PART I. IMPLEMENTING ENTERPRISE INTEGRATION PATTERNS

Abstract

This part describes how to build routes using Apache Camel. It covers the basic building blocks and EIP components.
CHAPTER 1. BUILDING BLOCKS FOR ROUTE DEFINITIONS

Abstract

Apache Camel supports two alternative Domain Specific Languages (DSL) for defining routes: a Java DSL and a Spring XML DSL. The basic building blocks for defining routes are endpoints and processors, where the behavior of a processor is typically modified by expressions or logical predicates. Apache Camel enables you to define expressions and predicates using a variety of different languages.

1.1. IMPLEMENTING A ROUTEBUILDER CLASS

Overview

To use the Domain Specific Language (DSL), you extend the RouteBuilder class and override its configure() method (where you define your routing rules).

You can define as many RouteBuilder classes as necessary. Each class is instantiated once and is registered with the CamelContext object. Normally, the lifecycle of each RouteBuilder object is managed automatically by the container in which you deploy the router.

RouteBuilder classes

As a router developer, your core task is to implement one or more RouteBuilder classes. There are two alternative RouteBuilder classes that you can inherit from:

- org.apache.camel.builder.RouteBuilder—this is the generic RouteBuilder base class that is suitable for deploying into any container type. It is provided in the camel-core artifact.
- org.apache.camel.spring.SpringRouteBuilder—this base class is specially adapted to the Spring container. In particular, it provides extra support for the following Spring specific features: looking up beans in the Spring registry (using the beanRef() Java DSL command) and transactions (see the Transactions Guide for details). It is provided in the camel-spring artifact.

The RouteBuilder class defines methods used to initiate your routing rules (for example, from(), intercept(), and exception()).

Implementing a RouteBuilder

Example 1.1, “Implementation of a RouteBuilder Class” shows a minimal RouteBuilder implementation. The configure() method body contains a routing rule; each rule is a single Java statement.

Example 1.1. Implementation of a RouteBuilder Class

```java
import org.apache.camel.builder.RouteBuilder;

public class MyRouteBuilder extends RouteBuilder {
```
The form of the rule `from(URL1).to(URL2)` instructs the router to read files from the directory `src/data` and send them to the directory `target/messages`. The option `noop=true` instructs the router to retain (not delete) the source files in the `src/data` directory.

1.2. BASIC JAVA DSL SYNTAX

What is a DSL?

A Domain Specific Language (DSL) is a mini-language designed for a special purpose. A DSL does not have to be logically complete but needs enough expressive power to describe problems adequately in the chosen domain. Typically, a DSL does not require a dedicated parser, interpreter, or compiler. A DSL can piggyback on top of an existing object-oriented host language, provided DSL constructs map cleanly to constructs in the host language API.

Consider the following sequence of commands in a hypothetical DSL:

```java
command01;
command02;
command03;
```

You can map these commands to Java method invocations, as follows:

```java
command01().command02().command03()
```

You can even map blocks to Java method invocations. For example:

```java
command01().startBlock().command02().command03().endBlock()
```

The DSL syntax is implicitly defined by the data types of the host language API. For example, the return type of a Java method determines which methods you can legally invoke next (equivalent to the next command in the DSL).

Router rule syntax

Apache Camel defines a router DSL for defining routing rules. You can use this DSL to define rules in the body of a `RouteBuilder.configure()` implementation. Figure 1.1, “Local Routing Rules” shows an overview of the basic syntax for defining local routing rules.
A local rule always starts with a `from("EndpointURL")` method, which specifies the source of messages (consumer endpoint) for the routing rule. You can then add an arbitrarily long chain of processors to the rule (for example, `filter()`). You typically finish off the rule with a `to("EndpointURL")` method, which specifies the target (producer endpoint) for the messages that pass through the rule. However, it is not always necessary to end a rule with `to()`. There are alternative ways of specifying the message target in a rule.

**NOTE**
You can also define a global routing rule, by starting the rule with a special processor type (such as `intercept()`, `exception()`, or `errorHandler()`). Global rules are outside the scope of this guide.

**Consumers and producers**
A local rule always starts by defining a consumer endpoint, using `from("EndpointURL")`, and typically (but not always) ends by defining a producer endpoint, using `to("EndpointURL")`. The endpoint URLs, `EndpointURL`, can use any of the components configured at deploy time. For example, you could use a file endpoint, `file:MyMessageDirectory`, an Apache CXF endpoint, `cxf:MyServiceName`, or an Apache ActiveMQ endpoint, `activemq:queue:MyQName`. For a complete list of component types, see...

**Exchanges**
An exchange object consists of a message, augmented by metadata. Exchanges are of central importance in Apache Camel, because the exchange is the standard form in which messages are propagated through routing rules. The main constituents of an exchange are, as follows:

- **In message**—is the current message encapsulated by the exchange. As the exchange progresses through a route, this message may be modified. So the In message at the start of a route is typically not the same as the In message at the end of the route. The `org.apache.camel.Message` type provides a generic model of a message, with the following parts:
  - Body.
  - Headers.
  - Attachments.
It is important to realize that this is a **generic** model of a message. Apache Camel supports a large variety of protocols and endpoint types. Hence, it is not possible to standardize the format of the message body or the message headers. For example, the body of a JMS message would have a completely different format to the body of a HTTP message or a Web services message. For this reason, the body and the headers are declared to be of **Object** type. The original content of the body and the headers is then determined by the endpoint that created the exchange instance (that is, the endpoint appearing in the **from()** command).

- **Out** message—is a temporary holding area for a reply message or for a transformed message. Certain processing nodes (in particular, the **to()** command) can modify the current message by treating the *In* message as a request, sending it to a producer endpoint, and then receiving a reply from that endpoint. The reply message is then inserted into the **Out** message slot in the exchange.

Normally, if an **Out** message has been set by the current node, Apache Camel modifies the exchange as follows before passing it to the next node in the route: the old **In** message is discarded and the **Out** message is moved to the **In** message slot. Thus, the reply becomes the new current message. For a more detailed discussion of how Apache Camel connects nodes together in a route, see Section 2.1, “Pipeline Processing”.

There is one special case where an **Out** message is treated differently, however. If the consumer endpoint at the start of a route is expecting a reply message, the **Out** message at the very end of the route is taken to be the consumer endpoint’s reply message (and, what is more, in this case the final node must create an **Out** message or the consumer endpoint would hang).

- Message exchange pattern (MEP)—affects the interaction between the exchange and endpoints in the route, as follows:

  - **Consumer endpoint**—the consumer endpoint that creates the original exchange sets the initial value of the MEP. The initial value indicates whether the consumer endpoint expects to receive a reply (for example, the **InOut** MEP) or not (for example, the **InOnly** MEP).

  - **Producer endpoints**—the MEP affects the producer endpoints that the exchange encounters along the route (for example, when an exchange passes through a **to()** node). For example, if the current MEP is **InOnly**, a **to()** node would not expect to receive a reply from the endpoint. Sometimes you need to change the current MEP in order to customize the exchange’s interaction with a producer endpoint. For more details, see Section 1.4, “Endpoints”.

- Exchange properties—a list of named properties containing metadata for the current message.

## Message exchange patterns

Using an **Exchange** object makes it easy to generalize message processing to different **message exchange patterns**. For example, an asynchronous protocol might define an MEP that consists of a single message that flows from the consumer endpoint to the producer endpoint (an **InOnly** MEP). An RPC protocol, on the other hand, might define an MEP that consists of a request message and a reply message (an **InOut** MEP). Currently, Apache Camel supports the following MEPs:

- **InOnly**
RobustInOnly
InOut
InOptionalOut
OutOnly
RobustOutOnly
OutIn
OutOptionalIn

Where these message exchange patterns are represented by constants in the enumeration type, `org.apache.camel.ExchangePattern`.

**Grouped exchanges**

Sometimes it is useful to have a single exchange that encapsulates multiple exchange instances. For this purpose, you can use a grouped exchange. A grouped exchange is essentially an exchange instance that contains a `java.util.List` of `Exchange` objects stored in the `Exchange.GROUPED_EXCHANGE` exchange property. For an example of how to use grouped exchanges, see Section 7.5, “Aggregator”.

**Processors**

A processor is a node in a route that can access and modify the stream of exchanges passing through the route. Processors can take expression or predicate arguments, that modify their behavior. For example, the rule shown in Figure 1.1, “Local Routing Rules” includes a `filter()` processor that takes an `xpath()` predicate as its argument.

**Expressions and predicates**

Expressions (evaluating to strings or other data types) and predicates (evaluating to true or false) occur frequently as arguments to the built-in processor types. For example, the following filter rule propagates In messages, only if the `foo` header is equal to the value `bar`:

```camel
from("seda:a").filter(header("foo").isEqualTo("bar")).to("seda:b");
```

Where the filter is qualified by the predicate, `header("foo").isEqualTo("bar")`. To construct more sophisticated predicates and expressions, based on the message content, you can use one of the expression and predicate languages (see Expression and Predicate Languages).

### 1.3. ROUTER SCHEMA IN A SPRING XML FILE

**Namespace**

The router schema—which defines the XML DSL—belongs to the following XML schema namespace:

```xml
http://camel.apache.org/schema/spring
```
Specifying the schema location

The location of the router schema is normally specified to be http://camel.apache.org/schema/spring/camel-spring.xsd, which references the latest version of the schema on the Apache Web site. For example, the root **beans** element of an Apache Camel Spring file is normally configured as shown in Example 1.2, “Specifying the Router Schema Location”.

Example 1.2. Specifying the Router Schema Location

```xml
<beans xmlns="http://www.springframework.org/schema/beans"
       xmlns:camel="http://camel.apache.org/schema/spring"
       xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
       xsi:schemaLocation="
           http://www.springframework.org/schema/beans
           http://www.springframework.org/schema/beans/spring-beans-2.0.xsd
           http://camel.apache.org/schema/spring
           http://camel.apache.org/schema/spring/camel-spring.xsd">
    <camelContext id="camel"
                  xmlns="http://camel.apache.org/schema/spring">
        <!-- Define your routing rules here -->
    </camelContext>
</beans>
```

Runtime schema location

At run time, Apache Camel does not download the router schema from schema location specified in the Spring file. Instead, Apache Camel automatically picks up a copy of the schema from the root directory of the camel-spring JAR file. This ensures that the version of the schema used to parse the Spring file always matches the current runtime version. This is important, because the latest version of the schema posted up on the Apache Web site might not match the version of the runtime you are currently using.

Using an XML editor

Generally, it is recommended that you edit your Spring files using a full-feature XML editor. An XML editor's auto-completion features make it much easier to author XML that complies with the router schema and the editor can warn you instantly, if the XML is badly-formed.

XML editors generally do rely on downloading the schema from the location that you specify in the **xsi:schemaLocation** attribute. In order to be sure you are using the correct schema version whilst editing, it is usually a good idea to select a specific version of the camel-spring.xsd file. For example, to edit a Spring file for the 2.3 version of Apache Camel, you could modify the beans element as follows:

```xml
<beans xmlns="http://www.springframework.org/schema/beans"
       xmlns:camel="http://camel.apache.org/schema/spring"
       xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
       xsi:schemaLocation="
           http://www.springframework.org/schema/beans
           http://www.springframework.org/schema/beans/spring-beans-2.0.xsd
           http://camel.apache.org/schema/spring
           http://camel.apache.org/schema/spring/camel-spring.xsd">
```

CHAPTER 1. BUILDING BLOCKS FOR ROUTE DEFINITIONS

15
1.4. ENDPOINTS

Overview

Apache Camel endpoints are the sources and sinks of messages in a route. An endpoint is a very general sort of building block: the only requirement it must satisfy is that it acts either as a source of messages (a consumer endpoint) or as a sink of messages (a producer endpoint). Hence, there are a great variety of different endpoint types supported in Apache Camel, ranging from protocol supporting endpoints, such as HTTP, to simple timer endpoints, such as Quartz, that generate dummy messages at regular time intervals. One of the major strengths of Apache Camel is that it is relatively easy to add a custom component that implements a new endpoint type.

Endpoint URIs

Endpoints are identified by endpoint URIs, which have the following general form:

```
scheme:contextPath[?queryOptions]
```

The URI scheme identifies a protocol, such as `http`, and the `contextPath` provides URI details that are interpreted by the protocol. In addition, most schemes allow you to define query options, `queryOptions`, which are specified in the following format:

```
?option01=value01&option02=value02&...
```

For example, the following HTTP URI can be used to connect to the Google search engine page:

```
http://www.google.com
```

The following File URI can be used to read all of the files appearing under the `C:\temp\src\data` directory:

```
file://C:/temp/src/data
```

Not every scheme represents a protocol. Sometimes a scheme just provides access to a useful utility, such as a timer. For example, the following Timer endpoint URI generates an exchange every second (=1000 milliseconds). You could use this to schedule activity in a route.

```
timer://tickTock?period=1000
```

Specifying time periods in a URI
Many of the Apache Camel components have options whose value is a time period (for example, for specifying timeout values and so on). By default, such time period options are normally specified as a pure number, which is interpreted as a millisecond time period. But Apache Camel also supports a more readable syntax for time periods, which enables you to express the period in hours, minutes, and seconds. Formally, the human-readable time period is a string that conforms to the following syntax:

\[
[N\text{Hour}(h|\text{hour})][N\text{Min}(m|\text{minute})][N\text{Sec}(s|\text{second})]
\]

Where each term in square brackets, [], is optional and the notation, (A|B), indicates that A and B are alternatives.

For example, you can configure `timer` endpoint with a 45 minute period as follows:

```java
from("timer:foo?period=45m")
  .to("log:foo");
```

You can also use arbitrary combinations of the hour, minute, and second units, as follows:

```java
from("timer:foo?period=1h15m")
  .to("log:foo");
from("timer:bar?period=2h30s")
  .to("log:bar");
from("timer:bar?period=3h45m58s")
  .to("log:bar");
```

### Specifying raw values in URI options

By default, the option values that you specify in a URI are automatically URI-encoded. In some cases this is undesirable behavior. For example, when setting a password option, it is preferable to transmit the raw character string without URI encoding.

It is possible to switch off URI encoding by specifying an option value with the syntax, `RAW(RawValue)`. For example,

```java
from("SourceURI")
  .to("ftp:joe@myftpserver.com?password=RAW(se+re?t&23)&binary=true")
```

In this example, the password value is transmitted as the literal value, `se+re?t&23`.

### Apache Camel components

Each URI scheme maps to a Apache Camel component, where a Apache Camel component is essentially an endpoint factory. In other words, to use a particular type of endpoint, you must deploy the corresponding Apache Camel component in your runtime container. For example, to use JMS endpoints, you would deploy the JMS component in your container.

Apache Camel provides a large variety of different components that enable you to integrate your application with various transport protocols and third-party products. For example, some of the more commonly used components are: File, JMS, CXF (Web services), HTTP, Jetty, Direct, and Mock. For the full list of supported components, see the Apache Camel component documentation.

Most of the Apache Camel components are packaged separately to the Camel core. If you
use Maven to build your application, you can easily add a component (and its third-party dependencies) to your application simply by adding a dependency on the relevant component artifact. For example, to include the HTTP component, you would add the following Maven dependency to your project POM file:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-http</artifactId>
  <version>${camel-version}</version>
</dependency>
```

The following components are built-in to the Camel core (in the `camel-core` artifact), so they are always available:

- Bean
- Browse
- Dataset
- Direct
- File
- Log
- Mock
- Properties
- Ref
- SEDA
- Timer
- VM

**Consumer endpoints**

A consumer endpoint is an endpoint that appears at the start of a route (that is, in a `from()` DSL command). In other words, the consumer endpoint is responsible for initiating processing in a route: it creates a new exchange instance (typically, based on some message that it has received or obtained), and provides a thread to process the exchange in the rest of the route.
For example, the following JMS consumer endpoint pulls messages off the payments queue and processes them in the route:

```java
from("jms:queue:payments")
    .process(SomeProcessor)
    .to("TargetURI");
```

Or equivalently, in Spring XML:

```xml
<route>
    <from uri="jms:queue:payments"/>
    <process ref="someProcessorId"/>
    <to uri="TargetURI"/>
</route>
```

Some components are consumer only—that is, they can only be used to define consumer endpoints. For example, the Quartz component is used exclusively to define consumer endpoints. The following Quartz endpoint generates an event every second (1000 milliseconds):

```java
from("quartz://secondTimer?trigger.repeatInterval=1000")
    .process(SomeProcessor)
    .to("TargetURI");
```

If you like, you can specify the endpoint URI as a formatted string, using the `fromF()` Java DSL command. For example, to substitute the username and password into the URI for an FTP endpoint, you could write the route in Java, as follows:

```java
fromF("ftp:%s@fusesource.com?password=%s", username, password)
    .process(SomeProcessor)
    .to("TargetURI");
```

Where the first occurrence of `%s` is replaced by the value of the `username` string and the second occurrence of `%s` is replaced by the `password` string. This string formatting mechanism is implemented by `String.format()` and is similar to the formatting provided by the C `printf()` function. For details, see `java.util.Formatter`.

### Producer endpoints

A producer endpoint is an endpoint that appears in the middle or at the end of a route (for example, in a `to()` DSL command). In other words, the producer endpoint receives an existing exchange object and sends the contents of the exchange to the specified endpoint.

For example, the following JMS producer endpoint pushes the contents of the current exchange onto the specified JMS queue:

```java
from("SourceURI")
    .process(SomeProcessor)
    .to("jms:queue:orderForms");
```

Or equivalently in Spring XML:
Some components are producer only—that is, they can only be used to define producer endpoints. For example, the HTTP endpoint is used exclusively to define producer endpoints.

```xml
<camelContext id="CamelContextID"
  xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="SourceURI"/>
    <process ref="someProcessorId"/>
    <to uri="jms:queue:orderForms"/>
  </route>
</camelContext>
```

If you like, you can specify the endpoint URI as a formatted string, using the `toF()` Java DSL command. For example, to substitute a custom Google query into the HTTP URI, you could write the route in Java, as follows:

```java
from("SourceURI")
  .process(SomeProcessor)
  .toF("http://www.google.com/search?hl=en&q=%s", myGoogleQuery);
```

Where the occurrence of `%s` is replaced by your custom query string, `myGoogleQuery`. For details, see `java.util.Formatter`.

## 1.5. PROCESSORS

### Overview

To enable the router to do something more interesting than simply connecting a consumer endpoint to a producer endpoint, you can add processors to your route. A processor is a command you can insert into a routing rule to perform arbitrary processing of messages that flow through the rule. Apache Camel provides a wide variety of different processors, as shown in Table 1.1, “Apache Camel Processors”.

### Table 1.1. Apache Camel Processors

<table>
<thead>
<tr>
<th>Java DSL</th>
<th>XML DSL</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>aggregate()</code></td>
<td><code>aggregate</code></td>
<td>Aggregator EIP: Creates an aggregator, which combines multiple incoming exchanges into a single exchange.</td>
</tr>
<tr>
<td><code>aop()</code></td>
<td><code>aop</code></td>
<td>Use Aspect Oriented Programming (AOP) to do work before and after a specified sub-route. See Section 2.8, “Aspect Oriented Programming”.</td>
</tr>
<tr>
<td>Java DSL</td>
<td>XML DSL</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>--------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>bean(), beanRef()</td>
<td>bean</td>
<td>Process the current exchange by invoking a method on a Java object (or bean). See Section 2.4, “Bean Integration”.</td>
</tr>
<tr>
<td>choice()</td>
<td>choice</td>
<td>Content Based Router EIP: Selects a particular sub-route based on the exchange content, using when and otherwise clauses.</td>
</tr>
<tr>
<td>convertBodyTo()</td>
<td>convertBodyTo</td>
<td>Converts the In message body to the specified type.</td>
</tr>
<tr>
<td>delay()</td>
<td>delay</td>
<td>Delayer EIP: Delays the propagation of the exchange to the latter part of the route.</td>
</tr>
<tr>
<td>doTry()</td>
<td>doTry</td>
<td>Creates a try/catch block for handling exceptions, using doCatch, doFinally, and end clauses.</td>
</tr>
<tr>
<td>end()</td>
<td>N/A</td>
<td>Ends the current command block.</td>
</tr>
<tr>
<td>enrich(), enrichRef()</td>
<td>enrich</td>
<td>Content Enricher EIP: Combines the current exchange with data requested from a specified producer endpoint URI.</td>
</tr>
<tr>
<td>filter()</td>
<td>filter</td>
<td>Message Filter EIP: Uses a predicate expression to filter incoming exchanges.</td>
</tr>
<tr>
<td>idempotentConsumer()</td>
<td>idempotentConsumer</td>
<td>Idempotent Consumer EIP: Implements a strategy to suppress duplicate messages.</td>
</tr>
<tr>
<td>inheritErrorHandler()</td>
<td>@inheritErrorHandler</td>
<td>Boolean option that can be used to disable the inherited error handler on a particular route node (defined as a sub-clause in the Java DSL and as an attribute in the XML DSL).</td>
</tr>
<tr>
<td>Java DSL</td>
<td>XML DSL</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>---------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>inOnly()</td>
<td>inOnly</td>
<td>Either sets the current exchange's MEP to <em>InOnly</em> (if no arguments) or sends the exchange as an <em>InOnly</em> to the specified endpoint(s).</td>
</tr>
<tr>
<td>inOut()</td>
<td>inOut</td>
<td>Either sets the current exchange's MEP to <em>InOut</em> (if no arguments) or sends the exchange as an <em>InOut</em> to the specified endpoint(s).</td>
</tr>
<tr>
<td>loadBalance()</td>
<td>loadBalance</td>
<td><strong>Load Balancer EIP:</strong> Implements load balancing over a collection of endpoints.</td>
</tr>
<tr>
<td>log()</td>
<td>log</td>
<td>Logs a message to the console.</td>
</tr>
<tr>
<td>loop()</td>
<td>loop</td>
<td><strong>Loop EIP:</strong> Repeatedly resends each exchange to the latter part of the route.</td>
</tr>
<tr>
<td>markRollbackOnly()</td>
<td>@markRollbackOnly</td>
<td><em>(Transactions)</em> Marks the current transaction for rollback only (no exception is raised). In the XML DSL, this option is set as a boolean attribute on the <em>rollback</em> element. See &quot;Transaction Guide&quot;.</td>
</tr>
<tr>
<td>markRollbackOnlyLast()</td>
<td>@markRollbackOnlyLast</td>
<td><em>(Transactions)</em> If one or more transactions have previously been associated with this thread and then suspended, this command marks the latest transaction for rollback only (no exception is raised). In the XML DSL, this option is set as a boolean attribute on the <em>rollback</em> element. See &quot;Transaction Guide&quot;.</td>
</tr>
<tr>
<td>marshal()</td>
<td>marshal</td>
<td>Transforms into a low-level or binary format using the specified data format, in preparation for sending over a particular transport protocol.</td>
</tr>
<tr>
<td>Java DSL</td>
<td>XML DSL</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>-----------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>multicast()</td>
<td>multicast</td>
<td><strong>Multicast EIP</strong>: Multicasts the current exchange to multiple destinations, where each destination gets its own copy of the exchange.</td>
</tr>
<tr>
<td>onCompletion()</td>
<td>onCompletion</td>
<td>Defines a sub-route (terminated by <code>end()</code> in the Java DSL) that gets executed after the main route has completed. For conditional execution, use the <code>onWhen</code> sub-clause. Can also be defined on its own line (not in a route).</td>
</tr>
<tr>
<td>onException()</td>
<td>onException</td>
<td>Defines a sub-route (terminated by <code>end()</code> in the Java DSL) that gets executed whenever the specified exception occurs. Usually defined on its own line (not in a route).</td>
</tr>
<tr>
<td>pipeline()</td>
<td>pipeline</td>
<td><strong>Pipes and Filters EIP</strong>: Sends the exchange to a series of endpoints, where the output of one endpoint becomes the input of the next endpoint. See also Section 2.1, “Pipeline Processing”.</td>
</tr>
<tr>
<td>policy()</td>
<td>policy</td>
<td>Apply a policy to the current route (currently only used for transactional policies—see “Transaction Guide”).</td>
</tr>
<tr>
<td>pollEnrich()</td>
<td>pollEnrich</td>
<td><strong>Content Enricher EIP</strong>: Combines the current exchange with data polled from a specified consumer endpoint URI.</td>
</tr>
<tr>
<td>process()</td>
<td>process</td>
<td>Execute a custom processor on the current exchange. See the section called “Custom processor” and Part IV, “Programming EIP Components”.</td>
</tr>
<tr>
<td>recipientList()</td>
<td>recipientList</td>
<td><strong>Recipient List EIP</strong>: Sends the exchange to a list of recipients that is calculated at runtime (for example, based on the contents of a header).</td>
</tr>
<tr>
<td><strong>Java DSL</strong></td>
<td><strong>XML DSL</strong></td>
<td><strong>Description</strong></td>
</tr>
<tr>
<td>-------------------</td>
<td>--------------------</td>
<td>---------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>removeHeader()</code></td>
<td><code>removeHeader</code></td>
<td>Removes the specified header from the exchange's <code>In</code> message.</td>
</tr>
<tr>
<td><code>removeHeaders()</code></td>
<td><code>removeHeaders</code></td>
<td>Removes the headers matching the specified pattern from the exchange's <code>In</code> message. The pattern can have the form, <code>prefix*</code>—in which case it matches every name starting with <code>prefix</code>—otherwise, it is interpreted as a regular expression.</td>
</tr>
<tr>
<td><code>removeProperty()</code></td>
<td><code>removeProperty</code></td>
<td>Removes the specified exchange property from the exchange.</td>
</tr>
<tr>
<td><code>requence()</code></td>
<td><code>requence</code></td>
<td><strong>Resequencer EIP:</strong> Re-orders incoming exchanges on the basis of a specified comparator operation. Supports a <code>batch</code> mode and a <code>stream</code> mode.</td>
</tr>
<tr>
<td><code>rollback()</code></td>
<td><code>rollback</code></td>
<td><em>(Transactions)</em> Marks the current transaction for rollback only (also raising an exception, by default). See “Transaction Guide”.*</td>
</tr>
<tr>
<td><code>routingSlip()</code></td>
<td><code>routingSlip</code></td>
<td><strong>Routing Slip EIP:</strong> Routes the exchange through a pipeline that is constructed dynamically, based on the list of endpoint URIs extracted from a slip header.</td>
</tr>
<tr>
<td><code>sample()</code></td>
<td><code>sample</code></td>
<td>Creates a sampling throttler, allowing you to extract a sample of exchanges from the traffic on a route.</td>
</tr>
<tr>
<td><code>setBody()</code></td>
<td><code>setBody</code></td>
<td>Sets the message body of the exchange's <code>In</code> message.</td>
</tr>
<tr>
<td><code>setExchangePattern()</code></td>
<td><code>setExchangePattern</code></td>
<td>Sets the current exchange's MEP to the specified value. See the section called “Message exchange patterns”.</td>
</tr>
<tr>
<td>Java DSL</td>
<td>XML DSL</td>
<td>Description</td>
</tr>
<tr>
<td>----------------</td>
<td>---------------</td>
<td>------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>setHeader()</td>
<td>setHeader</td>
<td>Sets the specified header in the exchange’s <em>In</em> message.</td>
</tr>
<tr>
<td>setOutHeader()</td>
<td>setOutHeader</td>
<td>Sets the specified header in the exchange’s <em>Out</em> message.</td>
</tr>
<tr>
<td>setProperty()</td>
<td>setProperty()</td>
<td>Sets the specified exchange property.</td>
</tr>
<tr>
<td>sort()</td>
<td>sort</td>
<td>Sorts the contents of the <em>In</em> message body (where a custom comparator can optionally be specified).</td>
</tr>
<tr>
<td>split()</td>
<td>split</td>
<td><strong>Splitter EIP</strong>: Splits the current exchange into a sequence of exchanges, where each split exchange contains a fragment of the original message body.</td>
</tr>
<tr>
<td>stop()</td>
<td>stop</td>
<td>Stops routing the current exchange and marks it as completed.</td>
</tr>
<tr>
<td>threads()</td>
<td>threads</td>
<td>Creates a thread pool for concurrent processing of the latter part of the route.</td>
</tr>
<tr>
<td>throttle()</td>
<td>throttle</td>
<td><strong>Throttler EIP</strong>: Limit the flow rate to the specified level (exchanges per second).</td>
</tr>
<tr>
<td>throwException()</td>
<td>throwException</td>
<td>Throw the specified Java exception.</td>
</tr>
<tr>
<td>to()</td>
<td>to</td>
<td>Send the exchange to one or more endpoints. See Section 2.1, “Pipeline Processing”.</td>
</tr>
<tr>
<td>toF()</td>
<td>N/A</td>
<td>Send the exchange to an endpoint, using string formatting. That is, the endpoint URI string can embed substitutions in the style of the <em>C printf()</em> function.</td>
</tr>
<tr>
<td>transacted()</td>
<td>transacted</td>
<td>Create a Spring transaction scope that encloses the latter part of the route. See “Transaction Guide”.</td>
</tr>
</tbody>
</table>
### Some sample processors

To get some idea of how to use processors in a route, see the following examples:

- the section called “Choice”.
- the section called “Filter”.
- the section called “Throttler”.
- the section called “Custom processor”.

#### Choice

The `choice()` processor is a conditional statement that is used to route incoming messages to alternative producer endpoints. Each alternative producer endpoint is preceded by a `when()` method, which takes a predicate argument. If the predicate is true, the following target is selected, otherwise processing proceeds to the next `when()` method in the rule. For example, the following `choice()` processor directs incoming messages to either `Target1`, `Target2`, or `Target3`, depending on the values of `Predicate1` and `Predicate2`:

```java
from("SourceURL")
  .choice()
    .when(Predicate1).to("Target1")
    .when(Predicate2).to("Target2")
    .otherwise().to("Target3");
```

<table>
<thead>
<tr>
<th>Java DSL</th>
<th>XML DSL</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>transform()</code></td>
<td><code>transform</code></td>
<td>Message Translator EIP: Copy the In message headers to the Out message headers and set the Out message body to the specified value.</td>
</tr>
<tr>
<td><code>unmarshal()</code></td>
<td><code>unmarshal</code></td>
<td>Transforms the In message body from a low-level or binary format to a high-level format, using the specified data format.</td>
</tr>
<tr>
<td><code>validate()</code></td>
<td><code>validate</code></td>
<td>Takes a predicate expression to test whether the current message is valid. If the predicate returns <code>false</code>, throws a <code>PredicateValidationException</code> exception.</td>
</tr>
<tr>
<td><code>wireTap()</code></td>
<td><code>wireTap</code></td>
<td>Wire Tap EIP: Sends a copy of the current exchange to the specified wire tap URI, using the <code>ExchangePattern.InOnly MEP</code>.</td>
</tr>
</tbody>
</table>
In the Java DSL, there is a special case where you might need to use the `endChoice()` command. Some of the standard Apache Camel processors enable you to specify extra parameters using special sub-clauses, effectively opening an extra level of nesting which is usually terminated by the `end()` command. For example, you could specify a load balancer clause as `loadBalance().roundRobin().to("mock:foo").to("mock:bar").end()`, which load balances messages between the `mock:foo` and `mock:bar` endpoints. If the load balancer clause is embedded in a choice condition, however, it is necessary to terminate the clause using the `endChoice()` command, as follows:

```java
from("direct:start")
    .choice()
        .when(bodyAs(String.class).contains("Camel"))
            .loadBalance().roundRobin().to("mock:foo").to("mock:bar").endChoice()
        .otherwise()
            .to("mock:result");
```

Filter

The `filter()` processor can be used to prevent uninteresting messages from reaching the producer endpoint. It takes a single predicate argument: if the predicate is true, the message exchange is allowed through to the producer; if the predicate is false, the message exchange is blocked. For example, the following filter blocks a message exchange, unless the incoming message contains a header, `foo`, with value equal to `bar`:

```java
from("SourceURL").filter(header("foo").isEqualTo("bar")).to("TargetURL");
```

Or equivalently in Spring XML:

```xml
<camelContext id="filterRoute"
    xmlns="http://camel.apache.org/schema/spring">
    <route>
        <from uri="SourceURL"/>
        <choice>
            <when>
                <!-- First predicate -->
                <simple>header.foo = 'bar'</simple>
                <to uri="Target1"/>
            </when>
            <when>
                <!-- Second predicate -->
                <simple>header.foo = 'manchu'</simple>
                <to uri="Target2"/>
            </when>
            <otherwise>
                <to uri="Target3"/>
            </otherwise>
        </choice>
    </route>
</camelContext>
```
The throttle() processor ensures that a producer endpoint does not get overloaded. The throttler works by limiting the number of messages that can pass through per second. If the incoming messages exceed the specified rate, the throttler accumulates excess messages in a buffer and transmits them more slowly to the producer endpoint. For example, to limit the rate of throughput to 100 messages per second, you can define the following rule:

```
from("SourceURL").throttle(100).to("TargetURL");
```

Or equivalently in Spring XML:

```
<route>
  <from uri="SourceURL"/>
  <throttle maximumRequestsPerPeriod="100" timePeriodMillis="1000">
    <to uri="TargetURL"/>
  </throttle>
</route>
```

### Custom processor

If none of the standard processors described here provide the functionality you need, you can always define your own custom processor. To create a custom processor, define a class that implements the `org.apache.camel.Processor` interface and overrides the `process()` method. The following custom processor, `MyProcessor`, removes the header named `foo` from incoming messages:

```
public class MyProcessor implements org.apache.camel.Processor {
    public void process(org.apache.camel.Exchange exchange) {
        inMessage = exchange.getIn();
        if (inMessage != null) {
            inMessage.removeHeader("foo");
        }
    }
}
```
To insert the custom processor into a router rule, invoke the `process()` method, which provides a generic mechanism for inserting processors into rules. For example, the following rule invokes the processor defined in Example 1.3, "Implementing a Custom Processor Class":

```java
org.apache.camel.Processor myProc = new MyProcessor();
from("SourceURL").process(myProc).to("TargetURL");
```
CHAPTER 2. BASIC PRINCIPLES OF ROUTE BUILDING

Abstract

Apache Camel provides several processors and components that you can link together in a route. This chapter provides a basic orientation by explaining the principles of building a route using the provided building blocks.

2.1. PIPELINE PROCESSING

Overview

In Apache Camel, pipelining is the dominant paradigm for connecting nodes in a route definition. The pipeline concept is probably most familiar to users of the UNIX operating system, where it is used to join operating system commands. For example, `ls | more` is an example of a command that pipes a directory listing, `ls`, to the page-scrolling utility, `more`. The basic idea of a pipeline is that the output of one command is fed into the input of the next. The natural analogy in the case of a route is for the Out message from one processor to be copied to the In message of the next processor.

Processor nodes

Every node in a route, except for the initial endpoint, is a processor, in the sense that they inherit from the `org.apache.camel.Processor` interface. In other words, processors make up the basic building blocks of a DSL route. For example, DSL commands such as `filter()`, `delayer()`, `setBody()`, `setHeader()`, and `to()` all represent processors. When considering how processors connect together to build up a route, it is important to distinguish two different processing approaches.

The first approach is where the processor simply modifies the exchange's In message, as shown in Figure 2.1, “Processor Modifying an In Message”. The exchange's Out message remains null in this case.

Figure 2.1. Processor Modifying an In Message

The following route shows a `setHeader()` command that modifies the current In message by adding (or modifying) the BillingSystem heading:

```java
from("activemq:orderQueue")
    .setHeader("BillingSystem", xpath("/order/billingSystem"))
    .to("activemq:billingQueue");
```

The second approach is where the processor creates an Out message to represent the result of the processing, as shown in Figure 2.2, “Processor Creating an Out Message”.

Figure 2.2. Processor Creating an Out Message

The following route shows a `setHeader()` command that modifies the current In message by adding (or modifying) the BillingSystem heading:
The following route shows a `transform()` command that creates an `Out` message with a message body containing the string, `DummyBody`:

```java
from("activemq:orderQueue")
  .transform(constant("DummyBody"))
  .to("activemq:billingQueue");
```

where `constant("DummyBody")` represents a constant expression. You cannot pass the string, `DummyBody`, directly, because the argument to `transform()` must be an expression type.

**Pipeline for InOnly exchanges**

Figure 2.3, “Sample Pipeline for InOnly Exchanges” shows an example of a processor pipeline for InOnly exchanges. Processor A acts by modifying the `In` message, while processors B and C create an `Out` message. The route builder links the processors together as shown. In particular, processors B and C are linked together in the form of a pipeline: that is, processor B's `Out` message is moved to the `In` message before feeding the exchange into processor C, and processor C's `Out` message is moved to the `In` message before feeding the exchange into the producer endpoint. Thus the processors' outputs and inputs are joined into a continuous pipeline, as shown in Figure 2.3, “Sample Pipeline for InOnly Exchanges”.

**Figure 2.3. Sample Pipeline for InOnly Exchanges**

Apache Camel employs the pipeline pattern by default, so you do not need to use any special syntax to create a pipeline in your routes. For example, the following route pulls messages from a `userdataQueue` queue, pipes the message through a Velocity template (to produce a customer address in text format), and then sends the resulting text address to the queue, `envelopeAddressQueue`:

```java
from("activemq:userdataQueue")
  .to(ExchangePattern.InOut, "velocity:file:AdressTemplate.vm")
  .to("activemq:envelopeAddresses");
```

Where the Velocity endpoint, `velocity:file:AdressTemplate.vm`, specifies the location of a Velocity template file, `file:AdressTemplate.vm`, in the file system. The `to()` command changes the exchange pattern to `InOut` before sending the exchange to the Velocity
endpoint and then changes it back to InOnly afterwards. For more details of the Velocity endpoint, see.

**Pipeline for InOut exchanges**

Figure 2.4, “Sample Pipeline for InOut Exchanges” shows an example of a processor pipeline for InOut exchanges, which you typically use to support remote procedure call (RPC) semantics. Processors A, B, and C are linked together in the form of a pipeline, with the output of each processor being fed into the input of the next. The final Out message produced by the producer endpoint is sent all the way back to the consumer endpoint, where it provides the reply to the original request.

![Figure 2.4. Sample Pipeline for InOut Exchanges](image)

Note that in order to support the InOut exchange pattern, it is essential that the last node in the route (whether it is a producer endpoint or some other kind of processor) creates an Out message. Otherwise, any client that connects to the consumer endpoint would hang and wait indefinitely for a reply message. You should be aware that not all producer endpoints create Out messages.

Consider the following route that processes payment requests, by processing incoming HTTP requests:

```java
from("jetty:http://localhost:8080/foo")
    .to("cxf:bean:addAccountDetails")
    .to("cxf:bean:getCreditRating")
    .to("cxf:bean:processTransaction");
```

Where the incoming payment request is processed by passing it through a pipeline of Web services, cxf:bean:addAccountDetails, cxf:bean:getCreditRating, and cxf:bean:processTransaction. The final Web service, processTransaction, generates a response (Out message) that is sent back through the JETTY endpoint.

When the pipeline consists of just a sequence of endpoints, it is also possible to use the following alternative syntax:

```java
from("jetty:http://localhost:8080/foo")
```

**Pipeline for InOptionalOut exchanges**

The pipeline for InOptionalOut exchanges is essentially the same as the pipeline in Figure 2.4, “Sample Pipeline for InOut Exchanges”. The difference between InOut and InOptionalOut is that an exchange with the InOptionalOut exchange pattern is allowed to have a null Out message as a reply. That is, in the case of an InOptionalOut exchange, a
null Out message is copied to the In message of the next node in the pipeline. By contrast, in the case of an InOut exchange, a null Out message is discarded and the original In message from the current node would be copied to the In message of the next node instead.

2.2. MULTIPLE INPUTS

Overview

A standard route takes its input from just a single endpoint, using the from(EndpointURL) syntax in the Java DSL. But what if you need to define multiple inputs for your route? Apache Camel provides several alternatives for specifying multiple inputs to a route. The approach to take depends on whether you want the exchanges to be processed independently of each other or whether you want the exchanges from different inputs to be combined in some way (in which case, you should use the the section called “Content enricher pattern”).

Multiple independent inputs

The simplest way to specify multiple inputs is using the multi-argument form of the from() DSL command, for example:

```java
from("URI1", "URI2", "URI3").to("DestinationUri");
```

Or you can use the following equivalent syntax:

```java
from("URI1").from("URI2").from("URI3").to("DestinationUri");
```

In both of these examples, exchanges from each of the input endpoints, URI1, URI2, and URI3, are processed independently of each other and in separate threads. In fact, you can think of the preceding route as being equivalent to the following three separate routes:

```java
from("URI1").to("DestinationUri");
from("URI2").to("DestinationUri");
from("URI3").to("DestinationUri");
```

Segmented routes

For example, you might want to merge incoming messages from two different messaging systems and process them using the same route. In most cases, you can deal with multiple inputs by dividing your route into segments, as shown in Figure 2.5, “Processing Multiple Inputs with Segmented Routes”.

Figure 2.5. Processing Multiple Inputs with Segmented Routes

```java
from("activemq:Nyse").to(InternalUrl)
    from(InternalUrl).to("activemq:USTxn")
    from("activemq:Nasdaq").to(InternalUrl)
```

The initial segments of the route take their inputs from some external queues—for example,
activemq:Nyse and activemq:Nasdaq—and send the incoming exchanges to an internal endpoint, InternalUrl. The second route segment merges the incoming exchanges, taking them from the internal endpoint and sending them to the destination queue, activemq:USTxn. The InternalUrl is the URL for an endpoint that is intended only for use within a router application. The following types of endpoints are suitable for internal use:

- the section called “Direct endpoints”.
- the section called “SEDA endpoints”.
- the section called “VM endpoints”.

The main purpose of these endpoints is to enable you to glue together different segments of a route. They all provide an effective way of merging multiple inputs into a single route.

**Direct endpoints**

The direct component provides the simplest mechanism for linking together routes. The event model for the direct component is synchronous, so that subsequent segments of the route run in the same thread as the first segment. The general format of a direct URL is direct:EndpointID, where the endpoint ID, EndpointID, is simply a unique alphanumeric string that identifies the endpoint instance.

For example, if you want to take the input from two message queues, activemq:Nyse and activemq:Nasdaq, and merge them into a single message queue, activemq:USTxn, you can do this by defining the following set of routes:

```java
from("activemq:Nyse").to("direct:mergeTxns");
from("activemq:Nasdaq").to("direct:mergeTxns");
from("direct:mergeTxns").to("activemq:USTxn");
```

Where the first two routes take the input from the message queues, Nyse and Nasdaq, and send them to the endpoint, direct:mergeTxns. The last queue combines the inputs from the previous two queues and sends the combined message stream to the activemq:USTxn queue.

The implementation of the direct endpoint behaves as follows: whenever an exchange arrives at a producer endpoint (for example, to("direct:mergeTxns")), the direct endpoint passes the exchange directly to all of the consumers endpoints that have the same endpoint ID (for example, from("direct:mergeTxns")). Direct endpoints can only be used to communicate between routes that belong to the same CamelContext in the same Java virtual machine (JVM) instance.

**SEDA endpoints**

The SEDA component provides an alternative mechanism for linking together routes. You can use it in a similar way to the direct component, but it has a different underlying event and threading model, as follows:

- Processing of a SEDA endpoint is not synchronous. That is, when you send an exchange to a SEDA producer endpoint, control immediately returns to the preceding processor in the route.
- SEDA endpoints contain a queue buffer (of `java.util.concurrent.BlockingQueue` type), which stores all of the incoming exchanges prior to processing by the next route segment.

- Each SEDA consumer endpoint creates a thread pool (the default size is 5) to process exchange objects from the blocking queue.

- The SEDA component supports the competing consumers pattern, which guarantees that each incoming exchange is processed only once, even if there are multiple consumers attached to a specific endpoint.

One of the main advantages of using a SEDA endpoint is that the routes can be more responsive, owing to the built-in consumer thread pool. The stock transactions example can be re-written to use SEDA endpoints instead of direct endpoints, as follows:

```java
from("activemq:Nyse").to("seda:mergeTxns");
from("activemq:Nasdaq").to("seda:mergeTxns");
from("seda:mergeTxns").to("activemq:USTxn");
```

The main difference between this example and the direct example is that when using SEDA, the second route segment (from `seda:mergeTxns` to `activemq:USTxn`) is processed by a pool of five threads.

### NOTE

There is more to SEDA than simply pasting together route segments. The staged event-driven architecture (SEDA) encompasses a design philosophy for building more manageable multi-threaded applications. The purpose of the SEDA component in Apache Camel is simply to enable you to apply this design philosophy to your applications. For more details about SEDA, see [http://www.eecs.harvard.edu/~mdw/proj/seda/](http://www.eecs.harvard.edu/~mdw/proj/seda/).

### VM endpoints

The VM component is very similar to the SEDA endpoint. The only difference is that, whereas the SEDA component is limited to linking together route segments from within the same `CamelContext`, the VM component enables you to link together routes from distinct Apache Camel applications, as long as they are running within the same Java virtual machine.

The stock transactions example can be re-written to use VM endpoints instead of SEDA endpoints, as follows:

```java
from("activemq:Nyse").to("vm:mergeTxns");
from("activemq:Nasdaq").to("vm:mergeTxns");
from("vm:mergeTxns").to("activemq:USTxn");
```

And in a separate router application (running in the same Java VM), you can define the second segment of the route as follows:

```java
from("vm:mergeTxns").to("activemq:USTxn");
```

### Content enricher pattern
The content enricher pattern defines a fundamentally different way of dealing with multiple inputs to a route. When an exchange enters the enricher processor, the enricher contacts an external resource to retrieve information, which is then added to the original message. In this pattern, the external resource effectively represents a second input to the message.

For example, suppose you are writing an application that processes credit requests. Before processing a credit request, you need to augment it with the data that assigns a credit rating to the customer, where the ratings data is stored in a file in the directory, `src/data/ratings`. You can combine the incoming credit request with data from the ratings file using the `pollEnrich()` pattern and a `GroupedExchangeAggregationStrategy` aggregation strategy, as follows:

```java
from("jms:queue:creditRequests")
    .pollEnrich("file:src/data/ratings?noop=true", new GroupedExchangeAggregationStrategy())
    .bean(new MergeCreditRequestAndRatings(), "merge")
    .to("jms:queue:reformattedRequests");
```

Where the `GroupedExchangeAggregationStrategy` class is a standard aggregation strategy from the `org.apache.camel.processor.aggregate` package that adds each new exchange to a `java.util.List` instance and stores the resulting list in the `Exchange.GROUPED_EXCHANGE` exchange property. In this case, the list contains two elements: the original exchange (from the `creditRequests` JMS queue); and the enricher exchange (from the file endpoint).

To access the grouped exchange, you can use code like the following:

```java
public class MergeCreditRequestAndRatings {
    public void merge(Exchange ex) {
        // Obtain the grouped exchange
        List<Exchange> list = ex.getProperty(Exchange.GROUPED_EXCHANGE, List.class);

        // Get the exchanges from the grouped exchange
        Exchange originalEx = list.get(0);
        Exchange ratingsEx = list.get(1);

        // Merge the exchanges
        ...
    }
}
```

An alternative approach to this application would be to put the merge code directly into the implementation of the custom aggregation strategy class.

For more details about the content enricher pattern, see Section 8.1, “Content Enricher”.

### 2.3. EXCEPTION HANDLING

**Abstract**

Apache Camel provides several different mechanisms, which let you handle exceptions at different levels of granularity: you can handle exceptions within a route using `doTry`, `doCatch`, and `doFinally`; or you can specify what action to take for each exception type
and apply this rule to all routes in a RouteBuilder using onException; or you can specify what action to take for all exception types and apply this rule to all routes in a RouteBuilder using errorHandler.

For more details about exception handling, see Section 5.3, “Dead Letter Channel”.

2.3.1. onException Clause

Overview

The onException clause is a powerful mechanism for trapping exceptions that occur in one or more routes: it is type-specific, enabling you to define distinct actions to handle different exception types; it allows you to define actions using essentially the same (actually, slightly extended) syntax as a route, giving you considerable flexibility in the way you handle exceptions; and it is based on a trapping model, which enables a single onException clause to deal with exceptions occurring at any node in any route.

Trapping exceptions using onException

The onException clause is a mechanism for trapping, rather than catching exceptions. That is, once you define an onException clause, it traps exceptions that occur at any point in a route. This contrasts with the Java try/catch mechanism, where an exception is caught, only if a particular code fragment is explicitly enclosed in a try block.

What really happens when you define an onException clause is that the Apache Camel runtime implicitly encloses each route node in a try block. This is why the onException clause is able to trap exceptions at any point in the route. But this wrapping is done for you automatically; it is not visible in the route definitions.

Java DSL example

In the following Java DSL example, the onException clause applies to all of the routes defined in the RouteBuilder class. If a ValidationException exception occurs while processing either of the routes (from("seda:inputA") or from("seda:inputB")), the onException clause traps the exception and redirects the current exchange to the validationFailed JMS queue (which serves as a deadletter queue).

```java
// Java
public class MyRouteBuilder extends RouteBuilder {

  public void configure() {
    onException(ValidationException.class)
      .to("activemq:validationFailed");

    from("seda:inputA")
      .to("validation:foo/bar.xsd", "activemq:someQueue");

    from("seda:inputB").to("direct:foo")
      .to("rnc:mySchema.rnc", "activemq:anotherQueue");
  
  }
}
```

XML DSL example

```xml
CHAPTER 2. BASIC PRINCIPLES OF ROUTE BUILDING
37
```
The preceding example can also be expressed in the XML DSL, using the `onException` element to define the exception clause, as follows:

```xml
<beans xmlns="http://www.springframework.org/schema/beans"
       xmlns:camel="http://camel.apache.org/schema/spring"
       xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
       xsi:schemaLocation="http://www.springframework.org/schema/beans
       http://www.springframework.org/schema/beans/spring-beans-2.0.xsd
       http://camel.apache.org/schema/spring
       http://camel.apache.org/schema/spring/camel-spring.xsd">
    <camelContext xmlns="http://camel.apache.org/schema/spring">
        <onException>
            <exception>com.mycompany.ValidationException</exception>
            <to uri="activemq:validationFailed"/>
        </onException>
        <route>
            <from uri="seda:inputA"/>
            <to uri="validation:foo/bar.xsd"/>
            <to uri="activemq:someQueue"/>
        </route>
        <route>
            <from uri="seda:inputB"/>
            <to uri="rnc:mySchema.rnc"/>
            <to uri="activemq:anotherQueue"/>
        </route>
    </camelContext>
</beans>
```

**Trapping multiple exceptions**

You can define multiple `onException` clauses to trap exceptions in a `RouteBuilder` scope. This enables you to take different actions in response to different exceptions. For example, the following series of `onException` clauses defined in the Java DSL define different deadletter destinations for `ValidationException`, `ValidationException`, and `Exception`:

```java
onException(ValidationException.class).to("activemq:validationFailed");
onException(java.io.IOException.class).to("activemq:ioExceptions");
onException(Exception.class).to("activemq:exceptions");
```

You can define the same series of `onException` clauses in the XML DSL as follows:

```xml
<onException>
    <exception>com.mycompany.ValidationException</exception>
    <to uri="activemq:validationFailed"/>
</onException>
<onException>
    <exception>java.io.IOException</exception>
    <to uri="activemq:ioExceptions"/>
</onException>
<onException>
    <exception>java.io.IOException</exception>
    <to uri="activemq:ioExceptions"/>
</onException>
<onException>
```
You can also group multiple exceptions together to be trapped by the same `onException` clause. In the Java DSL, you can group multiple exceptions as follows:

```java
onException(ValidationException.class, BusinessException.class)
    .to("activemq:validationFailed");
```

In the XML DSL, you can group multiple exceptions together by defining more than one `exception` element inside the `onException` element, as follows:

```xml
<onException>
    <exception>com.mycompany.ValidationException</exception>
    <exception>com.mycompany.BusinessException</exception>
    <to uri="activemq:validationFailed"/>
</onException>
```

When trapping multiple exceptions, the order of the `onException` clauses is significant. Apache Camel initially attempts to match the thrown exception against the *first* clause. If the first clause fails to match, the next `onException` clause is tried, and so on until a match is found. Each matching attempt is governed by the following algorithm:

1. If the thrown exception is a *chained exception* (that is, where an exception has been caught and rethrown as a different exception), the most nested exception type serves initially as the basis for matching. This exception is tested as follows:
   a. If the exception-to-test has exactly the type specified in the `onException` clause (tested using `instanceof`), a match is triggered.
   b. If the exception-to-test is a sub-type of the type specified in the `onException` clause, a match is triggered.

2. If the most nested exception fails to yield a match, the next exception in the chain (the wrapping exception) is tested instead. The testing continues up the chain until either a match is triggered or the chain is exhausted.

**Deadletter channel**

The basic examples of `onException` usage have so far all exploited the *deadletter channel* pattern. That is, when an `onException` clause traps an exception, the current exchange is routed to a special destination (the deadletter channel). The deadletter channel serves as a holding area for failed messages that have not been processed. An administrator can inspect the messages at a later time and decide what action needs to be taken.

For more details about the deadletter channel pattern, see Section 5.3, “Dead Letter Channel”.

**Use original message**

By the time an exception is raised in the middle of a route, the message in the exchange could have been modified considerably (and might not even be readable by a human). Often, it is easier for an administrator to decide what corrective actions to take, if the
messages visible in the deadletter queue are the original messages, as received at the start of the route.

In the Java DSL, you can replace the message in the exchange by the original message, using the `useOriginalMessage()` DSL command, as follows:

```java
onException(ValidationException.class)
    .useOriginalMessage()
    .to("activemq:validationFailed");
```

In the XML DSL, you can retrieve the original message by setting the `useOriginalMessage` attribute on the `onException` element, as follows:

```xml
<onException useOriginalMessage="true">
    <exception>com.mycompany.ValidationException</exception>
    <to uri="activemq:validationFailed"/>
</onException>
```

**Redelivery policy**

Instead of interrupting the processing of a message and giving up as soon as an exception is raised, Apache Camel gives you the option of attempting to redeliver the message at the point where the exception occurred. In networked systems, where timeouts can occur and temporary faults arise, it is often possible for failed messages to be processed successfully, if they are redelivered shortly after the original exception was raised.

The Apache Camel redelivery supports various strategies for redelivering messages after an exception occurs. Some of the most important options for configuring redelivery are as follows:

- `maximumRedeliveries()`
  
  Specifies the maximum number of times redelivery can be attempted (default is 0). A negative value means redelivery is always attempted (equivalent to an infinite value).

- `retryWhile()`
  
  Specifies a predicate (of Predicate type), which determines whether Apache Camel ought to continue redelivering. If the predicate evaluates to true on the current exchange, redelivery is attempted; otherwise, redelivery is stopped and no further redelivery attempts are made.

  This option takes precedence over the `maximumRedeliveries()` option.

In the Java DSL, redelivery policy options are specified using DSL commands in the `onException` clause. For example, you can specify a maximum of six redeliveries, after which the exchange is sent to the `validationFailed` deadletter queue, as follows:

```java
onException(ValidationException.class)
    .maximumRedeliveries(6)
    .retryAttemptedLogLevel(org.apache.camel.LogginLevel.WARN)
    .to("activemq:validationFailed");
```
In the XML DSL, redelivery policy options are specified by setting attributes on the `redeliveryPolicy` element. For example, the preceding route can be expressed in XML DSL as follows:

```xml
<onException useOriginalMessage="true">
  <exception>com.mycompany.ValidationException</exception>
  <redeliveryPolicy maximumRedeliveries="6"/>
  <to uri="activemq:validationFailed"/>
</onException>
```

The latter part of the route—after the redelivery options are set—is not processed until after the last redelivery attempt has failed. For detailed descriptions of all the redelivery options, see Section 5.3, “Dead Letter Channel”.

Alternatively, you can specify redelivery policy options in a `redeliveryPolicyProfile` instance. You can then reference the `redeliveryPolicyProfile` instance using the `onException` element's `redeliveryPolicyRef` attribute. For example, the preceding route can be expressed as follows:

```xml
<redeliveryPolicyProfile id="redelivPolicy" maximumRedeliveries="6" retryAttemptedLogLevel="WARN"/>
<onException useOriginalMessage="true" redeliveryPolicyRef="redelivPolicy">
  <exception>com.mycompany.ValidationException</exception>
  <to uri="activemq:validationFailed"/>
</onException>
```

**NOTE**

The approach using `redeliveryPolicyProfile` is useful, if you want to re-use the same redelivery policy in multiple `onException` clauses.

### Conditional trapping

Exception trapping with `onException` can be made conditional by specifying the `onWhen` option. If you specify the `onWhen` option in an `onException` clause, a match is triggered only when the thrown exception matches the clause and the `onWhen` predicate evaluates to `true` on the current exchange.

For example, in the following Java DSL fragment, the first `onException` clause triggers, only if the thrown exception matches `MyUserException` and the `user` header is non-null in the current exchange:

```java
// Java

// Here we define onException() to catch MyUserException when
// there is a header[user] on the exchange that is not null
onException(MyUserException.class)
  .onWhen(header("user").isNotNull())
  .maximumRedeliveries(2)
  .to(ERROR_USER_QUEUE);

// Here we define onException to catch MyUserException as a kind
```
The preceding `onException` clauses can be expressed in the XML DSL as follows:

```xml
<redeliveryPolicyProfile id="twoRedeliveries" maximumRedeliveries="2"/>

<onException redeliveryPolicyRef="twoRedeliveries">
  <exception>com.mycompany.MyUserException</exception>
  <onWhen>
    <simple>${header.user} != null</simple>
  </onWhen>
  <to uri="activemq:error_user_queue"/>
</onException>

<onException redeliveryPolicyRef="twoRedeliveries">
  <exception>com.mycompany.MyUserException</exception>
  <to uri="activemq:error_queue"/>
</onException>
```

### Handling exceptions

By default, when an exception is raised in the middle of a route, processing of the current exchange is interrupted and the thrown exception is propagated back to the consumer endpoint at the start of the route. When an `onException` clause is triggered, the behavior is essentially the same, except that the `onException` clause performs some processing before the thrown exception is propagated back.

But this default behavior is *not* the only way to handle an exception. The `onException` provides various options to modify the exception handling behavior, as follows:

- **the section called “Suppressing exception rethrow”—**you have the option of suppressing the rethrown exception after the `onException` clause has completed. In other words, in this case the exception does *not* propagate back to the consumer endpoint at the start of the route.

- **the section called “Continuing processing”—**you have the option of resuming normal processing of the exchange from the point where the exception originally occurred. Implicitly, this approach also suppresses the rethrown exception.

- **the section called “Sending a response”—**in the special case where the consumer endpoint at the start of the route expects a reply (that is, having an `InOut` MEP), you might prefer to construct a custom fault reply message, rather than propagating the exception back to the consumer endpoint.

### Suppressing exception rethrow

To prevent the current exception from being rethrown and propagated back to the consumer endpoint, you can set the `handled()` option to `true` in the Java DSL, as follows:

