When you have complete this process, any security domain definition that exists in the legacy security subsystem remains completely independent from the Elytron configuration.

1. Define a new security realm in the `elytron` subsystem that references the PicketBox properties files.

```
/subsystem=elytron/properties-realm=application-properties:add(users-properties=```
2. Define a security domain subsystem in the elytron subsystem.

```
/subsystem=elytron/security-domain=application-security:add(realms=[{realm=application-properties}], default-realm=application-properties, permission-mapper=default-permission-mapper)
```

This results in the following elytron subsystem configuration in the server configuration file.

```
<subsystem xmlns="urn:wildfly:elytron:4.0" final-providers="combined-providers" disallowed-providers="OracleUcrypto">
  ...
  <security-domains>
    ...
    <security-domain name="application-security" default-realm="application-properties" permission-mapper="default-permission-mapper">
      <realm name="application-properties"/>
    </security-domain>
    <security-domains>
      <security-realms>
        ...
        <properties-realm name="application-properties" groups-attribute="Roles">
          <users-properties path="example-users.properties" relative-to="jboss.server.config.dir" digest-realm-name="Application Security" plain-text="true"/>
          <groups-properties path="example-roles.properties" relative-to="jboss.server.config.dir"/>
        </properties-realm>
        <security-realms>
        ...
      </subsystem>

3. Map the application security domain referenced by the deployment to the newly defined HTTP authentication factory in the undertow subsystem.

```
/subsystem=undertow/application-security-domain=application-security:add(security-domain=application-security)
```

This results in the following undertow subsystem configuration in the server configuration file.

```
<subsystem xmlns="urn:jboss:domain:undertow:10.0">
  ...
  <application-security-domains>
    <application-security-domain name="application-security" security-domain="application-security"/>
  </application-security-domains>
  ...
</subsystem>
```
NOTE

In current web service-Elytron integration, the name of the security domain specified to secure a web service endpoint and the Elytron security domain name must be the same.

4. You must reload the server or redeploy the application for the new application security domain mapping to take effect.

Authentication is now configured to be equivalent to the PicketBox configuration; however Elytron components are now used exclusively for authentication.

7.3.1.2. Migrate Legacy Properties-based Configuration to Elytron

This section describes how to migrate a legacy security realm that loads user, password, and group information from properties files to Elytron. This type of legacy security realm is typically used to secure either the management interfaces or remoting connectors.

These examples assume that the legacy security domain is defined using the following management CLI commands.

**Example: Legacy Security Realm Commands**

```
/core-service=management/security-realm=ApplicationSecurity:add
/core-service=management/security-realm=ApplicationSecurity/authentication=properties:add(relative-to=jboss.server.config.dir, path=example-users.properties, plain-text=true)
/core-service=management/security-realm=ApplicationSecurity/authorization=properties:add(relative-to=jboss.server.config.dir, path=example-roles.properties)
```

This results in the following server configuration.

**Example: Legacy Security Realm Configuration**

```
<security-realm name="ApplicationSecurity">
  <authentication>
    <properties path="example-users.properties" relative-to="jboss.server.config.dir" plain-text="true"/>
  </authentication>
  <authorization>
    <properties path="example-roles.properties" relative-to="jboss.server.config.dir"/>
  </authorization>
</security-realm>
```

One of the motivations for adding the Elytron security to the application server is to allow a consistent security solution to be used across the server. The initial steps to migrate a properties-based legacy security realm to Elytron are similar to those used to migrate a PicketBox properties-based authentication to Elytron. Follow these steps to migrate a properties-based legacy security realm to Elytron.

1. Define a new security realm in the **elytron** subsystem that references the properties files.

```
/subsystem=elytron/properties-realm=application-properties:add(users-properties=
  {path=example-users.properties, relative-to=jboss.server.config.dir, plain-text=true, digest-
  realm-name="Application Security"}, groups-properties={path=example-roles.properties,
```
2. Define a security domain subsystem in the `elytron` subsystem.

```
/subsystem=elytron/security-domain=application-security:add(realms=[{realm=application-properties}], default-realm=application-properties, permission-mapper=default-permission-mapper)
```

This results in the following Elytron configuration.

```
<subsystem xmlns="urn:wildfly:elytron:4.0" final-providers="combined-providers" disallowed-providers="OracleUcrypto">
  ...
  <security-domains>
    ...
    <security-domain name="application-security" default-realm="application-properties" permission-mapper="default-permission-mapper">
      <realm name="application-properties"/>
    </security-domain>
  </security-domains>
  ...
  <security-realms>
    ...
    <properties-realm name="application-properties" groups-attribute="Roles">
      <users-properties path="example-users.properties" relative-to="jboss.server.config.dir" digest-realm-name="Application Security" plain-text="true"/>
    </properties-realm>
  </security-realms>
</subsystem>
```

3. Define a `sasl-authentication-factory` so that the legacy security realm can also be used for Simple Authentication Security Layer (SASL) authentication.

```
/subsystem=elytron/sasl-authentication-factory=application-security-sasl:add(sasl-server-factory=elytron, security-domain=application-security, mechanism-configurations=[{mechanism-name=PLAIN}])
```

This results in the following Elytron configuration.

```
<subsystem xmlns="urn:wildfly:elytron:4.0" final-providers="combined-providers" disallowed-providers="OracleUcrypto">
  ...
  <sasl>
    ...
    <sasl-authentication-factory name="application-security-sasl" sasl-server-factory="elytron" security-domain="application-security">
      <mechanism-configuration>
        <mechanism mechanism-name="PLAIN"/>
      </mechanism-configuration>
    </sasl-authentication-factory>
  </sasl>
</subsystem>
```
4. Configure a remoting connector for the SASL authentication and remove the association with the legacy security realm.

```
/subsystem=remoting/http-connector=http-remoting-connector:write-attribute(name=sasl-authentication-factory, value=application-security-sasl)
/subsystem=remoting/http-connector=http-remoting-connector:undefine-attribute(name=security-realm)
```

This results in the following configuration in the `remoting` subsystem of the server configuration file.

```
<subsystem xmlns="urn:jboss:domain:remoting:4.0">
...<http-connector name="http-remoting-connector" connector-ref="default" sasl-authentication-factory="application-security-sasl"/>
</subsystem>
```

5. Add the two authentication factories and remove the legacy security realm references to secure the `http-interface` with Elytron.

```
/core-service=management/management-interface=http-interface:write-attribute(name=http-authentication-factory, value=application-security-http)
/core-service=management/management-interface=http-interface:write-attribute(name=http-upgrade.sasl-authentication-factory, value=application-security-sasl)
/core-service=management/management-interface=http-interface:undefine-attribute(name=security-realm)
```

This results in the following configuration.

```
<management-interfaces>
  <http-interface http-authentication-factory="application-security-http">
    <http-upgrade enabled="true" sasl-authentication-factory="application-security-sasl"/>
    <socket-binding http="management-http"/>
  </http-interface>
</management-interfaces>
```

**NOTE**

You should choose more suitable names than those used in these examples when securing management interfaces.

The migration of the legacy properties-based configuration to Elytron is now complete.

### 7.3.2. Migrate to Filesystem-based Security Realm Using the filesystem-realm Command

This section describes how to migrate the legacy properties-based security realm to a filesystem-based realm in Elytron with the `filesystem-realm` command of the `elytron.sh` tool.

A filesystem-based realm is a filesystem-based identity store used by Elytron for storing user identities. The `filesystem-realm` command converts the `properties-realm` files to `filesystem-realm`. It also generates commands for adding this realm and a security domain to the `elytron` subsystem.
The steps for migrating properties-based authentication to filesystem-based authentication are the following:

1. Migrate the properties file.
   You can migrate a single user-properties file at a time, or migrate the properties files in bulk. The following examples illustrate the procedures for both types of migration.

   - Migrate a single properties file.
     The following example converts a single users-properties file with the associated roles-properties file to filesystem-realm. The example assumes that the legacy security domain has the following user-properties and role-properties files:

       example-users.properties
       example-roles.properties

       **Example: Single user-property file migration**

       ```
       $./bin/elytron-tool.sh filesystem-realm --users-file example-users.properties --roles-file example-roles.properties --output-location realms/example
       ```

       This creates filesystem-realm files and a script containing management CLI commands. The script is stored in the realms/example directory.

   - Migrate multiple properties files.
     The following example converts the users-properties files with the associated roles-properties files in bulk to filesystem-realm. The example assumes that the legacy security domain has the following properties files:

       users-1.properties
       users-2.properties
       roles-1.properties
       roles-2.properties

       To convert users-roles files in bulk, you must create a descriptor file to use with the filesystem-realm command. For this example, a descriptor file example-descriptor-file located in the /bin directory is created with the following content:

       **Example: descriptor file**

       ```
       users-file:/full/path/to/users-1.properties
       roles-file:/full/path/to/roles-1.properties
       output-location:./realms/bulk-1-example
       filesystem-realm-name:exampleFileSystemRealm1
       security-domain-name:exampleSecurityDomain1

       users-file:/full/path/to/users-2.properties
       roles-file:/full/path/to/roles-2.properties
       output-location:./realms/bulk-2-example
       filesystem-realm-name:exampleFileSystemRealm2
       security-domain-name:exampleSecurityDomain2
       ```

       A blank line in the descriptor file is used to separate the operations for each users-properties file.
The following example converts two users-properties files with the associated roles-properties file using a descriptor file to filesystem-realm.

**Example: Bulk migration**

```
$./bin/elytron-tool.sh filesystem-realm --bulk-convert example-descriptor-file
```

This creates the filesystem-realm files and scripts containing the management CLI commands. The scripts are stored in directories specified in the descriptor file’s output-location attribute.

2. Add the filesystem security realm to Elytron.
   After migrating the files, add the new security realm and the security domain to the elytron subsystem using the CLI commands generated by the Elytron tool.

**Example: Adding the filesystem-realm**

```
/subsystem=elytron/filesystem-realm=converted-propertiesfilesystem-realm:add(path=/full/path/to/realms/example)
/subsystem=elytron/security-domain=converted-properties-security-domain:add(realms=
  [{realm=converted-properties-filesystem-realm}],default-realm=converted-properties-
  filesystem-realm,permission-mapper=default-permission-mapper)
```

### 7.3.3. Migrate LDAP Authentication Configuration to Elytron

This section describes how to migrate legacy LDAP authentication to Elytron so that it can manage the information as identity attributes. Much of the information provided in the section entitled Migrate Properties-based Authentication and Authorization to Elytron applies here, particularly regarding how to define security domains and authentication factories, and how to map them to be used for authentication. This section does not repeat those instructions, so be sure to read through that section before you continue.

The following examples assume that group or role information is loaded directly from LDAP and that the legacy LDAP authentication is configured as follows.

- The LDAP server contains the following user and group entries.

**Example: LDAP Server User Entries**

```
dn: uid=TestUserOne,ou=users,dc=group-to-principal,dc=wildfly,dc=org
objectClass: top
objectClass: inetOrgPerson
objectClass: uidObject
objectClass: person
objectClass: organizationalPerson
cn: Test User One
sn: Test User One
uid: TestUserOne
userPassword: {SSHA}UG8ov2rnnBKakcARVvraZHqTa7mFWJZIWi2HA=
```

**Example: LDAP Server Group Entries**

```
dn: uid=GroupOne,ou=groups,dc=group-to-principal,dc=wildfly,dc=org
```
For authentication purposes the user name is matched against the uid attribute and the resulting group name is taken from the uid attribute of the group entry.

- The connection to the LDAP server and related security realm is defined using the following management CLI commands.

**Example: LDAP Security Realm Configuration Commands**

```
batch
/core-service=management/ldap-connection=MyLdapConnection:add(url="ldap://localhost:10389", search-dn="uid=admin,ou=system", search-credential="secret")

/core-service=management/security-realm=LDAPRealm:add
/core-service=management/security-realm=LDAPRealm/authentication=ldap:add(connection="MyLdapConnection", username-attribute=uid, base-dn="ou=users,dc=group-to-principal,dc=wildfly,dc=org")

/core-service=management/security-realm=LDAPRealm/authorization=ldap:add(connection=MyLdapConnection)
/core-service=management/security-realm=LDAPRealm/authorization=ldap/username-to-dn=username-filter:add(attribute=uid, base-dn="ou=users,dc=group-to-principal,dc=wildfly,dc=org")
/core-service=management/security-realm=LDAPRealm/authorization=ldap/group-search=group-to-principal:add(base-dn="ou=groups,dc=group-to-principal,dc=wildfly,dc=org", iterative=true, prefer-original-connection=true, principal-attribute=uniqueMember, search-by=DISTINGUISHED_NAME, group-name=SIMPLE, group-name-attribute=uid)
run-batch
```

This results in the following server configuration.

**Example: LDAP Security Realm Configuration**

```xml
<security-realms>
  ...
  <security-realm name="LDAPRealm">
    <authentication>
      <ldap connection="MyLdapConnection" base-dn="ou=users,dc=group-to-principal,dc=wildfly,dc=org">
        <username-filter attribute="uid"/>
      </ldap>
    </authentication>
    <authorization>
      <ldap connection="MyLdapConnection">
        <username-to-dn>
          <username-filter base-dn="ou=users,dc=group-to-principal,dc=wildfly,dc=org"/>
attribute="uid" />
  </username-to-dn>
  <group-search group-name="SIMPLE" iterative="true" group-name-attribute="uid">
    <group-to-principal search-by="DISTINGUISHED_NAME" base-dn="ou=groups,dc=group-to-principal,dc=wildfly,dc=org" prefer-original-connection="true">
      <membership-filter principal-attribute="uniqueMember"/>
    </group-to-principal>
  </group-search>
</ldap>
</security-realm>
</security-realms>
</outbound-connections>
</ldap>
</authorization>
</security-realm>
</security-realms>
</outbound-connections>
...  
</management>

- The following management CLI commands are used to configure a PicketBox security domain, which uses the LdapExtLoginModule to verify a user name and password.

Example: Security Domain Configuration Commands

```
/subsystem=security/security-domain=application-security:add
/subsystem=security/security-domain=application-security/authentication=classic:add(login-modules=[{code=LdapExtended, flag=Required, module-options={
  java.naming.factory.initial=com.sun.jndi.ldap.LdapCtxFactory,
  java.naming.provider.url=ldap://localhost:10389, java.naming.security.authentication=simple,
  bindDN="uid=admin,ou=system", bindCredential=secret, baseCtxDN="ou=users,dc=group-to-principal,dc=wildfly,dc=org", baseFilter="(uid={0})", rolesCtxDN="ou=groups,dc=group-to-principal,dc=wildfly,dc=org", roleFilter="(uniqueMember={1})", roleAttributeID="uid" }])
```

This results in the following server configuration.

Example: Security Domain Configuration

```
<subsystem xmlns="urn:jboss:domain:security:2.0">
  ...  
  <security-domains>
    ...  
    <security-domain name="application-security">
      <authentication>
        <login-module code="LdapExtended" flag="required">
          <module-option name="java.naming.factory.initial" value="com.sun.jndi.ldap.LdapCtxFactory"/>
          <module-option name="java.naming.provider.url" value="ldap://localhost:10389"/>
          <module-option name="java.naming.security.authentication" value="simple"/>
          <module-option name="bindDN" value="uid=admin,ou=system"/>
          <module-option name="bindCredential" value="secret"/>
          <module-option name="baseCtxDN" value="ou=users,dc=group-to-principal,dc=wildfly,dc=org"/>
          <module-option name="baseFilter" value="(uid={0})"/>
          <module-option name="rolesCtxDN" value="ou=groups,dc=group-to-principal,dc=wildfly,dc=org"/>
          <module-option name="roleFilter" value="(uniqueMember={1})", roleAttributeID="uid" }])
```

Red Hat JBoss Enterprise Application Platform 7.4 Migration Guide
7.3.3.1. Migrate the Legacy LDAP Authentication to Elytron

Follow these steps to migrate the previous LDAP authentication example configuration to Elytron. This section applies to the migration of a legacy security LDAP realm as well as a PicketBox LDAP security domain.

1. Define a connection to LDAP in the elytron subsystem.

```xml
<subsystem xmlns="urn:wildfly:elytron:4.0" final-providers="combined-providers" disallowed-providers="OracleUcrypto">
  ...
  <security-realms>
    ...
    <ldap-realm name="ldap-realm" dir-context="ldap-connection" direct-verification="true">
      <identity-mapping rdn-identifier="uid" search-base-dn="ou=users, dc=group-to-principal, dc=wildfly, dc=org">
        <attribute-mapping>
          <attribute from="uid" to="Roles" filter="(uniqueMember={1})" filter-base-dn="ou=groups, dc=group-to-principal, dc=wildfly, dc=org"/>
        </attribute-mapping>
      </identity-mapping>
    </ldap-realm>
  </security-realms>
  ...
  <dir-contexts>
    <dir-context name="ldap-connection" url="ldap://localhost:10389" principal="uid=admin, ou=system">
      <credential-reference clear-text="secret"/>
    </dir-context>
  </dir-contexts>
</subsystem>
```

2. Create a security realm to search LDAP and verify the supplied password.

```xml
<subsystem xmlns="urn:wildfly:elytron:4.0" final-providers="combined-providers" disallowed-providers="OracleUcrypto">
  ...
  <security-realms>
    ...
    <ldap-realm name="ldap-realm" dir-context="ldap-connection" direct-verification="true" identity-mapping={search-base-dn="ou=users, dc=group-to-principal, dc=wildfly, dc=org", rdn-identifier="uid", attribute-mapping={filter-base-dn="ou=groups, dc=group-to-principal, dc=wildfly, dc=org", filter="(uniqueMember={1})", from="uid", to="Roles"}}>
      ...
    </ldap-realm>
  </security-realms>
  ...
  <dir-contexts>
    <dir-context name="ldap-connection" url="ldap://localhost:10389" principal="uid=admin, ou=system">
      <credential-reference clear-text="secret"/>
    </dir-context>
  </dir-contexts>
</subsystem>
```

These steps result in the following elytron subsystem configuration in the server configuration file.

<module-option name="roleFilter" value="(uniqueMember={1})"/>
<module-option name="roleAttributeID" value="uid"/>
</login-module>
</authentication>
</security-domain>
</security-domains>
</subsystem>

NOTE
<module-option name="roleFilter" value="(uniqueMember={1})"/>
<module-option name="roleAttributeID" value="uid"/>
</login-module>
</authentication>
</security-domain>
</security-domains>
</subsystem>

CHAPTER 7. MIGRATING TO ELYTRON
NOTE

By default, if no role-decoder is defined for a given security-domain, the "Roles" identity attribute is mapped to the identity roles.

Information loaded from LDAP can now be associated with identities as attributes. These attributes can be mapped to roles, but they can also be loaded and used for other purposes. The newly created security realm can be used in a security domain in the same way as it is described in the Migrate Properties-based Authentication and Authorization to Elytron section of this guide.

7.3.4. Migrate Database Authentication Configuration to Elytron

This section describes how to migrate JDBC datasource-based PicketBox authentication to Elytron. Much of the information provided in the section entitled Migrate Properties-based Authentication and Authorization to Elytron applies here, particularly regarding how to define security domains and authentication factories, and how to map them to be used for authentication. This section does not repeat those instructions, so be sure to read through that section before you continue.

The following examples assume that the user authentication data is stored in a database table created using syntax similar to the following example.

**Example: Syntax to Create the Database User Table**

```sql
CREATE TABLE User (
    id BIGINT NOT NULL,
    username VARCHAR(255),
    password VARCHAR(255),
    role ENUM('admin', 'manager', 'user'),
    PRIMARY KEY (id),
    UNIQUE (username)
)
```

For authentication purposes the username is matched against data stored in the `username` column, the password is expected to be stored as a hex-encoded MD5 hash in the `password` column, and the user role for authorization purposes is stored in the `role` column.

The PicketBox security domain is configured to use a JBDC datasource to retrieve data from the database table, and then use it to verify the username and password, and to assign roles. Assume the PicketBox security domain is configured using the following management CLI commands.

**Example: PicketBox Database LoginModule Configuration Commands**

```bash
/subsystem=security/security-domain=application-security:add
/subsystem=security/security-domain=application-security/authentication=classic:add( login-modules=[ { code=Database, flag=Required, module-options={
    dsJndiName="java:jboss/datasources/ExampleDS", principalsQuery="SELECT password FROM User WHERE username = ?", rolesQuery="SELECT role, 'Roles' FROM User WHERE username = ?", hashAlgorithm=MD5, hashEncoding=base64 } } ]
```

This results in the following login-module configuration in the legacy security subsystem.

**Example: PicketBox LoginModule Configuration**

```xml
<subsystem xmlns="urn:jboss:domain:security:2.0">
```
7.3.4.1. Migrate the Legacy Database Authentication to Elytron

To migrate the previous database authentication example configuration to Elytron, you must define a JDBC realm to enable JDBC datasource access by Elytron.

Use the following management command to define the `jdbc-realm`.

```
/subsystem=elytron/jdbc-realm=jdbc-realm:add(principal-query=[ { data-source=ExampleDS, sql="SELECT role, password FROM User WHERE username = ?", attribute-mapping=[{index=1, to=Roles } ] simple-digest-mapper={algorithm=simple-digest-md5, password-index=2} } ])
```

This results in the following `jdbc-realm` configuration in the `elytron` subsystem of the server configuration file.

```
<security-domains>
  ...
  <security-domain name="application-security">
    <authentication>
      <login-module code="Database" flag="required">
        <module-option name="dsJndiName" value="java:jboss/datasources/ExampleDS"/>
        <module-option name="principalsQuery" value="SELECT password FROM User WHERE username = ?"/>
        <module-option name="rolesQuery" value="SELECT role, 'Roles' FROM User WHERE username = ?"/>
        <module-option name="hashAlgorithm" value="MD5"/>
        <module-option name="hashEncoding" value="base64"/>
      </login-module>
    </authentication>
  
  <security-domain>
  </security-domains>
</subsystem>

Elytron now manages the database authentication using the JDBC realm configuration. Elytron is more efficient than PicketBox because it uses one SQL query to obtain all of the user attributes and credentials, and then extracts data from the SQL results and creates a mapping of the attributes to use for authentication.
7.3.5. Migrate Kerberos Authentication to Elytron

When working with a Kerberos configuration, the JBoss EAP server can rely on configuration information from the environment, or the key configuration can be specified using system properties. This section discusses how to migrate Kerberos HTTP and Kerberos SASL authentication.

The examples that follow assume that Kerberos is configured using the following system properties. These system properties are applicable to both the legacy configuration and the migrated Elytron configuration.

Example: Kerberos System Properties Management CLI Commands

```
# Enable debugging
/system-property=sun.security.krb5.debug:add(value=true)
# Identify the Kerberos realm to use
/system-property=java.security.krb5.realm:add(value=ELYTRON.ORG)
# Identify the address of the KDC
/system-property=java.security.krb5.kdc:add(value=kdc.elytron.org)
```

Example: Kerberos System Properties Server Configuration

```
<system-properties>
  <property name="sun.security.krb5.debug" value="true"/>
  <property name="java.security.krb5.realm" value="ELYTRON.ORG"/>
  <property name="java.security.krb5.kdc" value="kdc.elytron.org"/>
</system-properties>
```

Choose one of the following migration options:

- Migrate Kerberos HTTP Authentication.
- Migrate Kerberos Remoting SASL Authentication.

Migrate Kerberos HTTP Authentication

In legacy security configurations, you can define a security realm to enable SPNEGO authentication for the HTTP management interface as follows.

Example: Enable SPNEGO authentication for the HTTP management interface

```
/core-service=management/security-realm=Kerberos:add
/core-service=management/security-realm=Kerberos/server-identity=kerberos:add
/core-service=management/security-realm=Kerberos/server-identity=kerberos/keytab=HTTP\test-server.elytron.org@ELYTRON.ORG:add(path="/path/to/test-server.keytab", debug=true)
/core-service=management/security-realm=Kerberos/authentication=kerberos:add(remove-realm=true)
```

Example: Kerberos Security Realm Configuration

```
<security-realms>
  ...
  <security-realm name="Kerberos">
    <server-identities>
      <kerberos>
        <keytab principal="HTTP\test-server.elytron.org@ELYTRON.ORG" path="/path/to/test-"/>
      </kerberos>
    </server-identities>
  </security-realm>
</security-realms>
```
You can also define a pair of legacy security domains to allow applications to use Kerberos HTTP authentication.

Example: Define Multiple Security Domains

```xml
# Define the first security domain
<subsystem xmlns="urn:jboss:domain:security:2.0" security-domains="host:SPNEGO">
  ...
  <security-domain name="host">
    <authentication>
      <login-module name="1" code="Kerberos" flag="required">
        <module-option name="storeKey" value="true"/>
        <module-option name="useKeyTab" value="true"/>
        <module-option name="principal" value="HTTP/test-server.elytron.org@ELYTRON.ORG"/>
        <module-option name="keyTab" value="/path/to/test-server.keytab"/>
        <module-option name="debug" value="true"/>
      </login-module>
    </authentication>
  </security-domain>
  <security-domain name="SPNEGO">
    ...
    <login-module name="1" code="SPNEGO" flag="requisite">
      <module-option name="password-stacking" value="useFirstPass"/>
      <module-option name="serverSecurityDomain" value="host"/>
      <module-option name="module" value="org.jboss.security.negotiation"/>
      <module-option name="usersProperties" value="/path/to/kerberos/spnego-users.properties"/>
      <module-option name="rolesProperties" value="/path/to/kerberos/spnego-roles.properties"/>
      <module-option name="defaultUsersProperties" value="/path/to/kerberos/spnego-users.properties"/>
      <module-option name="defaultRolesProperties" value="/path/to/kerberos/spnego-roles.properties"/>
    </login-module>
  </security-domain>
</security-domains>
```

Example: Configuration Using a Pair of Security Domains

```xml
<subsystem=security/security-domain=host:add
/subsystem=security/security-domain=host/authentication=classic:add
/subsystem=security/security-domain=host/authentication=classic/login-module=1:add(code=Kerberos, flag=Required, module-options={storeKey=true, useKeyTab=true, principal=HTTP/test-server.elytron.org@ELYTRON.ORG, keyTab=path/to/test-server.keytab, debug=true}>

# Define the second SPNEGO security domain
/subsystem=security/security-domain=SPNEGO:add
/subsystem=security/security-domain=SPNEGO/authentication=classic:add
/subsystem=security/security-domain=SPNEGO/authentication=classic/login-module=1:add(code=SPNEGO, flag=requisite, module-options={password-stacking=useFirstPass, serverSecurityDomain=host})
/subsystem=security/security-domain=SPNEGO/authentication=classic/login-module=1:write-attribute(name=module, value=org.jboss.security.negotiation)
```
The legacy applications are then deployed referencing the SPNEGO security domain and secured with the SPNEGO mechanism.

**Migrate the Kerberos HTTP Authentication to Elytron**

Both the management interface and applications can be secured in Elytron by using a security realm and a Kerberos security factory.

1. Define a security realm to be used to load identity information.

   ```
   /subsystem=elytron/properties-realm=spnego-properties:add(users-properties={path=\path/to/spnego-users.properties, plain-text=true, digest-realm-name=ELYTRON.ORG}, groups-properties={path=\path/to/spnego-roles.properties})
   ```

2. Define a Kerberos security factory that allows the server to load its own Kerberos identity.

   ```
   /subsystem=elytron/kerberos-security-factory=test-server:add(path=\path/to/test-server.keytab, principal=HTTP/test-server.elytron.org@ELYTRON.ORG, debug=true)
   ```

3. Define a security domain to pull together the policy as well as an HTTP authentication factory for the authentication policy.

   ```
   /subsystem=elytron/security-domain=SPNEGODomain:add(default-realm=spnego-properties, realms=[{realm=spnego-properties, role-decoder=groups-to-roles}], permission-mapper=default-permission-mapper)
   ```

This results in the following configuration in the `elytron` subsystem of the server configuration file.

**Example: Migrated Elytron Configuration**

```
<subsystem xmlns="urn:wildfly:elytron:4.0" final-providers="combined-providers" disallowed-providers="OracleUcrypto">
...
<security-domains>
```
To secure the application, define an application security domain in the *undertow* subsystem to map security domains to this *http-authentication-factory*. The HTTP management interface can be updated to reference the *http-authentication-factory* defined in this configuration. This process is documented in the Migrate Properties-based Authentication and Authorization to Elytron section of this guide.