```java
// of fallback when the above did not match.
// Notice: The order how we have defined these onException is
// important as Camel will resolve in the same order as they
// have been defined
onException(MyUserException.class)
  .maximumRedeliveries(2)
  .to(ERROR_QUEUE);
```

```xml
<redeliveryPolicyProfile id="twoRedeliveries" maximumRedeliveries="2"/>

<redeliveryPolicyProfile id="twoRedeliveries" maximumRedeliveries="2"/>

<onException redeliveryPolicyRef="twoRedeliveries">
  <exception>com.mycompany.MyUserException</exception>
  <onWhen>
    <simple>${header.user} != null</simple>
  </onWhen>
  <to uri="activemq:error_user_queue"/>
</onException>

<onException redeliveryPolicyRef="twoRedeliveries">
  <exception>com.mycompany.MyUserException</exception>
  <to uri="activemq:error_queue"/>
</onException>
```
In the Java DSL, the argument to the `handled()` option can be of boolean type, of `Predicate` type, or of `Expression` type (where any non-boolean expression is interpreted as `true`, if it evaluates to a non-null value).

The same route can be configured to suppress the rethrown exception in the XML DSL, using the `handled` element, as follows:

```xml
<onException>
    <exception>com.mycompany.ValidationException</exception>
    <handled>
        <constant>true</constant>
    </handled>
    <to uri="activemq:validationFailed"/>
</onException>
```

**Continuing processing**

To continue processing the current message from the point in the route where the exception was originally thrown, you can set the `continued` option to `true` in the Java DSL, as follows:

```java
onException(ValidationException.class)
    .continued(true);
```

In the Java DSL, the argument to the `continued()` option can be of boolean type, of `Predicate` type, or of `Expression` type (where any non-boolean expression is interpreted as `true`, if it evaluates to a non-null value).

The same route can be configured in the XML DSL, using the `continued` element, as follows:

```xml
<onException>
    <exception>com.mycompany.ValidationException</exception>
    <continued>
        <constant>true</constant>
    </continued>
</onException>
```

**Sending a response**

When the consumer endpoint that starts a route expects a reply, you might prefer to construct a custom fault reply message, instead of simply letting the thrown exception propagate back to the consumer. There are two essential steps you need to follow in this case: suppress the rethrown exception using the `handled` option; and populate the exchange's `Out` message slot with a custom fault message.

For example, the following Java DSL fragment shows how to send a reply message containing the text string, *Sorry*, whenever the `MyFunctionalException` exception occurs:

```java
onException(MyFunctionalException.class)
    .handled(true)
    .to("activemq:validationFailed");
```
If you are sending a fault response to the client, you will often want to incorporate the text of the exception message in the response. You can access the text of the current exception message using the `exceptionMessage()` builder method. For example, you can send a reply containing just the text of the exception message whenever the `MyFunctionalException` exception occurs, as follows:

```java
// we catch MyFunctionalException and want to mark it as handled (= no failure returned to client)
// but we want to return a fixed text response, so we transform OUT body as Sorry.
onException(MyFunctionalException.class)
    .handled(true)
    .transform().constant("Sorry");
```

The exception message text is also accessible from the Simple language, through the `exception.message` variable. For example, you could embed the current exception text in a reply message, as follows:

```java
// we catch MyFunctionalException and want to mark it as handled (= no failure returned to client)
// but we want to return a fixed text response, so we transform OUT body and return the exception message
onException(MyFunctionalException.class)
    .handled(true)
    .transform(exceptionMessage());
```

The preceding `onException` clause can be expressed in XML DSL as follows:

```xml
<onException>
    <exception>com.mycompany.MyFunctionalException</exception>
    <handled>
        <constant>true</constant>
    </handled>
    <transform>
        <simple>Error reported: ${exception.message} - cannot process this message.</simple>
    </transform>
</onException>
```

Exception thrown while handling an exception

An exception that gets thrown while handling an existing exception (in other words, one that gets thrown in the middle of processing an `onException` clause) is handled in a special way. Such an exception is handled by the special fallback exception handler, which handles
the exception as follows:

- All existing exception handlers are ignored and processing fails immediately.
- The new exception is logged.
- The new exception is set on the exchange object.

The simple strategy avoids complex failure scenarios which could otherwise end up with an onException clause getting locked into an infinite loop.

**Scopes**

The onException clauses can be effective in either of the following scopes:

- **RouteBuilder scope**—onException clauses defined as standalone statements inside a RouteBuilder.configure() method affect all of the routes defined in that RouteBuilder instance. On the other hand, these onException clauses have no effect whatsoever on routes defined inside any other RouteBuilder instance. The onException clauses must appear before the route definitions.

  All of the examples up to this point are defined using the RouteBuilder scope.

- **Route scope**—onException clauses can also be embedded directly within a route. These onException clauses affect only the route in which they are defined.

**Route scope**

You can embed an onException clause anywhere inside a route definition, but you must terminate the embedded onException clause using the end() DSL command.

For example, you can define an embedded onException clause in the Java DSL, as follows:

```java
// Java
from("direct:start")
 .onException(OrderFailedException.class)
 .maximumRedeliveries(1)
 .handled(true)
 .beanRef("orderService", "orderFailed")
 .to("mock:error")
 .end()
 .beanRef("orderService", "handleOrder")
 .to("mock:result");
```

You can define an embedded onException clause in the XML DSL, as follows:

```xml
<route errorHandlerRef="deadLetter">
  <from uri="direct:start"/>
  <onException>
    <exception>com.mycompany.OrderFailedException</exception>
    <redeliveryPolicy maximumRedeliveries="1"/>
    <handled>
      <constant>true</constant>
    </handled>
    <bean ref="orderService" method="orderFailed"/>
    <to uri="mock:error"/>
  </onException>
</route>
```
2.3.2. Error Handler

Overview

The `errorHandler()` clause provides similar features to the `onException` clause, except that this mechanism is not able to discriminate between different exception types. The `errorHandler()` clause is the original exception handling mechanism provided by Apache Camel and was available before the `onException` clause was implemented.

Java DSL example

The `errorHandler()` clause is defined in a `RouteBuilder` class and applies to all of the routes in that `RouteBuilder` class. It is triggered whenever an exception of any kind occurs in one of the applicable routes. For example, to define an error handler that routes all failed exchanges to the ActiveMQ `deadLetter` queue, you can define a `RouteBuilder` as follows:

```java
public class MyRouteBuilder extends RouteBuilder {
    public void configure() {
        errorHandler(deadLetterChannel("activemq:deadLetter"));

        // The preceding error handler applies
        // to all of the following routes:
        from("activemq:orderQueue")
            .to("pop3://fulfillment@acme.com");
        from("file:src/data?noop=true")
            .to("file:target/messages");
        // ...
    }
}
```

Redirection to the dead letter channel will not occur, however, until all attempts at redelivery have been exhausted.

XML DSL example

In the XML DSL, you define an error handler within a `camelContext` scope using the `errorHandler` element. For example, to define an error handler that routes all failed exchanges to the ActiveMQ `deadLetter` queue, you can define an `errorHandler` element as follows:

```xml
<beans xmlns="http://www.springframework.org/schema/beans"
    xmlns:camel="http://camel.apache.org/schema/spring"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="
        http://www.springframework.org/schema/beans
        http://www.springframework.org/schema/beans/spring-beans-2.0.xsd
        http://camel.apache.org/schema/spring
        http://camel.apache.org/schema/spring/camel-spring.xsd">
```
Types of error handler

Table 2.1, “Error Handler Types” provides an overview of the different types of error handler you can define.

<table>
<thead>
<tr>
<th>Java DSL Builder</th>
<th>XML DSL Type Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>defaultErrorHandler()</td>
<td>DefaultErrorHandler</td>
<td>Propagates exceptions back to the caller and supports the redelivery policy, but it does not support a dead letter queue.</td>
</tr>
<tr>
<td>deadLetterChannel()</td>
<td>DeadLetterChannel</td>
<td>Supports the same features as the default error handler and, in addition, supports a dead letter queue.</td>
</tr>
<tr>
<td>loggingErrorChannel()</td>
<td>LoggingErrorChannel</td>
<td>Logs the exception text whenever an exception occurs.</td>
</tr>
<tr>
<td>noErrorHandler()</td>
<td>NoErrorHandler</td>
<td>Dummy handler implementation that can be used to disable the error handler.</td>
</tr>
<tr>
<td>TransactionErrorHandler</td>

2.3.3. doTry, doCatch, and doFinally

Overview

To handle exceptions within a route, you can use a combination of the doTry, doCatch, and doFinally clauses, which handle exceptions in a similar way to Java's try, catch, and finally blocks.

Similarities between doCatch and Java catch

In general, the doCatch() clause in a route definition behaves in an analogous way to the catch() statement in Java code. In particular, the following features are supported by the doCatch() clause:

- **Multiple doCatch clauses**—you can have multiple doCatch clauses within a single doTry block. The doCatch clauses are tested in the order they appear, just like Java catch() statements. Apache Camel executes the first doCatch clause that matches the thrown exception.

  **NOTE**
  
  This algorithm is different from the exception matching algorithm used by the onException clause—see Section 2.3.1, “onException Clause” for details.

- **Rethrowing exceptions**—you can rethrow the current exception from within a doCatch clause using the handled sub-clause (see the section called “Rethrowing exceptions in doCatch”).

Special features of doCatch

There are some special features of the doCatch() clause, however, that have no analogue in the Java catch() statement. The following features are specific to doCatch():

- **Catching multiple exceptions**—the doCatch clause allows you to specify a list of exceptions to catch, in contrast to the Java catch() statement, which catches only one exception (see the section called “Example”).

- **Conditional catching**—you can catch an exception conditionally, by appending an onWhen sub-clause to the doCatch clause (see the section called “Conditional exception catching using onWhen”).

Example

The following example shows how to write a doTry block in the Java DSL, where the doCatch() clause will be executed, if either the IOException exception or the IllegalStateException exception are raised, and the doFinally() clause is always executed, irrespective of whether an exception is raised or not.

```java
from("direct:start")
  .doTry()
    .process(new ProcessorFail())
  .to("mock:result")
  .doCatch(IOException.class, IllegalStateException.class)
```

Red Hat JBoss Fuse 6.1 Apache Camel Development Guide

48
Or equivalently, in Spring XML:

```xml
<route>
    <from uri="direct:start"/>
    <!-- here the try starts. it's a try .. catch .. finally just as regular java code -->
    <doTry>
        <process ref="processorFail"/>
        <to uri="mock:result"/>
        <doCatch>
            <!-- catch multiple exceptions -->
            <exception>java.io.IOException</exception>
            <exception>java.lang.IllegalStateException</exception>
            <to uri="mock:catch"/>
        </doCatch>
    </doFinally>
</route>
```

### Rethrowing exceptions in doCatch

It is possible to rethrow an exception in a `doCatch()` clause by calling the `handled()` sub-clause with its argument set to `false`, as follows:

```java
from("direct:start")
    .doTry()
        .process(new ProcessorFail())
        .to("mock:result")
        .doCatch(IOException.class)
            // mark this as NOT handled, eg the caller will also get the exception
            .handled(false)
            .to("mock:io")
        .doCatch(Exception.class)
            // and catch all other exceptions
            .to("mock:error")
    .end();
```

In the preceding example, if the `IOException` is caught by `doCatch()`, the current exchange is sent to the `mock:io` endpoint, and then the `IOException` is rethrown. This gives the consumer endpoint at the start of the route (in the `from()` command) an opportunity to handle the exception as well.

The following example shows how to define the same route in Spring XML:

```xml
<route>
    <from uri="direct:start"/>
    <doTry>
```

49
A special feature of the Apache Camel `doCatch()` clause is that you can conditionalize the catching of exceptions based on an expression that is evaluated at run time. In other words, if you catch an exception using a clause of the form, `doCatch(ExceptionList).doWhen(Expression)`, an exception will only be caught, if the predicate expression, `Expression`, evaluates to `true` at run time.

For example, the following `doTry` block will catch the exceptions, `IOException` and `IllegalStateException`, only if the exception message contains the word, `Severe`:

```java
from("direct:start")
  .doTry()
    .process(new ProcessorFail())
    .to("mock:result")
  .doCatch(IOException.class, IllegalStateException.class)
    .onWhen(exceptionMessage().contains("Severe"))
      .to("mock:catch")
    .doCatch(CamelExchangeException.class)
      .to("mock:catchCamel")
    .doFinally()
      .to("mock:finally")
  .end();
```

Or equivalently, in Spring XML:

```xml
<route>
  <from uri="direct:start"/>
  <doTry>
    <process ref="processorFail"/>
    <to uri="mock:result"/>
    <doCatch>
      <exception>java.io.IOException</exception>
      <!-- mark this as NOT handled, eg the caller will also get the exception -->
      <handled>
        <constant>false</constant>
      </handled>
      <to uri="mock:io"/>
    </doCatch>
    <!-- and catch all other exceptions they are handled by default (ie handled = true) -->
    <doCatch>
      <exception>java.lang.Exception</exception>
      <to uri="mock:error"/>
    </doCatch>
  </doTry>
</route>
```
2.3.4. Propagating SOAP Exceptions

Overview

The Camel CXF component provides an integration with Apache CXF, enabling you to send and receive SOAP messages from Apache Camel endpoints. You can easily define Apache Camel endpoints in XML, which can then be referenced in a route using the endpoint’s bean ID. For more details, see CXF.

How to propagate stack trace information

It is possible to configure a CXF endpoint so that, when a Java exception is thrown on the server side, the stack trace for the exception is marshalled into a fault message and returned to the client. To enable this feature, set the dataFormat to PAYLOAD and set the faultStackTraceEnabled property to true in the cxfEndpoint element, as follows:

```
<simple>${exception.message} contains 'Severe'</simple>
</onWhen>
<to uri="mock:catch"/>
</doCatch>
<doCatch>
  <exception>org.apache.camel.CamelExchangeException</exception>
  <to uri="mock:catchCamel"/>
</doCatch>
<doFinally>
  <to uri="mock:finally"/>
</doFinally>
</doTry>
</route>
```

For security reasons, the stack trace does not include the causing exception (that is, the part of a stack trace that follows Caused by). If you want to include the causing exception in the stack trace, set the exceptionMessageCauseEnabled property to true in the cxfEndpoint element, as follows:

```
<cf:cxfEndpoint id="router" address="http://localhost:9002/TestMessage"
  wsdlURL="ship.wsdl"
  endpointName="s:TestSoapEndpoint"
  serviceName="s:TestService"
  xmlns:s="http://test">
  <cxf:properties>
    <!-- enable sending the stack trace back to client; the default value is false-->
    <entry key="faultStackTraceEnabled" value="true" />
    <entry key="dataFormat" value="PAYLOAD" />
  </cxf:properties>
</cf:cxfEndpoint>
```
2.4. BEAN INTEGRATION

Overview

Bean integration provides a general purpose mechanism for processing messages using arbitrary Java objects. By inserting a bean reference into a route, you can call an arbitrary method on a Java object, which can then access and modify the incoming exchange. The mechanism that maps an exchange's contents to the parameters and return values of a bean method is known as parameter binding. Parameter binding can use any combination of the following approaches in order to initialize a method's parameters:

- **Conventional method signatures** — If the method signature conforms to certain conventions, the parameter binding can use Java reflection to determine what parameters to pass.

- **Annotations and dependency injection** — For a more flexible binding mechanism, employ Java annotations to specify what to inject into the method's arguments. This dependency injection mechanism relies on Spring 2.5 component scanning. Normally, if you are deploying your Apache Camel application into a Spring container, the dependency injection mechanism will work automatically.

- **Explicitly specified parameters** — You can specify parameters explicitly (either as constants or using the Simple language), at the point where the bean is invoked.

Bean registry

Beans are made accessible through a bean registry, which is a service that enables you to look up beans using either the class name or the bean ID as a key. The way that you create an entry in the bean registry depends on the underlying framework—for example, plain Java, Spring, Guice, or Blueprint. Registry entries are usually created implicitly (for example, when you instantiate a Spring bean in a Spring XML file).
Registry plug-in strategy

Apache Camel implements a plug-in strategy for the bean registry, defining an integration layer for accessing beans which makes the underlying registry implementation transparent. Hence, it is possible to integrate Apache Camel applications with a variety of different bean registries, as shown in Table 2.2, “Registry Plug-Ins”.

Table 2.2. Registry Plug-Ins

<table>
<thead>
<tr>
<th>Registry Implementation</th>
<th>Camel Component with Registry Plug-In</th>
</tr>
</thead>
<tbody>
<tr>
<td>Spring bean registry</td>
<td>camel-spring</td>
</tr>
<tr>
<td>Guice bean registry</td>
<td>camel-guice</td>
</tr>
<tr>
<td>Blueprint bean registry</td>
<td>camel-blueprint</td>
</tr>
<tr>
<td>OSGi service registry</td>
<td>deployed in OSGi container</td>
</tr>
</tbody>
</table>

Normally, you do not have to worry about configuring bean registries, because the relevant bean registry is automatically installed for you. For example, if you are using the Spring framework to define your routes, the Spring ApplicationContextRegistry plug-in is automatically installed in the current CamelContext instance.

Deployment in an OSGi container is a special case. When an Apache Camel route is deployed into the OSGi container, the CamelContext automatically sets up a registry chain for resolving bean instances: the registry chain consists of the OSGi registry, followed by the Blueprint (or Spring) registry.

Accessing a bean created in Java

To process exchange objects using a Java bean (which is a plain old Java object or POJO), use the bean() processor, which binds the inbound exchange to a method on the Java object. For example, to process inbound exchanges using the class, MyBeanProcessor, define a route like the following:

```java
from("file:data/inbound")
  .bean(MyBeanProcessor.class, "processBody")
  .to("file:data/outbound");
```

Where the bean() processor creates an instance of MyBeanProcessor type and invokes the processBody() method to process inbound exchanges. This approach is adequate if you only want to access the MyBeanProcessor instance from a single route. However, if you want to access the same MyBeanProcessor instance from multiple routes, use the variant of bean() that takes the Object type as its first argument. For example:

```java
MyBeanProcessor myBean = new MyBeanProcessor();
from("file:data/inbound")
  .bean(myBean, "processBody")
  .to("file:data/outbound");
```
Accessing overloaded bean methods

If a bean defines overloaded methods, you can choose which of the overloaded methods to invoke by specifying the method name along with its parameter types. For example, if the MyBeanProcessor class has two overloaded methods, processBody(String) and processBody(String, String), you can invoke the latter overloaded method as follows:

```java
from("file:data/inbound")
  .bean(MyBeanProcessor.class, "processBody(String,String)")
  .to("file:data/outbound");
```

Alternatively, if you want to identify a method by the number of parameters it takes, rather than specifying the type of each parameter explicitly, you can use the wildcard character, *. For example, to invoke a method named processBody that takes two parameters, irrespective of the exact type of the parameters, invoke the bean() processor as follows:

```java
from("file:data/inbound")
  .bean(MyBeanProcessor.class, "processBody(*,*)")
  .to("file:data/outbound");
```

When specifying the method, you can use either a simple unqualified type name—for example, processBody(Exchange)—or a fully qualified type name—for example, processBody(org.apache.camel.Exchange).

**NOTE**

In the current implementation, the specified type name must be an exact match of the parameter type. Type inheritance is not taken into account.

Specify parameters explicitly

You can specify parameter values explicitly, when you call the bean method. The following simple type values can be passed:

- Boolean: true or false.
- Numeric: 123, 7, and so on.
- String: 'In single quotes' or "In double quotes".
- Null object: null.

The following example shows how you can mix explicit parameter values with type specifiers in the same method invocation:

```java
from("file:data/inbound")
  .bean(MyBeanProcessor.class, "processBody(String, 'Sample string value', true, 7")
  .to("file:data/outbound");
```
In the preceding example, the value of the first parameter would presumably be determined by a parameter binding annotation (see the section called “Basic annotations”).

In addition to the simple type values, you can also specify parameter values using the Simple language (Chapter 27, The Simple Language). This means that the full power of the Simple language is available when specifying parameter values. For example, to pass the message body and the value of the title header to a bean method:

```java
from("file:data/inbound")
    .bean(MyBeanProcessor.class,
        "processBodyAndHeader(${body},${header.title})")
    .to("file:data/outbound");
```

You can also pass the entire header hash map as a parameter. For example, in the following example, the second method parameter must be declared to be of type `java.util.Map`:

```java
from("file:data/inbound")
    .bean(MyBeanProcessor.class,
        "processBodyAndAllHeaders(${body},${header})")
    .to("file:data/outbound");
```

**Basic method signatures**

To bind exchanges to a bean method, you can define a method signature that conforms to certain conventions. In particular, there are two basic conventions for method signatures:

- the section called “Method signature for processing message bodies”;
- the section called “Method signature for processing exchanges”.

**Method signature for processing message bodies**

If you want to implement a bean method that accesses or modifies the incoming message body, you must define a method signature that takes a single `String` argument and returns a `String` value. For example:

```java
// Java
package com.acme;

public class MyBeanProcessor {
    public String processBody(String body) {
        // Do whatever you like to 'body'...
        return newBody;
    }
}
```

**Method signature for processing exchanges**

For greater flexibility, you can implement a bean method that accesses the incoming exchange. This enables you to access or modify all headers, bodies, and exchange properties. For processing exchanges, the method signature takes a single `org.apache.camel.Exchange` parameter and returns `void`. For example:
Instead of creating a bean instance in Java, you can create an instance using Spring XML. In fact, this is the only feasible approach if you are defining your routes in XML. To define a bean in XML, use the standard Spring `bean` element. The following example shows how to create an instance of `MyBeanProcessor`:

```xml
<bean id="myBeanId" class="com.acme.MyBeanProcessor"/>
```

It is also possible to pass data to the bean's constructor arguments using Spring syntax. For full details of how to use the Spring `bean` element, see The IoC Container from the Spring reference guide.

When you create an object instance using the `bean` element, you can reference it later using the bean's ID (the value of the `bean` element's `id` attribute). For example, given the `bean` element with ID equal to `myBeanId`, you can reference the bean in a Java DSL route using the `beanRef()` processor, as follows:

```java
from("file:data/inbound").beanRef("myBeanId", "processBody").to("file:data/outbound");
```

Where the `beanRef()` processor invokes the `MyBeanProcessor.processBody()` method on the specified bean instance. You can also invoke the bean from within a Spring XML route, using the Camel schema's `bean` element. For example:

```xml
<camelContext id="CamelContextID" xmlns="http://camel.apache.org/schema/spring">
    <route>
        <from uri="file:data/inbound"/>
        <bean ref="myBeanId" method="processBody"/>
        <to uri="file:data/outbound"/>
    </route>
</camelContext>
```

### Parameter binding annotations

The basic parameter bindings described in the section called “Basic method signatures” might not always be convenient to use. For example, if you have a legacy Java class that performs some data manipulation, you might want to extract data from an inbound exchange and map it to the arguments of an existing method signature. For this kind of parameter binding, Apache Camel provides the following kinds of Java annotation:
Basic annotations

Table 2.3, “Basic Bean Annotations” shows the annotations from the `org.apache.camel` Java package that you can use to inject message data into the arguments of a bean method.

Table 2.3. Basic Bean Annotations

<table>
<thead>
<tr>
<th>Annotation</th>
<th>Meaning</th>
<th>Parameter?</th>
</tr>
</thead>
<tbody>
<tr>
<td>@Attachments</td>
<td>Binds to a list of attachments.</td>
<td></td>
</tr>
<tr>
<td>@Body</td>
<td>Binds to an inbound message body.</td>
<td></td>
</tr>
<tr>
<td>@Header</td>
<td>Binds to an inbound message header.</td>
<td>String name of the header.</td>
</tr>
<tr>
<td>@Headers</td>
<td>Binds to a <code>java.util.Map</code> of the inbound message headers.</td>
<td></td>
</tr>
<tr>
<td>@OutHeaders</td>
<td>Binds to a <code>java.util.Map</code> of the outbound message headers.</td>
<td></td>
</tr>
<tr>
<td>@Property</td>
<td>Binds to a named exchange property.</td>
<td>String name of the property.</td>
</tr>
<tr>
<td>@Properties</td>
<td>Binds to a <code>java.util.Map</code> of the exchange properties.</td>
<td></td>
</tr>
</tbody>
</table>

For example, the following class shows you how to use basic annotations to inject message data into the `processExchange()` method arguments.

```java
// Java
import org.apache.camel.*;

public class MyBeanProcessor {
    public void processExchange(
            @Header(name="user") String user,
            @Body String body,
            Exchange exchange
    ) {
        // Do whatever you like to 'exchange'...
```
Notice how you are able to mix the annotations with the default conventions. As well as injecting the annotated arguments, the parameter binding also automatically injects the exchange object into the `org.apache.camel.Exchange` argument.

### Expression language annotations

The expression language annotations provide a powerful mechanism for injecting message data into a bean method's arguments. Using these annotations, you can invoke an arbitrary script, written in the scripting language of your choice, to extract data from an inbound exchange and inject the data into a method argument. Table 2.4, “Expression Language Annotations” shows the annotations from the `org.apache.camel.language` package (and sub-packages, for the non-core annotations) that you can use to inject message data into the arguments of a bean method.

<table>
<thead>
<tr>
<th>Annotation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>@Bean</td>
<td>Injects a Bean expression.</td>
</tr>
<tr>
<td>@Constant</td>
<td>Injects a Constant expression.</td>
</tr>
<tr>
<td>@EL</td>
<td>Injects an EL expression.</td>
</tr>
<tr>
<td>@Groovy</td>
<td>Injects a Groovy expression.</td>
</tr>
<tr>
<td>@Header</td>
<td>Injects a Header expression.</td>
</tr>
<tr>
<td>@JavaScript</td>
<td>Injects a JavaScript expression.</td>
</tr>
<tr>
<td>@OGNL</td>
<td>Injects an OGNL expression.</td>
</tr>
<tr>
<td>@PHP</td>
<td>Injects a PHP expression.</td>
</tr>
<tr>
<td>@Python</td>
<td>Injects a Python expression.</td>
</tr>
<tr>
<td>@Ruby</td>
<td>Injects a Ruby expression.</td>
</tr>
<tr>
<td>@Simple</td>
<td>Injects a Simple expression.</td>
</tr>
<tr>
<td>@XPath</td>
<td>Injects an XPath expression.</td>
</tr>
<tr>
<td>@XQuery</td>
<td>Injects an XQuery expression.</td>
</tr>
</tbody>
</table>

For example, the following class shows you how to use the `@XPath` annotation to extract a username and a password from the body of an incoming message in XML format:
The `@Bean` annotation is a special case, because it enables you to inject the result of invoking a registered bean. For example, to inject a correlation ID into a method argument, you can use the `@Bean` annotation to invoke an ID generator class, as follows:

```java
// Java
import org.apache.camel.language.*;

public class MyBeanProcessor {
    public void processCorrelatedMsg(
        @Bean("myCorrIdGenerator") String corrId,
        @Body String body
    ) {
        // Check the user/pass credentials...
        ...
    }
}
```

Where the string, `myCorrIdGenerator`, is the bean ID of the ID generator instance. The ID generator class can be instantiated using the Spring `bean` element, as follows:

```xml
<beans ...>
    ...  
    <bean id="myCorrIdGenerator" class="com.acme.MyIdGenerator"/>
</beans>
```

Where the `MySimpleIdGenerator` class could be defined as follows:

```java
// Java
package com.acme;

public class MyIdGenerator {
    private UserManager userManager;

    public String generate(
        @Header(name = "user") String user,
        @Body String payload
    ) throws Exception {
        User user = userManager.lookupUser(user);
        String userId = user.getPrimaryId();
        String id = userId + generateHashCodeForPayload(payload);
    }
}
```
Notice that you can also use annotations in the referenced bean class, `MyIdGenerator`. The only restriction on the `generate()` method signature is that it must return the correct type to inject into the argument annotated by `@Bean`. Because the `@Bean` annotation does not let you specify a method name, the injection mechanism simply invokes the first method in the referenced bean that has the matching return type.

**NOTE**

Some of the language annotations are available in the core component (`@Bean`, `@Constant`, `@Simple`, and `@XPath`). For non-core components, however, you will have to make sure that you load the relevant component. For example, to use the OGNL script, you must load the `camel-ognl` component.

**Inherited annotations**

Parameter binding annotations can be inherited from an interface or from a superclass. For example, if you define a Java interface with a `Header` annotation and a `Body` annotation, as follows:

```java
// Java
import org.apache.camel.*;

public interface MyBeanProcessorIntf {
    void processExchange(
        @Header(name="user") String user,
        @Body String body,
        Exchange exchange
    );
}
```

The overloaded methods defined in the implementation class, `MyBeanProcessor`, now inherit the annotations defined in the base interface, as follows:

```java
// Java
import org.apache.camel.*;

public class MyBeanProcessor implements MyBeanProcessorIntf {
    public void processExchange(
        String user, // Inherits Header annotation
        String body, // Inherits Body annotation
        Exchange exchange
    ) {
        ...
    }
}
```

**Interface implementations**

The class that implements a Java interface is often `protected`, `private` or in `package-only` scope. If you try to invoke a method on an implementation class that is restricted in this
way, the bean binding falls back to invoking the corresponding interface method, which is publicly accessible.

For example, consider the following public `BeanIntf` interface:

```java
// Java
public interface BeanIntf {
    void processBodyAndHeader(String body, String title);
}
```

Where the `BeanIntf` interface is implemented by the following protected `BeanIntfImpl` class:

```java
// Java
protected class BeanIntfImpl implements BeanIntf {
    void processBodyAndHeader(String body, String title) {
        ...
    }
}
```

The following bean invocation would fall back to invoking the public `BeanIntf.processBodyAndHeader` method:

```java
from("file:data/inbound")
    .bean(BeanIntfImpl.class, "processBodyAndHeader(${body},
    ${header.title})")
    .to("file:data/outbound");
```

**Invoking static methods**

Bean integration has the capability to invoke static methods *without* creating an instance of the associated class. For example, consider the following Java class that defines the static method, `changeSomething()`:

```java
// Java
... public final class MyStaticClass {
    private MyStaticClass() { }

    public static String changeSomething(String s) {
        if ("Hello World".equals(s)) {
            return "Bye World";
        }
        return null;
    }

    public void doSomething() {
        // noop
    }
}
```

You can use bean integration to invoke the static `changeSomething` method, as follows:
from("direct:a")
    .bean(MyStaticClass.class, "changeSomething")
    .to("mock:a");

Note that, although this syntax looks identical to the invocation of an ordinary function, bean integration exploits Java reflection to identify the method as static and proceeds to invoke the method without instantiating MyStaticClass.

**Invoking an OSGi service**

In the special case where a route is deployed into a Red Hat JBoss Fuse container, it is possible to invoke an OSGi service directly using bean integration. For example, assuming that one of the bundles in the OSGi container has exported the service, org.fusesource.example.HelloWorldOsgiService, you could invoke the sayHello method using the following bean integration code:

```
from("file:data/inbound")
    .bean(org.fusesource.example.HelloWorldOsgiService.class, "sayHello")
    .to("file:data/outbound");
```

You could also invoke the OSGi service from within a Spring or Blueprint XML file, using the bean component, as follows:

```
<to uri="bean:org.fusesource.example.HelloWorldOsgiService?method=sayHello"/>
```

The way this works is that Apache Camel sets up a chain of registries when it is deployed in the OSGi container. First of all, it looks up the specified class name in the OSGi service registry; if this lookup fails, it then falls back to the local Spring DM or Blueprint registry.

**2.5. CREATING EXCHANGE INSTANCES**

**Overview**

When processing messages with Java code (for example, in a bean class or in a processor class), it is often necessary to create a fresh exchange instance. If you need to create an Exchange object, the easiest approach is to invoke the methods of the ExchangeBuilder class, as described here.

**ExchangeBuilder class**

The fully qualified name of the ExchangeBuilder class is as follows:

```
org.apache.camel.builder.ExchangeBuilder
```

The ExchangeBuilder exposes the static method, anExchange, which you can use to start building an exchange object.

**Example**
For example, the following code creates a new exchange object containing the message body string, **Hello World!**, and with headers containing username and password credentials:

```java
// Java
import org.apache.camel.Exchange;
import org.apache.camel.builder.ExchangeBuilder;
...
Exchange exch = ExchangeBuilder.anExchange(camelCtx)
    .withBody("Hello World!")
    .withHeader("username", "jdoe")
    .withHeader("password", "pass")
    .build();
```

### ExchangeBuilder methods

The **ExchangeBuilder** class supports the following methods:

- **ExchangeBuilder anExchange(CamelContext context)**
  
  (static method) Initiate building an exchange object.

- **Exchange build()**

  Build the exchange.

- **ExchangeBuilder withBody(Object body)**

  Set the message body on the exchange (that is, sets the exchange's *In* message body).

- **ExchangeBuilder withHeader(String key, Object value)**

  Set a header on the exchange (that is, sets a header on the exchange's *In* message).

- **ExchangeBuilder withPattern(ExchangePattern pattern)**

  Sets the exchange pattern on the exchange.

- **ExchangeBuilder withProperty(String key, Object value)**

  Sets a property on the exchange.

### 2.6. TRANSFORMING MESSAGE CONTENT

#### Abstract

Apache Camel supports a variety of approaches to transforming message content. In addition to a simple native API for modifying message content, Apache Camel supports integration with several different third-party libraries and transformation standards.

#### 2.6.1. Simple Message Transformations

**Overview**
The Java DSL has a built-in API that enables you to perform simple transformations on incoming and outgoing messages. For example, the rule shown in Example 2.1, “Simple Transformation of Incoming Messages” appends the text, World!, to the end of the incoming message body.

Example 2.1. Simple Transformation of Incoming Messages

```java
from("SourceURL").setBody(body().append(" World!")).to("TargetURL");
```

Where the setBody() command replaces the content of the incoming message's body.

API for simple transformations

You can use the following API classes to perform simple transformations of the message content in a router rule:

- org.apache.camel.model.ProcessorDefinition
- org.apache.camel.builder.Builder
- org.apache.camel.builder.ValueBuilder

ProcessorDefinition class

The org.apache.camel.model.ProcessorDefinition class defines the DSL commands you can insert directly into a router rule—for example, the setBody() command in Example 2.1, “Simple Transformation of Incoming Messages”. Table 2.5, “Transformation Methods from the ProcessorDefinition Class” shows the ProcessorDefinition methods that are relevant to transforming message content:

Table 2.5. Transformation Methods from the ProcessorDefinition Class

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Type convertBodyTo(Class type)</td>
<td>Converts the IN message body to the specified type.</td>
</tr>
<tr>
<td>Type removeFaultHeader(String name)</td>
<td>Adds a processor which removes the header on the FAULT message.</td>
</tr>
<tr>
<td>Type removeHeader(String name)</td>
<td>Adds a processor which removes the header on the IN message.</td>
</tr>
<tr>
<td>Type removeProperty(String name)</td>
<td>Adds a processor which removes the exchange property.</td>
</tr>
<tr>
<td>ExpressionClause&lt;ProcessorDefinition&lt;Type&gt;&gt; setBody()</td>
<td>Adds a processor which sets the body on the IN message.</td>
</tr>
<tr>
<td>Type setFaultBody(Expression expression)</td>
<td>Adds a processor which sets the body on the FAULT message.</td>
</tr>
</tbody>
</table>
### Type setFaultHeader(String name, Expression expression)

Adds a processor which sets the header on the FAULT message.

### ExpressionClause<ProcessorDefinition<Type>> setHeader(String name)

Adds a processor which sets the header on the IN message.

### Type setHeader(String name, Expression expression)

Adds a processor which sets the header on the IN message.

### ExpressionClause<ProcessorDefinition<Type>> setOutHeader(String name)

Adds a processor which sets the header on the OUT message.

### Type setOutHeader(String name, Expression expression)

Adds a processor which sets the header on the OUT message.

### ExpressionClause<ProcessorDefinition<Type>> setProperty(String name)

Adds a processor which sets the exchange property.

### Type setProperty(String name, Expression expression)

Adds a processor which sets the exchange property.

### ExpressionClause<ProcessorDefinition<Type>> transform()

Adds a processor which sets the body on the OUT message.

### Type transform(Expression expression)

Adds a processor which sets the body on the OUT message.

## Builder class

The `org.apache.camel.builder.Builder` class provides access to message content in contexts where expressions or predicates are expected. In other words, `Builder` methods are typically invoked in the arguments of DSL commands—for example, the `body()` command in Example 2.1, “Simple Transformation of Incoming Messages”. Table 2.6, “Methods from the Builder Class” summarizes the static methods available in the `Builder` class.

### Table 2.6. Methods from the Builder Class

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>static &lt;E extends Exchange&gt; ValueBuilder&lt;E&gt; body()</code></td>
<td>Returns a predicate and value builder for the inbound body on an exchange.</td>
</tr>
<tr>
<td><code>static &lt;E extends Exchange,T&gt; ValueBuilder&lt;E&gt; bodyAs(Class&lt;T&gt; type)</code></td>
<td>Returns a predicate and value builder for the inbound message body as a specific type.</td>
</tr>
<tr>
<td>Method</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------------------------------------------</td>
<td>----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>static &lt;E extends Exchange&gt; ValueBuilder&lt;E&gt; constant(Object value)</td>
<td>Returns a constant expression.</td>
</tr>
<tr>
<td>static &lt;E extends Exchange&gt; ValueBuilder&lt;E&gt; faultBody()</td>
<td>Returns a predicate and value builder for the fault body on an exchange.</td>
</tr>
<tr>
<td>static &lt;E extends Exchange&gt; ValueBuilder&lt;E&gt; faultBodyAs(Class&lt;T&gt; type)</td>
<td>Returns a predicate and value builder for the fault message body as a specific type.</td>
</tr>
<tr>
<td>static &lt;E extends Exchange&gt; ValueBuilder&lt;E&gt; header(String name)</td>
<td>Returns a predicate and value builder for headers on an exchange.</td>
</tr>
<tr>
<td>static &lt;E extends Exchange&gt; ValueBuilder&lt;E&gt; outBody()</td>
<td>Returns a predicate and value builder for the outbound body on an exchange.</td>
</tr>
<tr>
<td>static &lt;E extends Exchange&gt; ValueBuilder&lt;E&gt; outBodyAs(Class&lt;T&gt; type)</td>
<td>Returns a predicate and value builder for the outbound message body as a specific type.</td>
</tr>
<tr>
<td>static ValueBuilder property(String name)</td>
<td>Returns a predicate and value builder for properties on an exchange.</td>
</tr>
<tr>
<td>static ValueBuilder regexReplaceAll(Expression content, String regex, Expression replacement)</td>
<td>Returns an expression that replaces all occurrences of the regular expression with the given replacement.</td>
</tr>
<tr>
<td>static ValueBuilder regexReplaceAll(Expression content, String regex, String replacement)</td>
<td>Returns an expression that replaces all occurrences of the regular expression with the given replacement.</td>
</tr>
<tr>
<td>static ValueBuilder sendTo(String uri)</td>
<td>Returns an expression processing the exchange to the given endpoint uri.</td>
</tr>
<tr>
<td>static &lt;E extends Exchange&gt; ValueBuilder&lt;E&gt; systemProperty(String name)</td>
<td>Returns an expression for the given system property.</td>
</tr>
<tr>
<td>static &lt;E extends Exchange&gt; ValueBuilder&lt;E&gt; systemProperty(String name, String defaultValue)</td>
<td>Returns an expression for the given system property.</td>
</tr>
</tbody>
</table>

**ValueBuilder class**

The `org.apache.camel.builder.ValueBuilder` class enables you to modify values
returned by the Builder methods. In other words, the methods in ValueBuilder provide a simple way of modifying message content. Table 2.7, “Modifier Methods from the ValueBuilder Class” summarizes the methods available in the ValueBuilder class. That is, the table shows only the methods that are used to modify the value they are invoked on (for full details, see the API Reference documentation).

Table 2.7. Modifier Methods from the ValueBuilder Class

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ValueBuilder&lt;E&gt; append(Object value)</td>
<td>Appends the string evaluation of this expression with the given value.</td>
</tr>
<tr>
<td>Predicate contains(Object value)</td>
<td>Create a predicate that the left hand expression contains the value of the right hand expression.</td>
</tr>
<tr>
<td>ValueBuilder&lt;E&gt; convertTo(Class type)</td>
<td>Converts the current value to the given type using the registered type converters.</td>
</tr>
<tr>
<td>ValueBuilder&lt;E&gt; convertToString()</td>
<td>Converts the current value a String using the registered type converters.</td>
</tr>
<tr>
<td>Predicate endsWith(Object value)</td>
<td></td>
</tr>
<tr>
<td>&lt;T&gt; T evaluate(Exchange exchange, Class&lt;T&gt; type)</td>
<td></td>
</tr>
<tr>
<td>Predicate in(Object... values)</td>
<td></td>
</tr>
<tr>
<td>Predicate in(Predicate... predicates)</td>
<td></td>
</tr>
<tr>
<td>Predicate isEqualTo(Object value)</td>
<td>Returns true, if the current value is equal to the given value argument.</td>
</tr>
<tr>
<td>Predicate isGreaterThan(Object value)</td>
<td>Returns true, if the current value is greater than the given value argument.</td>
</tr>
<tr>
<td>Predicate isGreaterThanOrEqualTo(Object value)</td>
<td>Returns true, if the current value is greater than or equal to the given value argument.</td>
</tr>
<tr>
<td>Predicate isInstanceOf(Class type)</td>
<td>Returns true, if the current value is an instance of the given type.</td>
</tr>
<tr>
<td>Predicate isLessThan(Object value)</td>
<td>Returns true, if the current value is less than the given value argument.</td>
</tr>
<tr>
<td>Method</td>
<td>Description</td>
</tr>
<tr>
<td>--------</td>
<td>-------------</td>
</tr>
<tr>
<td>Predicate isLessThanOrEqualTo(Object value)</td>
<td>Returns true, if the current value is less than or equal to the given value argument.</td>
</tr>
<tr>
<td>Predicate isNotEqualTo(Object value)</td>
<td>Returns true, if the current value is not equal to the given value argument.</td>
</tr>
<tr>
<td>Predicate isNotNull()</td>
<td>Returns true, if the current value is not null.</td>
</tr>
<tr>
<td>Predicate isNull()</td>
<td>Returns true, if the current value is null.</td>
</tr>
<tr>
<td>Predicate matches(Expression expression)</td>
<td></td>
</tr>
<tr>
<td>Predicate not(Predicate predicate)</td>
<td>Negates the predicate argument.</td>
</tr>
<tr>
<td>ValueBuilder prepend(Object value)</td>
<td>Prepends the string evaluation of this expression to the given value.</td>
</tr>
<tr>
<td>Predicate regex(String regex)</td>
<td></td>
</tr>
<tr>
<td>ValueBuilder&lt;String&gt; regexReplaceAll(String regex, Expression&lt;String&gt; replacement)</td>
<td>Replaces all occurrences of the regular expression with the given replacement.</td>
</tr>
<tr>
<td>ValueBuilder&lt;String&gt; regexReplaceAll(String regex, String replacement)</td>
<td>Replaces all occurrences of the regular expression with the given replacement.</td>
</tr>
<tr>
<td>ValueBuilder&lt;String&gt; regexTokenize(String regex)</td>
<td>Tokenizes the string conversion of this expression using the given regular expression.</td>
</tr>
<tr>
<td>ValueBuilder sort(Comparator comparator)</td>
<td>Sorts the current value using the given comparator.</td>
</tr>
<tr>
<td>Predicate startsWith(Object value)</td>
<td>Returns true, if the current value matches the string value of the value argument.</td>
</tr>
<tr>
<td>ValueBuilder&lt;String&gt; tokenize()</td>
<td>Tokenizes the string conversion of this expression using the comma token separator.</td>
</tr>
<tr>
<td>ValueBuilder&lt;String&gt; tokenize(String token)</td>
<td>Tokenizes the string conversion of this expression using the given token separator.</td>
</tr>
</tbody>
</table>

2.6.2. Marshalling and Unmarshalling

Java DSL commands
You can convert between low-level and high-level message formats using the following commands:

- `marshal()` — Converts a high-level data format to a low-level data format.
- `unmarshal()` — Converts a low-level data format to a high-level data format.

**Data formats**

Apache Camel supports marshalling and unmarshalling of the following data formats:

- Java serialization
- JAXB
- XMLBeans
- XStream

**Java serialization**

Enables you to convert a Java object to a blob of binary data. For this data format, unmarshalling converts a binary blob to a Java object, and marshalling converts a Java object to a binary blob. For example, to read a serialized Java object from an endpoint, `SourceURL`, and convert it to a Java object, you use a rule like the following:

```java
from("SourceURL").unmarshal().serialization().
    .<FurtherProcessing>.to("TargetURL");
```

Or alternatively, in Spring XML:

```xml
<camelContext id="serialization" xmlns="http://camel.apache.org/schema/spring">
    <route>
        <from uri="SourceURL"/>
        <unmarshal>
            <serialization/>
        </unmarshal>
        <to uri="TargetURL"/>
    </route>
</camelContext>
```

**JAXB**

Provides a mapping between XML schema types and Java types (see [https://jaxb.dev.java.net/](https://jaxb.dev.java.net/)). For JAXB, unmarshalling converts an XML data type to a Java object, and marshalling converts a Java object to an XML data type. Before you can use JAXB data formats, you must compile your XML schema using a JAXB compiler to generate the Java classes that represent the XML data types in the schema. This is called binding the schema. After the schema is bound, you define a rule to unmarshal XML data to a Java object, using code like the following:

```java
```
where `GeneratedPackagename` is the name of the Java package generated by the JAXB compiler, which contains the Java classes representing your XML schema.

Or alternatively, in Spring XML:

```
<camelContext id="jaxb" xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="SourceURL"/>
    <unmarshal>
      <jaxb prettyPrint="true" contextPath="GeneratedPackagename"/>
    </unmarshal>
    <to uri="TargetURL"/>
  </route>
</camelContext>
```

**XMLBeans**

Provides an alternative mapping between XML schema types and Java types (see [http://xmlbeans.apache.org/](http://xmlbeans.apache.org/)). For XMLBeans, unmarshalling converts an XML data type to a Java object and marshalling converts a Java object to an XML data type. For example, to unmarshal XML data to a Java object using XMLBeans, you use code like the following:

```
from("SourceURL").unmarshal().xmlBeans()
  .<FurtherProcessing>.to("TargetURL");
```

Or alternatively, in Spring XML:

```
<camelContext id="xmlBeans" xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="SourceURL"/>
    <unmarshal>
      <xmlBeans prettyPrint="true"/>
    </unmarshal>
    <to uri="TargetURL"/>
  </route>
</camelContext>
```

**XStream**

Provides another mapping between XML types and Java types (see [http://xstream.codehaus.org/](http://xstream.codehaus.org/)). XStream is a serialization library (like Java serialization), enabling you to convert any Java object to XML. For XStream, unmarshalling converts an XML data type to a Java object, and marshalling converts a Java object to an XML data type.

```
from("SourceURL").unmarshal().xstream()
  .<FurtherProcessing>.to("TargetURL");
```

**NOTE**

The XStream data format is currently not supported in Spring XML.
2.6.3. Endpoint Bindings

What is a binding?

In Apache Camel, a binding is a way of wrapping an endpoint in a contract—for example, by applying a Data Format, a Content Enricher or a validation step. A condition or transformation is applied to the messages coming in, and a complementary condition or transformation is applied to the messages going out.

DataFormatBinding

The **DataFormatBinding** class is useful for the specific case where you want to define a binding that marshals and unmarshals a particular data format (see Section 2.6.2, “Marshalling and Unmarshalling”). In this case, all that you need to do to create a binding is to create a **DataFormatBinding** instance, passing a reference to the relevant data format in the constructor.

For example, the XML DSL snippet in Example 2.2, “JAXB Binding” shows a binding (with ID, **jaxb**) that is capable of marshalling and unmarshalling the JAXB data format when it is associated with an Apache Camel endpoint:

```
Example 2.2. JAXB Binding

<beans ... >
  ...
  <bean id="jaxb"
    class="org.apache.camel.processor.binding.DataFormatBinding">
    <constructor-arg ref="jaxbformat"/>
  </bean>

  <bean id="jaxbformat"
    class="org.apache.camel.model.dataformat.JaxbDataFormat">
    <property name="prettyPrint" value="true"/>
    <property name="contextPath" value="org.apache.camel.example"/>
  </bean>

</beans>
```

Associating a binding with an endpoint

The following alternatives are available for associating a binding with an endpoint:

- the section called “Binding URI”
- the section called “BindingComponent”

Binding URI

To associate a binding with an endpoint, you can prefix the endpoint URI with **binding:** **NameOfBinding**, where **NameOfBinding** is the bean ID of the binding (for example, the ID of a binding bean created in Spring XML).
For example, the following example shows how to associate ActiveMQ endpoints with the JAXB binding defined in Example 2.2, “JAXB Binding”.

```xml
<beans ...>
  ...
  <camelContext xmlns="http://camel.apache.org/schema/spring">
    <route>
      <from uri="binding:jaxb:activemq:orderQueue" />
      <to uri="binding:jaxb:activemq:otherQueue" />
    </route>
  </camelContext>
  ...
</beans>
```

### BindingComponent

Instead of using a prefix to associate a binding with an endpoint, you can make the association implicit, so that the binding does not need to appear in the URI. For existing endpoints that do not have an implicit binding, the easiest way to achieve this is to wrap the endpoint using the `BindingComponent` class.

For example, to associate the `jaxb` binding with `activemq` endpoints, you could define a new `BindingComponent` instance as follows:

```xml
<beans ...>
  ...
  <bean id="jaxbmq" class="org.apache.camel.component.binding.BindingComponent">
    <constructor-arg ref="jaxb"/>
    <constructor-arg value="activemq:foo."/>
  </bean>
  ...
</beans>
```

Where the (optional) second constructor argument to `jaxbmq` defines a URI prefix. You can now use the `jaxbmq` ID as the scheme for an endpoint URI. For example, you can define the following route using this binding component:

```xml
<beans ...>
  ...
  <camelContext xmlns="http://camel.apache.org/schema/spring">
    <route>
      <from uri="jaxbmq:firstQueue" />
      <to uri="jaxbmq:otherQueue" />
    </route>
  </camelContext>
  ...
</beans>
```
The preceding route is equivalent to the following route, which uses the binding URI approach:

```xml
<beans ...>
  ...</camelContext>
</beans>
```

The preceding route is equivalent to the following route, which uses the binding URI approach:

```xml
<beans ...>
  ...
  <camelContext xmlns="http://camel.apache.org/schema/spring">
    <route>
      <from uri="binding:jaxb:activemq:foo.firstQueue"/>
      <to uri="binding:jaxb:activemq:foo.otherQueue"/>
    </route>
  </camelContext>
  ...
</beans>
```

**NOTE**

For developers that implement a custom Apache Camel component, it is possible to achieve this by implementing an endpoint class that inherits from the `org.apache.camel.spi.HasBinding` interface.

**BindingComponent constructors**

The `BindingComponent` class supports the following constructors:

- **public BindingComponent()**
  
  No arguments form. Use property injection to configure the binding component instance.

- **public BindingComponent(Binding binding)**
  
  Associate this binding component with the specified `Binding` object, `binding`.

- **public BindingComponent(Binding binding, String uriPrefix)**
  
  Associate this binding component with the specified `Binding` object, `binding`, and URI prefix, `uriPrefix`. This is the most commonly used constructor.

- **public BindingComponent(Binding binding, String uriPrefix, String uriPostfix)**
  
  This constructor supports the additional URI post-fix, `uriPostfix`, argument, which is automatically appended to any URIs defined using this binding component.

**Implementing a custom binding**

In addition to the `DataFormatBinding`, which is used for marshalling and unmarshalling data formats, you can implement your own custom bindings. Define a custom binding as follows:

1. Implement an `org.apache.camel.Processor` class to perform a transformation on messages incoming to a consumer endpoint (appearing in a `from` element).
2. Implement a complementary `org.apache.camel.Processor` class to perform the reverse transformation on messages outgoing from a producer endpoint (appearing in a `to` element).

3. Implement the `org.apache.camel.spi.Binding` interface, which acts as a factory for the processor instances.

**Binding interface**

`Example 2.3, “The org.apache.camel.spi.Binding Interface”` shows the definition of the `org.apache.camel.spi.Binding` interface, which you must implement to define a custom binding.

```java
// Java
package org.apache.camel.spi;
import org.apache.camel.Processor;

/**
 * Represents a &lt;a href="http://camel.apache.org/binding.html">Binding</a> or contract
 * which can be applied to an Endpoint; such as ensuring that a
 * particular &lt;a href="http://camel.apache.org/data-format.html">Data Format</a> is
 * used on messages in and out of an endpoint.
 */
public interface Binding {

    /**
     * Returns a new {link Processor} which is used by a producer on an
     * endpoint to implement
     * the producer side binding before the message is sent to the
     * underlying endpoint.
     */
    Processor createProduceProcessor();

    /**
     * Returns a new {link Processor} which is used by a consumer on an
     * endpoint to process the
     * message with the binding before its passed to the endpoint
     * consumer producer.
     */
    Processor createConsumeProcessor();
}
```

**When to use bindings**

Bindings are useful when you need to apply the same kind of transformation to many different kinds of endpoint.

**2.7. PROPERTY PLACEHOLDERS**
Overview

The property placeholders feature can be used to substitute strings into various contexts (such as endpoint URIs and attributes in XML DSL elements), where the placeholder settings are stored in Java properties files. This feature can be useful, if you want to share settings between different Apache Camel applications or if you want to centralize certain configuration settings.

For example, the following route sends requests to a Web server, whose host and port are substituted by the placeholders, {{remote.host}} and {{remote.port}}:

```java
from("direct:start").to("http://{{remote.host}}:{{remote.port}}");
```

The placeholder values are defined in a Java properties file, as follows:

```java
# Java properties file
remote.host=myserver.com
remote.port=8080
```

Property files

Property settings are stored in one or more Java properties files and must conform to the standard Java properties file format. Each property setting appears on its own line, in the format `Key=Value`. Lines with # or ! as the first non-blank character are treated as comments.

For example, a property file could have content as shown in Example 2.4, “Sample Property File”.

**Example 2.4. Sample Property File**

```java
# Property placeholder settings
# (in Java properties file format)
cool.end=mock:result
cool.result=result
cool.concat=mock:{{cool.result}}
cool.start=direct:cool
cool.showid=true

cheese.end=mock:cheese
cheese.quote=Camel rocks
cheese.type=Gouda

bean.foo=foo
bean.bar=bar
```

Resolving properties

The properties component must be configured with the locations of one or more property files before you can start using it in route definitions. You must provide the property values using one of the following resolvers:

```java
classpath:PathName,PathName,...
```
Specifies locations on the classpath, where PathName is a file pathname delimited using forward slashes.

**file:** PathName, PathName, ...

Specifies locations on the file system, where PathName is a file pathname delimited using forward slashes.

**ref:** BeanID

Specifies the ID of a java.util.Properties object in the registry.

**blueprint:** BeanID

Specifies the ID of a cm:property-placeholder bean, which is used in the context of an OSGi Blueprint file to access properties defined in the OSGi Configuration Admin service. For details, see the section called “Integration with OSGi Blueprint property placeholders”.

For example, to specify the com/fusesource/cheese.properties property file and the com/fusesource/bar.properties property file, both located on the classpath, you would use the following location string:

```
com/fusesource/cheese.properties,com/fusesource/bar.properties
```

**NOTE**

You can omit the classpath: prefix in this example, because the classpath resolver is used by default.

### Specifying locations using system properties and environment variables

You can embed Java system properties and O/S environment variables in a location PathName.

Java system properties can be embedded in a location resolver using the syntax, `${PropertyName}`. For example, if the root directory of Red Hat JBoss Fuse is stored in the Java system property, karaf.home, you could embed that directory value in a file location, as follows:

```
file:${karaf.home}/etc/foo.properties
```

O/S environment variables can be embedded in a location resolver using the syntax, `${env:VarName}`. For example, if the root directory of JBoss Fuse is stored in the environment variable, SMX_HOME, you could embed that directory value in a file location, as follows:

```
file:${env:SMX_HOME}/etc/foo.properties
```

### Configuring the properties component

Before you can start using property placeholders, you must configure the properties component, specifying the locations of one or more property files.
In the Java DSL, you can configure the properties component with the property file locations, as follows:

```
// Java
import org.apache.camel.component.properties.PropertiesComponent;
...
PropertiesComponent pc = new PropertiesComponent();
pc.setLocation("com/fusesource/cheese.properties,com/fusesource/bar.properties");
context.addComponent("properties", pc);
```

As shown in the `addComponent()` call, the name of the properties component must be set to `properties`.

In the XML DSL, you can configure the properties component using the dedicated `propertyPlaceholder` element, as follows:

```
<camelContext ...>
  <propertyPlaceholder
    id="properties"
    location="com/fusesource/cheese.properties,com/fusesource/bar.properties" />
</camelContext>
```

If you want the properties component to ignore any missing `.properties` files when it is being initialized, you can set the `ignoreMissingLocation` option to `true` (normally, a missing `.properties` file would result in an error being raised).

**Placeholder syntax**

After it is configured, the property component automatically substitutes placeholders (in the appropriate contexts). The syntax of a placeholder depends on the context, as follows:

- **In endpoint URIs and in Spring XML files**—the placeholder is specified as `{{Key}}`.

- **When setting XML DSL attributes**—`xs:string` attributes are set using the following syntax:

  ```
  AttributeName="{{Key}}"
  ```

  Other attribute types (for example, `xs:int` or `xs:boolean`) must be set using the following syntax:

  ```
  prop:AttributeName="Key"
  ```

  Where `prop` is associated with the `http://camel.apache.org/schema/placeholder` namespace.

- **When setting Java DSL EIP options**—to set an option on an Enterprise Integration Pattern (EIP) command in the Java DSL, add a `placeholder()` clause like the following to the fluent DSL:

  ```
  .placeholder("OptionName", "Key")
  ```
In Simple language expressions—the placeholder is specified as \${\text{properties:Key}}.

Substitution in endpoint URIs

Wherever an endpoint URI string appears in a route, the first step in parsing the endpoint URI is to apply the property placeholder parser. The placeholder parser automatically substitutes any property names appearing between double braces, {{Key}}. For example, given the property settings shown in Example 2.4, “Sample Property File”, you could define a route as follows:

```
from("{{cool.start}}")
  .to("log:{{cool.start}}?showBodyType=false&showExchangeId=
    {{cool.showid}}")
  .to("mock:{{cool.result}}");
```

By default, the placeholder parser looks up the properties bean ID in the registry to find the property component. If you prefer, you can explicitly specify the scheme in the endpoint URIs. For example, by prefixing properties: to each of the endpoint URIs, you can define the following equivalent route:

```
from("properties:{{cool.start}}")
  .to("properties:log:{{cool.start}}?showBodyType=false&showExchangeId=
    {{cool.showid}}")
  .to("properties:mock:{{cool.result}}");
```

When specifying the scheme explicitly, you also have the option of specifying options to the properties component. For example, to override the property file location, you could set the location option as follows:

```
from("direct:start").to("properties:{{bar.end}}?location=com/mycompany/bar.properties");
```

Substitution in Spring XML files

You can also use property placeholders in the XML DSL, for setting various attributes of the DSL elements. In this context, the placeholder syntax also uses double braces, {{Key}}. For example, you could define a jmxAgent element using property placeholders, as follows:

```
<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
  <propertyPlaceholder id="properties" location="org/apache/camel/spring/jmx.properties"/>

  <!-- we can use property placeholders when we define the JMX agent -->
  <jmxAgent id="agent" registryPort="{{myjmx.port}}"
    usePlatformMBeanServer="{{myjmx.usePlatform}}"
    createConnector="true"
    statisticsLevel="RoutesOnly"
  />

  <route>
    <from uri="seda:start"/>
  </route>
</camelContext>
```
Substitution of XML DSL attribute values

You can use the regular placeholder syntax for specifying attribute values of `xs:string` type—for example, `<jmxAgent registryPort="{{myjmx.port}}" ...>`. But for attributes of any other type (for example, `xs:int` or `xs:boolean`), you must use the special syntax, `prop:AttributeName="Key"`.

For example, given that a property file defines the `stop.flag` property to have the value, `true`, you can use this property to set the `stopOnException` boolean attribute, as follows:

```xml
<beans xmlns="http://www.springframework.org/schema/beans"
       xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
       xmlns:prop="http://camel.apache.org/schema/placeholder"
       ...>
   <bean id="illegal" class="java.lang.IllegalArgumentException">
       <constructor-arg index="0" value="Good grief!"/>
   </bean>
   <camelContext xmlns="http://camel.apache.org/schema/spring">
       <propertyPlaceholder id="properties"
                             location="classpath:org/apache/camel/component/properties/myprop.properties"
                             xmlns="http://camel.apache.org/schema/spring"/>
       <route>
           <from uri="direct:start"/>
           <multicast prop:stopOnException="stop.flag">
               <to uri="mock:a"/>
               <throwException ref="damn"/>
               <to uri="mock:b"/>
           </multicast>
       </route>
   </camelContext>
</beans>
```

**IMPORTANT**

The `prop` prefix must be explicitly assigned to the `http://camel.apache.org/schema/placeholder` namespace in your Spring file, as shown in the `beans` element of the preceding example.

Substitution of Java DSL EIP options
When invoking an EIP command in the Java DSL, you can set any EIP option using the value of a property placeholder, by adding a sub-clause of the form, 

```
placeholder("OptionName", "Key")
```

For example, given that a property file defines the `stop.flag` property to have the value, `true`, you can use this property to set the `stopOnException` option of the multicast EIP, as follows:

```
from("direct:start")
   .multicast().placeholder("stopOnException", "stop.flag")
   .to("mock:a").throwException(new
   IllegalAccessException("Damn")).to("mock:b");
```

**Substitution in Simple language expressions**

You can also substitute property placeholders in Simple language expressions, but in this case the syntax of the placeholder is `${properties:Key}`. For example, you can substitute the `cheese.quote` placeholder inside a Simple expression, as follows:

```
from("direct:start")
   .transform().simple("Hi ${body} do you think
   ${properties:cheese.quote}?"); 
```

It is also possible to override the location of the property file using the syntax, `${properties:Location:Key}`. For example, to substitute the `bar.quote` placeholder using the settings from the `com/mycompany/bar.properties` property file, you can define a Simple expression as follows:

```
from("direct:start")
   .transform().simple("Hi ${body}.
   ${properties:com/mycompany/bar.properties:bar.quote}."));
```

**Integration with OSGi Blueprint property placeholders**

If you deploy your route into the Red Hat JBoss Fuse OSGi container, you can integrate the Apache Camel property placeholder mechanism with JBoss Fuse's Blueprint property placeholder mechanism (in fact, the integration is enabled by default). There are two basic approaches to setting up the integration, as follows:

- the section called “Implicit Blueprint integration”.
- the section called “Explicit Blueprint integration”.

**Implicit Blueprint integration**

If you define a `camelContext` element inside an OSGi Blueprint file, the Apache Camel property placeholder mechanism automatically integrates with the Blueprint property placeholder mechanism. That is, placeholders obeying the Apache Camel syntax (for example, `{{cool.end}}`) that appear within the scope of `camelContext` are implicitly resolved by looking up the Blueprint property placeholder mechanism.

For example, consider the following route defined in an OSGi Blueprint file, where the last endpoint in the route is defined by the property placeholder, `{{result}}`:
The Blueprint property placeholder mechanism is initialized by creating a `cm:property-placeholder` bean. In the preceding example, the `cm:property-placeholder` bean is associated with the `camel.blueprint` persistent ID, where a persistent ID is the standard way of referencing a group of related properties from the OSGi Configuration Admin service. In other words, the `cm:property-placeholder` bean provides access to all of the properties defined under the `camel.blueprint` persistent ID. It is also possible to specify default values for some of the properties (using the nested `cm:property` elements).

In the context of Blueprint, the Apache Camel placeholder mechanism searches for an instance of `cm:property-placeholder` in the bean registry. If it finds such an instance, it automatically integrates the Apache Camel placeholder mechanism, so that placeholders like, `{{result}}`, are resolved by looking up the key in the Blueprint property placeholder mechanism (in this example, through the `myblueprint.placeholder` bean).

**NOTE**

The default Blueprint placeholder syntax (accessing the Blueprint properties directly) is `{Key}`). Hence, outside the scope of a `camelContext` element, the placeholder syntax you must use is `{Key}`). Whereas, inside the scope of a `camelContext` element, the placeholder syntax you must use is `{{Key}}`.

**Explicit Blueprint integration**
If you want to have more control over where the Apache Camel property placeholder mechanism finds its properties, you can define a `propertyPlaceholder` element and specify the resolver locations explicitly.

For example, consider the following Blueprint configuration, which differs from the previous example in that it creates an explicit `propertyPlaceholder` instance:

```xml
<blueprint xmlns="http://www.osgi.org/xmlns/blueprint/v1.0.0"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xmlns:cm="http://aries.apache.org/blueprint/xmlns/blueprint-cm/v1.0.0"
    xsi:schemaLocation="http://www.osgi.org/xmlns/blueprint/v1.0.0
        http://www.osgi.org/xmlns/blueprint/v1.0.0/blueprint.xsd">
    <!-- OSGI blueprint property placeholder -->
    <cm:property-placeholder id="myblueprint.placeholder" persistent-id="camel.blueprint">
        <!-- list some properties for this test -->
        <cm:default-properties>
            <cm:property name="result" value="mock:result"/>
        </cm:default-properties>
    </cm:property-placeholder>

    <camelContext xmlns="http://camel.apache.org/schema/blueprint">
        <!-- using Camel properties component and refer to the blueprint
            property placeholder by its id -->
        <propertyPlaceholder id="properties" location="blueprint:myblueprint.placeholder"/>

        <!-- in the route we can use {{ }} placeholders which will lookup
            in blueprint -->
        <route>
            <from uri="direct:start"/>
            <to uri="mock:foo"/>
            <to uri="{{result}}"/>
        </route>
    </camelContext>
</blueprint>
```

In the preceding example, the `propertyPlaceholder` element specifies explicitly which `cm:property-placeholder` bean to use by setting the location to `blueprint:myblueprint.placeholder`. That is, the `blueprint` resolver explicitly references the ID, `myblueprint.placeholder`, of the `cm:property-placeholder` bean.

This style of configuration is useful, if there is more than one `cm:property-placeholder` bean defined in the Blueprint file and you need to specify which one to use. It also makes it possible to source properties from multiple locations, by specifying a comma-separated list of locations. For example, if you wanted to look up properties both from the `cm:property-placeholder` bean and from the properties file, `myproperties.properties`, on the classpath, you could define the `propertyPlaceholder` element as follows:

```xml
<propertyPlaceholder id="properties"
```
Integration with Spring property placeholders

If you define your Apache Camel application using XML DSL in a Spring XML file, you can integrate the Apache Camel property placeholder mechanism with Spring property placeholder mechanism by declaring a Spring bean of type, org.apache.camel.spring.spi.BridgePropertyPlaceholderConfigurer.

Define a BridgePropertyPlaceholderConfigurer, which replaces both Apache Camel's propertyPlaceholder element and Spring's ctx:property-placeholder element in the Spring XML file. You can then refer to the configured properties using either the Spring ${PropName} syntax or the Apache Camel {{PropName}} syntax.

For example, defining a bridge property placeholder that reads its property settings from the cheese.properties file:

```xml
<?xml version="1.0" encoding="UTF-8"?>
  <!-- Bridge Spring property placeholder with Camel -->
  <!-- Do not use <ctx:property-placeholder ... > at the same time -->
  <bean id="bridgePropertyPlaceholder" class="org.apache.camel.spring.spi.BridgePropertyPlaceholderConfigurer">
    <property name="location" value="classpath:org/apache/camel/component/properties/cheese.properties"/>
  </bean>
  <!-- A bean that uses Spring property placeholder -->
  <!-- The ${hi} is a spring property placeholder -->
  <bean id="hello" class="org.apache.camel.component.properties.HelloBean">
    <property name="greeting" value="${hi}"/>
  </bean>
  <camelContext xmlns="http://camel.apache.org/schema/spring">
    <!-- Use Camel's property placeholder {{ }} style -->
    <route>
      <from uri="direct:{{cool.bar}}"/>
      <bean ref="hello"/>
      <to uri="{{cool.end}}"/>
    </route>
  </camelContext>
</beans>
```
2.8. ASPECT ORIENTED PROGRAMMING

Overview

The aspect oriented programming (AOP) feature in Apache Camel enables you to apply before and after processing to a specified portion of a route. As a matter of fact, AOP does not provide anything that you could not do with the regular route syntax. The advantage of the AOP syntax, however, is that it enables you to specify before and after processing at a single point in the route. In some cases, this gives a more readable syntax. The typical use case for AOP is the application of a symmetrical pair of operations before and after a route fragment is processed. For example, typical pairs of operations that you might want to apply using AOP are: encrypt and decrypt; begin transaction and commit transaction; allocate resources and deallocate resources; and so on.

Java DSL example

In Java DSL, the route fragment to which you apply before and after processing is bracketed between \texttt{aop()} and \texttt{end()}. For example, the following route performs AOP processing around the route fragment that calls the bean methods:

```java
from("jms:queue:inbox")
    .aop().around("log:before", "log:after")
    .to("bean:order?method=validate")
    .to("bean:order?method=handle")
    .end()
    .to("jms:queue:order");
```

Where the \texttt{around()} subclause specifies an endpoint, \texttt{log:before}, where the exchange is routed before processing the route fragment and an endpoint, \texttt{log:after}, where the exchange is routed after processing the route fragment.

AOP options in the Java DSL

Starting an AOP block with \texttt{aop().around()} is probably the most common use case, but the AOP block supports other subclauses, as follows:

- \texttt{around()}—specifies before and after endpoints.
- \texttt{begin()}—specifies before endpoint only.
- \texttt{after()}—specifies after endpoint only.
- \texttt{aroundFinally()}—specifies a before endpoint, and an after endpoint that is always called, even when an exception occurs in the enclosed route fragment.
- `afterFinally()`—specifies an after endpoint that is always called, even when an exception occurs in the enclosed route fragment.

### Spring XML example

In the XML DSL, the route fragment to which you apply `before` and `after` processing is enclosed in the `aop` element. For example, the following Spring XML route performs AOP processing around the route fragment that calls the bean methods:

```xml
<route>
  <from uri="jms:queue:inbox"/>
  <aop beforeUri="log:before" afterUri="log:after">
    <to uri="bean:order?method=validate"/>
    <to uri="bean:order?method=handle"/>
  </aop>
  <to uri="jms:queue:order"/>
</route>
```

Where the `beforeUri` attribute specifies the endpoint where the exchange is routed before processing the route fragment, and the `afterUri` attribute specifies the endpoint where the exchange is routed after processing the route fragment.

### AOP options in the Spring XML

The `aop` element supports the following optional attributes:

- `beforeUri`
- `afterUri`
- `afterFinallyUri`

The various use cases described for the Java DSL can be obtained in Spring XML using the appropriate combinations of these attributes. For example, the `aroundFinally()` Java DSL subclause is equivalent to the combination of `beforeUri` and `afterFinallyUri` in Spring XML.

### 2.9. THREADING MODEL

#### Java thread pool API

The Apache Camel threading model is based on the powerful Java concurrency API, `java.util.concurrent`, that first became available in Sun's JDK 1.5. The key interface in this API is the `ExecutorService` interface, which represents a thread pool. Using the concurrency API, you can create many different kinds of thread pool, covering a wide range of scenarios.

#### Apache Camel thread pool API

The Apache Camel thread pool API builds on the Java concurrency API by providing a central factory (of `org.apache.camel.spi.ExecutorServiceManager` type) for all of the thread pools in your Apache Camel application. Centralising the creation of thread pools in this way provides several advantages, including:
- Simplified creation of thread pools, using utility classes.
- Integrating thread pools with graceful shutdown.
- Threads automatically given informative names, which is beneficial for logging and management.

**Component threading model**

Some Apache Camel components—such as SEDA, JMS, and Jetty—are inherently multi-threaded. These components have all been implemented using the Apache Camel threading model and thread pool API.

If you are planning to implement your own Apache Camel component, it is recommended that you integrate your threading code with the Apache Camel threading model. For example, if your component needs a thread pool, it is recommended that you create it using the CamelContext's `ExecutorServiceManager` object.

**Processor threading model**

Some of the standard processors in Apache Camel create their own thread pool by default. These threading-aware processors are also integrated with the Apache Camel threading model and they provide various options that enable you to customize the thread pools that they use.

Table 2.8, “Processor Threading Options” shows the various options for controlling and setting thread pools on the threading-aware processors built-in to Apache Camel.

**Table 2.8. Processor Threading Options**

<table>
<thead>
<tr>
<th>Processor</th>
<th>Java DSL</th>
<th>XML DSL</th>
</tr>
</thead>
<tbody>
<tr>
<td>aggregate</td>
<td><code>parallelProcessing()</code> <code>executorService()</code> <code>executorServiceRef()</code></td>
<td><code>@parallelProcessing</code> <code>@executorServiceRef</code></td>
</tr>
<tr>
<td>multicast</td>
<td><code>parallelProcessing()</code> <code>executorService()</code> <code>executorServiceRef()</code></td>
<td><code>@parallelProcessing</code> <code>@executorServiceRef</code></td>
</tr>
<tr>
<td>recipientList</td>
<td><code>parallelProcessing()</code> <code>executorService()</code> <code>executorServiceRef()</code></td>
<td><code>@parallelProcessing</code> <code>@executorServiceRef</code></td>
</tr>
<tr>
<td>split</td>
<td><code>parallelProcessing()</code> <code>executorService()</code> <code>executorServiceRef()</code></td>
<td><code>@parallelProcessing</code> <code>@executorServiceRef</code></td>
</tr>
</tbody>
</table>
Creating a default thread pool

To create a default thread pool for one of the threading-aware processors, enable the `parallelProcessing` option, using the `parallelProcessing()` sub-clause, in the Java DSL, or the `parallelProcessing` attribute, in the XML DSL.

For example, in the Java DSL, you can invoke the multicast processor with a default thread pool (where the thread pool is used to process the multicast destinations concurrently) as follows:

```java
from("direct:start")
  .multicast().parallelProcessing()
  .to("mock:first")
  .to("mock:second")
  .to("mock:third");
```

You can define the same route in XML DSL as follows

```xml
<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="direct:start"/>
    <multicast parallelProcessing="true">
      <to uri="mock:first"/>
      <to uri="mock:second"/>
      <to uri="mock:third"/>
    </multicast>
  </route>
</camelContext>
```

Default thread pool profile settings

<table>
<thead>
<tr>
<th>Processor</th>
<th>Java DSL</th>
<th>XML DSL</th>
</tr>
</thead>
<tbody>
<tr>
<td>threads</td>
<td>executorService() executorserviceRef() poolSize() maxPoolSize() keepAliveTime() timeUnit() maxQueueSize() rejectedPolicy()</td>
<td>@executorServiceRef @poolSize @maxPoolSize @keepAliveTime @timeUnit @maxQueueSize @rejectedPolicy</td>
</tr>
<tr>
<td>wireTap</td>
<td>wireTap(String uri, ExecutorService executorService) wireTap(String uri, String executorServiceRef)</td>
<td>@executorServiceRef</td>
</tr>
</tbody>
</table>
The default thread pools are automatically created by a thread factory that takes its settings from the *default thread pool profile*. The default thread pool profile has the settings shown in Table 2.9, “Default Thread Pool Profile Settings” (assuming that these settings have not been modified by the application code).

### Table 2.9. Default Thread Pool Profile Settings

<table>
<thead>
<tr>
<th>Thread Option</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>maxQueueSize</td>
<td>1000</td>
</tr>
<tr>
<td>poolSize</td>
<td>10</td>
</tr>
<tr>
<td>maxPoolSize</td>
<td>20</td>
</tr>
<tr>
<td>keepAliveTime</td>
<td>60 (seconds)</td>
</tr>
<tr>
<td>rejectedPolicy</td>
<td>CallerRuns</td>
</tr>
</tbody>
</table>

**Changing the default thread pool profile**

It is possible to change the default thread pool profile settings, so that all subsequent default thread pools will be created with the custom settings. You can change the profile either in Java or in Spring XML.

For example, in the Java DSL, you can customize the `poolSize` option and the `maxQueueSize` option in the default thread pool profile, as follows:

```java
// Java
import org.apache.camel.spi.ExecutorServiceManager;
import org.apache.camel.spi.ThreadPoolProfile;
...
ExecutorServiceManager manager = context.getExecutorServiceManager();
ThreadPoolProfile defaultProfile = manager.getDefaultThreadPoolProfile();

// Now, customize the profile settings.
defaultProfile.setPoolSize(3);
defaultProfile.setMaxQueueSize(100);
...
```

In the XML DSL, you can customize the default thread pool profile, as follows:

```xml
<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
  <threadPoolProfile id="changedProfile" defaultProfile="true"
                     poolSize="3"
                     maxQueueSize="100"/>
  ...
</camelContext>
```

Note that it is essential to set the `defaultProfile` attribute to `true` in the preceding XML DSL example, otherwise the thread pool profile would be treated like a custom thread pool.
profile (see the section called “Creating a custom thread pool profile”), instead of replacing the default thread pool profile.

**Customizing a processor's thread pool**

It is also possible to specify the thread pool for a threading-aware processor more directly, using either the `executorService` or `executorServiceRef` options (where these options are used instead of the `parallelProcessing` option). There are two approaches you can use to customize a processor’s thread pool, as follows:

- **Specify a custom thread pool**—explicitly create an `ExecutorService` (thread pool) instance and pass it to the `executorService` option.

- **Specify a custom thread pool profile**—create and register a custom thread pool factory. When you reference this factory using the `executorServiceRef` option, the processor automatically uses the factory to create a custom thread pool instance.

When you pass a bean ID to the `executorServiceRef` option, the threading-aware processor first tries to find a custom thread pool with that ID in the registry. If no thread pool is registered with that ID, the processor then attempts to look up a custom thread pool profile in the registry and uses the custom thread pool profile to instantiate a custom thread pool.

**Creating a custom thread pool**

A custom thread pool can be any thread pool of `java.util.concurrent.ExecutorService` type. The following approaches to creating a thread pool instance are recommended in Apache Camel:

- Use the `org.apache.camel.builder.ThreadPoolBuilder` utility to build the thread pool class.

- Use the `org.apache.camel.spi.ExecutorServiceManager` instance from the current `CamelContext` to create the thread pool class.

Ultimately, there is not much difference between the two approaches, because the `ThreadPoolBuilder` is actually defined using the `ExecutorServiceManager` instance. Normally, the `ThreadPoolBuilder` is preferred, because it offers a simpler approach. But there is at least one kind of thread (the `ScheduledExecutorService`) that can only be created by accessing the `ExecutorServiceManager` instance directory.

Table 2.10, “Thread Pool Builder Options” shows the options supported by the `ThreadPoolBuilder` class, which you can set when defining a new custom thread pool.

**Table 2.10. Thread Pool Builder Options**

<table>
<thead>
<tr>
<th>Builder Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>maxQueueSize()</code></td>
<td>Sets the maximum number of pending tasks that this thread pool can store in its incoming task queue. A value of <code>-1</code> specifies an unbounded queue. Default value is taken from default thread pool profile.</td>
</tr>
<tr>
<td>Builder Option</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>poolSize()</td>
<td>Sets the minimum number of threads in the pool (this is also the initial pool size). Default value is taken from default thread pool profile.</td>
</tr>
<tr>
<td>maxPoolSize()</td>
<td>Sets the maximum number of threads that can be in the pool. Default value is taken from default thread pool profile.</td>
</tr>
<tr>
<td>keepAliveTime()</td>
<td>If any threads are idle for longer than this period of time (specified in seconds), they are terminated. This allows the thread pool to shrink when the load is light. Default value is taken from default thread pool profile.</td>
</tr>
<tr>
<td>rejectedPolicy()</td>
<td>Specifies what course of action to take, if the incoming task queue is full. You can specify four possible values:</td>
</tr>
<tr>
<td></td>
<td><strong>CallerRuns</strong> <em>(Default value)</em> Gets the caller thread to run the latest incoming task. As a side effect, this option prevents the caller thread from receiving any more tasks until it has finished processing the latest incoming task.</td>
</tr>
<tr>
<td></td>
<td><strong>Abort</strong> Aborts the latest incoming task by throwing an exception.</td>
</tr>
<tr>
<td></td>
<td><strong>Discard</strong> Quietly discards the latest incoming task.</td>
</tr>
<tr>
<td></td>
<td><strong>DiscardOldest</strong> Discards the oldest unhandled task and then attempts to enqueue the latest incoming task in the task queue.</td>
</tr>
<tr>
<td>build()</td>
<td>Finishes building the custom thread pool and registers the new thread pool under the ID specified as the argument to build().</td>
</tr>
</tbody>
</table>

In Java DSL, you can define a custom thread pool using the `ThreadPoolBuilder`, as follows:

```java
// Java
import org.apache.camel.builder.ThreadPoolBuilder;
import java.util.concurrent.ExecutorService;
...
ThreadPoolBuilder poolBuilder = new ThreadPoolBuilder(context);
ExecutorService customPool =
```
Instead of passing the object reference, `customPool`, directly to the `executorService()` option, you can look up the thread pool in the registry, by passing its bean ID to the `executorServiceRef()` option, as follows:

```java
from("direct:start")
    .multicast().executorService(customPool)
    .to("mock:first")
    .to("mock:second")
    .to("mock:third");
```

Instead of passing the object reference, `customPool`, directly to the `executorService()` option, you can look up the thread pool in the registry, by passing its bean ID to the `executorServiceRef()` option, as follows:

```java
from("direct:start")
    .multicast().executorServiceRef("customPool")
    .to("mock:first")
    .to("mock:second")
    .to("mock:third");
```

In XML DSL, you access the `ThreadPoolBuilder` using the `threadPool` element. You can then reference the custom thread pool using the `executorServiceRef` attribute to look up the thread pool by ID in the Spring registry, as follows:

```xml
<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
    <threadPool id="customPool"
        poolSize="5"
        maxPoolSize="5"
        maxQueueSize="100" />
    <route>
        <from uri="direct:start"/>
        <multicast executorServiceRef="customPool">
            <to uri="mock:first"/>
            <to uri="mock:second"/>
            <to uri="mock:third"/>
        </multicast>
    </route>
</camelContext>
```

Creating a custom thread pool profile

If you have many custom thread pool instances to create, you might find it more convenient to define a custom thread pool profile, which acts as a factory for thread pools. Whenever you reference a thread pool profile from a threading-aware processor, the processor automatically uses the profile to create a new thread pool instance. You can define a custom thread pool profile either in Java DSL or in XML DSL.

For example, in Java DSL you can create a custom thread pool profile with the bean ID, `customProfile`, and reference it from within a route, as follows:

```java
import org.apache.camel.spi.ThreadPoolProfile;
```
In XML DSL, use the <code>threadPoolProfile</code> element to create a custom pool profile (where you let the <code>defaultProfile</code> option default to <code>false</code>, because this is not a default thread pool profile). You can create a custom thread pool profile with the bean ID, <code>customProfile</code>, and reference it from within a route, as follows:

```java
import org.apache.camel.impl.ThreadPoolProfileSupport;
...
// Create the custom thread pool profile
ThreadPoolProfile customProfile = new ThreadPoolProfileSupport("customProfile");
customProfile.setPoolSize(5);
customProfile.setMaxPoolSize(5);
customProfile.setMaxQueueSize(100);
context.getExecutorServiceManager().registerThreadPoolProfile(customProfile);
...
// Reference the custom thread pool profile in a route
from("direct:start")
  .multicast().executorServiceRef("customProfile")
    .to("mock:first")
    .to("mock:second")
    .to("mock:third");
```

In XML DSL, use the <code>ThreadPoolProfile</code> element to create a custom pool profile (where you let the <code>defaultProfile</code> option default to <code>false</code>, because this is not a default thread pool profile). You can create a custom thread pool profile with the bean ID, <code>customProfile</code>, and reference it from within a route, as follows:

```xml
<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
  <threadPoolProfile
    id="customProfile"
    poolSize="5"
    maxPoolSize="5"
    maxQueueSize="100" />

  <route>
    <from uri="direct:start"/>
    <multicast executorServiceRef="customProfile">
      <to uri="mock:first"/>
      <to uri="mock:second"/>
      <to uri="mock:third"/>
    </multicast>
  </route>
</camelContext>
```

**Sharing a thread pool between components**

Some of the standard poll-based components—such as File and FTP—allow you to specify the thread pool to use. This makes it possible for different components to share the same thread pool, reducing the overall number of threads in the JVM.

For example, the File component and the FTP component both expose the <code>scheduledExecutorService</code> property, which you can use to specify the component's <code>ExecutorService</code> object.

**Customizing thread names**

To make the application logs more readable, it is often a good idea to customize the thread names (which are used to identify threads in the log). To customize thread names, you can configure the <code>thread name pattern</code> by calling the <code>setThreadNamePattern</code> method on the...
ExecutorServiceStrategy class or the ExecutorServiceManager class. Alternatively, an easier way to set the thread name pattern is to set the threadNamePattern property on the CamelContext object.

The following placeholders can be used in a thread name pattern:

#camelId#
   The name of the current CamelContext.

#counter#
   A unique thread identifier, implemented as an incrementing counter.

#name#
   The regular Camel thread name.

#longName#
   The long thread name—which can include endpoint parameters and so on.

The following is a typical example of a thread name pattern:

Camel (#camelId#) thread #counter# - #name#

The following example shows how to set the threadNamePattern attribute on a Camel context using XML DSL:

```xml
<camelContext xmlns="http://camel.apache.org/schema/spring" threadNamePattern="Riding the thread #counter#">
   <route>
      <from uri="seda:start"/>
      <to uri="log:result"/>
      <to uri="mock:result"/>
   </route>
</camelContext>
```

2.10. CONTROLLING START-UP AND SHUTDOWN OF ROUTES

Overview

By default, routes are automatically started when your Apache Camel application (as represented by the CamelContext instance) starts up and routes are automatically shut down when your Apache Camel application shuts down. For non-critical deployments, the details of the shutdown sequence are usually not very important. But in a production environment, it is often crucial that existing tasks should run to completion during shutdown, in order to avoid data loss. You typically also want to control the order in which routes shut down, so that dependencies are not violated (which would prevent existing tasks from running to completion).

For this reason, Apache Camel provides a set of features to support graceful shutdown of applications. Graceful shutdown gives you full control over the stopping and starting of routes, enabling you to control the shutdown order of routes and enabling current tasks to run to completion.
Setting the route ID

It is good practice to assign a route ID to each of your routes. As well as making logging messages and management features more informative, the use of route IDs enables you to apply greater control over the stopping and starting of routes.

For example, in the Java DSL, you can assign the route ID, `myCustomerRouteId`, to a route by invoking the `routeId()` command as follows:

```java
from("SourceURI").routeId("myCustomRouteId").process(...).to(TargetURI);
```

In the XML DSL, set the `route` element's `id` attribute, as follows:

```xml
<route id="myCustomRouteId">
  <from uri="SourceURI"/>
  <process ref="someProcessorId"/>
  <to uri="TargetURI"/>
</route>
</camelContext>
```

Disabling automatic start-up of routes

By default, all of the routes that the CamelContext knows about at start time will be started automatically. If you want to control the start-up of a particular route manually, however, you might prefer to disable automatic start-up for that route.

To control whether a Java DSL route starts up automatically, invoke the `autoStartup` command, either with a `boolean` argument (`true` or `false`) or a `String` argument (`true` or `false`). For example, you can disable automatic start-up of a route in the Java DSL, as follows:

```java
from("SourceURI")
  .routeId("nonAuto")
  .autoStartup(false)
  .to(TargetURI);
```

You can disable automatic start-up of a route in the XML DSL by setting the `autoStartup` attribute to `false` on the `route` element, as follows:

```xml
<route id="nonAuto" autoStartup="false">
  <from uri="SourceURI"/>
  <to uri="TargetURI"/>
</route>
</camelContext>
```

Manually starting and stopping routes

You can manually start or stop a route at any time in Java by invoking the `startRoute()` and `stopRoute()` methods on the `CamelContext` instance. For example, to start the route having the route ID, `nonAuto`, invoke the `startRoute()` method on the `CamelContext`
instance, `context`, as follows:

```java
// Java
context.startRoute("nonAuto");
```

To stop the route having the route ID, `nonAuto`, invoke the `stopRoute()` method on the `CamelContext` instance, `context`, as follows:

```java
// Java
context.stopRoute("nonAuto");
```

### Startup order of routes

By default, Apache Camel starts up routes in a non-deterministic order. In some applications, however, it can be important to control the startup order. To control the startup order in the Java DSL, use the `startupOrder()` command, which takes a positive integer value as its argument. The route with the lowest integer value starts first, followed by the routes with successively higher startup order values.

For example, the first two routes in the following example are linked together through the `seda:buffer` endpoint. You can ensure that the first route segment starts after the second route segment by assigning startup orders (2 and 1 respectively), as follows:

**Example 2.5. Startup Order in Java DSL**

```java
from("jetty:http://fooserver:8080")
 .routeId("first")
 .startupOrder(2)
 .to("seda:buffer");

from("seda:buffer")
 .routeId("second")
 .startupOrder(1)
 .to("mock:result");
```

// This route's startup order is unspecified
from("jms:queue:foo").to("jms:queue:bar");

Or in Spring XML, you can achieve the same effect by setting the `route` element's `startupOrder` attribute, as follows:

**Example 2.6. Startup Order in XML DSL**

```xml
<route id="first" startupOrder="2">
   <from uri="jetty:http://fooserver:8080"/>
   <to uri="seda:buffer"/>
</route>

<route id="second" startupOrder="1">
   <from uri="seda:buffer"/>
   <to uri="mock:result"/>
</route>
```
Each route must be assigned a unique startup order value. You can choose any positive integer value that is less than 1000. Values of 1000 and over are reserved for Apache Camel, which automatically assigns these values to routes without an explicit startup value. For example, the last route in the preceding example would automatically be assigned the startup value, 1000 (so it starts up after the first two routes).

**Shutdown sequence**

When a CamelContext instance is shutting down, Apache Camel controls the shutdown sequence using a pluggable shutdown strategy. The default shutdown strategy implements the following shutdown sequence:

1. Routes are shut down in the reverse of the start-up order.

2. Normally, the shutdown strategy waits until the currently active exchanges have finished processing. The treatment of running tasks is configurable, however.

3. Overall, the shutdown sequence is bound by a timeout (default, 300 seconds). If the shutdown sequence exceeds this timeout, the shutdown strategy will force shutdown to occur, even if some tasks are still running.

**Shutdown order of routes**

Routes are shut down in the reverse of the start-up order. That is, when a start-up order is defined using the `startupOrder()` command (in Java DSL) or `startupOrder` attribute (in XML DSL), the first route to shut down is the route with the highest integer value assigned by the start-up order and the last route to shut down is the route with the lowest integer value assigned by the start-up order.

For example, in Example 2.5, “Startup Order in Java DSL”, the first route segment to be shut down is the route with the ID, `first`, and the second route segment to be shut down is the route with the ID, `second`. This example illustrates a general rule, which you should observe when shutting down routes: the routes that expose externally-accessible consumer endpoints should be shut down first, because this helps to throttle the flow of messages through the rest of the route graph.

**NOTE**

Apache Camel also provides the option `shutdownRoute(Defer)`, which enables you to specify that a route must be amongst the last routes to shut down (overriding the start-up order value). But you should rarely ever need this option. This option was mainly needed as a workaround for earlier versions of Apache Camel (prior to 2.3), for which routes would shut down in the same order as the start-up order.

**Shutting down running tasks in a route**

If a route is still processing messages when the shutdown starts, the shutdown strategy
normally waits until the currently active exchange has finished processing before shutting down the route. This behavior can be configured on each route using the `shutdownRunningTask` option, which can take either of the following values:

**ShutdownRunningTask.CompleteCurrentTaskOnly**

*(Default)* Usually, a route operates on just a single message at a time, so you can safely shut down the route after the current task has completed.

**ShutdownRunningTask.CompleteAllTasks**

Specify this option in order to shut down *batch consumers* gracefully. Some consumer endpoints (for example, File, FTP, Mail, iBATIS, and JPA) operate on a batch of messages at a time. For these endpoints, it is more appropriate to wait until all of the messages in the current batch have completed.

For example, to shut down a File consumer endpoint gracefully, you should specify the `CompleteAllTasks` option, as shown in the following Java DSL fragment:

```java
// Java
public void configure() throws Exception {
    from("file:target/pending")
        .routeId("first").startupOrder(2)
        .shutdownRunningTask(ShutdownRunningTask.CompleteAllTasks)
        .delay(1000).to("seda:foo");

    from("seda:foo")
        .routeId("second").startupOrder(1)
        .to("mock:bar");
}
```

The same route can be defined in the XML DSL as follows:

```xml
<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
  <!-- let this route complete all its pending messages when asked to shut down -->
  <route id="first" startupOrder="2">
    <shutdownRunningTask="CompleteAllTasks"/>

    <from uri="file:target/pending"/>
    <delay><constant>1000</constant></delay>
    <to uri="seda:foo"/>
  </route>

  <route id="second" startupOrder="1">
    <from uri="seda:foo"/>
    <to uri="mock:bar"/>
  </route>
</camelContext>
```

**Shutdown timeout**

The shutdown timeout has a default value of 300 seconds. You can change the value of the timeout by invoking the `setTimeout()` method on the shutdown strategy. For example, you can change the timeout value to 600 seconds, as follows:

```java
from("file:target/pending")
    .routeId("first").startupOrder(2)
    .shutdownRunningTask(ShutdownRunningTask.CompleteAllTasks)
    .delay(1000).to("seda:foo");
```
Integration with custom components

If you are implementing a custom Apache Camel component (which also inherits from the org.apache.camel.Service interface), you can ensure that your custom code receives a shutdown notification by implementing the org.apache.camel.spi.ShutdownPrepared interface. This gives the component an opportunity to execute custom code in preparation for shutdown.

2.11. SCHEDULED ROUTE POLICY

2.11.1. Overview of Scheduled Route Policies

Overview

A scheduled route policy can be used to trigger events that affect a route at runtime. In particular, the implementations that are currently available enable you to start, stop, suspend, or resume a route at any time (or times) specified by the policy.

Scheduling tasks

The scheduled route policies are capable of triggering the following kinds of event:

- **Start a route**—start the route at the time (or times) specified. This event only has an effect, if the route is currently in a stopped state, awaiting activation.

- **Stop a route**—stop the route at the time (or times) specified. This event only has an effect, if the route is currently active.

- **Suspend a route**—temporarily de-activate the consumer endpoint at the start of the route (as specified in `from()`). The rest of the route is still active, but clients will not be able to send new messages into the route.

- **Resume a route**—re-activate the consumer endpoint at the start of the route, returning the route to a fully active state.

Quartz component

The Quartz component is a timer component based on Terracotta's Quartz, which is an open source implementation of a job scheduler. The Quartz component provides the underlying implementation for both the simple scheduled route policy and the cron scheduled route policy.

2.11.2. Simple Scheduled Route Policy

Overview

The simple scheduled route policy is a route policy that enables you to start, stop, suspend, and resume routes, where the timing of these events is defined by providing the time and

```java
// Java
// context = CamelContext instance
context.getShutdownStrategy().setTimeout(600);
```
date of an initial event and (optionally) by specifying a certain number of subsequent repetitions. To define a simple scheduled route policy, create an instance of the following class:

```java
org.apache.camel.routepolicy.quartz.SimpleScheduledRoutePolicy
```

**Dependency**

The simple scheduled route policy depends on the Quartz component, `camel-quartz`. For example, if you are using Maven as your build system, you would need to add a dependency on the `camel-quartz` artifact.

**Java DSL example**

Example 2.7, “Java DSL Example of Simple Scheduled Route” shows how to schedule a route to start up using the Java DSL. The initial start time, `startTime`, is defined to be 3 seconds after the current time. The policy is also configured to start the route a second time, 3 seconds after the initial start time, which is configured by setting `routeStartRepeatCount` to 1 and `routeStartRepeatInterval` to 3000 milliseconds.

In Java DSL, you attach the route policy to the route by calling the `routePolicy()` DSL command in the route.

```java
Example 2.7. Java DSL Example of Simple Scheduled Route

// Java
SimpleScheduledRoutePolicy policy = new SimpleScheduledRoutePolicy();
long startTime = System.currentTimeMillis() + 3000L;
policy.setRouteStartDate(new Date(startTime));
policy.setRouteStartRepeatCount(1);
policy.setRouteStartRepeatInterval(3000);

from("direct:start")
  .routeId("test")
  .routePolicy(policy)
  .to("mock:success");
```

**NOTE**

You can specify multiple policies on the route by calling `routePolicy()` with multiple arguments.

**XML DSL example**

Example 2.8, “XML DSL Example of Simple Scheduled Route” shows how to schedule a route to start up using the XML DSL.

In XML DSL, you attach the route policy to the route by setting the `routePolicyRef` attribute on the `route` element.

```xml
Example 2.8. XML DSL Example of Simple Scheduled Route
```

```
// Java
SimpleScheduledRoutePolicy policy = new SimpleScheduledRoutePolicy();
long startTime = System.currentTimeMillis() + 3000L;
policy.setRouteStartDate(new Date(startTime));
policy.setRouteStartRepeatCount(1);
policy.setRouteStartRepeatInterval(3000);

from("direct:start")
  .routeId("test")
  .routePolicy(policy)
  .to("mock:success");
```
You can specify multiple policies on the route by setting the value of `routePolicyRef` as a comma-separated list of bean IDs.

**Defining dates and times**

The initial times of the triggers used in the simple scheduled route policy are specified using the `java.util.Date` type. The most flexible way to define a `Date` instance is through the `java.util.GregorianCalendar` class. Use the convenient constructors and methods of the `GregorianCalendar` class to define a date and then obtain a `Date` instance by calling `GregorianCalendar.getTime()`.

For example, to define the time and date for January 1, 2011 at noon, call a `GregorianCalendar` constructor as follows:

```java
// Java
import java.util.GregorianCalendar;
import java.util.Calendar;

GregorianCalendar gc = new GregorianCalendar(
    2011, // year
    Calendar.JANUARY, // month
    1, // day
    12, // hourOfDay
    0, // minutes
    0    // seconds
);
java.util.Date triggerDate = gc.getTime();
```

The `GregorianCalendar` class also supports the definition of times in different time zones. By default, it uses the local time zone on your computer.

**Graceful shutdown**

When you configure a simple scheduled route policy to stop a route, the route stopping...
algorithm is automatically integrated with the graceful shutdown procedure (see Section 2.10, “Controlling Start-Up and Shutdown of Routes”). This means that the task waits until the current exchange has finished processing before shutting down the route. You can set a timeout, however, that forces the route to stop after the specified time, irrespective of whether or not the route has finished processing the exchange.

Scheduling tasks

You can use a simple scheduled route policy to define one or more of the following scheduling tasks:

- the section called “Starting a route”.
- the section called “Stopping a route”.
- the section called “Suspending a route”.
- the section called “Resuming a route”.

Starting a route

The following table lists the parameters for scheduling one or more route starts.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>routeStartDate</td>
<td>java.util.Date</td>
<td>None</td>
<td>Specifies the date and time when the route is started for the first time.</td>
</tr>
<tr>
<td>routeStartRepeatCount</td>
<td>int</td>
<td>0</td>
<td>When set to a non-zero value, specifies how many times the route should be started.</td>
</tr>
<tr>
<td>routeStartRepeatInterval</td>
<td>long</td>
<td>0</td>
<td>Specifies the time interval between starts, in units of milliseconds.</td>
</tr>
</tbody>
</table>

Stopping a route

The following table lists the parameters for scheduling one or more route stops.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>routeStopDate</td>
<td>java.util.Date</td>
<td>None</td>
<td>Specifies the date and time when the route is stopped for the first time.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Type</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------</td>
<td>---------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>routeStopRepeatCount</td>
<td>int</td>
<td>0</td>
<td>When set to a non-zero value, specifies how many times the route should be stopped.</td>
</tr>
<tr>
<td>routeStopRepeatInterval</td>
<td>long</td>
<td>0</td>
<td>Specifies the time interval between stops, in units of milliseconds.</td>
</tr>
<tr>
<td>routeStopGracePeriod</td>
<td>int</td>
<td>10000</td>
<td>Specifies how long to wait for the current exchange to finish processing (grace period) before forcibly stopping the route. Set to 0 for an infinite grace period.</td>
</tr>
<tr>
<td>routeStopTimeUnit</td>
<td>long</td>
<td>TimeUnit.MILLISECONDS</td>
<td>Specifies the time unit of the grace period.</td>
</tr>
</tbody>
</table>

**Suspending a route**

The following table lists the parameters for scheduling the suspension of a route one or more times.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>routeSuspendDate</td>
<td>java.util.Date</td>
<td>None</td>
<td>Specifies the date and time when the route is suspended for the first time.</td>
</tr>
<tr>
<td>routeSuspendRepeatCount</td>
<td>int</td>
<td>0</td>
<td>When set to a non-zero value, specifies how many times the route should be suspended.</td>
</tr>
<tr>
<td>routeSuspendRepeatInterval</td>
<td>long</td>
<td>0</td>
<td>Specifies the time interval between suspends, in units of milliseconds.</td>
</tr>
</tbody>
</table>

**Resuming a route**
The following table lists the parameters for scheduling the resumption of a route one or more times.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>routeResumeDate</td>
<td>java.util.Date</td>
<td>None</td>
<td>Specifies the date and time when the route is resumed for the first time.</td>
</tr>
<tr>
<td>routeResumeRepeatCount</td>
<td>int</td>
<td>0</td>
<td>When set to a non-zero value, specifies how many times the route should be resumed.</td>
</tr>
<tr>
<td>routeResumeRepeatInterval</td>
<td>long</td>
<td>0</td>
<td>Specifies the time interval between resumes, in units of milliseconds.</td>
</tr>
</tbody>
</table>

2.11.3. Cron Scheduled Route Policy

**Overview**

The cron scheduled route policy is a route policy that enables you to start, stop, suspend, and resume routes, where the timing of these events is specified using cron expressions. To define a cron scheduled route policy, create an instance of the following class:

```java
org.apache.camel.routepolicy.quartz.CronScheduledRoutePolicy
```

**Dependency**

The simple scheduled route policy depends on the Quartz component, camel-quartz. For example, if you are using Maven as your build system, you would need to add a dependency on the camel-quartz artifact.

**Java DSL example**

Example 2.9, "Java DSL Example of a Cron Scheduled Route" shows how to schedule a route to start up using the Java DSL. The policy is configured with the cron expression, */3 * * * * ?, which triggers a start event every 3 seconds.

In Java DSL, you attach the route policy to the route by calling the `routePolicy()` DSL command in the route.

```java
// Java
CronScheduledRoutePolicy policy = new CronScheduledRoutePolicy();
policy.setRouteStartTime("*/3 * * * *?");
```
NOTE
You can specify multiple policies on the route by calling `routePolicy()` with multiple arguments.

XML DSL example

Example 2.10, “XML DSL Example of a Cron Scheduled Route” shows how to schedule a route to start up using the XML DSL.

In XML DSL, you attach the route policy to the route by setting the `routePolicyRef` attribute on the `route` element.

Example 2.10. XML DSL Example of a Cron Scheduled Route

```xml
<bean id="date" class="org.apache.camel.routepolicy.quartz.SimpleDate"/>

<bean id="startPolicy" class="org.apache.camel.routepolicy.quartz.CronScheduledRoutePolicy">
    <property name="routeStartTime" value="*/3 * * * * ?"/>
</bean>

<camelContext xmlns="http://camel.apache.org/schema/spring">
    <route id="testRoute" routePolicyRef="startPolicy">
        <from uri="direct:start"/>
        <to uri="mock:success"/>
    </route>
</camelContext>
```

NOTE
You can specify multiple policies on the route by setting the value of `routePolicyRef` as a comma-separated list of bean IDs.

Defining cron expressions

The `cron expression` syntax has its origins in the UNIX `cron` utility, which schedules jobs to run in the background on a UNIX system. A cron expression is effectively a syntax for wildcarding dates and times that enables you to specify either a single event or multiple events that recur periodically.

A cron expression consists of 6 or 7 fields in the following order:

- Seconds
- Minutes
- Hours
- DayOfMonth
- Month
- DayOfWeek
- [Year]
The **Year** field is optional and usually omitted, unless you want to define an event that occurs once and once only. Each field consists of a mixture of literals and special characters. For example, the following cron expression specifies an event that fires once every day at midnight:

```
0 0 24 * * ?
```

The * character is a wildcard that matches every value of a field. Hence, the preceding expression matches every day of every month. The ? character is a dummy placeholder that means *ignore this field*. It always appears either in the **DayOfMonth** field or in the **DayOfWeek** field, because it is not logically consistent to specify both of these fields at the same time. For example, if you want to schedule an event that fires once a day, but only from Monday to Friday, use the following cron expression:

```
0 0 24 ? * MON-FRI
```

Where the hyphen character specifies a range, **MON-FRI**. You can also use the forward slash character, /, to specify increments. For example, to specify that an event fires every 5 minutes, use the following cron expression:

```
0 0/5 * * * ?
```

For a full explanation of the cron expression syntax, see the Wikipedia article on **CRON expressions**.

### Scheduling tasks

You can use a cron scheduled route policy to define one or more of the following scheduling tasks:

- the section called “Starting a route”.
- the section called “Stopping a route”.
- the section called “Suspending a route”.
- the section called “Resuming a route”.

### Starting a route

The following table lists the parameters for scheduling one or more route starts.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>routeStartString</td>
<td>String</td>
<td>None</td>
<td>Specifies a cron expression that triggers one or more route start events.</td>
</tr>
</tbody>
</table>

### Stopping a route

The following table lists the parameters for scheduling one or more route stops.
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>routeStopTime</td>
<td>String</td>
<td>None</td>
<td>Specifies a cron expression that triggers one or more route stop events.</td>
</tr>
<tr>
<td>routeStopGracePeriod</td>
<td>int</td>
<td>10000</td>
<td>Specifies how long to wait for the current exchange to finish processing (grace period) before forcibly stopping the route. Set to 0 for an infinite grace period.</td>
</tr>
<tr>
<td>routeStopTimeUnit</td>
<td>long</td>
<td>TimeUnit.MILLISECONDS</td>
<td>Specifies the time unit of the grace period.</td>
</tr>
</tbody>
</table>

**Suspending a route**

The following table lists the parameters for scheduling the suspension of a route one or more times.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>routeSuspendTime</td>
<td>String</td>
<td>None</td>
<td>Specifies a cron expression that triggers one or more route suspend events.</td>
</tr>
</tbody>
</table>

**Resuming a route**

The following table lists the parameters for scheduling the resumption of a route one or more times.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>routeResumeTime</td>
<td>String</td>
<td>None</td>
<td>Specifies a cron expression that triggers one or more route resume events.</td>
</tr>
</tbody>
</table>

**2.12. JMX NAMING**

**Overview**
Apache Camel allows you to customise the name of a CamelContext bean as it appears in JMX, by defining a management name pattern for it. For example, you can customise the name pattern of an XML CamelContext instance, as follows:

```xml
<camelContext id="myCamel" managementNamePattern="#name#">
    ...
</camelContext>
```

If you do not explicitly set a name pattern for the CamelContext bean, Apache Camel reverts to a default naming strategy.

**Default naming strategy**

By default, the JMX name of a CamelContext bean is equal to the value of the bean's `id` attribute, prefixed by the current bundle ID. For example, if the `id` attribute on a `camelContext` element is `myCamel` and the current bundle ID is 250, the JMX name would be `250-myCamel`. In cases where there is more than one CamelContext instance with the same `id` in the bundle, the JMX name is disambiguated by adding a counter value as a suffix. For example, if there are multiple instances of `myCamel` in the bundle, the corresponding JMX MBeans are named as follows:

```text
250-myCamel-1
250-myCamel-2
250-myCamel-3
...```

**Customising the JMX naming strategy**

One drawback of the default naming strategy is that you cannot guarantee that a given CamelContext bean will have the same JMX name between runs. If you want to have greater consistency between runs, you can control the JMX name more precisely by defining a JMX name pattern for the CamelContext instances.

**Specifying a name pattern in Java**

To specify a name pattern on a CamelContext in Java, call the `setNamePattern` method, as follows:

```java
// Java
camelContext.setNamePattern("#name#");
```

**Specifying a name pattern in XML**

To specify a name pattern on a CamelContext in XML, set the `managementNamePattern` attribute on the camelContext element, as follows:

```xml
<camelContext id="myCamel" managementNamePattern="#name#"/>
```

**Name pattern tokens**

You can construct a JMX name pattern by mixing literal text with any of the following tokens:

- `#name#`
- `#id#`
- `#bundleId#`
- `#counter#`
- `#bundleGroupId#`
- `#bundleVersion#`
Table 2.11. JMX Name Pattern Tokens

<table>
<thead>
<tr>
<th>Token</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>#camelId#</td>
<td>Value of the id attribute on the CamelContext bean.</td>
</tr>
<tr>
<td>#name#</td>
<td>Same as #camelId#.</td>
</tr>
<tr>
<td>#counter#</td>
<td>An incrementing counter (starting at 1).</td>
</tr>
<tr>
<td>#bundleId#</td>
<td>The OSGi bundle ID of the deployed bundle (OSGi only).</td>
</tr>
<tr>
<td>#symbolicName#</td>
<td>The OSGi symbolic name (OSGi only).</td>
</tr>
<tr>
<td>#version#</td>
<td>The OSGi bundle version (OSGi only).</td>
</tr>
</tbody>
</table>

Examples

Here are some examples of JMX name patterns you could define using the supported tokens:

```xml
<camelContext id="fooContext" managementNamePattern="FooApplication-#name#">
  ...
</camelContext>
<camelContext id="myCamel" managementNamePattern="#bundleID#-#symbolicName#-#name#">
  ...
</camelContext>
<camelContext id="foo" managementNamePattern="SameOldSameOld">
  ...
</camelContext>
<camelContext id="bar" managementNamePattern="SameOldSameOld">
  ...
</camelContext>
```

Ambiguous names

Because the customised naming pattern overrides the default naming strategy, it is possible to define ambiguous JMX MBean names using this approach. For example:

```xml
<camelContext id="foo" managementNamePattern="SameOldSameOld">
  ...
</camelContext>
<camelContext id="bar" managementNamePattern="SameOldSameOld">
  ...
</camelContext>
```

In this case, Apache Camel would fail on start-up and report an MBean already exists exception. You should, therefore, take extra care to ensure that you do not define ambiguous name patterns.

2.13. PERFORMANCE AND OPTIMIZATION

Avoid unnecessary message copying
You can avoid making an unnecessary copy of the original message, by setting the `allowUseOriginalMessage` option to `false` on the `CamelContext` object. For example, in Blueprint XML you can set this option as follows:

```xml
<camelContext xmlns="http://camel.apache.org/schema/blueprint"
              allowUseOriginalMessage="false">
    ...
</camelContext>
```

You can safely set `allowUseOriginalMessage` to `false`, if the following conditions are satisfied:

- You do not set `useOriginalMessage=true` on any of the error handlers or on the `onException` element.
- You do not use the `getOriginalMessage` method anywhere in your Java application code.
CHAPTER 3. INTRODUCING ENTERPRISE INTEGRATION PATTERNS

Abstract

The Apache Camel's Enterprise Integration Patterns are inspired by a book of the same name written by Gregor Hohpe and Bobby Woolf. The patterns described by these authors provide an excellent toolbox for developing enterprise integration projects. In addition to providing a common language for discussing integration architectures, many of the patterns can be implemented directly using Apache Camel's programming interfaces and XML configuration.

3.1. OVERVIEW OF THE PATTERNS

Enterprise Integration Patterns book

Apache Camel supports most of the patterns from the book, Enterprise Integration Patterns by Gregor Hohpe and Bobby Woolf.

Messaging systems

The messaging systems patterns, shown in Table 3.1, “Messaging Systems”, introduce the fundamental concepts and components that make up a messaging system.

Table 3.1. Messaging Systems

<table>
<thead>
<tr>
<th>Icon</th>
<th>Name</th>
<th>Use Case</th>
</tr>
</thead>
<tbody>
<tr>
<td><img src="image" alt="Message Icon" /></td>
<td>Message</td>
<td>How can two applications connected by a message channel exchange a piece of information?</td>
</tr>
<tr>
<td><img src="image" alt="Message Channel Icon" /></td>
<td>Message Channel</td>
<td>How does one application communicate with another application using messaging?</td>
</tr>
<tr>
<td><img src="image" alt="Message Endpoint Icon" /></td>
<td>Message Endpoint</td>
<td>How does an application connect to a messaging channel to send and receive messages?</td>
</tr>
<tr>
<td><img src="image" alt="Pipes and Filters Icon" /></td>
<td>Pipes and Filters</td>
<td>How can we perform complex processing on a message while still maintaining independence and flexibility?</td>
</tr>
</tbody>
</table>
## Message Router

How can you decouple individual processing steps so that messages can be passed to different filters depending on a set of defined conditions?

## Message Translator

How do systems using different data formats communicate with each other using messaging?

### Messaging channels

A messaging channel is the basic component used for connecting the participants in a messaging system. The patterns in Table 3.2, “Messaging Channels” describe the different kinds of messaging channels available.

### Table 3.2. Messaging Channels

<table>
<thead>
<tr>
<th>Icon</th>
<th>Name</th>
<th>Use Case</th>
</tr>
</thead>
<tbody>

CHAPTER 4. MESSAGING SYSTEMS

Abstract

This chapter introduces the fundamental building blocks of a messaging system, such as endpoints, messaging channels, and message routers.

4.1. MESSAGE

Overview

A message is the smallest unit for transmitting data in a messaging system (represented by the grey dot in the figure below). The message itself might have some internal structure—for example, a message containing multiple parts—which is represented by geometrical figures attached to the grey dot in Figure 4.1, “Message Pattern”.

Figure 4.1. Message Pattern

Types of message

Apache Camel defines the following distinct message types:

- **In message** — A message that travels through a route from a consumer endpoint to a producer endpoint (typically, initiating a message exchange).

- **Out message** — A message that travels through a route from a producer endpoint back to a consumer endpoint (usually, in response to an In message).

All of these message types are represented internally by the *org.apache.camel.Message* interface.

Message structure

By default, Apache Camel applies the following structure to all message types:

- **Headers** — Contains metadata or header data extracted from the message.

- **Body** — Usually contains the entire message in its original form.

- **Attachments** — Message attachments (required for integrating with certain messaging systems, such as JBI).

It is important to remember that this division into headers, body, and attachments is an abstract model of the message. Apache Camel supports many different components, that generate a wide variety of message formats. Ultimately, it is the underlying component implementation that decides what gets placed into the headers and body of a message.
Correlating messages

Internally, Apache Camel remembers the message IDs, which are used to correlate individual messages. In practice, however, the most important way that Apache Camel correlates messages is through exchange objects.

Exchange objects

An exchange object is an entity that encapsulates related messages, where the collection of related messages is referred to as a message exchange and the rules governing the sequence of messages are referred to as an exchange pattern. For example, two common exchange patterns are: one-way event messages (consisting of an In message), and request-reply exchanges (consisting of an In message, followed by an Out message).

Accessing messages

When defining a routing rule in the Java DSL, you can access the headers and body of a message using the following DSL builder methods:

- `header(String name), body()` — Returns the named header and the body of the current In message.
- `outBody()` — Returns the body of the current Out message.

For example, to populate the In message's `username` header, you can use the following Java DSL route:

```java
from(SourceURL).setHeader("username", "John.Doe").to(TargetURL);
```

4.2. MESSAGE CHANNEL

Overview

A message channel is a logical channel in a messaging system. That is, sending messages to different message channels provides an elementary way of sorting messages into different message types. Message queues and message topics are examples of message channels. You should remember that a logical channel is not the same as a physical channel. There can be several different ways of physically realizing a logical channel.

In Apache Camel, a message channel is represented by an endpoint URI of a message-oriented component as shown in Figure 4.2, “Message Channel Pattern”.
Message-oriented components

The following message-oriented components in Apache Camel support the notion of a message channel:

- **ActiveMQ**
- **JMS**
- **AMQP**

**ActiveMQ**

In ActiveMQ, message channels are represented by *queues* or *topics*. The endpoint URI for a specific queue, *QueueName*, has the following format:

```
activemq:QueueName
```

The endpoint URI for a specific topic, *TopicName*, has the following format:

```
activemq:topic:TopicName
```

For example, to send messages to the queue, *Foo.Bar*, use the following endpoint URI:

```
activemq:Foo.Bar
```

See for more details and instructions on setting up the ActiveMQ component.