Migrate Kerberos Remoting SASL Authentication

It is possible to define a legacy security realm for Kerberos / GSSAPI SASL authentication to be used for remoting authentication, such as the native management interface.

Example: Kerberos Authentication for Remoting Management CLI Commands

```bash
/core-service=management/security-realm=Kerberos:add
/core-service=management/security-realm=Kerberos/server-identity=kerberos:add
/core-service=management/security-realm=Kerberos/server-identity=kerberos/keytab=remote/test-server.elytron.org@ELYTRON.ORG:add(path=path/to/remote-test-server.keytab, debug=true)
/core-service=management/security-realm=Kerberos/authentication=kerberos:add(remove-realm=true)
```

Example: Kerberos Remoting Security Realm Configuration

```xml
<management>
  <security-realms>
    ...
    <properties-realm name="spnego-properties">
      <users-properties path="path/to/spnego-users.properties" digest-realm-name="ELYTRON.ORG" plain-text="true"/>
      <groups-properties path="path/to/spnego-roles.properties"/>
    </properties-realm>
    ...
    <http>
      ...
      <http-authentication-factory name="spnego-http-authentication" http-server-mechanism-factory="global" security-domain="SPNEGODomain">
        <mechanism-configuration>
          <mechanism mechanism-name="SPNEGO" credential-security-factory="test-server"/>
        </mechanism-configuration>
      </http-authentication-factory>
    </http>
    ...
  </security-realms>
</management>
```

4. To secure the application, define an application security domain in the **undertow** subsystem to map security domains to this **http-authentication-factory**. The HTTP management interface can be updated to reference the **http-authentication-factory** defined in this configuration. This process is documented in the Migrate Properties-based Authentication and Authorization to Elytron section of this guide.
Migrate the Kerberos Remoting SASL Authentication to Elytron

The steps to define the equivalent Elytron configuration are very similar to those described in Migrate Kerberos HTTP Authentication.

1. Define a security realm to be used to load identity information.

```
/path=kerberos:add(relative-to=user.home, path=src/kerberos)
/subsystem=elytron/properties-realm=kerberos-properties:add(users-properties={path=kerberos-users.properties, relative-to=kerberos, digest-realm-name=ELYTRON.ORG},
groups-properties={path=kerberos-groups.properties, relative-to=kerberos})
```

2. Define the Kerberos security factory for the server’s identity.

```
/subsystem=elytron/kerberos-security-factory=test-server:add(relative-to=kerberos, path=remote-test-server.keytab, principal=remote/test-server.elytron.org@ELYTRON.ORG)
```

3. Define the security domain and a SASL authentication factory.

```
/subsystem=elytron/security-domain=KerberosDomain:add(default-realm=kerberos-properties, realms=[{realm=kerberos-properties, role-decoder=groups-to-roles}], permission-mapper=default-permission-mapper)
/subsystem=elytron/sasl-authentication-factory=gssapi-authentication-factory:add(security-domain=KerberosDomain, sasl-server-factory=elytron, mechanism-configurations=[{mechanism-name=GSSAPI, credential-security-factory=test-server}])
```

This results in the following configuration in the `elytron` subsystem of the server configuration file.

```
<subsystem xmlns="urn:wildfly:elytron:4.0" final-providers="combined-providers" disallowed-providers="OracleUcrypto">
...
<security-domains>
...
<security-domain name="KerberosDomain" default-realm="kerberos-properties" permission-mapper="default-permission-mapper">
  <realm name="kerberos-properties" role-decoder="groups-to-roles"/>
</security-domain>
</security-domains>
<security-realms>
```
The management interface or remoting connectors can now be updated to reference the SASL authentication factory.

The two Elytron examples defined here could also be combined to use a shared security domain and security realm and just use protocol-specific authentication factories each referencing their own Kerberos security factory.

### 7.3.6. Migrate Composite Stores to Elytron

This section describes how to migrate a PicketBox or legacy security realm configuration that uses multiple identity stores to Elytron. When using either PicketBox or the legacy security realms, it is possible to define a configuration where authentication is performed against one identity store while the information used for authorization is loaded from a different store. When migrating to Elytron, this can be achieved by using an aggregate security realm.

The following examples perform user authentication using the `example-users.properties` properties file, and then query LDAP to load the group and role information.

```xml
... 
<properties-realm name="kerberos-properties">
  <users-properties path="kerberos-users.properties" relative-to="kerberos" digest-realm-name="ELYTRON.ORG"/>
  <groups-properties path="kerberos-groups.properties" relative-to="kerberos"/>
</properties-realm>
</security-realms>
<credential-security-factories>
  <kerberos-security-factory name="test-server" principal="remote/test-server.elytron.org@ELYTRON.ORG" path="remote-test-server.keytab" relative-to="kerberos"/>
</credential-security-factories>
... 
<sasl>
... 
<sasl-authentication-factory name="gssapi-authentication-factory" sasl-server-factory="elytron" security-domain="KerberosDomain">
  <mechanism-configuration>
    <mechanism mechanism-name="GSSAPI" credential-security-factory="test-server"/>
  </mechanism-configuration>
</sasl-authentication-factory>
... 
</sasl>
</subsystem>
```

The management interface or remoting connectors can now be updated to reference the SASL authentication factory.

The two Elytron examples defined here could also be combined to use a shared security domain and security realm and just use protocol-specific authentication factories each referencing their own Kerberos security factory.

The configurations shown are based on the examples in the following sections, which provide additional background information:

- Migrate Properties-based Authentication and Authorization to Elytron
- Migrate LDAP Authentication Configuration to Elytron

### PicketBox Composite Store Configuration

The PicketBox security domain for this scenario is configured using the following management CLI commands.

```xml
... 
<properties-realm name="kerberos-properties">
  <users-properties path="kerberos-users.properties" relative-to="kerberos" digest-realm-name="ELYTRON.ORG"/>
  <groups-properties path="kerberos-groups.properties" relative-to="kerberos"/>
</properties-realm>
</security-realms>
<credential-security-factories>
  <kerberos-security-factory name="test-server" principal="remote/test-server.elytron.org@ELYTRON.ORG" path="remote-test-server.keytab" relative-to="kerberos"/>
</credential-security-factories>
... 
<sasl>
... 
<sasl-authentication-factory name="gssapi-authentication-factory" sasl-server-factory="elytron" security-domain="KerberosDomain">
  <mechanism-configuration>
    <mechanism mechanism-name="GSSAPI" credential-security-factory="test-server"/>
  </mechanism-configuration>
</sasl-authentication-factory>
... 
</sasl>
</subsystem>
```
Example: PicketBox Configuration Commands

/subsystem=security/security-domain=application-security:add

/subsystem=security/security-domain=application-security/authentication=classic:add(login-modules=[ {code=UsersRoles, flag=Required, module-options={ password-stacking=useFirstPass, usersProperties=file://${jboss.server.config.dir}/example-users.properties}} {code=LdapExtended, flag=Required, module-options={ password-stacking=useFirstPass, java.naming.factory.initial=com.sun.jndi.ldap.LdapCtxFactory, java.naming.provider.url=ldap://localhost:10389, java.naming.security.authentication=simple, bindDN="uid=admin,ou=system", bindCredential=secret, baseCtxDN="ou=users,dc=group-to-principal,dc=wildfly,dc=org", baseFilter="(uid={0})", rolesCtxDN="ou=groups,dc=group-to-principal,dc=wildfly,dc=org", roleFilter="(uniqueMember={1})", roleAttributeID="uid" }])

This results in the following server configuration.

Example: PicketBox Security Domain Configuration

<security-domain name="application-security">
  <authentication>
    <login-module code="UsersRoles" flag="required">
      <module-option name="password-stacking" value="useFirstPass"/>
      <module-option name="usersProperties" value="file://${jboss.server.config.dir}/example-users.properties"/>
    </login-module>
    <login-module code="LdapExtended" flag="required">
      <module-option name="password-stacking" value="useFirstPass"/>
      <module-option name="java.naming.factory.initial" value="com.sun.jndi.ldap.LdapCtxFactory"/>
      <module-option name="java.naming.provider.url" value="ldap://localhost:10389"/>
      <module-option name="java.naming.security.authentication" value="simple"/>
      <module-option name="bindDN" value="uid=admin,ou=system"/>
      <module-option name="bindCredential" value="secret"/>
      <module-option name="baseCtxDN" value="ou=users,dc=group-to-principal,dc=wildfly,dc=org"/>
      <module-option name="baseFilter" value="(uid={0})"/>
      <module-option name="rolesCtxDN" value="ou=groups,dc=group-to-principal,dc=wildfly,dc=org"/>
      <module-option name="roleFilter" value="(uniqueMember={1})"/>
      <module-option name="roleAttributeID" value="uid"/>
    </login-module>
  </authentication>
</security-domain>

See Elytron Aggregate Security Realm Configuration for how to configure an aggregate security realm in the elytron subsystem to accomplish this.

Legacy Security Realm Composite Store Configuration

The legacy security realm configuration for this scenario is configured using the following management CLI commands.

Example: Legacy Security Realm Configuration Commands

/core-service=management/ldap-connection=MyLdapConnection:add(url="ldap://localhost:10389", search-dn="uid=admin,ou=system", search-credential="secret")

/core-service=management/security-realm=ApplicationSecurity:add
/core-service=management/security-
realm=ApplicationSecurity/authentication=properties:add(path=example-users.properties, relative-to=jboss.server.config.dir, plain-text=true)

batch
/core-service=management/security-realm=ApplicationSecurity/authorization=ldap:add(connection=MyLdapConnection)
/core-service=management/security-realm=ApplicationSecurity/authorization=ldap/username-to-dn=username-filter:add(attribute=uid, base-dn="ou=users,dc=group-to-principal,dc=wildfly,dc=org")
/core-service=management/security-realm=ApplicationSecurity/authorization=ldap/group-search=group-to-principal:add(base-dn="ou=groups,dc=group-to-principal,dc=wildfly,dc=org", iterative=true, prefer-original-connection=true, principal-attribute=uniqueMember, search-by=DISTINGUISHED_NAME, group-name=SIMPLE, group-name-attribute=uid)
run-batch

This results in the following server configuration.

Example: Legacy Security Realm Configuration

```xml
<security-realms>
  ...
  <security-realm name="ApplicationSecurity">
    <authentication>
      <properties path="example-users.properties" relative-to="jboss.server.config.dir" plain-text="true"/>
    </authentication>
    <authorization>
      <ldap connection="MyLdapConnection">
        <username-to-dn>
          <username-filter base-dn="ou=users,dc=group-to-principal,dc=wildfly,dc=org" attribute="uid"/>
        </username-to-dn>
        <group-search group-name="SIMPLE" iterative="true" group-name-attribute="uid">
          <group-to-principal search-by="DISTINGUISHED_NAME" base-dn="ou=groups,dc=group-to-principal,dc=wildfly,dc=org" prefer-original-connection="true">
            <membership-filter principal-attribute="uniqueMember"/>
          </group-to-principal>
        </group-search>
      </ldap>
    </authorization>
    </security-realm>
  </security-realm>
<outbound-connections>
  <ldap name="MyLdapConnection" url="ldap://localhost:10389" search-dn="uid=admin,ou=system" search-credential="secret"/>
</outbound-connections>
```

See Elytron Aggregate Security Realm Configuration for how to configure an aggregate security realm in the elytron subsystem to accomplish this.

Elytron Aggregate Security Realm Configuration

The equivalent Elytron configuration for this scenario is configured using the following management CLI commands.

Example: Elytron Configuration Commands

```
/subsystem=elytron/dir-context=ldap-connection:add(url=ldap://localhost:10389,
```
principal="uid=admin,ou=system", credential-reference={clear-text=secret})

/subsystem=elytron/ldap-realm=ldap-realm:add(dir-context=ldap-connection, direct-verification=true, identity-mapping={search-base-dn="ou=users,dc=group-to-principal,dc=wildfly,dc=org", rdn-identifier="uid", attribute-mapping={filter-base-dn="ou=groups,dc=group-to-principal,dc=wildfly,dc=org",filter="(uniqueMember={1})",from="uid",to="Roles"})}

/subsystem=elytron/properties-realm=application-properties:add(users-properties={path=example-users.properties, relative-to=jboss.server.config.dir, plain-text=true, digest-realm-name="Application Security")

/subsystem=elytron/aggregate-realm=combined-realm:add(authentication-realm=application-properties, authorization-realm=ldap-realm)

/subsystem=elytron/security-domain=application-security:add(realms=[{realm=combined-realm}], default-realm=combined-realm, permission-mapper=default-permission-mapper)
/subsystem=elytron/http-authentication-factory=application-security-http:add(http-server-mechanism-factory=global, security-domain=application-security, mechanism-configurations=[{mechanism-name=BASIC}])

This results in the following server configuration.

Example: Elytron Configuration

```xml
<subsystem xmlns="urn:wildfly:elytron:4.0" final-providers="combined-providers" disallowed-providers="OracleUcrypto">
  ...
  <security-domains>
    ...
    <security-domain name="application-security" default-realm="combined-realm" permission-mapper="default-permission-mapper">
      <realm name="combined-realm"/>
    </security-domain>
  </security-domains>
  <security-realms>
    <aggregate-realm name="combined-realm" authentication-realm="application-properties" authorization-realm="ldap-realm"/>
    ...
    <properties-realm name="application-properties">
      <users-properties path="example-users.properties" relative-to="jboss.server.config.dir" digest-realm-name="Application Security" plain-text="true"/>
    </properties-realm>
    <ldap-realm name="ldap-realm" dir-context="ldap-connection" direct-verification="true">
      <identity-mapping rdn-identifier="uid" search-base-dn="ou=users,dc=group-to-principal,dc=wildfly,dc=org">
        <attribute-mapping>
          <attribute from="uid" to="Roles" filter="(uniqueMember={1})" filter-base-dn="ou=groups,dc=group-to-principal,dc=wildfly,dc=org"/>
        </attribute-mapping>
        </identity-mapping>
      </ldap-realm>
    </ldap-realms>
  </http>
```

Red Hat JBoss Enterprise Application Platform 7.4 Migration Guide
In the **elytron** subsystem, an **aggregate-realm** has been defined that specifies which security realms to use for authentication and which to use for authorization decisions.

### 7.3.7. Migrate Security Domains That Use Caching to Elytron

When using PicketBox, it is possible to define a security domain and enable in-memory caching for its access. This allows you to access the identity data in memory and avoids additional direct access to the identity store. It is possible to achieve a similar configuration with Elytron. This section describes how to configure security domain caching when using Elytron.

**PicketBox Cached Security Domain Configuration**

The following commands show how to configure a PicketBox security domain that enables caching.

#### Example: PicketBox Cached Security Domain Commands

```xml
<subsystem xmlns="urn:jboss:domain:security:2.0">
  <security-domains>
    ...
    <security-domain name="application-security" cache-type="default">
      <authentication>
        <login-module code="LdapExtended" flag="required">
          <module-option name="java.naming.factory.initial" value="com.sun.jndi.ldap.LdapCtxFactory"/>
          <module-option name="java.naming.provider.url" value="ldap://localhost:10389"/>
          <module-option name="java.naming.security.authentication" value="simple"/>
          <module-option name="bindDN" value="uid=admin,ou=system"/>
          <module-option name="bindCredential" value="secret"/>
        </login-module>
        ...
      </authentication>
    </security-domain>
  </security-domains>
</subsystem>
```

This results in the following server configuration.

#### Example: PicketBox Cached Security Domain Configuration

```xml
<subsystem xmlns="global" security-domain="application-security">
  <mechanism-configuration>
    <mechanism mechanism-name="BASIC"/>
  </mechanism-configuration>
</http-authentication-factory>

...<dir-contexts>
  <dir-context name="ldap-connection" url="ldap://localhost:10389">
    <credential-reference clear-text="secret"/>
  </dir-context>
</dir-contexts>
</subsystem>
```
NOTE

This command and resulting configuration is similar to the example shown in Migrate LDAP Authentication Configuration to Elytron; however, here the attribute cache-type is defined with a value of default. The default cache type is an in-memory cache. When using PicketBox, you can also specify a cache-type of infinispan, however this type is not supported with Elytron.

Elytron Cached Security Domain Configuration
Follow the steps below to create a similar configuration that caches a security domain when using Elytron.

1. Define a security realm and wrap the security realm in a caching realm. The caching realm can then be used in a security domain and subsequently in an authentication factory.

Example: Elytron Security Realm Configuration Commands

```xml
<module-option name="baseCtxDN" value="ou=users,dc=group-to-principal,dc=wildfly,dc=org"/>
<module-option name="baseFilter" value="(uid={0})"/>
<module-option name="rolesCtxDN" value="ou=groups,dc=group-to-principal,dc=wildfly,dc=org"/>
<module-option name="roleFilter" value="(uniqueMember={1})"/>
<module-option name="roleAttributeID" value="uid"/>
</login-module>
</authentication>
</security-domain>
</security-domains>
```

2. Define a security domain and an HTTP authentication factory that use the cached-ldap realm defined in the previous step.

Example: Elytron Security Domain and Authentication Factory Configuration Commands

```xml
/subsystem=elytron/security-domain=application-security:add(realms=[{realm=cached-ldap}], default-realm=cached-ldap, permission-mapper=default-permission-mapper)
/subsystem=elytron/http-authentication-factory=application-security-http:add(http-server-mechanism-factory=global, security-domain=application-security, mechanism-configuration=[{mechanism-name=BASIC}])
```
In this step, it is important that you reference the **caching-realm** instead of the original realm. Otherwise, caching is bypassed.

These commands result in the following additions to the server configuration.

**Example: Elytron Cached Security Domain Configuration**

```xml
<subsystem xmlns="urn:wildfly:elytron:4.0" final-providers="combined-providers" disallowed-providers="OracleUcrypto">
    ...
    <security-domains>
        ...
        <security-domain name="application-security" default-realm="cached-ldap" permission-mapper="default-permission-mapper">
            <realm name="cached-ldap"/>
        </security-domain>
        <security-domains>
            ...
            <实力 realm name="cached-ldap"/>
        </security-realms>
        ...
    </security-domain>
    <security-realms>
        ...
        <ldap-realm name="ldap-realm" dir-context="ldap-connection" direct-verification="true">
            <identity-mapping rdn-identifier="uid" search-base-dn="ou=users,dc=group-to-principal,dc=wildfly,dc=org">
                <attribute-mapping>
                    <attribute from="uid" to="Roles" filter="(uniqueMember={1})" filter-base-dn="ou=groups,dc=group-to-principal,dc=wildfly,dc=org"/>
                </attribute-mapping>
            </identity-mapping>
        </ldap-realm>
        <caching-realm name="cached-ldap" realm="ldap-realm"/>
    </security-realms>
    ...
    <http>
        ...
        <http-authentication-factory name="application-security-http" http-server-mechanism-factory="global" security-domain="application-security">
            <mechanism-configuration>
                <mechanism mechanism-name="BASIC"/>
            </mechanism-configuration>
        </http-authentication-factory>
        ...
    </http>
    ...
    <dir-contexts>
        <dir-context name="ldap-connection" url="ldap://localhost:10389" principal="uid=admin,ou=system">
            <credential-reference clear-text="secret"/>
        </dir-context>
    </dir-contexts>
    ...
</subsystem>
```

7.3.8. Migrate Jakarta Authorization Security to Elytron
By default, JBoss EAP uses the legacy security subsystem to configure the Jakarta Authorization policy provider and factory. The default configuration maps to implementations from PicketBox.

The elytron subsystem provides a built-in policy provider based on the Jakarta Authorization specification. Before you configure your server to allow Elytron to manage Jakarta Authorization configurations and other policies, you must first disable Jakarta Authorization in the legacy security subsystem by using the following management CLI command.

```
/subsystem=security:write-attribute(name=initialize-jacc, value=false)
```

Failure to do so can result in the following error in the server log: MSC000004: Failure during stop of service org.wildfly.security.policy: java.lang.StackOverflowError.

For information about how to enable Jakarta Authorization and define a Jakarta Authorization policy provider in the elytron subsystem, see Enabling Jakarta Authorization Using the elytron Subsystem in the Development Guide for JBoss EAP.

7.4. MIGRATE APPLICATION CLIENTS

7.4.1. Migrate a Naming Client Configuration to Elytron

This section describes how to migrate a client application that performs a remote JNDI lookup using an org.jboss.naming.remote.client.InitialContext class, which is backed by an org.jboss.naming.remote.client.InitialContextFactory class, to Elytron.

The following examples assume that the InitialContextFactory class is created by specifying properties for the user credentials and for the URL of the naming provider that it connects to.

Example: InitialContext Code Used in the Previous Release

```java
Properties properties = new Properties();
properties.put(Context.INITIAL_CONTEXT_FACTORY, "org.jboss.naming.remote.client.InitialContextFactory");
properties.put(Context.PROVIDER_URL, "http-remoting://127.0.0.1:8080");
properties.put(Context.SECURITY_PRINCIPAL, "bob");
properties.put(Context.SECURITY_CREDENTIALS, "secret");
InitialContext context = new InitialContext(properties);
Bar bar = (Bar) context.lookup("foo/bar");
...
```

You can choose from one of the following migration approaches:

- Migrate the Naming Client Using the Configuration File Approach
- Migrate the Naming Client Using the Programmatic Approach

7.4.1.1. Migrate the Naming Client Using the Configuration File Approach

Follow these steps to migrate your naming client to Elytron using the configuration approach.

1. Create a wildfly-config.xml file in the client application META-INF/ directory. The file should contain the user credentials that are to be used when establishing a connection to the naming provider.
2. Create an InitialContext as in the following example. Note that the InitialContext is backed by the org.wildfly.naming.client.WildFlyInitialContextFactory class.

Example: InitialContext Code

```java
Properties properties = new Properties();
properties.put(Context.INITIAL_CONTEXT_FACTORY, "org.wildfly.naming.client.WildFlyInitialContextFactory");
properties.put(Context.PROVIDER_URL, "remote+http://127.0.0.1:8080");
InitialContext context = new InitialContext(properties);
Bar bar = (Bar) context.lookup("foo/bar");
...
```

7.4.1.2. Migrate the Naming Client Using the Programmatic Approach

Using this approach, you provide the user credentials that are used to establish a connection to the naming provider directly in the application code.

Example: Code Using the Programmatic Approach

```java
// Create the authentication configuration
AuthenticationConfiguration namingConfig = AuthenticationConfiguration.empty().useName("bob").usePassword("secret");

// Create the authentication context
AuthenticationContext context = AuthenticationContext.empty().with(MatchRule.ALL.matchHost("127.0.0.1"), namingConfig);

// Create a callable that creates and uses an InitialContext
Callable<Void> callable = () -> {
    Properties properties = new Properties();
    properties.put(Context.INITIAL_CONTEXT_FACTORY, "org.wildfly.naming.client.WildFlyInitialContextFactory");
    // ...
7.4.2. Migrate a Jakarta Enterprise Beans client to Elytron

This migration example assumes that the client application is configured to invoke a Jakarta Enterprise Beans deployed to a remote server using a `jboss-ejb-client.properties` file. This file, which is located in the client application `META-INF/` directory, contains the following information needed to connect to the remote server.

Example: `jboss-ejb-client.properties` file

```java
remote.connectionprovider.create.options.org.xnio.Options.SSL_ENABLED=false
remote.connections=default
remote.connection.default.host=127.0.0.1
remote.connection.default.port = 8080
remote.connection.default.username=bob
remote.connection.default.password=secret
```

The client looks up the Jakarta Enterprise Beans and calls one of its methods using code similar to the following example.

Example: Client code that calls a remote Jakarta Enterprise Beans

```java
// Create an InitialContext
Properties properties = new Properties();
properties.put(Context.URL_PKG_PREFIXES, "org.jboss.ejb.client.naming");
InitialContext context = new InitialContext(properties);

// Look up the {JEB} and invoke one of its methods
RemoteCalculator statelessRemoteCalculator = (RemoteCalculator) context.lookup("ejb:/ejb-remote-server-side//CalculatorBean!") + RemoteCalculator.class.getName());
int sum = statelessRemoteCalculator.add(101, 202);
```

You can choose from one of the following migration approaches:

- Migrate the Jakarta Enterprise Beans client using a configuration file
- Migrate the Jakarta Enterprise Beans client programmatically

7.4.2.1. Migrate the Jakarta Enterprise Beans client using a configuration file

Follow these steps to migrate your naming client to Elytron using the configuration approach.

1. Configure a `wildfly-config.xml` file in the client application `META-INF/` directory. The file should contain the user credentials that are to be used when establishing a connection to the naming provider.
Example: wildfly-config.xml file

```xml
<configuration>
  <authentication-client xmlns="urn:elytron:client:1.2">
    <authentication-rules>
      <rule use-configuration="ejbConfig">
        <match-host name="127.0.0.1"/>
      </rule>
    </authentication-rules>
    <authentication-configurations>
      <configuration name="ejbConfig">
        <set-user-name name="bob"/>
        <credentials>
          <clear-password password="secret"/>
        </credentials>
      </configuration>
    </authentication-configurations>
  </authentication-client>
  <jboss-ejb-client xmlns="urn:jboss:wildfly-client-ejb:3.0">
    <connections>
      <connection uri="remote+http://127.0.0.1:8080"/>
    </connections>
  </jboss-ejb-client>
</configuration>
```

2. Create an `InitialContext` as in the following example. Note that the `InitialContext` is backed by the `org.wildfly.naming.client.WildFlyInitialContextFactory` class.

Example: InitialContext code

```java
// Create an InitialContext
Properties properties = new Properties();
properties.put(Context.INITIAL_CONTEXT_FACTORY, "org.wildfly.naming.client.WildFlyInitialContextFactory");
InitialContext context = new InitialContext(properties);

// Look up an (JEB) and invoke one of its methods
// Note that this code is the same as before
RemoteCalculator statelessRemoteCalculator = (RemoteCalculator) context.lookup("ejb:ejb-remote-server-side//CalculatorBean!" + RemoteCalculator.class.getName());
int sum = statelessRemoteCalculator.add(101, 202);---
```

3. You can now delete the obsolete `jboss-ejb-client.properties` file as that file is no longer needed.

7.4.2.2. Migrate the Jakarta Enterprise Beans client programmatically

Using this approach, you provide the information needed to connect to the remote server directly in the application code.

Example: Code using the programmatic approach

```java
// Create the authentication configuration
AuthenticationConfiguration ejbConfig =
```
You can now delete the obsolete `jboss-ejb-client.properties` file as that file is no longer needed.

## 7.5. MIGRATE SSL CONFIGURATIONS

### 7.5.1. Migrate a Simple SSL Configuration to Elytron

If you secured HTTP connections to the JBoss EAP server using a security realm, you can migrate that configuration to Elytron using the information provided in this section.

The following examples assume you have the following `keystore` configured in the `security-realm`.

**Example: SSL Configuration Using a Security Realm Keystore**

```xml
<security-realm name="ApplicationRealm">
    <server-identities>
        <ssl>
            <keystore path="server.keystore" relative-to="jboss.server.config.dir" keystore-password="keystore_password" alias="server" key-password="key_password" />
        </ssl>
    </server-identities>
</security-realm>
```

Follow the steps below to achieve the same configuration using Elytron.
1. Create a **key-store** in the **elytron** subsystem that specifies the location of the keystore and the password by which it is encrypted. This command assumes the keystore was generated using the keytool command and its type is **JKS**.

   ```
   /subsystem=elytron/key-store=LocalhostKeyStore:add(path=server.keystore,relative-to=jboss.server.config.dir,credential-reference={clear-text="keystore_password"},type=JKS)
   ```

2. Create a **key-manager** in the **elytron** subsystem that specifies the **key-store** defined in the previous step, the alias, and password of the key.

   ```
   /subsystem=elytron/key-manager=LocalhostKeyManager:add(key-store=LocalhostKeyStore,alias-filter=server,credential-reference={clear-text="key_password"})
   ```

3. Create a **server-ssl-context** in the **elytron** subsystem that references the **key-manager** that was defined in the previous step.

   ```
   /subsystem=elytron/server-ssl-context=LocalhostSslContext:add(key-manager=LocalhostKeyManager)
   ```

4. Switch the **https-listener** from the legacy **security-realm** to the newly created Elytron **ssl-context**.

   ```
   batch
   /subsystem=undertow/server=default-server/https-listener=https:undefine-attribute(name=security-realm)
   /subsystem=undertow/server=default-server/https-listener=https:write-attribute(name=ssl-context,value=LocalhostSslContext)
   run-batch
   ```

5. Reload the server.