**JMS**

The Java Messaging Service (JMS) is a generic wrapper layer that is used to access many different kinds of message systems (for example, you can use it to wrap ActiveMQ, MQSeries, Tibco, BEA, Sonic, and others). In JMS, message channels are represented by queues, or topics. The endpoint URI for a specific queue, *QueueName*, has the following format:

```
jms:QueueName
```
The endpoint URI for a specific topic, \textit{TopicName}, has the following format:

\texttt{jms:topic:TopicName}

See for more details and instructions on setting up the JMS component.

\textbf{AMQP}

In AMQP, message channels are represented by queues, or topics. The endpoint URI for a specific queue, \textit{QueueName}, has the following format:

\texttt{amqp:QueueName}

The endpoint URI for a specific topic, \textit{TopicName}, has the following format:

\texttt{amqp:topic:TopicName}

See for more details and instructions on setting up the AMQP component.

\section*{4.3. MESSAGE ENDPOINT}

\textbf{Overview}

A \textit{message endpoint} is the interface between an application and a messaging system. As shown in Figure 4.3, “Message Endpoint Pattern”, you can have a sender endpoint, sometimes called a proxy or a service consumer, which is responsible for sending \textit{In} messages, and a receiver endpoint, sometimes called an endpoint or a service, which is responsible for receiving \textit{In} messages.

\textbf{Figure 4.3. Message Endpoint Pattern}

\textbf{Types of endpoint}

Apache Camel defines two basic types of endpoint:

- \textit{Consumer endpoint} — Appears at the start of a Apache Camel route and reads\texttt{In} messages from an incoming channel (equivalent to a \textit{receiver} endpoint).

- \textit{Producer endpoint} — Appears at the end of a Apache Camel route and writes\texttt{In} messages to an outgoing channel (equivalent to a \textit{sender} endpoint). It is possible to define a route with multiple producer endpoints.

\textbf{Endpoint URIs}
In Apache Camel, an endpoint is represented by an **endpoint URI**, which typically encapsulates the following kinds of data:

- **Endpoint URI for a consumer endpoint** — Advertises a specific location (for example, to expose a service to which senders can connect). Alternatively, the URI can specify a message source, such as a message queue. The endpoint URI can include settings to configure the endpoint.

- **Endpoint URI for a producer endpoint** — Contains details of where to send messages and includes the settings to configure the endpoint. In some cases, the URI specifies the location of a remote receiver endpoint; in other cases, the destination can have an abstract form, such as a queue name.

An endpoint URI in Apache Camel has the following general form:

```
ComponentPrefix:ComponentSpecificURI
```

Where **ComponentPrefix** is a URI prefix that identifies a particular Apache Camel component (see for details of all the supported components). The remaining part of the URI, **ComponentSpecificURI**, has a syntax defined by the particular component. For example, to connect to the JMS queue, Foo.Bar, you can define an endpoint URI like the following:

```
jms:Foo.Bar
```

To define a route that connects the consumer endpoint, `file://local/router/messages/foo`, directly to the producer endpoint `jms:Foo.Bar`, you can use the following Java DSL fragment:

```
from("file://local/router/messages/foo").to("jms:Foo.Bar");
```

Alternatively, you can define the same route in XML, as follows:

```
<camelContext id="CamelContextID"
    xmlns="http://camel.apache.org/schema/spring">
    <route>
        <from uri="file://local/router/messages/foo"/>
        <to uri="jms:Foo.Bar"/>
    </route>
</camelContext>
```

### 4.4. PIPES AND FILTERS

#### Overview

The **pipes and filters** pattern, shown in Figure 4.4, “Pipes and Filters Pattern”, describes a way of constructing a route by creating a chain of filters, where the output of one filter is fed into the input of the next filter in the pipeline (analogous to the UNIX `pipe` command). The advantage of the pipeline approach is that it enables you to compose services (some of which can be external to the Apache Camel application) to create more complex forms of message processing.
Pipeline for the InOut exchange pattern

Normally, all of the endpoints in a pipeline have an input (In message) and an output (Out message), which implies that they are compatible with the InOut message exchange pattern. A typical message flow through an InOut pipeline is shown in Figure 4.5, “Pipeline for InOut Exchanges”.

Pipeline for the InOnly and RobustInOnly exchange patterns

When there are no Out messages available from the endpoints in the pipeline (as is the case for the InOnly and RobustInOnly exchange patterns), a pipeline cannot be connected in the normal way. In this special case, the pipeline is constructed by passing a copy of the
original In message to each of the endpoints in the pipeline, as shown in Figure 4.6, “Pipeline for InOnly Exchanges”. This type of pipeline is equivalent to a recipient list with fixed destinations (see Section 7.3, “Recipient List”).

**Figure 4.6. Pipeline for InOnly Exchanges**

The route for this pipeline is defined using the same syntax as an InOut pipeline (either in Java DSL or in XML).

**Comparison of pipeline() and to() DSL commands**

In the Java DSL, you can define a pipeline route using either of the following syntaxes:

- *Using the pipeline() processor command* — Use the pipeline processor to construct a pipeline route as follows:

  ```java
to(SourceURI).pipeline(FilterA, FilterB, TargetURI);
  ```

- *Using the to() command* — Use the to() command to construct a pipeline route as follows:

  ```java
to(SourceURI).to(FilterA, FilterB, TargetURI);
  ```

Alternatively, you can use the equivalent syntax:

```java
to(SourceURI).to(FilterA).to(FilterB).to(TargetURI);
```

Exercise caution when using the to() command syntax, because it is not always equivalent to a pipeline processor. In Java DSL, the meaning of to() can be modified by the preceding command in the route. For example, when the multicast() command precedes the to() command, it binds the listed endpoints into a multicast pattern, instead of a pipeline pattern (see Section 7.11, “Multicast”).

**4.5. MESSAGE ROUTER**

**Overview**

A *message router*, shown in Figure 4.7, “Message Router Pattern”, is a type of filter that consumes messages from a single consumer endpoint and redirects them to the appropriate target endpoint, based on a particular decision criterion. A message router is concerned only with redirecting messages; it does not modify the message content.
A message router can easily be implemented in Apache Camel using the `choice()` processor, where each of the alternative target endpoints can be selected using a `when()` subclause (for details of the choice processor, see Section 1.5, “Processors”).

### Java DSL example

The following Java DSL example shows how to route messages to three alternative destinations (either `seda:a`, `seda:b`, or `seda:c`) depending on the contents of the `foo` header:

```java
from("seda:a").choice()
    .when(header("foo").isEqualTo("bar")).to("seda:b")
    .when(header("foo").isEqualTo("cheese")).to("seda:c")
    .otherwise().to("seda:d");
```

### XML configuration example

The following example shows how to configure the same route in XML:

```xml
<camelContext id="buildSimpleRouteWithChoice"
    xmlns="http://camel.apache.org/schema/spring">
    <route>
        <from uri="seda:a"/>
        <choice>
            <when>
                <xpath>$foo = 'bar'</xpath>
                <to uri="seda:b"/>
            </when>
            <when>
                <xpath>$foo = 'cheese'</xpath>
                <to uri="seda:c"/>
            </when>
            <otherwise>
                <to uri="seda:d"/>
            </otherwise>
        </choice>
    </route>
</camelContext>
```

### Choice without otherwise

---

Red Hat JBoss Fuse 6.1 Apache Camel Development Guide

124
If you use `choice()` without an `otherwise()` clause, any unmatched exchanges are dropped by default.

## 4.6. MESSAGE TRANSLATOR

### Overview

The *message translator* pattern, shown in Figure 4.8, “Message Translator Pattern” describes a component that modifies the contents of a message, translating it to a different format. You can use Apache Camel’s bean integration feature to perform the message translation.

### Figure 4.8. Message Translator Pattern

![Message Translator Pattern Diagram]

 Incoming Message  
Translator  
Translated Message

### Bean integration

You can transform a message using bean integration, which enables you to call a method on any registered bean. For example, to call the method, `myMethodName()`, on the bean with ID, `myTransformerBean`:

```
from("activemq:SomeQueue")
    .beanRef("myTransformerBean", "myMethodName")
    .to("mqseries:AnotherQueue");
```

Where the `myTransformerBean` bean is defined in either a Spring XML file or in JNDI. If, you omit the method name parameter from `beanRef()`, the bean integration will try to deduce the method name to invoke by examining the message exchange.

You can also add your own explicit `Processor` instance to perform the transformation, as follows:

```
from("direct:start").process(new Processor() {
    public void process(Exchange exchange) {
        Message in = exchange.getIn();
        in.setBody(in.getBody(String.class) + " World!");
    }
}).to("mock:result");
```

Or, you can use the DSL to explicitly configure the transformation, as follows:

```
from("direct:start").setBody(body().append(" World!")).to("mock:result");
```
You can also use templating to consume a message from one destination, transform it with something like Velocity or XQuery and then send it on to another destination. For example, using the InOnly exchange pattern (one-way messaging):

```camel
from("activemq:My.Queue").
to("velocity:com/acme/MyResponse.vm").
to("activemq:Another.Queue");
```

If you want to use InOut (request-reply) semantics to process requests on the `My.Queue` queue on ActiveMQ with a template generated response, then you could use a route like the following to send responses back to the `JMSReplyTo` destination:

```camel
from("activemq:My.Queue").
to("velocity:com/acme/MyResponse.vm");
```
CHAPTER 5. MESSAGING CHANNELS

Abstract

Messaging channels provide the plumbing for a messaging application. This chapter describes the different kinds of messaging channels available in a messaging system, and the roles that they play.

5.1. POINT-TO-POINT CHANNEL

Overview

A point-to-point channel, shown in Figure 5.1, “Point to Point Channel Pattern” is a message channel that guarantees that only one receiver consumes any given message. This is in contrast with a publish-subscribe channel, which allows multiple receivers to consume the same message. In particular, with a point-to-point channel, it is possible for multiple receivers to subscribe to the same channel. If more than one receiver competes to consume a message, it is up to the message channel to ensure that only one receiver actually consumes the message.

Figure 5.1. Point to Point Channel Pattern

Components that support point-to-point channel

The following Apache Camel components support the point-to-point channel pattern:

- JMS
- ActiveMQ
- SEDA
- JPA
- XMPP

JMS

In JMS, a point-to-point channel is represented by a queue. For example, you can specify the endpoint URI for a JMS queue called Foo.Bar as follows:

```java
jms:queue:Foo.Bar
```

The qualifier, `queue:`, is optional, because the JMS component creates a queue endpoint by default. Therefore, you can also specify the following equivalent endpoint URI:

```java
queue:Foo.Bar
```
### ActiveMQ

In ActiveMQ, a point-to-point channel is represented by a queue. For example, you can specify the endpoint URI for an ActiveMQ queue called `Foo.Bar` as follows:

```
activemq:queue:Foo.Bar
```

See for more details.

### SEDA

The Apache Camel Staged Event-Driven Architecture (SEDA) component is implemented using a blocking queue. Use the SEDA component if you want to create a lightweight point-to-point channel that is *internal* to the Apache Camel application. For example, you can specify an endpoint URI for a SEDA queue called `SedaQueue` as follows:

```
seda:SedaQueue
```

### JPA

The Java Persistence API (JPA) component is an EJB 3 persistence standard that is used to write entity beans out to a database. See for more details.

### XMPP

The XMPP (Jabber) component supports the point-to-point channel pattern when it is used in the person-to-person mode of communication. See for more details.

## 5.2. PUBLISH-SUBSCRIBE CHANNEL

### Overview

A *publish-subscribe channel*, shown in Figure 5.2, “Publish Subscribe Channel Pattern”, is a message channel that enables multiple subscribers to consume any given message. This is in contrast with a *point-to-point channel*. Publish-subscribe channels are frequently used as a means of broadcasting events or notifications to multiple subscribers.
Components that support publish-subscribe channel

The following Apache Camel components support the publish-subscribe channel pattern:

- JMS
- ActiveMQ
- XMPP
- SEDA for working with SEDA in the same CamelContext which can work in pub-sub, but allowing multiple consumers.
- VM as SEDA, but for use within the same JVM.

**JMS**

In JMS, a publish-subscribe channel is represented by a topic. For example, you can specify the endpoint URI for a JMS topic called StockQuotes as follows:

```
.jms:topic:StockQuotes
```

See for more details.

**ActiveMQ**

In ActiveMQ, a publish-subscribe channel is represented by a topic. For example, you can specify the endpoint URI for an ActiveMQ topic called StockQuotes, as follows:
XMPP

The XMPP (Jabber) component supports the publish-subscribe channel pattern when it is used in the group communication mode. See for more details.

Static subscription lists

If you prefer, you can also implement publish-subscribe logic within the Apache Camel application itself. A simple approach is to define a static subscription list, where the target endpoints are all explicitly listed at the end of the route. However, this approach is not as flexible as a JMS or ActiveMQ topic.

Java DSL example

The following Java DSL example shows how to simulate a publish-subscribe channel with a single publisher, `seda:a`, and three subscribers, `seda:b`, `seda:c`, and `seda:d`:

```
from("seda:a").to("seda:b", "seda:c", "seda:d");
```

**NOTE**

This only works for the InOnly message exchange pattern.

XML configuration example

The following example shows how to configure the same route in XML:

```
<camelContext id="buildStaticRecipientList"
   xmlns="http://camel.apache.org/schema/spring">
   <route>
     <from uri="seda:a"/>
     <to uri="seda:b"/>
     <to uri="seda:c"/>
     <to uri="seda:d"/>
   </route>
</camelContext>
```

5.3. DEAD LETTER CHANNEL

Overview

The dead letter channel pattern, shown in Figure 5.3, “Dead Letter Channel Pattern”, describes the actions to take when the messaging system fails to deliver a message to the intended recipient. This includes such features as retrying delivery and, if delivery ultimately fails, sending the message to a dead letter channel, which archives the undelivered messages.
Creating a dead letter channel in Java DSL

The following example shows how to create a dead letter channel using Java DSL:

```java
errorHandler(deadLetterChannel("seda:errors");
from("seda:a").to("seda:b");
```

Where the `errorHandler()` method is a Java DSL interceptor, which implies that all of the routes defined in the current route builder are affected by this setting. The `deadLetterChannel()` method is a Java DSL command that creates a new dead letter channel with the specified destination endpoint, `seda:errors`.

The `errorHandler()` interceptor provides a catch-all mechanism for handling all error types. If you want to apply a more fine-grained approach to exception handling, you can use the `onException` clauses instead (see the section called “onException clause”).

XML DSL example

You can define a dead letter channel in the XML DSL, as follows:

```xml
<route errorHandlerRef="myDeadLetterErrorHandler">
    ...
</route>

<bean id="myDeadLetterErrorHandler" class="org.apache.camel.builder.DeadLetterChannelBuilder">
    <property name="deadLetterUri" value="jms:queue:dead"/>
    <property name="redeliveryPolicy" ref="myRedeliveryPolicyConfig"/>
</bean>

<bean id="myRedeliveryPolicyConfig" class="org.apache.camel.processor.RedeliveryPolicy">
```

Figure 5.3. Dead Letter Channel Pattern

![Diagram of the dead letter channel pattern](image)
Redelivery policy

Normally, you do not send a message straight to the dead letter channel, if a delivery attempt fails. Instead, you re-attempt delivery up to some maximum limit, and after all redelivery attempts fail you would send the message to the dead letter channel. To customize message redelivery, you can configure the dead letter channel to have a redelivery policy. For example, to specify a maximum of two redelivery attempts, and to apply an exponential backoff algorithm to the time delay between delivery attempts, you can configure the dead letter channel as follows:

```xml
<property name="maximumRedeliveries" value="3"/>  
<property name="redeliveryDelay" value="5000"/>
</bean>
```

Where you set the redelivery options on the dead letter channel by invoking the relevant methods in a chain (each method in the chain returns a reference to the current RedeliveryPolicy object). Table 5.1, “Redelivery Policy Settings” summarizes the methods that you can use to set redelivery policies.

Table 5.1. Redelivery Policy Settings

**Redelivery headers**

If Apache Camel attempts to redeliver a message, it automatically sets the headers described in Table 5.2, “Dead Letter Redelivery Headers” on the In message.

**Table 5.2. Dead Letter Redelivery Headers**

<table>
<thead>
<tr>
<th>Header Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
</table>
| Red Hat JBoss Fuse 6.1 Apache Camel Development Guide

134
### Header Name | Type | Description
--- | --- | ---
CamelRedeliveryCounter | Integer | Apache Camel 2.0: Counts the number of unsuccessful delivery attempts. This value is also set in `Exchange.REDELIVERY_COUNTER`.

CamelRedelivered | Boolean | Apache Camel 2.0: True, if one or more redelivery attempts have been made. This value is also set in `Exchange.REDELEVERED`.

CamelRedeliveryMaxCount | Integer | Apache Camel 2.6: Holds the maximum redelivery setting (also set in the `Exchange.REDELIVERY_MAX_COUNTER` exchange property). This header is absent if you use `retryWhile` or have unlimited maximum redelivery configured.

### Redelivery exchange properties

If Apache Camel attempts to redeliver a message, it automatically sets the exchange properties described in Table 5.3, “Redelivery Exchange Properties”.

**Table 5.3. Redelivery Exchange Properties**

<table>
<thead>
<tr>
<th>Exchange Property Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Exchange.FAILURE_ROUTE_ID</code></td>
<td>String</td>
<td>Provides the route ID of the route that failed. The literal name of this property is <code>CamelFailureRouteId</code>.</td>
</tr>
</tbody>
</table>

### Using the original message

**Available as of Apache Camel 2.0** Because an exchange object is subject to modification as it passes through the route, the exchange that is current when an exception is raised is not necessarily the copy that you would want to store in the dead letter channel. In many cases, it is preferable to log the message that arrived at the start of the route, before it was subject to any kind of transformation by the route. For example, consider the following route:

```java
from("jms:queue:order:input")
    .to("bean:validateOrder");
    .to("bean:transformOrder")
```
The preceding route listen for incoming JMS messages and then processes the messages using the sequence of beans: `validateOrder`, `transformOrder`, and `handleOrder`. But when an error occurs, we do not know in which state the message is in. Did the error happen before the `transformOrder` bean or after? We can ensure that the original message from `jms:queue:order:input` is logged to the dead letter channel by enabling the `useOriginalMessage` option as follows:

```java
// will use original body
errorHandler(deadLetterChannel("jms:queue:dead")
    .useOriginalMessage().maximumRedeliveries(5).redeliveryDelay(5000);
```

### Redeliver delay pattern

**Available as of Apache Camel 2.0** The `delayPattern` option is used to specify delays for particular ranges of the redelivery count. The delay pattern has the following syntax: `limit1:delay1; limit2:delay2; limit3:delay3;...`, where each `delayN` is applied to redeliveries in the range `limitN <= redeliveryCount < limitN+1`

For example, consider the pattern, `5:1000;10:5000;20:20000`, which defines three groups and results in the following redelivery delays:

- Attempt number 1..4 = 0 milliseconds (as the first group starts with 5).
- Attempt number 5..9 = 1000 milliseconds (the first group).
- Attempt number 10..19 = 5000 milliseconds (the second group).
- Attempt number 20.. = 20000 milliseconds (the last group).

You can start a group with limit 1 to define a starting delay. For example, `1:1000;5:5000` results in the following redelivery delays:

- Attempt number 1..4 = 1000 millis (the first group)
- Attempt number 5.. = 5000 millis (the last group)

There is no requirement that the next delay should be higher than the previous and you can use any delay value you like. For example, the delay pattern, `1:5000;3:1000`, starts with a 5 second delay and then reduces the delay to 1 second.

### Which endpoint failed?

When Apache Camel routes messages, it updates an `Exchange` property that contains the last endpoint the `Exchange` was sent to. Hence, you can obtain the URI for the current exchange’s most recent destination using the following code:

```java
// Java
String lastEndpointUri = exchange.getProperty(Exchange.TO_ENDPOINT,
    String.class);
```

Where `Exchange.TO_ENDPOINT` is a string constant equal to `CamelToEndpoint`. This property is updated whenever Camel sends a message to any endpoint.
If an error occurs during routing and the exchange is moved into the dead letter queue, Apache Camel will additionally set a property named `CamelFailureEndpoint`, which identifies the last destination the exchange was sent to before the error occurred. Hence, you can access the failure endpoint from within a dead letter queue using the following code:

```java
// Java
String failedEndpointUri = exchange.getProperty(Exchange.FAILURE_ENDPOINT, String.class);
```

Where `Exchange.FAILURE_ENDPOINT` is a string constant equal to `CamelFailureEndpoint`.

**NOTE**

These properties remain set in the current exchange, even if the failure occurs after the given destination endpoint has finished processing. For example, consider the following route:

```java
from("activemq:queue:foo")
  .to("http://someserver/somepath")
  .beanRef("foo");
```

Now suppose that a failure happens in the `foo` bean. In this case the `Exchange.TO_ENDPOINT` property and the `Exchange.FAILURE_ENDPOINT` property still contain the value, `http://someserver/somepath`.

**onRedelivery processor**

When a dead letter channel is performing redeliveries, it is possible to configure a Processor that is executed just before every redelivery attempt. This can be used for situations where you need to alter the message before it is redelivered.

For example, the following dead letter channel is configured to call the `MyRedeliverProcessor` before redelivering exchanges:

```java
// we configure our Dead Letter Channel to invoke
// MyRedeliverProcessor before a redelivery is
// attempted. This allows us to alter the message before
errorHandler(deadLetterChannel("mock:error").maximumRedeliveries(5)
  .onRedelivery(new MyRedeliverProcessor())
  // setting delay to zero is just to make unit testing faster
  .redeliveryDelay(0L));
```

Where the `MyRedeliverProcessor` process is implemented as follows:

```java
public class MyRedeliverProcessor implements Processor {
    public void process(Exchange exchange) throws Exception {
        // the message is being redelivered so we can alter it
        // we just append the redelivery counter to the body
```
Control redelivery during shutdown or stopping

If you stop a route or initiate graceful shutdown, the default behavior of the error handler is to continue attempting redelivery. Because this is typically not the desired behavior, you have the option of disabling redelivery during shutdown or stopping, by setting the `allowRedeliveryWhileStopping` option to `false`, as shown in the following example:

```java
errorHandler(deadLetterChannel("jms:queue:dead")
    .allowRedeliveryWhileStopping(false)
    .maximumRedeliveries(20)
    .redeliveryDelay(1000)
    .retryAttemptedLogLevel(LoggingLevel.INFO));
```

**NOTE**

The `allowRedeliveryWhileStopping` option is `true` by default, for backwards compatibility reasons. During aggressive shutdown, however, redelivery is always suppressed, irrespective of this option setting (for example, after graceful shutdown has timed out).

**onException clause**

Instead of using the `errorHandler()` interceptor in your route builder, you can define a series of `onException()` clauses that define different redelivery policies and different dead letter channels for various exception types. For example, to define distinct behavior for each of the `NullPointerException`, `IOException`, and `Exception` types, you can define the following rules in your route builder using Java DSL:

```java
onException(NullPointerException.class)
    .maximumRedeliveries(1)
    .setHeader("messageInfo", "Oh dear! An NPE.")
    .to("mock:npe_error");

onException(IOException.class)
    .initialRedeliveryDelay(5000L)
    .maximumRedeliveries(3)
    .backOffMultiplier(1.0)
    .useExponentialBackOff()
    .setHeader("messageInfo", "Oh dear! Some kind of I/O exception.");
```
Where the redelivery options are specified by chaining the redelivery policy methods (as listed in Table 5.1, “Redelivery Policy Settings”), and you specify the dead letter channel's endpoint using the to() DSL command. You can also call other Java DSL commands in the onException() clauses. For example, the preceding example calls setHeader() to record some error details in a message header named, messageInfo.

In this example, the NullPointerException and the IOException exception types are configured specially. All other exception types are handled by the generic Exception exception interceptor. By default, Apache Camel applies the exception interceptor that most closely matches the thrown exception. If it fails to find an exact match, it tries to match the closest base type, and so on. Finally, if no other interceptor matches, the interceptor for the Exception type matches all remaining exceptions.

5.4. GUARANTEED DELIVERY

Overview

Guaranteed delivery means that once a message is placed into a message channel, the messaging system guarantees that the message will reach its destination, even if parts of the application should fail. In general, messaging systems implement the guaranteed delivery pattern, shown in Figure 5.4, “Guaranteed Delivery Pattern”, by writing messages to persistent storage before attempting to deliver them to their destination.

Components that support guaranteed delivery

The following Apache Camel components support the guaranteed delivery pattern:

- JMS
- ActiveMQ
JMS

In JMS, the `deliveryPersistent` query option indicates whether or not persistent storage of messages is enabled. Usually it is unnecessary to set this option, because the default behavior is to enable persistent delivery. To configure all the details of guaranteed delivery, it is necessary to set configuration options on the JMS provider. These details vary, depending on what JMS provider you are using. For example, MQSeries, TibCo, BEA, Sonic, and others, all provide various qualities of service to support guaranteed delivery.

See for more details.

ActiveMQ

In ActiveMQ, message persistence is enabled by default. From version 5 onwards, ActiveMQ uses the AMQ message store as the default persistence mechanism. There are several different approaches you can use to enable message persistence in ActiveMQ.

The simplest option (different from Figure 5.4, “Guaranteed Delivery Pattern”) is to enable persistence in a central broker and then connect to that broker using a reliable protocol. After a message is been sent to the central broker, delivery to consumers is guaranteed. For example, in the Apache Camel configuration file, `META-INF/spring/camel-context.xml`, you can configure the ActiveMQ component to connect to the central broker using the OpenWire/TCP protocol as follows:

```xml
<beans ... >
  ...
  <bean id="activemq"
       class="org.apache.activemq.camel.component.ActiveMQComponent">
    <property name="brokerURL" value="tcp://somehost:61616"/>
  </bean>
  ...
</beans>
```

If you prefer to implement an architecture where messages are stored locally before being sent to a remote endpoint (similar to Figure 5.4, “Guaranteed Delivery Pattern”), you do this by instantiating an embedded broker in your Apache Camel application. A simple way to achieve this is to use the ActiveMQ Peer-to-Peer protocol, which implicitly creates an embedded broker to communicate with other peer endpoints. For example, in the `camel-context.xml` configuration file, you can configure the ActiveMQ component to connect to all of the peers in group, `GroupA`, as follows:

```xml
<beans ... >
  ...
  <bean id="activemq"
       class="org.apache.activemq.camel.component.ActiveMQComponent">
    <property name="brokerURL" value="peer://GroupA/broker1"/>
  </bean>
  ...
</beans>
```

Where `broker1` is the broker name of the embedded broker (other peers in the group
should use different broker names). One limiting feature of the Peer-to-Peer protocol is that it relies on IP multicast to locate the other peers in its group. This makes it unsuitable for use in wide area networks (and in some local area networks that do not have IP multicast enabled).

A more flexible way to create an embedded broker in the ActiveMQ component is to exploit ActiveMQ's VM protocol, which connects to an embedded broker instance. If a broker of the required name does not already exist, the VM protocol automatically creates one. You can use this mechanism to create an embedded broker with custom configuration. For example:

```xml
<beans ... >
  ...
  <bean id="activemq"
    class="org.apache.activemq.camel.component.ActiveMQComponent">
    <property name="brokerURL" value="vm://broker1?
    brokerConfig=xbean:activemq.xml"/>
  </bean>
  ...
</beans>
```

Where `activemq.xml` is an ActiveMQ file which configures the embedded broker instance. Within the ActiveMQ configuration file, you can choose to enable one of the following persistence mechanisms:

- **AMQ persistence** *(the default)* — A fast and reliable message store that is native to ActiveMQ. For details, see `amqPersistenceAdapter` and AMQ Message Store.

- **JDBC persistence** — Uses JDBC to store messages in any JDBC-compatible database. For details, see `jdbcPersistenceAdapter` and ActiveMQ Persistence.

- **Journal persistence** — A fast persistence mechanism that stores messages in a rolling log file. For details, see `journalPersistenceAdapter` and ActiveMQ Persistence.

- **Kaha persistence** — A persistence mechanism developed specifically for ActiveMQ. For details, see `kahaPersistenceAdapter` and ActiveMQ Persistence.

See for more details.

### ActiveMQ Journal

The ActiveMQ Journal component is optimized for a special use case where multiple, concurrent producers write messages to queues, but there is only one active consumer. Messages are stored in rolling log files and concurrent writes are aggregated to boost efficiency.

See for more details.

### 5.5. MESSAGE BUS

#### Overview

*Message bus* refers to a messaging architecture, shown in Figure 5.5, “Message Bus Pattern”, that enables you to connect diverse applications running on diverse computing platforms. In effect, the Apache Camel and its components constitute a message bus.
The following features of the message bus pattern are reflected in Apache Camel:

- **Common communication infrastructure** — The router itself provides the core of the common communication infrastructure in Apache Camel. However, in contrast to some message bus architectures, Apache Camel provides a heterogeneous infrastructure: messages can be sent into the bus using a wide variety of different transports and using a wide variety of different message formats.

- **Adapters** — Where necessary, Apache Camel can translate message formats and propagate messages using different transports. In effect, Apache Camel is capable of behaving like an adapter, so that external applications can hook into the message bus without refactoring their messaging protocols.