```
reload
```

This results in the following **elytron** subsystem configuration in the server configuration file.

```xml
<subsystem xmlns="urn:wildfly:elytron:4.0" ...>
...
<tls>
<key-stores>
<key-store name="LocalhostKeyStore">
  <credential-reference clear-text="keystore_password"/>
  <implementation type="JKS"/>
  <file path="server.keystore" relative-to="jboss.server.config.dir"/>
</key-store>
</key-stores>
<key-managers>
<key-manager name="LocalhostKeyManager" key-store="LocalhostKeyStore" alias-filter="server">
  <credential-reference clear-text="key_password"/>
</key-manager>
</key-managers>
<server-ssl-contexts>
<server-ssl-context name="LocalhostSslContext" key-manager="LocalhostKeyManager"/>
```
This results in the following **undertow** subsystem configuration in the server configuration file.

```
<https-listener name="https" socket-binding="https" ssl-context="LocalhostSslContext" enable-http2="true"/>
```

For more information, see *Elytron Subsystem* and *How to Secure the Management Interfaces* in *How to Configure Server Security* for JBoss EAP.

### 7.5.2. Migrate CLIENT-CERT SSL Authentication to Elytron

To enable **CLIENT-CERT** SSL authentication, add a `truststore` element to the `authentication` element.

```
<security-realm name="ManagementRealm">
  <server-identities>
    <ssl>
      <keystore path="server.keystore" relative-to="jboss.server.config.dir" keystore-password="KEYSTORE_PASSWORD" alias="server" key-password="key_password"/>
    </ssl>
  </server-identities>
  <authentication>
    <truststore path="server.truststore" relative-to="jboss.server.config.dir" keystore-password="TRUSTSTORE_PASSWORD"/>
    <local default-user="$local"/>
    <properties path="mgmt-users.properties" relative-to="jboss.server.config.dir"/>
  </authentication>
</security-realm>
```

**NOTE**

With this configuration if the **CLIENT-CERT** authentication does not occur, clients can fall back to use either the local mechanism or the **username/password** authentication mechanism. To make **CLIENT-CERT** based authentication mandatory, remove the **local** and **properties** elements.

A legacy **truststore** can be used in two ways:

- Legacy **truststore** containing only CA
- Legacy **truststore** containing client’s certificate

**Legacy truststore** Containing Only CA

Follow these steps to configure the server to prevent users without a valid certificate and private key from accessing the server using Elytron.

1. Create a **key-store** in the **elytron** subsystem that specifies the location of the keystore and the password by which it is encrypted. This command assumes the keystore was generated using the keytool command and its type is **JKS**.

   ```
   /subsystem=elytron/key-store=LocalhostKeyStore:add(path=server.keystore,relative-to=jboss.server.config.dir,credential-reference={clear-text="keystore_password"},type=JKS)
   ```

A legacy **truststore** can be used in two ways:

- Legacy **truststore** containing only CA
- Legacy **truststore** containing client’s certificate
2. Create a **key-store** in the **elytron** subsystem that specifies the location of the truststore and the password by which it is encrypted. This command assumes the keystore was generated using the keytool command and its type is **JKS**.

   ```text
   /subsystem=elytron/key-store=TrustStore:add(path=server.truststore,relative-to=jboss.server.config.dir,credential-reference={clear-text="truststore_password"},type=JKS)
   ```

3. Create a **key-manager** in the **elytron** subsystem that specifies the previously defined **LocalhostKeyStore** keystore, the alias, and password of the key.

   ```text
   /subsystem=elytron/key-manager=LocalhostKeyManager:add(key-store=LocalhostKeyStore,alias-filter=server,credential-reference={clear-text="key_password"})
   ```

4. Create a **trust-manager** in the **elytron** subsystem that specifies the **key-store** of the previously created truststore.

   ```text
   /subsystem=elytron/trust-manager=TrustManager:add(key-store=TrustStore)
   ```

5. Create a **server-ssl-context** in the **elytron** subsystem that references the previously defined **key-manager**, sets the **trust-manager** attribute, and enables client authentication.

   ```text
   /subsystem=elytron/server-ssl-context=LocalhostSslContext:add(key-manager=LocalhostKeyManager,trust-manager=TrustManager,need-client-auth=true)
   ```

6. Switch the **https-listener** from the legacy **security-realm** to the newly created Elytron **ssl-context**.

   ```text
   batch
   /subsystem=undertow/server=default-server/https-listener=https:undefine-attribute(name=security-realm)
   /subsystem=undertow/server=default-server/https-listener=https:write-attribute(name=ssl-context,value=LocalhostSslContext)
   run-batch
   ```

7. Reload the server.

   ```text
   reload
   ```

This results in the following **elytron** subsystem configuration in the server configuration file.

```xml
<subsystem xmlns="urn:wildfly:elytron:4.0"/>
...
<tls>
  <key-stores>
    <key-store name="LocalhostKeyStore">
      <credential-reference clear-text="keystore_password"/>
      <implementation type="JKS"/>
      <file path="server.keystore" relative-to="jboss.server.config.dir"/>
    </key-store>
    <key-store name="TrustStore">
      <credential-reference clear-text="truststore_password"/>
      <implementation type="JKS"/>
    </key-store>
  </key-stores>
```
This results in the following `undertow` subsystem configuration in the server configuration file.

```
<subsystem xmlns="urn:jboss:domain:undertow:10.0">
  ...
  <https-listener name="https" socket-binding="https" ssl-context="LocalhostSslContext" enable-http2="true"/>
  ...
</subsystem>
```

**Realms and Domains**

To allow using the predefined Elytron `ManagementDomain` security domain and `ManagementRealm` security realm, users are stored in standard properties files.

```
<security-domains>
  <security-domain name="ManagementDomain" default-realm="ManagementRealm" permission-mapper="default-permission-mapper">
    <realm name="ManagementRealm" role-decoder="groups-to-roles"/>
    <realm name="local"/>
  </security-domain>
</security-domains>
```

The security realm is used in two situations:

- When certificate authentication fails, the security realm is used in password fallback case.
- When authorization is done for password as well as certificate, the realm provides the roles of individual users.

Thus, for any client certificate, a user must exist in the security realm.
Principal Decoder
When certificate authentication is used and the security realm accepts user names to resolve an identity, there has to be a defined way to obtain the username from a client certificate.

In this case the CN attribute is used in the certificate subject.

```
/subsystem=elytron/x500-attribute-principal-decoder=x500-decoder:add(attribute-name=CN)
```

HTTP Authentication Factory
For the HTTP connections, an HTTP authentication factory is defined, using the previously defined resources. It is configured to support CLIENT_CERT and DIGEST authentication.

Since a properties realm only verifies passwords and is not able to verify client certificates, you need to first add a configuring mechanism factory. This disables certificate verification against the security realm.

```
/subsystem=elytron/configurable-http-server-mechanism-factory=configured-cert:add(http-server-mechanism-factory=global, properties={org.wildfly.security.http.skip-certificate-verification=true})
```

The HTTP authentication can be created as:

```
/subsystem=elytron/http-authentication-factory=client-cert-digest:add(http-server-mechanism-factory=configured-cert,security-domain=ManagementDomain,mechanism-configurations=[[mechanism-name=CLIENT_CERT,pre-realm-principal-transformer=x500-decoder],[mechanism-name=DIGEST, mechanism-realm-configurations=[[realm-name=ManagementRealm]]])
```

The above command results in:

```
<subsystem xmlns="urn:wildfly:elytron:4.0" final-providers="combined-providers" disallowed-providers="OracleUcrypto">
  ...
  <http>
    ...
    <http-authentication-factory name="client-cert-digest" http-server-mechanism-factory="configured-cert" security-domain="ManagementDomain">
      <mechanism-configuration>
        <mechanism mechanism-name="CLIENT_CERT" pre-realm-principal-transformer="x500-decoder"/>
        <mechanism mechanism-name="DIGEST">
          <mechanism realm-name="ManagementRealm"/>
        </mechanism>
        <mechanism-configuration>
      </http-authentication-factory>
    ...
    <configurable-http-server-mechanism-factory name="configured-cert" http-server-mechanism-factory="configured-cert">
      <properties>
        <property name="org.wildfly.security.http.skip-certificate-verification" value="true"/>
      </properties>
    </configurable-http-server-mechanism-factory>
  ...
  </http>
</subsystem>
```
CHAPTER 8. MIGRATING FROM OLDGER RELEASES OF JBOSS EAP

8.1. MIGRATING FROM JBOSS EAP 5 TO JBOSS EAP 7

This guide focuses on the changes that are required to successfully run and deploy JBoss EAP 6 applications on JBoss EAP 7. If you plan to migrate your applications directly from JBoss EAP 5 to JBoss EAP 7, there are a number of resources available to help you plan and execute your migration. We suggest you take the following approach.

1. See Summary of Changes Made to Each Release in this guide for a quick, high-level overview of the changes made to each release of JBoss EAP.

2. Read through the JBoss EAP 6 Migration Guide and this guide to become familiar with the contents of each one.

3. Use the JBoss EAP 5 Component Upgrade Reference as a quick reference to migration information about specific components and features.

4. The rule-based Migration Toolkit for Applications continues to add rules to help you migrate directly from JBoss EAP 5 to JBoss EAP 7. You can use these tools to analyze your application and to generate detailed reports about the changes needed to migrate to JBoss EAP 7. For more information, see Use Migration Toolkit for Applications to Analyze Applications for Migration.

5. The Customer Portal Knowledgebase currently contains articles and solutions to help with migration from JBoss EAP 5 to JBoss EAP 6. There are plans in place to add additional content for migration from JBoss EAP 5 to JBoss EAP 7 over time.

8.2. SUMMARY OF CHANGES MADE TO EACH RELEASE

Before you plan your migration, you should be aware of the changes that were made to JBoss EAP 6 and JBoss EAP 7.

The JBoss EAP 6 Migration Guide covers changes that were made between JBoss EAP 5 and JBoss EAP 6. The following is a condensed list of the most significant changes made in JBoss EAP 6.

- Implemented a new architecture built on the Modular Service Container
- Was a certified implementation of the Java Enterprise Edition 6 specification
- Introduced domain management, new deployment configuration, and a new file directory structure and scripts
- Standardized on new portable Java Naming and Directory Interface namespaces

See Review What’s New and Different in JBoss EAP 6 in the JBoss EAP 6 Migration Guide for a detailed list of changes made in that release.

JBoss EAP 7 is built on the same modular structure as JBoss EAP 6 and includes the same domain management, deployment configuration, file directory structure, and scripts. It also still uses the same standardized Java Naming and Directory Interface namespaces. However, JBoss EAP 7 introduces the following changes.

- Adds support for the Jakarta Enterprise Edition (Jakarta EE) 8 specification
Replaces the web server with Undertow
Replaces the JacORB IIOP implementation with a downstream branch of the OpenJDK ORB
Includes Apache ActiveMQ Artemis as the new messaging provider
Removes the **cmp**, **jaxr**, and **threads** subsystems
Removes support for enterprise entity beans

For a more complete list of changes, see Review What’s New in JBoss EAP 7

### 8.3. REVIEW THE CONTENT IN THE MIGRATION GUIDES

Review the entire contents of the Migration Guide for each release to become aware of the features that were added or deprecated, and to understand the server configuration and the application changes required to run existing applications for that release.

Because the underlying architecture was not changed between JBoss EAP 6 and JBoss EAP 7, many of the changes documented in the JBoss EAP 6 *Migration Guide* still apply. For example, changes documented under Changes Required by Most Applications are related to the underlying architectural changes made in JBoss EAP 6, which still apply to this release. The change to the new modular class loading system is significant and impacts the packaging and dependencies of almost every JBoss EAP 5 application. Many of the changes listed under Changes Dependent on Your Application Architecture and Components are also still valid. However, because JBoss EAP 7 replaced the web server, ORB, and messaging provider, removed the **cmp**, **threads**, and **jaxr** subsystems, and removed support for entity beans, you must consult this guide for any changes related to those component areas. Pay particular attention to the Server Configuration Changes and Application Migration Changes detailed in this guide before you begin.

### 8.4. JBOSS EAP 5 COMPONENT UPGRADE REFERENCE

Use the following table to find information about how to migrate a particular feature or component from JBoss EAP 5 to JBoss EAP 7.4.

<table>
<thead>
<tr>
<th>JBoss EAP 5 Feature or Component</th>
<th>Summary of Changes and Where to Find Migration Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Application Packaging and Class Loading</td>
<td>In JBoss EAP 6, the previous hierarchical class loading structure was replaced with a modular architecture based on JBoss Modules. Application packaging also changed due to the new modular class loading structure. This architecture is still used in JBoss EAP 7. For information about the new modular architecture, see the following chapter in the JBoss EAP 7.4 <em>Development Guide</em>.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Class Loading and Modules</strong></td>
</tr>
<tr>
<td></td>
<td>For information about how to update and repackage applications for the new modular architecture, see the following section in the JBoss EAP 6 <em>Migration Guide</em>.</td>
</tr>
<tr>
<td></td>
<td>- <strong>Class Loading Changes</strong></td>
</tr>
</tbody>
</table>
Due to the changes in JBoss EAP 6 to use modular class loading, you might need to create or modify one or more application configuration files to add dependencies or to prevent automatic dependencies from loading. This has not changed in JBoss EAP 7. For details, see the following section in the JBoss EAP 6 Migration Guide.

- Configuration File Changes

JBoss Cache was replaced by Infinispan for internal use by the server only in JBoss EAP 6. See the following sections in the JBoss EAP 6 Migration Guide for information about how to replace JBoss Cache in application code.

- Cache Changes

Infinispan caching strategy and configuration changes for JBoss EAP 7 are documented in the following section of this guide.

- Infinispan Server Configuration Changes

JBoss EAP 6 consolidated configuration of data sources and resource adapters into mainly one file and this is still true in JBoss EAP 7. See the following section in the JBoss EAP 6 Migration Guide for more information.

- Datasource and Resource Adapter Configuration Changes

In JBoss EAP 6, the directory structure, scripts, and deployment configuration changed. These changes are still valid in JBoss EAP 7. See the following section of the JBoss EAP 6 Migration Guide for more information.

- Review What’s New and Different in JBoss EAP 6
<table>
<thead>
<tr>
<th>JBoss EAP 5 Feature or Component</th>
<th>Summary of Changes and Where to Find Migration Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enterprise beans</td>
<td>Your application code must use the enterprise beans 3.x API and Jakarta Persistence. For information about deprecated features and changes required to run Enterprise Beans 2.1, see the following section in the JBoss EAP 6 Migration Guide:</td>
</tr>
<tr>
<td></td>
<td>- EJB 2.x and Earlier Changes</td>
</tr>
<tr>
<td></td>
<td>In JBoss EAP 6, stateful session bean cache and stateless session bean pool size is configured in the <code>ejb3</code> subsystem of the server configuration file. The <code>jboss-ejb3.xml</code> deployment descriptor replaces the <code>jboss.xml</code> deployment descriptor file. For more information about these changes, see the following section in the JBoss EAP 6 Migration Guide.</td>
</tr>
<tr>
<td></td>
<td>- EJB Changes</td>
</tr>
<tr>
<td></td>
<td>The default remote connector and port has changed in JBoss EAP 7. For more information about this and server configuration changes, see the following sections in this guide.</td>

</tr>
<tr>
<td>---------------------------------</td>
<td>----------------------------------------------------------</td>
</tr>
</tbody>
</table>
| Logging                         | JBoss EAP 6 introduced a new JBoss Logging framework that is still used in JBoss EAP 7. Applications that use third-party logging frameworks might be impacted by the modular class loading changes. Review the following section in the JBoss EAP 6 Migration Guide for information about these changes.  
  - Logging Changes  
  In JBoss EAP 7, annotations in the `org.jboss.logging` package are now deprecated, which impacts source code and Maven GAVs (groupId:artifactId:version). The prefixes for all log messages were also changed. For more information about these changes, see the following sections in this guide.  
  - JBoss Logging Changes  
  - Logging Message Prefix Changes |
| Messaging and Jakarta Messaging  | In JBoss EAP 7, ActiveMQ Artemis replaced HornetQ as the built-in messaging provider.  
  The best approach to migrating your messaging configuration is to start with the JBoss EAP 7 default server configuration and use the following guide to apply your current messaging configuration changes.  
  - Configuring Messaging for JBoss EAP 7.4  
  If you want to understand the changes required to move from JBoss Messaging to HornetQ, review the following section of the JBoss EAP 6 Migration Guide.  
  - HornetQ Changes  
  Then review the following information about how to migrate the HornetQ configuration and related messaging data in this guide.  
  - Messaging Server Configuration Changes  
  - Messaging Application Changes |
| ORB                             | In JBoss EAP 6, JacORB configuration was moved from the `EAP_HOME/server/production/conf/jacob.properties` file to the server configuration file. JBoss EAP 7 then replaced the JacORB IIOP implementation with a downstream branch of the OpenJDK ORB.  
  The best approach to migrating your ORB configuration is to start with the JBoss EAP 7 default server configuration and use the following section in the JBoss EAP 7.4 Configuration Guide to apply the your current ORB configuration changes.  
  - ORB Configuration |
Remote Invocation

A new enterprise bean client API was introduced in JBoss EAP 6 for remote invocations; however, if you preferred not to rewrite your application code to use the new API, you could modify your existing code to use the `ejb:BEAN_REFERENCE` for remote access to enterprise beans. See the following section in the JBoss EAP 6 Migration Guide for more information.

- Remote Invocation Changes

In JBoss EAP 7, the default connector and default remote connection port changed. For more information, see the following sections in this guide.

- Update the Remote URL Connector and Port
- Update External Clients
- Migrate Jakarta Enterprise Beans Client Code

Seam 2.x

While official support for Seam 2.2 applications was dropped in JBoss EAP 6, it was still possible to configure dependencies for Seam 2.2 applications to run on that release. JBoss EAP 7.4, which now includes Jakarta Server Faces 2.3 and Hibernate 5.3, does not support Seam 2.2 or Seam 2.3 due to end of life of Red Hat JBoss Web Framework Kit. It is recommended that you rewrite your Seam components using Weld CDI beans.

Security

Security updates in JBoss EAP 6 included changes to security domain names and changes to how to configure security for basic authentication. The LDAP security realm configuration was moved to the server configuration file. See the following sections in the JBoss EAP 6 Migration Guide for more information.

- Security Changes
- LDAP Security Realm Changes

Updates that impact security in JBoss EAP 7 include server configuration changes and application changes. Information can be found in the following sections of this guide.

- Security Server Configuration Changes
- Security Application Changes

Spring Applications

Spring 4.2.x is the earliest stable Spring version supported by JBoss EAP 7. For information about Apache CXF Spring web services and Spring RESTEasy integration changes, see the following sections in this guide.

- Apache CXF Spring Web Services Changes
- Spring RESTEasy Integration Changes

APPENDIX A. REFERENCE MATERIAL

A.1. JACORB SUBSYSTEM MIGRATION OPERATION WARNINGS

The migrate operation is not able to process all resources and attributes. The following table lists some of the warnings you might see when you run either the migrate or describe-migration operation for the jacorb subsystem.

NOTE

If you see "Could not migrate" or "Can not migrate" entries in the output of the migrate operation, this indicates the migration of the server configuration completed successfully but it was not able to automatically migrate all of the elements and attributes. You must follow the suggestions provided by the "migration-warnings" to modify those configurations.

<table>
<thead>
<tr>
<th>Warning Message</th>
<th>What It Means / How to Fix It</th>
</tr>
</thead>
<tbody>
<tr>
<td>The iiop migration can be performed when the server is in admin-only mode</td>
<td>The migrate operation requires starting the server in admin-only mode, which is done by adding <code>--start-mode=admin-only</code> to the server start command:</td>
</tr>
<tr>
<td></td>
<td>$ EAP_HOME/bin/standalone.sh --start-mode=admin-only</td>
</tr>
<tr>
<td>Properties X cannot be emulated using OpenJDK ORB and are not supported</td>
<td>Configuration of the specified property is not supported and is not included in the new iiop-openjdk subsystem configuration. The behavior exhibited by this property in the previous release of JBoss EAP is not migrated and the administrator must verify that the new iiop-openjdk subsystem in JBoss EAP 7 is able to operate correctly without that behavior.</td>
</tr>
</tbody>
</table>
The properties $X$ use expressions. Configuration properties that are used to resolve those expressions should be transformed manually to the new `iiop-openjdk` subsystem format.

Properties that use expressions must be configured manually by the administrator.

For example, the `jacob` subsystem in JBoss EAP 6 defined a `giop-minor-version` property. The `iiop-openjdk` subsystem in JBoss EAP 7 defines a `giop-version` property. Suppose the `jacob` subsystem minor version attribute is set to `${iiop-giop-minor-version}` and the system property is configured in the `standalone.conf` file as `-Diiop-giop-minor-version=1`. After the `migrate` operation, the administrator must change the system property value to 1.1 to ensure the new subsystem is configured correctly.

<table>
<thead>
<tr>
<th>Warning Message</th>
<th>What It Means / How to Fix It</th>
</tr>
</thead>
<tbody>
<tr>
<td>Can not migrate: the new <code>iiop-openjdk</code> subsystem is already defined</td>
<td>The message contains the explanation.</td>
</tr>
</tbody>
</table>

### A.2. MESSAGING SUBSYSTEM MIGRATION OPERATION WARNINGS

The `migrate` operation is not able to process all resources and attributes. The following table lists some of the warnings you might see when you run either the `migrate` or `describe-migration` operation for the `messaging` subsystem.

**NOTE**

If you see "Could not migrate" or "Can not migrate" entries in the output of the `migrate` operation, this indicates the migration of the server configuration completed successfully but it was not able to automatically migrate all of the elements and attributes. You must follow the suggestions provided by the "migration-warnings" to modify those configurations.

<table>
<thead>
<tr>
<th>Warning Message</th>
<th>What It Means / How to Fix It</th>
</tr>
</thead>
<tbody>
<tr>
<td>The <code>migrate</code> operation can not be performed: the server must be in <code>admin-only</code> mode</td>
<td>The <code>migrate</code> operation requires starting the server in <code>admin-only</code> mode, which is done by adding: <code>--start-mode=admin-only</code> to the server start command: $EAP_HOME/bin/standalone.sh --start-mode=admin-only</td>
</tr>
<tr>
<td>Can not migrate attribute <code>local-bind-address</code> from resource $X$. Use instead the <code>socket-binding</code> attribute to configure this <code>broadcast-group</code>.</td>
<td>The message contains the explanation and how to fix it.</td>
</tr>
<tr>
<td>Warning Message</td>
<td>What It Means / How to Fix It</td>
</tr>
<tr>
<td>-------------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Can not migrate attribute <code>local-bind-port</code> from resource <code>X</code>. Use instead the <code>socket-binding</code> attribute to configure this <code>broadcast-group</code>.</td>
<td>The message contains the explanation and how to fix it.</td>
</tr>
<tr>
<td>Can not migrate attribute <code>group-address</code> from resource <code>X</code>. Use instead the <code>socket-binding</code> attribute to configure this <code>broadcast-group</code>.</td>
<td>The message contains the explanation and how to fix it.</td>
</tr>
<tr>
<td>Can not migrate attribute <code>group-port</code> from resource <code>X</code>. Use instead the <code>socket-binding</code> attribute to configure this <code>broadcast-group</code>.</td>
<td>The <code>broadcast-group</code> resource no longer accepts the <code>local-bind-address</code>, <code>local-bind-port</code>, <code>group-address</code>, or <code>group-port</code> attributes. It only accepts a <code>socket-binding</code> attribute. The warning is notification that resource <code>X</code> has an unsupported attribute. You must manually set the <code>socket-binding</code> attribute on the resource and ensure it corresponds to a defined <code>socket-binding</code> resource.</td>
</tr>
<tr>
<td>Classes providing the <code>X</code> are discarded during the migration. To use them in the new <code>messaging-activemq</code> subsystem, you will have to extend the Artemis-based <code>Interceptor</code>.</td>
<td>Messaging interceptors support is significantly different in JBoss EAP 7. Any interceptors configured in the previous version of the subsystem are discarded during migration. See Migrate Messaging Interceptors for more information.</td>
</tr>
<tr>
<td>Can not migrate the HA configuration of <code>X</code>. Its <code>shared-store</code> and <code>backup</code> attributes holds expressions and it is not possible to determine unambiguously how to create the corresponding <code>ha-policy</code> for the messaging-activemq’s server.</td>
<td>This means the <code>hornetq-server</code> <code>X</code>’s <code>shared-store</code> or <code>backup</code> attributes contained an expression, such as <code>${xxx}</code>, and the migration operation was not able to resolve it to a concrete expression. The value is discarded and the <code>ha-policy</code> for the <code>messaging-activemq</code> must be updated manually.</td>
</tr>
<tr>
<td>Can not migrate attribute <code>local-bind-address</code> from resource <code>X</code>. Use instead the <code>socket-binding</code> attribute to configure this <code>discovery-group</code>.</td>
<td>The message contains the explanation and how to fix it.</td>
</tr>
<tr>
<td>Can not migrate attribute <code>local-bind-port</code> from resource <code>X</code>. Use instead the <code>socket-binding</code> attribute to configure this <code>discovery-group</code>.</td>
<td>The message contains the explanation and how to fix it.</td>
</tr>
<tr>
<td>Can not migrate attribute <code>group-address</code> from resource <code>X</code>. Use instead the <code>socket-binding</code> attribute to configure this <code>discovery-group</code>.</td>
<td>The message contains the explanation and how to fix it.</td>
</tr>
<tr>
<td>Warning Message</td>
<td>What It Means / How to Fix It</td>
</tr>
<tr>
<td>--------------------------------------------------------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Can not migrate attribute <code>group-port</code> from resource X. Use instead the <code>socket-binding</code> attribute to configure this <code>discovery-group</code>.</td>
<td>The <code>discovery-group</code> resources no longer accept <code>local-bind-address</code>, <code>local-bind-port</code>, <code>group-address</code>, or <code>group-port</code> attributes. It only accepts a <code>socket-binding</code>. The warning is notification that resource X has an unsupported attribute. You must manually set the <code>socket-binding</code> attribute on the resource and ensures it corresponds to a defined <code>socket-binding</code> resource.</td>
</tr>
<tr>
<td>Can not create a <code>legacy-connection-factory</code> based on <code>connection-factory</code> X. It uses a HornetQ <code>in-vm</code> connector that is not compatible with Artemis <code>in-vm</code> connector</td>
<td>The legacy HornetQ remote connection-factory resources are migrated into <code>legacy-connection-factory</code> resources to allow JBoss EAP 6 clients to connect to JBoss EAP 7. However, <code>legacy-connection-factory</code> resources are only created when the <code>connection-factory</code> is using remote connectors. Any <code>connection-factory</code> using <code>in-vm</code> is not migrated because <code>in-vm</code> clients are based on JBoss EAP 7, not JBoss EAP 6. This warning is notification that the <code>in-vm connection-factory</code> was not migrated.</td>
</tr>
</tbody>
</table>
| Can not migrate attribute X from resource Y. The attribute uses an expression that can be resolved differently depending on system properties. After migration, this attribute must be added back with an actual value instead of the expression. | This warning appears when the migration can not resolve attribute X to a concrete value during the migration process. The value is discarded and the attribute must be migrated manually. This happens in the following cases:  

  - `cluster-connection forward-when-no-consumers`  
    This boolean attribute has been replaced by the `message-load-balancing-type` attribute, which is an enum with a value of `OFF`, `STRICT`, or `ON_DEMAND`.  
  - `broadcast-group` and `discovery-group`'s `jgroups-stack` and `jgroups-channel` attributes  
    They reference other resources and JBoss EAP 7 no longer accepts these expressions.  

  | Can not migrate attribute X from resource Y. This attribute is not supported by the new `messaging-activemq` subsystem. | Some attributes are no longer supported in the new `messaging-activemq` subsystem and are simply discarded:  

  - `hornetq-server`'s `failback-delay`  
  - `http-connector`'s `use-nio` attribute  
  - `http-acceptor`'s `use-nio` attribute  
  - `remote-connector`'s `use-nio` attribute  
  - `remote-acceptor`'s `use-nio` attribute |
Warning Message | What It Means / How to Fix It
--- | ---
Can not migrate attribute **failback-delay** from resource X. Artemis detects failback deterministically and it no longer requires to specify a delay for failback to occur. | The message contains the explanation.

**Replace the Deprecated broadcast-group or discovery-group Attributes**

If you are advised to replace the deprecated **broadcast-group** or **discovery-group** attributes with the **socket-binding** attribute, you can add the new attribute using the management CLI.

This example assumes you are migrating a standalone server that contains the following **discovery-group** configuration in the **messaging** subsystem.

```xml
<discovery-groups>
  <discovery-group name="my-discovery-group">
    <group-address>224.0.1.105</group-address>
    <group-port>56789</group-port>
  </discovery-group>
</discovery-groups>
```

When you run the **migrate** operation for the **messaging** subsystem, you see the following output and warnings:

```
/subsystem=messaging:migrate
{
  "outcome" => "success",
  "result" => {
    "migration-warnings" => [
      "WFLYMSG0084: Can not migrate attribute group-address from resource [
        ("subsystem" => "messaging-activemq"),
        ("server" => "default"),
        ("discovery-group" => "my-discovery-group")
      ]; Use instead the socket-binding attribute to configure this discovery-group."
      "WFLYMSG0084: Can not migrate attribute group-port from resource [
        ("subsystem" => "messaging-activemq"),
        ("server" => "default"),
        ("discovery-group" => "my-discovery-group")
      ]; Use instead the socket-binding attribute to configure this discovery-group."
    ]
  }
}
```

The **migrate** operation creates a **discovery-group** named "my-discovery-group" in the new **messaging-activemq** subsystem that is now configured like the following.

```xml
<discovery-group name="my-discovery-group"/>
```

You must now use the following management CLI command to create a **socket-binding** element in the server configuration file named "my-discovery-group/socket-binding".

```
/socket-binding-group=standard-sockets/socket-binding=my-discovery-group/socket-binding:add(multicast-address=224.0.1.105, multicast-port=56789)
```
Next, add the newly created **socket-binding** to the **discovery-group** named "my-discovery-group" in the **messaging-activemq** subsystem in the server configuration file using the following management CLI command.

```
$subsystem=messaging-activemq/server=default/discovery-group=my-discovery-group:write-attribute(name=socket-binding,value=my-discovery-group-socket-binding)
```

These commands create the following XML in the server configuration file.

```xml
<subsystem xmlns="urn:jboss:domain:messaging-activemq:4.0">
  <server name="default">
    ...
    <discovery-group name="my-discovery-group" socket-binding="my-discovery-group-socket-binding"/>
    ...
  </server>
</subsystem>
...
<socket-binding-group name="standard-sockets" default-interface="public" port-offset="${jboss.socket.binding.port-offset:0}"
  ...
  <socket-binding name="my-discovery-group-socket-binding" multicast-address="224.0.1.105" multicast-port="56789"/>
  ...
</socket-binding-group>
```

### A.3. WEB SUBSYSTEM MIGRATION OPERATION WARNINGS

The **migrate** operation is not able to process all resources and attributes. The following table lists some of the warnings you might see when you run either the **migrate** or **describe-migration** operation for the **web** subsystem.

<table>
<thead>
<tr>
<th>Warning Message</th>
<th>What It Means / How to Fix It</th>
</tr>
</thead>
<tbody>
<tr>
<td>Migrate operation only allowed in admin only mode</td>
<td>The <strong>migrate</strong> operation requires starting the server in <strong>admin-only</strong> mode, which is done by adding parameter <strong>--admin-only</strong> to the server start command:</td>
</tr>
<tr>
<td></td>
<td><code>$ EAP_HOME/bin/standalone.sh --admin-only</code></td>
</tr>
<tr>
<td>Warning Message</td>
<td>What It Means / How to Fix It</td>
</tr>
<tr>
<td>-----------------</td>
<td>--------------------------------</td>
</tr>
<tr>
<td>Could not migrate resource X</td>
<td>The behavior exhibited by this resource in the previous release of JBoss EAP was not migrated. The administrator must verify if the new <code>undertow</code> subsystem in JBoss EAP 7 is able to operate correctly without that behavior or whether the behavior must be migrated manually.</td>
</tr>
</tbody>
</table>
| Could not migrate attribute X from resource Y. | The behavior exhibited by this resource attribute in the previous release of JBoss EAP was not migrated. The administrator must verify if the new `undertow` subsystem in JBoss EAP 7 is able to operate correctly without that behavior or whether the behavior must be migrated manually.  
See [Web Subsystem Migration Operation Attribute Warnings](#) for the list of attributes that are not migrated. |
<p>| Could not migrate SSL connector as no SSL config is defined | The message contains the explanation. |
| Could not migrate <code>verify-client</code> attribute X to the Undertow equivalent | The message contains the explanation. |
| Could not migrate <code>verify-client</code> expression X | The message contains the explanation. |</p>
<table>
<thead>
<tr>
<th>Warning Message</th>
<th>What It Means / How to Fix It</th>
</tr>
</thead>
<tbody>
<tr>
<td>Could not migrate valve X</td>
<td>The behavior exhibited by this valve in the previous release of JBoss EAP was not migrated. The administrator must verify if the new <strong>undertow</strong> subsystem in JBoss EAP 7 is able to operate correctly without that behavior or whether the behavior must be migrated manually.</td>
</tr>
</tbody>
</table>

This warning can occur for the following valves:

- **org.apache.catalina.valves.RemoteAddrValve**
  It must have at least one allowed or denied value.

- **org.apache.catalina.valves.RemoteHostValve**
  It must have at least one allowed or denied value.

- **org.apache.catalina.authenticator.BasicAuthenticator**

- **org.apache.catalina.authenticator.DigestAuthenticator**

- **org.apache.catalina.authenticator.FormAuthenticator**

- **org.apache.catalina.authenticator.SSLAuthenticator**

- **org.apache.catalina.authenticator.SpnegoAuthenticator**

- **custom valves**
<table>
<thead>
<tr>
<th>Warning Message</th>
<th>What It Means / How to Fix It</th>
</tr>
</thead>
<tbody>
<tr>
<td>Could not migrate attribute X from valve Y</td>
<td>The behavior exhibited by this valve attribute in the previous release of JBoss EAP was not migrated. The administrator must verify if the new <strong>undertow</strong> subsystem in JBoss EAP 7 is able to operate correctly without that behavior or whether the behavior must be migrated manually. This warning can occur for the following valve attributes:</td>
</tr>
</tbody>
</table>

- **org.apache.catalina.valves.AccessLogValve**
  - resolveHosts
  - fileDateFormat
  - renameOnRotate
  - encoding
  - locale
  - requestAttributesEnabled
  - buffered

- **org.apache.catalina.valves.ExtendedAccessLogValve**
  - resolveHosts
  - fileDateFormat
  - renameOnRotate
  - encoding
  - locale
  - requestAttributesEnabled
  - buffered

- **org.apache.catalina.valves.RemoteIpValve**
  - httpServerPort
  - httpsServerPort
  - remotelpHeader
    - If it is defined but not set to "x-forwarded-for"
  - protocolHeader
    - If it is defined but not set to "x-forwarded-proto"
The migrate operation is not able to process all JBoss Web attributes. See the following reference tables for information about how to migrate the unprocessed attributes manually.

### Web SSL Connector Attributes

The following attributes were used in JBoss EAP 6 to configure the SSL connector. OpenSSL native libraries are not supported in JBoss EAP 7 so there are no equivalent settings.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
<th>Undertow Equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>ca-revocation-url</td>
<td>The file or URL that contains the revocation list.</td>
<td>No equivalent in Undertow.</td>
</tr>
<tr>
<td>certificate-file</td>
<td>When using OpenSSL encryption, the path to the file containing the server certificate.</td>
<td>No equivalent in Undertow.</td>
</tr>
<tr>
<td>ssl-protocol</td>
<td>The SSL protocol string.</td>
<td>No equivalent in Undertow.</td>
</tr>
<tr>
<td>verify-depth</td>
<td>The maximum number of intermediate certificate issuers checked before deciding that the clients do not have a valid certificate.</td>
<td>No equivalent in Undertow.</td>
</tr>
</tbody>
</table>

### Web Static Resource Attributes

The following static-resources element attributes were used to describe how static resources were handled by the DefaultServlet or by the WebdavServlet. There are no equivalents for these attributes because WebDAV is not supported by Undertow. For more information, see [https://issues.jboss.org/browse/JBEAP-1036](https://issues.jboss.org/browse/JBEAP-1036).

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
<th>Undertow Equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>disabled</td>
<td>Enable the default Servlet mapping.</td>
<td>No equivalent setting in Undertow.</td>
</tr>
<tr>
<td>file-encoding</td>
<td>File encoding to be used when reading static files.</td>
<td>No equivalent setting in Undertow.</td>
</tr>
<tr>
<td>max-depth</td>
<td>Maximum recursion for PROPFRIND.</td>
<td>This is a WebDAV setting and WebDAV is not supported by Undertow.</td>
</tr>
<tr>
<td>read-only</td>
<td>Allow write HTTP methods (PUT, DELETE).</td>
<td>This is a WebDAV setting and WebDAV is not supported by Undertow.</td>
</tr>
<tr>
<td>secret</td>
<td>Secret for WebDAV locking operations.</td>
<td>This is a WebDAV setting and WebDAV is not supported by Undertow.</td>
</tr>
<tr>
<td>sendfile</td>
<td>Enable sendfile if possible, for files bigger than the specified byte size.</td>
<td>This is set to a sensible default value in Undertow and is not configurable.</td>
</tr>
<tr>
<td>webdav</td>
<td>Enable WebDAV functionality.</td>
<td>WebDAV is not supported by Undertow.</td>
</tr>
</tbody>
</table>
Web SSO Resource Attributes
SSO is handled differently than in the previous release and there are no equivalent attribute settings in JBoss EAP 7.

<table>
<thead>
<tr>
<th>JBoss Web Attribute</th>
<th>Description</th>
<th>Undertow Equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>cache-container</td>
<td>Name of the cache container to use for clustered SSO.</td>
<td>This setting is no longer needed in Undertow. This works by default across a distributed clustered environment.</td>
</tr>
<tr>
<td>cache-name</td>
<td>Name of the cache to use for clustered SSO.</td>
<td>This setting is no longer needed in Undertow. This works by default across a distributed clustered environment.</td>
</tr>
<tr>
<td>reauthenticate</td>
<td>Whether each request should cause a reauthentication.</td>
<td>There is no equivalent setting in Undertow, which behaves similarly to the <code>reauthenticate=true</code> setting in JBoss EAP 6. While <code>reauthenticate=false</code> could possibly improve performance, it could also create security issues.</td>
</tr>
</tbody>
</table>

Web Access Log Attributes

<table>
<thead>
<tr>
<th>JBoss Web Attribute</th>
<th>Description</th>
<th>Undertow Equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>resolve-hosts</td>
<td>Whether to enable resolving hosts for access logging.</td>
<td>Use the setting on the connector to accomplish the same behavior.</td>
</tr>
</tbody>
</table>

Web Connector Attributes

<table>
<thead>
<tr>
<th>JBoss Web Attribute</th>
<th>Description</th>
<th>Undertow Equivalent</th>
</tr>
</thead>
<tbody>
<tr>
<td>executor</td>
<td>The name of the executor that should be used to process the threads of this connector.</td>
<td>You now reference a worker that is defined in the io subsystem. See Migrate the Threads Subsystem Configuration for more information.</td>
</tr>
<tr>
<td>proxy-binding</td>
<td>The socket binding to define the host and port that is used when sending a redirect.</td>
<td>There is no direct equivalent. See https-listener Attributes in the JBoss EAP Configuration Guide for available configuration options.</td>
</tr>
</tbody>
</table>
redirect-port

The port for redirection to a secure connector.

This attribute was deprecated in JBoss EAP 6 and replaced with redirect-binding. Undertow provides the redirect-socket attribute on the http-listener element, which is a replacement for redirect-binding.

See https-listener Attributes in the JBoss EAP Configuration Guide for more information.

### A.4. MIGRATE JBOSS WEB SYSTEM PROPERTIES REFERENCE

This reference describes how to map system properties previously used for JBoss Web configuration to the equivalent configuration for Undertow in JBoss EAP 7.

- Map Servlet Container and Connectors System Properties
- Map EL System Properties
- Map Server Pages System Properties
- Map Security System Properties

#### Table A.1. Map Servlet Container and Connectors System Properties

<table>
<thead>
<tr>
<th>JBoss EAP 6 System Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>jvmRoute</td>
<td>Provides a default value for the jvmRoute attribute. It does not override the automatically generated value when using the standalone-ha.xml configuration file. It supports reload.</td>
</tr>
<tr>
<td></td>
<td>Management CLI command:</td>
</tr>
<tr>
<td></td>
<td>/subsystem=undertow:write-attribute(name=instance-id,value=VALUE)</td>
</tr>
<tr>
<td>org.apache.tomcat.util.buf.StringCache.byte.enabled</td>
<td>If true, the String cache is enabled for Chunk. If the value is not specified, the default value of false is used.</td>
</tr>
<tr>
<td></td>
<td>No equivalent configuration</td>
</tr>
<tr>
<td>org.apache.tomcat.util.buf.StringCache.char.enabled</td>
<td>If true, the String cache is enabled for Chunk. If the value is not specified, the default value of false is used.</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>org.apache.tomcat.util.buf.StringCache.cacheSize</td>
<td>The size of the String cache. If the value is not specified, the default value of <strong>5000</strong> is used.</td>
</tr>
<tr>
<td>org.apache.tomcat.util.buf.StringCache.maxStringSize</td>
<td>The maximum length of String that will be cached. If the value is not specified, the default value of <strong>128</strong> is used.</td>
</tr>
<tr>
<td>org.apache.tomcat.util.http.FastHttpDateFormat.CACHE_SIZE</td>
<td>The size of the cache to use parsed and formatted date value. If the value is not specified, the default value of <strong>1000</strong> is used.</td>
</tr>
<tr>
<td>org.apache.catalina.core.StandardService.DELAY_CONNECTOR_STARTUP</td>
<td>If <strong>true</strong>, the connector startup is not done automatically. It is useful in embedded mode.</td>
</tr>
<tr>
<td>org.apache.catalina.connector.Request.SESSION_ID_CHECK</td>
<td>If <strong>true</strong>, the Servlet container verifies that a session exists in a context with the specified session ID before creating a session with that ID.</td>
</tr>
<tr>
<td>org.apache.coyote.USE_CUSTOM_STATUS_MSG_IN_HEADER</td>
<td>If <strong>true</strong>, custom HTTP status messages are used within HTTP headers. Users must ensure that any such message is <strong>ISO-8859-1</strong> encoded, particularly if user provided input is included in the message, to prevent a possible XSS vulnerability. If value is not specified the default value of <strong>false</strong> is used. Must be enabled programmatically by implementing a custom <code>io.undertow.servlet.ServletExtension</code>. Then use the extension to call <code>setSendCustomReasonPhraseOnError(true)</code> on the <code>io.undertow.servlet.api.DeploymentInfo</code> structure instance.</td>
</tr>
<tr>
<td>org.apache.tomcat.util.http.Parameters.MAX_COUNT</td>
<td>The maximum number of parameters that can be parsed in a post body. If exceeded, parsing fails using an <code>IllegalStateException</code>. The default value is <strong>512</strong> parameters.</td>
</tr>
</tbody>
</table>
### Management CLI command:

```
/subsystem=undertow/server=default-server/http-listener=default:write-attribute(name=max-parameters,value=VALUE)
/subsystem=undertow/server=default-server/https-listener=default:write-attribute(name=max-parameters,value=VALUE)
/subsystem=undertow/server=default-server/ajp-listener=default:write-attribute(name=max-parameters,value=VALUE)
```

<table>

</tr>
</tbody>
</table>
| `/subsystem=undertow/server=default-server/https-listener=default:write-attribute(name=max-header-size,value=VALUE)` | # Create a filter  
`/subsystem=undertow/configuration=filter/gzip=gzipfilter:add()`  
`/subsystem=undertow/server=default-server/host=default-host/filter-ref=gzipfilter:add()` |
| `/subsystem=undertow/server=default-server/ajp-listener=default:write-attribute(name=max-header-size,value=VALUE)` | Configure a predicate in a filter using the management CLI: |
| | # Use a predicate in a filter  
`/subsystem=undertow/configuration=filter/gzip=gzipfilter:add()`  
`/subsystem=undertow/server=default-server/host=default-host/filter-ref=gzipfilter:add(predicate="regex[pattern='AppleWebKit',value=%{i,User-Agent}]")` |
| org.apache.coyote.http11.Http11Protocol.COMPRESSION_RESTRICTED_UA | Configure a predicate in a filter using the management CLI: |
| | # Use a predicate in a filter  
`/subsystem=undertow/configuration=filter/gzip=gzipfilter:add()`  
`/subsystem=undertow/server=default-server/host=default-host/filter-ref=gzipfilter:add(predicate="regex[pattern='text/html',value=%{o,Content-Type}]")` |
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| org.apache.coyote.http11.Http11Protocol.COMPRESSION_MIN_SIZE | Minimum size of content that will be compressed. The default value is 2048 bytes. Configure a predicate in a filter using the management CLI:  
```
# Use a predicate in a filter
/subsystem=undertow/configuration=filter/gzip=gzipfilter:add()
/subsystem=undertow/server=default-server/host=default-host/filter-ref=gzipfilter:add(predicate="max-content-size[value=MIN_SIZE]")
``` |
| org.apache.coyote.http11.DEFAULT_CONNECTION_TIMEOUT | Default socket timeout. The default value is 60000 ms. Management CLI command:  
```
/subsystem=undertow/server=default-server/http-listener=default:write-attribute(name=no-request-timeout,value=VALUE)
/subsystem=undertow/server=default-server/https-listener=default:write-attribute(name=no-request-timeout,value=VALUE)
/subsystem=undertow/server=default-server/ajp-listener=default:write-attribute(name=no-request-timeout,value=VALUE)
``` |
| org.jboss.as.web.deployment.DELETE_WORK_DIR_ONCONTEXTDESTROY | Use this property to remove .java and .class files to ensure that JSP sources are recompiled. The default value is false. Default socket timeout for keep-alive. The default value is -1 ms, which means it will use the default socket timeout. No equivalent configuration |
| org.apache.tomcat.util.buf.StringCache.trainThreshold | Specifies the number of times toString() must be invoked before activating cache. The default value is 100000. No equivalent configuration |

**Table A.2. Map EL System Properties**

<table>
<thead>
<tr>
<th>JBoss EAP 6 System Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Equivalent in JBoss EAP 7</td>
<td></td>
</tr>
</tbody>
</table>
According to the Expression Language (EL) 2.0 specification, if true, when coercing expressions to non-primitive data types, empty strings ("") and null are coerced to zero. If a value is not specified, the default value of true is used.

No equivalent configuration. In accordance with the EL 3.0 specification, empty strings and null do not coerce to zero for non-primitive data types.

Table A.3. Map Server Pages System Properties

<table>
<thead>
<tr>
<th>JBoss EAP 6 System Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>org.apache.jasper.compiler.Generator.VAR_EXPRESSIONFACTORY</td>
<td>The name of the variable to use for the expression language expression factory. If value is not specified, the default value of _el_expressionfactory is used.</td>
</tr>
<tr>
<td>org.apache.jasper.compiler.Generator.VAR_INSTANCEMANAGER</td>
<td>The name of the variable to use for the instance manager factory. If value is not specified, the default value of _jsp_instancemanager is used.</td>
</tr>
<tr>
<td>org.apache.jasper.compiler.Parser.STRICT_QUOTE_ESCAPING</td>
<td>If false, the requirements for escaping quotes in JSP attributes are relaxed so that a missing required quote does not cause an error. If value is not specified, the specification compliant default of true is used.</td>
</tr>
<tr>
<td>org.apache.jasper.Constants.DEFAULT_TAG_BUFFER_SIZE</td>
<td>Any tag buffer that expands beyond org.apache.jasper.Constants.DEFAULT_TAG_BUFFER_SIZE is destroyed and a new buffer is created of the default size. If value is not specified, the default value of 512 is used.</td>
</tr>
<tr>
<td>org.apache.jasper.runtime.JspFactoryImpl.USE_POOL</td>
<td>If true, a ThreadLocal PageContext pool is used. If value is not specified, the default value of true is used.</td>
</tr>
<tr>
<td>org.apache.jasper.runtime.JspFactoryImpl.POOL_SIZE</td>
<td>The size of the ThreadLocal PageContext. If value is not specified, the default value of 8 is used.</td>
</tr>
<tr>
<td>System Property</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------</td>
<td>-------------</td>
</tr>
<tr>
<td>org.apache.jasper.Constants.JSP_SERVLET_BASE</td>
<td>The base class of the Servlets generated from the JSP. If value is not specified, the default value of org.apache.jasper.runtime.HttpJspBase is used.</td>
</tr>
<tr>
<td>org.apache.jasper.Constants.SERVICE_METHOD_NAME</td>
<td>The name of the service method called by the base class. If value is not specified, the default value of _jspService is used.</td>
</tr>
<tr>
<td>org.apache.jasper.Constants.SERVLET_CLASSPATH</td>
<td>The name of the ServletContext attribute that provides the class path for the JSP. If value is not specified, the default value of org.apache.catalina.jsp_classpath is used.</td>
</tr>
<tr>
<td>org.apache.jasper.Constants.JSP_FILE</td>
<td>The name of the request attribute for <code>&lt;jsp-file&gt;</code> element of a servlet definition. If present on a request, this overrides the value returned by request.getServletPath() to select the JSP to be executed. If value is not specified, the default value of org.apache.catalina.jsp_file is used.</td>
</tr>
<tr>
<td>org.apache.jasper.Constants.PRECOMPILE</td>
<td>The name of the query parameter that causes the JSP engine to just pregenerate the servlet but not invoke it. If value is not specified, the default value of org.apache.catalina.jsp_precompile is used.</td>
</tr>
<tr>
<td>org.apache.jasper.Constants.JSP_PACKAGE_NAME</td>
<td>The default package name for compiled JSP. If value not specified, the default value of org.apache.jsp is used.</td>
</tr>
<tr>
<td>org.apache.jasper.Constants.TAG_FILE_PACKAGE_NAME</td>
<td>The default package name for tag handlers generated from tag files. If value is not specified, the default value of org.apache.jsp.tag is used.</td>
</tr>
<tr>
<td>org.apache.jasper.Constants.TEMP_VARIABLE_NAME_PREFIX</td>
<td>Prefix to use for generated temporary variable names. If value is not specified, the default value of _jspx_temp is used.</td>
</tr>
<tr>
<td>JBoss EAP 6 System Property</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>

<tr>
<td><code>org.apache.catalina.STRICT_SERVLET_COMPLIANCE</code></td>
<td>If value is not specified, <code>true</code> is used. If this is <code>true</code> the following actions will occur: any wrapped request or response object passed to an application dispatcher is checked to ensure that it has wrapped the original request or response. (SRV.8.2 / SRV.14.2.5.1) A call to <code>Response.getWriter()</code> if no character encoding has been specified results in subsequent calls to <code>Response.getCharacterEncoding()</code> returning <code>ISO-8859-1</code> and the <code>Content-Type</code> response header will include a <code>charset=ISO-8859-1</code> component. (SRV.15.2.22.1) Every request that is associated with a session causes the session’s last accessed time to be updated regardless of whether or not the request explicitly accesses the session. (SRV.7.6)</td>
</tr>
<tr>
<td>Compliant by default</td>
<td></td>
</tr>
<tr>
<td><code>org.apache.catalina.core.StandardWrapperValve.SERVLET_STATS</code></td>
<td>If <code>true</code> or if <code>org.apache.catalina.STRICT_SERVLET_COMPLIANCE</code> is <code>true</code>, the wrapper will collect the JSR-77 statistics for individual servlets. If value is not specified, the default value of <code>false</code> is used. The Jakarta equivalent for this map security system property is Jakarta Management.</td>
</tr>
<tr>
<td>No equivalent configuration</td>
<td></td>
</tr>
<tr>
<td><code>org.apache.catalina.session.StandardSession.ACTIVITY_CHECK</code></td>
<td>If this is <code>true</code> or if <code>org.apache.catalina.STRICT_SERVLET_COMPLIANCE</code> is <code>true</code> Tomcat tracks the number of active requests for each session. When determining if a session is valid, any session with at least one active request is always be considered valid. If value is not specified, the default value of <code>false</code> is used.</td>
</tr>
<tr>
<td>No equivalent configuration</td>
<td></td>
</tr>
</tbody>
</table>

**A.5. COMPATIBILITY AND INTEROPERABILITY BETWEEN RELEASES**

This section describes the compatibility and interoperability of client and server enterprise beans and messaging components between the JBoss EAP 5, JBoss EAP 6, and JBoss EAP 7 releases.

**Enterprise beans remoting over IIOP**

You should not encounter problems with any of the following configurations.

- Connecting from a JBoss EAP 5 client to a JBoss EAP 7 server
- Connecting from a JBoss EAP 6 client to a JBoss EAP 7 server
- Connecting from a JBoss EAP 7 client to a JBoss EAP 6 server
- Connecting from a JBoss EAP 7 client to a JBoss EAP 5 server

**Enterprise beans remoting using Java Naming and Directory Interface**
You should not encounter problems with any of the following configurations.

- Connecting from a JBoss EAP 6 client to a JBoss EAP 7 server
- Connecting from a JBoss EAP 7 client to a JBoss EAP 6 server

JBoss EAP 6 provided support for the Enterprise Beans 3.1 specification and introduced the use of standardized global Java Naming and Directory Interface namespaces, which are still used in JBoss EAP 7. Due to the change in Java Naming and Directory Interface namespace names, the following configurations are not compatible:

- Connecting from a JBoss EAP 5 client to a JBoss EAP 7 or a JBoss EAP 6 server
- Connecting from a JBoss EAP 7 or JBoss EAP 6 client to a JBoss EAP 5 server

For more information about standardized Java Naming and Directory Interface namespace changes, see Java Naming and Directory Interface Changes in the JBoss EAP 6 Migration Guide.

**Enterprise beans remoting Using @WebService**

You should not encounter problems with any of the following configurations.

- Connecting from a JBoss EAP 5 client to a JBoss EAP 7 server
- Connecting from a JBoss EAP 6 client to a JBoss EAP 7 server
- Connecting from a JBoss EAP 7 client to a JBoss EAP 6 server
- Connecting from a JBoss EAP 7 client to a JBoss EAP 5 server

**Messaging Standalone Client**

You should not encounter problems with any of the following configurations.

- Connecting from a JBoss EAP 6 client to a JBoss EAP 7 server
- Connecting from a JBoss EAP 7 client to a JBoss EAP 6 server

In the following configuration, if the client is using the messaging broker-specific HornetQ API rather than the generic messaging API, the connection is possible. However, Java Naming and Directory Interface lookups must be addressed using the JBoss EAP legacy Java Naming and Directory Interface naming extension that is delivered with JBoss EAP 7.

- Connecting from a JBoss EAP 5 client to a JBoss EAP 7 server

JBoss EAP 7 built-in messaging is not able to connect to HornetQ 2.2.x that shipped with JBoss EAP 5 due to protocol compatibility issues. For this reason, the following configurations are not compatible.

- Connecting from a JBoss EAP 7 client to a JBoss EAP 5 server

**Messaging MDBs**

You should not encounter problems with any of the following configurations.

- Connecting from a JBoss EAP 6 client to a JBoss EAP 7 server
- Connecting from a JBoss EAP 7 client to a JBoss EAP 6 server

In the following configuration, if the client is using the messaging broker-specific HornetQ API rather than the generic Jakarta Messaging API, the connection is possible. However, Java Naming and
Directory Interface lookups must be addressed using the JBoss EAP legacy Java Naming and Directory Interface naming extension that is delivered with JBoss EAP 7.

- Connecting from a JBoss EAP 5 client to a JBoss EAP 7 server

JBoss EAP 7 built-in messaging is not able to connect to HornetQ 2.2.x that shipped with JBoss EAP 5 due to protocol compatibility issues. For this reason, the following configurations are not compatible.

- Connecting from a JBoss EAP 7 client to a JBoss EAP 5 server

**Messaging bridges**
You should not encounter problems with any of the following configurations.

- Connecting from a JBoss EAP 5 client to a JBoss EAP 7 server
- Connecting from a JBoss EAP 6 client to a JBoss EAP 7 server
- Connecting from a JBoss EAP 7 client to a JBoss EAP 6 server
- Connecting from a JBoss EAP 7 client to a JBoss EAP 5 server