In some cases, it is also possible to integrate an adapter directly into an external application. For example, if you develop an application using Apache CXF, where the service is implemented using JAX-WS and JAXB mappings, it is possible to bind a variety of different transports to the service. These transport bindings function as adapters.
CHAPTER 6. MESSAGE CONSTRUCTION

Abstract

The message construction patterns describe the various forms and functions of the messages that pass through the system.

6.1. CORRELATION IDENTIFIER

Overview

The correlation identifier pattern, shown in Figure 6.1, “Correlation Identifier Pattern”, describes how to match reply messages with request messages, given that an asynchronous messaging system is used to implement a request-reply protocol. The essence of this idea is that request messages should be generated with a unique token, the request ID, that identifies the request message and reply messages should include a token, the correlation ID, that contains the matching request ID.

Apache Camel supports the Correlation Identifier from the EIP patterns by getting or setting a header on a Message.

When working with the ActiveMQ or JMS components, the correlation identifier header is called JMSCorrelationID. You can add your own correlation identifier to any message exchange to help correlate messages together in a single conversation (or business process). A correlation identifier is usually stored in a Apache Camel message header.

Some EIP patterns spin off a sub message and, in those cases, Apache Camel adds a correlation ID to the Exchange as a property with they key, Exchange.CORRELATION_ID, which links back to the source Exchange. For example, the Splitter, Multicast, Recipient List, and Wire Tap EIPs do this.

Figure 6.1. Correlation Identifier Pattern

6.2. EVENT MESSAGE
Event Message

Camel supports the Event Message from the Introducing Enterprise Integration Patterns by supporting the Exchange Pattern on a Message which can be set to InOnly to indicate a oneway event message. Camel Components then implement this pattern using the underlying transport or protocols.

The default behaviour of many Components is InOnly such as for JMS, File or SEDA

Explicitly specifying InOnly

If you are using a component which defaults to InOut you can override the Exchange Pattern for an endpoint using the pattern property.

```
foo:bar?exchangePattern=InOnly
```

From 2.0 onwards on Camel you can specify the Exchange Pattern using the dsl.

Using the Fluent Builders

```
from("mq:someQueue").
inOnly().
bean(Foo.class);
```

or you can invoke an endpoint with an explicit pattern

```
from("mq:someQueue").
inOnly("mq:anotherQueue");
```

Using the Spring XML Extensions

```
<route>
  <from uri="mq:someQueue"/>
```

6.3. RETURN ADDRESS

Return Address

Apache Camel supports the Return Address from the Introducing Enterprise Integration Patterns using the JMSReplyTo header.

For example when using JMS with InOut, the component will by default be returned to the address given in JMSReplyTo.

Example

Requestor Code

```java
getMockEndpoint("mock:bar").expectedBodiesReceived("Bye World");
template.sendBodyAndHeader("direct:start", "World", "JMSReplyTo", "queue:bar");
```

Route Using the Fluent Builders

```java
from("direct:start").to("activemq:queue:foo?preserveMessageQos=true");
from("activemq:queue:foo").transform(body().prepend("Bye "));
from("activemq:queue:bar?disableReplyTo=true").to("mock:bar");
```
Route Using the **Spring XML Extensions**

```xml
<route>
    <from uri="direct:start"/>
    <to uri="activemq:queue:foo?preserveMessageQos=true"/>
</route>

<route>
    <from uri="activemq:queue:foo"/>
    <transform>
        <simple>Bye ${in.body}</simple>
    </transform>
</route>

<route>
    <from uri="activemq:queue:bar?disableReplyTo=true"/>
    <to uri="mock:bar"/>
</route>
```

For a complete example of this pattern, see this [junit test case](#)
CHAPTER 7. MESSAGE ROUTING

Abstract

The message routing patterns describe various ways of linking message channels together. This includes various algorithms that can be applied to the message stream (without modifying the body of the message).

7.1. CONTENT-BASED ROUTER

Overview

A content-based router, shown in Figure 7.1, “Content-Based Router Pattern”, enables you to route messages to the appropriate destination based on the message contents.

Figure 7.1. Content-Based Router Pattern

Java DSL example

The following example shows how to route a request from an input, seda:a, endpoint to either seda:b, queue:c, or seda:d depending on the evaluation of various predicate expressions:

```java
RouteBuilder builder = new RouteBuilder() {
    public void configure() {
        from("seda:a").choice()
            .when(header("foo").isEqualTo("bar")).to("seda:b")
            .when(header("foo").isEqualTo("cheese")).to("seda:c")
            .otherwise().to("seda:d");
    }
};
```

XML configuration example

The following example shows how to configure the same route in XML:

```xml
<camelContext id="buildSimpleRouteWithChoice"
    xmlns="http://camel.apache.org/schema/spring">
    <route>
        <from uri="seda:a"/>
        <choice>
            <when>
                <xpath>$foo = 'bar'</xpath>
            </when>
            <otherwise>
                <xpath>$foo = 'cheese'</xpath>
            </otherwise>
        </choice>
    </route>
</camelContext>
```
7.2. MESSAGE FILTER

Overview

A message filter is a processor that eliminates undesired messages based on specific criteria. In Apache Camel, the message filter pattern, shown in Figure 7.2, “Message Filter Pattern”, is implemented by the `filter()` Java DSL command. The `filter()` command takes a single predicate argument, which controls the filter. When the predicate is `true`, the incoming message is allowed to proceed, and when the predicate is `false`, the incoming message is blocked.

Figure 7.2. Message Filter Pattern

Java DSL example

The following example shows how to create a route from endpoint, `seda:a`, to endpoint, `seda:b`, that blocks all messages except for those messages whose `foo` header have the value, `bar`:

```java
RouteBuilder builder = new RouteBuilder() {
    public void configure() {
        from("seda:a").filter(header("foo").isEqualTo("bar")).to("seda:b");
    }
};
```

To evaluate more complex filter predicates, you can invoke one of the supported scripting languages, such as XPath, XQuery, or SQL (see Expression and Predicate Languages). The following example defines a route that blocks all messages except for those containing a `person` element whose `name` attribute is equal to `James`:
XML configuration example

The following example shows how to configure the route with an XPath predicate in XML (see Expression and Predicate Languages):

```xml
<camelContext id="simpleFilterRoute" xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="seda:a"/>
    <filter>
      <xpath>$foo = 'bar'</xpath>
      <to uri="seda:b"/>
    </filter>
  </route>
</camelContext>
```

**FILTERED ENDPOINT REQUIRED INSIDE</FILTER> TAG**

Make sure you put the endpoint you want to filter (for example, `<to uri="seda:b"/>`) before the closing `</filter>` tag or the filter will not be applied (in 2.8+, omitting this will result in an error).

Filtering with beans

Here is an example of using a bean to define the filter behavior:

```java
public static class MyBean {
    public boolean isGoldCustomer(@Header("level") String level) {
        return level.equals("gold");
    }
}
```

Using `stop()`

**Available as of Camel 2.0**

Stop is a special type of filter that filters out all messages. Stop is convenient to use in a Content-Based Router when you need to stop further processing in one of the predicates.

In the following example, we do not want messages with the word `Bye` in the message body to propagate any further in the route. We prevent this in the `when()` predicate using `.stop()`.

```java
from("direct:start")
    .filter().method(MyBean.class, "isGoldCustomer").to("mock:result").to("mock:end");
```
Knowing if Exchange was filtered or not

Available as of Camel 2.5

The Message Filter EIP will add a property on the Exchange which states if it was filtered or not.

The property has the key `Exchange.FILTER_MATCHED` which has the String value of `CamelFilterMatched`. Its value is a boolean indicating `true` or `false`. If the value is `true` then the Exchange was routed in the filter block.

7.3. RECIPIENT LIST

Overview

A recipient list, shown in Figure 7.3, “Recipient List Pattern”, is a type of router that sends each incoming message to multiple different destinations. In addition, a recipient list typically requires that the list of recipients be calculated at run time.

Figure 7.3. Recipient List Pattern

Recipient list with fixed destinations

The simplest kind of recipient list is where the list of destinations is fixed and known in advance, and the exchange pattern is `InOnly`. In this case, you can hardwire the list of destinations into the `to()` Java DSL command.
The examples given here, for the recipient list with fixed destinations, work only with the InOnly exchange pattern (similar to a pipeline). If you want to create a recipient list for exchange patterns with Out messages, use the multicast pattern instead.

Java DSL example

The following example shows how to route an InOnly exchange from a consumer endpoint, queue:a, to a fixed list of destinations:

```java
from("seda:a").to("seda:b", "seda:c", "seda:d");
```

XML configuration example

The following example shows how to configure the same route in XML:

```xml
<camelContext id="buildStaticRecipientList" xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="seda:a"/>
    <to uri="seda:b"/>
    <to uri="seda:c"/>
    <to uri="seda:d"/>
  </route>
</camelContext>
```

Recipient list calculated at run time

In most cases, when you use the recipient list pattern, the list of recipients should be calculated at runtime. To do this use the recipientList() processor, which takes a list of destinations as its sole argument. Because Apache Camel applies a type converter to the list argument, it should be possible to use most standard Java list types (for example, a collection, a list, or an array). For more details about type converters, see Section 40.3, “Built-In Type Converters”.

The recipients receive a copy of the same exchange instance and Apache Camel executes them sequentially.

Java DSL example

The following example shows how to extract the list of destinations from a message header called recipientListHeader, where the header value is a comma-separated list of endpoint URIs:

```java
from("direct:a").recipientList(header("recipientListHeader").tokenize("",""));
```

In some cases, if the header value is a list type, you might be able to use it directly as the argument to recipientList(). For example:

```java
from("seda:a").recipientList(header("recipientListHeader"));
```
However, this example is entirely dependent on how the underlying component parses this particular header. If the component parses the header as a simple string, this example will not work. The header must be parsed into some type of Java list.

XML configuration example

The following example shows how to configure the preceding route in XML, where the header value is a comma-separated list of endpoint URIs:

```xml
<camelContext id="buildDynamicRecipientList"
xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="seda:a"/>
    <recipientList delimiter=",">
      <header>recipientListHeader</header>
    </recipientList>
  </route>
</camelContext>
```

Sending to multiple recipients in parallel

Available as of Camel 2.2

The Recipient List supports `parallelProcessing`, which is similar to the corresponding feature in Splitter. Use the parallel processing feature to send the exchange to multiple recipients concurrently—for example:

```java
from("direct:a").recipientList(header("myHeader")).parallelProcessing();
```

In Spring XML, the parallel processing feature is implemented as an attribute on the `recipientList` tag—for example:

```xml
<route>
  <from uri="direct:a"/>
  <recipientList parallelProcessing="true">
    <header>myHeader</header>
  </recipientList>
</route>
```

Stop on exception

Available as of Camel 2.2

The Recipient List supports the `stopOnException` feature, which you can use to stop sending to any further recipients, if any recipient fails.

```java
from("direct:a").recipientList(header("myHeader")).stopOnException();
```

And in Spring XML its an attribute on the recipient list tag.

In Spring XML, the stop on exception feature is implemented as an attribute on the `recipientList` tag—for example:
NOTE
You can combine `parallelProcessing` and `stopOnException` in the same route.

Ignore invalid endpoints

Available as of Camel 2.3

The Recipient List supports the `ignoreInvalidEndpoints` option, which enables the recipient list to skip invalid endpoints (Routing Slip also supports this option). For example:

```xml
<route>
    <from uri="direct:a"/>
    <recipientList stopOnException="true">
        <header>myHeader</header>
    </recipientList>
</route>
```

And in Spring XML, you can enable this option by setting the `ignoreInvalidEndpoints` attribute on the `recipientList` tag, as follows

```xml
<route>
    <from uri="direct:a"/>
    <recipientList ignoreInvalidEndpoints="true">
        <header>myHeader</header>
    </recipientList>
</route>
```

Consider the case where `myHeader` contains the two endpoints, `direct:foo,xxx:bar`. The first endpoint is valid and works. The second is invalid and, therefore, ignored. Apache Camel logs at INFO level whenever an invalid endpoint is encountered.

Using custom AggregationStrategy

Available as of Camel 2.2

You can use a custom `AggregationStrategy` with the Recipient List, which is useful for aggregating replies from the recipients in the list. By default, Apache Camel uses the `UseLatestAggregationStrategy` aggregation strategy, which keeps just the last received reply. For a more sophisticated aggregation strategy, you can define your own implementation of the `AggregationStrategy` interface—see Aggregator EIP for details. For example, to apply the custom aggregation strategy, `MyOwnAggregationStrategy`, to the reply messages, you can define a Java DSL route as follows:

```java
    from("direct:a")
        .recipientList(header("myHeader")).aggregationStrategy(new MyOwnAggregationStrategy())
        .to("direct:b");
```
In Spring XML, you can specify the custom aggregation strategy as an attribute on the `recipientList` tag, as follows:

```xml
<route>
  <from uri="direct:a"/>
  <recipientList strategyRef="myStrategy">
    <header>myHeader</header>
  </recipientList>
  <to uri="direct:b"/>
</route>

<bean id="myStrategy" class="com.mycompany.MyOwnAggregationStrategy"/>
```

**Using custom thread pool**

**Available as of Camel 2.2**

This is only needed when you use `parallelProcessing`. By default Camel uses a thread pool with 10 threads. Notice this is subject to change when we overhaul thread pool management and configuration later (hopefully in Camel 2.2).

You configure this just as you would with the custom aggregation strategy.

**Using method call as recipient list**

You can use a **Bean** to provide the recipients, for example:

```java
from("activemq:queue:test").recipientList().method(MessageRouter.class, "routeTo");
```

Where the **MessageRouter** bean is defined as follows:

```java
public class MessageRouter {

    public String routeTo() {
        String queueName = "activemq:queue:test2";
        return queueName;
    }
}
```

**Bean as recipient list**

You can make a bean behave as a recipient list by adding the `@RecipientList` annotation to a methods that returns a list of recipients. For example:

```java
public class MessageRouter {

    @RecipientList
    public String routeTo() {
        String queueList = "activemq:queue:test1,activemq:queue:test2";
        return queueList;
    }
}
```
In this case, do not include the recipientList DSL command in the route. Define the route as follows:

```java
from("activemq:queue:test").bean(MessageRouter.class, "routeTo");
```

**Using timeout**

**Available as of Camel 2.5**

If you use `parallelProcessing`, you can configure a total `timeout` value in milliseconds. Camel will then process the messages in parallel until the timeout is hit. This allows you to continue processing if one message is slow.

In the example below, the `recipientlist` header has the value, `direct:a,direct:b,direct:c`, so that the message is sent to three recipients. We have a timeout of 250 milliseconds, which means only the last two messages can be completed within the timeframe. The aggregation therefore yields the string result, **BC**.

```java
from("direct:start")
    .recipientList(header("recipients"), ",")
    .aggregationStrategy(new AggregationStrategy() {
        public Exchange aggregate(Exchange oldExchange, Exchange newExchange) {
            if (oldExchange == null) {
                return newExchange;
            }

            String body = oldExchange.getIn().getBody(String.class);
            oldExchange.getIn().setBody(body +
            newExchange.getIn().getBody(String.class));
            return oldExchange;
        }
    })
    .parallelProcessing().timeout(250)
    // use end to indicate end of recipientList clause
    .end()
    .to("mock:result");
```

```java
from("direct:a").delay(500).to("mock:A").setBody(constant("A"));
from("direct:b").to("mock:B").setBody(constant("B"));
from("direct:c").to("mock:C").setBody(constant("C"));
```

**NOTE**

This `timeout` feature is also supported by `splitter` and both `multicast` and `recipientList`.

By default if a timeout occurs the AggregationStrategy is not invoked. However you can implement a specialized version

```java
// Java
public interface TimeoutAwareAggregationStrategy extends
```
This allows you to deal with the timeout in the AggregationStrategy if you really need to.

**TIMEOUT IS TOTAL**

The timeout is total, which means that after X time, Camel will aggregate the messages which has completed within the timeframe. The remainders will be cancelled. Camel will also only invoke the timeout method in the TimeoutAwareAggregationStrategy once, for the first index which caused the timeout.

**Apply custom processing to the outgoing messages**

Before recipientList sends a message to one of the recipient endpoints, it creates a message replica, which is a shallow copy of the original message. If you want to perform some custom processing on each message replica before the replica is sent to its endpoint, you can invoke the onPrepare DSL command in the recipientList clause. The onPrepare command inserts a custom processor just after the message has been shallow-copied and just before the message is dispatched to its endpoint. For example, in the following route, the CustomProc processor is invoked on the message replica for each recipient endpoint:

```java
from("direct:start")
    .recipientList().onPrepare(new CustomProc());
```

A common use case for the onPrepare DSL command is to perform a deep copy of some or all elements of a message. This allows each message replica to be modified independently of the others. For example, the following CustomProc processor class performs a deep copy of the message body, where the message body is presumed to be of type, BodyType, and the deep copy is performed by the method, BodyType.deepCopy().

```java
import org.apache.camel.*;
...
public class CustomProc implements Processor {
    public void process(Exchange exchange) throws Exception {
        BodyType body = exchange.getIn().getBody(BodyType.class);

        // Make a _deep_ copy of of the body object
        BodyType clone = BodyType.deepCopy();
        exchange.getIn().setBody(clone);
    }
}
```
Options

The **recipientList** DSL command supports the following options:

<table>
<thead>
<tr>
<th>Name</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>delimiter</td>
<td>,</td>
<td>Delimiter used if the <strong>Expression</strong> returned multiple endpoints.</td>
</tr>
<tr>
<td>strategyRef</td>
<td></td>
<td>Refers to an <strong>AggregationStrategy</strong> to be used to assemble the replies from the recipients, into a single outgoing message from the <strong>Recipient List</strong>. By default Camel will use the last reply as the outgoing message.</td>
</tr>
<tr>
<td>parallelProcessing</td>
<td>false</td>
<td><strong>Camel 2.2:</strong> If enables then sending messages to the recipients occurs concurrently. Note the caller thread will still wait until all messages has been fully processed, before it continues. Its only the sending and processing the replies from the recipients which happens concurrently.</td>
</tr>
<tr>
<td>executorServiceRef</td>
<td></td>
<td><strong>Camel 2.2:</strong> Refers to a custom <strong>Thread Pool</strong> to be used for parallel processing. Notice if you set this option, then parallel processing is automatic implied, and you do not have to enable that option as well.</td>
</tr>
</tbody>
</table>

// Headers and attachments have already been shallow-copied. If you need deep copies, add some more code here.
<table>
<thead>
<tr>
<th>Property</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>stopOnException</code></td>
<td><code>false</code></td>
<td><strong>Camel 2.2:</strong> Whether or not to stop continue processing immediately when an exception occurred. If disable, then Camel will send the message to all recipients regardless if one of them failed. You can deal with exceptions in the <code>AggregationStrategy</code> class where you have full control how to handle that.</td>
</tr>
<tr>
<td><code>ignoreInvalidEndpoints</code></td>
<td><code>false</code></td>
<td><strong>Camel 2.3:</strong> If an endpoint uri could not be resolved, should it be ignored. Otherwise Camel will thrown an exception stating the endpoint uri is not valid.</td>
</tr>
<tr>
<td><code>streaming</code></td>
<td><code>false</code></td>
<td><strong>Camel 2.5:</strong> If enabled then Camel will process replies out-of-order, eg in the order they come back. If disabled, Camel will process replies in the same order as the <code>Expression</code> specified.</td>
</tr>
<tr>
<td><code>timeout</code></td>
<td></td>
<td><strong>Camel 2.5:</strong> Sets a total timeout specified in millis. If the <code>Recipient List</code> hasn't been able to send and process all replies within the given timeframe, then the timeout triggers and the <code>Recipient List</code> breaks out and continues. Notice if you provide a <code>TimeoutAwareAggregationStrategy</code> then the <code>timeout</code> method is invoked before breaking out.</td>
</tr>
<tr>
<td><code>onPrepareRef</code></td>
<td></td>
<td><strong>Camel 2.8:</strong> Refers to a custom Processor to prepare the copy of the Exchange each recipient will receive. This allows you to do any custom logic, such as deep-cloning the message payload if that's needed etc.</td>
</tr>
</tbody>
</table>
### 7.4. SPLITTER

#### Overview

A splitter is a type of router that splits an incoming message into a series of outgoing messages. Each of the outgoing messages contains a piece of the original message. In Apache Camel, the splitter pattern, shown in Figure 7.4, “Splitter Pattern”, is implemented by the `split()` Java DSL command.

**Figure 7.4. Splitter Pattern**

![Splitter Pattern Diagram](image)

The Apache Camel splitter actually supports two patterns, as follows:

- **Simple splitter**—implements the splitter pattern on its own.
- **Splitter/aggregator**—combines the splitter pattern with the aggregator pattern, such that the pieces of the message are recombined after they have been processed.

#### Java DSL example

The following example defines a route from `seda:a` to `seda:b` that splits messages by converting each line of an incoming message into a separate outgoing message:

```java
RouteBuilder builder = new RouteBuilder() {
    public void configure() {
        from("seda:a")
            .split(bodyAs(String.class).tokenize("\n"))
            .to("seda:b");
    }
};
```

The splitter can use any expression language, so you can split messages using any of the supported scripting languages, such as XPath, XQuery, or SQL (see Part II, “Routing Expression and Predicate Languages”). The following example extracts `bar` elements from an incoming message and insert them into separate outgoing messages:
XML configuration example

The following example shows how to configure a splitter route in XML, using the XPath scripting language:

```xml
<camelContext id="buildSplitter" xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="seda:a"/>
    <split>
      <xpath>//foo/bar</xpath>
      <to uri="seda:b"/>
    </split>
  </route>
</camelContext>
```

You can use the tokenize expression in the XML DSL to split bodies or headers using a token, where the tokenize expression is defined using the `tokenize` element. In the following example, the message body is tokenized using the `\n` separator character. To use a regular expression pattern, set `regex=true` in the `tokenize` element.

```xml
<camelContext xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="direct:start"/>
    <split>
      <tokenize token="\n"/>
      <to uri="mock:result"/>
    </split>
  </route>
</camelContext>
```

Splitting into groups of lines

To split a big file into chunks of 1000 lines, you can define a splitter route as follows in the Java DSL:

```java
from("file:inbox")
  .split().tokenize("\n", 1000).streaming()
  .to("activemq:queue:order");
```

The second argument to `tokenize` specifies the number of lines that should be grouped into a single chunk. The `streaming()` clause directs the splitter not to read the whole file at once (resulting in much better performance if the file is large).

The same route can be defined in XML DSL as follows:

```xml
<route>
  <from uri="file:inbox"/>
  <split streaming="true">
```
CHAPTER 7. MESSAGE ROUTING

<tokenize token="\n" group="1000"/>
<to uri="activemq:queue:order"/>
</split>
</route>
The output when using the group option is always of java.lang.String type.

Splitter reply
If the exchange that enters the splitter has the InOut message-exchange pattern (that is, a
reply is expected), the splitter returns a copy of the original input message as the reply
message in the Out message slot. You can override this default behavior by implementing
your own aggregation strategy.

Parallel execution
If you want to execute the resulting pieces of the message in parallel, you can enable the
parallel processing option, which instantiates a thread pool to process the message pieces.
For example:
XPathBuilder xPathBuilder = new XPathBuilder("//foo/bar");
from("activemq:my.queue").split(xPathBuilder).parallelProcessing().to("act
ivemq:my.parts");
You can customize the underlying ThreadPoolExecutor used in the parallel splitter. For
example, you can specify a custom executor in the Java DSL as follows:
XPathBuilder xPathBuilder = new XPathBuilder("//foo/bar");
ThreadPoolExecutor threadPoolExecutor = new ThreadPoolExecutor(8, 16, 0L,
TimeUnit.MILLISECONDS, new LinkedBlockingQueue());
from("activemq:my.queue")
.split(xPathBuilder)
.parallelProcessing()
.executorService(threadPoolExecutor)
.to("activemq:my.parts");
You can specify a custom executor in the XML DSL as follows:
<camelContext xmlns="http://camel.apache.org/schema/spring">
<route>
<from uri="direct:parallel-custom-pool"/>
<split executorServiceRef="threadPoolExecutor">
<xpath>/invoice/lineItems</xpath>
<to uri="mock:result"/>
</split>
</route>
</camelContext>
<bean id="threadPoolExecutor"
class="java.util.concurrent.ThreadPoolExecutor">
<constructor-arg index="0" value="8"/>
<constructor-arg index="1" value="16"/>
<constructor-arg index="2" value="0"/>
<constructor-arg index="3" value="MILLISECONDS"/>

161


Using a bean to perform splitting

As the splitter can use any expression to do the splitting, we can use a bean to perform splitting, by invoking the method() expression. The bean should return an iterable value such as: java.util.Collection, java.util.Iterator, or an array.

The following route defines a method() expression that calls a method on the mySplitterBean bean instance:

```xml
from("direct:body")
   // here we use a POJO bean mySplitterBean to do the split of the payload
   .split()
   .method("mySplitterBean", "splitBody")
   .to("mock:result");
from("direct:message")
   // here we use a POJO bean mySplitterBean to do the split of the message
   // with a certain header value
   .split()
   .method("mySplitterBean", "splitMessage")
   .to("mock:result");
```

Where mySplitterBean is an instance of the MySplitterBean class, which is defined as follows:

```java
public class MySplitterBean {

    /**
     * The split body method returns something that is iterable such as a java.util.List.
     *
     * @param body the payload of the incoming message
     * @return a list containing each part split
     */
    public List<String> splitBody(String body) {
        // since this is based on an unit test you can of couse
        // use different logic for splitting as Apache Camel have out
        // of the box support for splitting a String based on comma
        // but this is for show and tell, since this is java code
        // you have the full power how you like to split your messages
        List<String> answer = new ArrayList<String>();
        String[] parts = body.split(",");
        for (String part : parts) {
            answer.add(part);
        }
        return answer;
    }

    /**
     * The split message method returns something that is iterable such
Exchange properties

The following properties are set on each split exchange:

<table>
<thead>
<tr>
<th>header</th>
<th>type</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelSplitIndex</td>
<td>int</td>
<td>Apache Camel 2.0: A split counter that increases for each Exchange being split. The counter starts from 0.</td>
</tr>
<tr>
<td>CamelSplitSize</td>
<td>int</td>
<td>Apache Camel 2.0: The total number of Exchanges that was split. This header is not applied for stream based splitting.</td>
</tr>
<tr>
<td>CamelSplitComplete</td>
<td>boolean</td>
<td>Apache Camel 2.4: Whether or not this Exchange is the last.</td>
</tr>
</tbody>
</table>

Splitter/aggregator pattern

It is a common pattern for the message pieces to be aggregated back into a single exchange, after processing of the individual pieces has completed. To support this pattern, the `split()` DSL command lets you provide an `AggregationStrategy` object as the second argument.

```java
as a java.util.List.
*  
* @param header the header of the incoming message with the name user
* @param body the payload of the incoming message
* @return a list containing each part split
*/
public List<Message> splitMessage(@Header(value = "user") String header, @Body String body) {
    // we can leverage the Parameter Binding Annotations
    // http://camel.apache.org/parameter-binding-annotations.html
    // to access the message header and body at same time,
    // then create the message that we want, splitter will
    // take care rest of them.
    // *NOTE* this feature requires Apache Camel version >= 1.6.1
    List<Message> answer = new ArrayList<Message>();
    String[] parts = header.split(",");
    for (String part : parts) {
        DefaultMessage message = new DefaultMessage();
        message.setHeader("user", part);
        message.setBody(body);
        answer.add(message);
    }
    return answer;
}
```
Java DSL example

The following example shows how to use a custom aggregation strategy to recombine a split message after all of the message pieces have been processed:

```java
from("direct:start")
    .split(body().tokenize("@"), new MyOrderStrategy())
    // each split message is then send to this bean where we can process it
    .to("bean:MyOrderService?method=handleOrder")
    // this is important to end the splitter route as we do not want to do more routing
    // on each split message
    .end()
    // after we have split and handled each message we want to send a single combined
    // response back to the original caller, so we let this bean build it for us
    // this bean will receive the result of the aggregate strategy:
    MyOrderStrategy
    .to("bean:MyOrderService?method=buildCombinedResponse")
```

AggregationStrategy implementation

The custom aggregation strategy, `MyOrderStrategy`, used in the preceding route is implemented as follows:

```java
/**
 * This is our own order aggregation strategy where we can control
 * how each split message should be combined. As we do not want to
 * lose any message, we copy from the new to the old to preserve the
 * order lines as long we process them
 */
public static class MyOrderStrategy implements AggregationStrategy {

    public Exchange aggregate(Exchange oldExchange, Exchange newExchange) {
        // put order together in old exchange by adding the order from new exchange

        if (oldExchange == null) {
            // the first time we aggregate we only have the new exchange,
            // so we just return it
            return newExchange;
        }

        String orders = oldExchange.getIn().getBody(String.class);
        String newLine = newExchange.getIn().getBody(String.class);

        LOG.debug("Aggregate old orders: " + orders);
        LOG.debug("Aggregate new order: " + newLine);

        // put orders together separating by semi colon
        orders = orders + ";" + newLine;
        // put combined order back on old to preserve it
```
Stream based processing

When parallel processing is enabled, it is theoretically possible for a later message piece to be ready for aggregation before an earlier piece. In other words, the message pieces might arrive at the aggregator out of order. By default, this does not happen, because the splitter implementation rearranges the message pieces back into their original order before passing them into the aggregator.

If you would prefer to aggregate the message pieces as soon as they are ready (and possibly out of order), you can enable the streaming option, as follows:

```
from("direct:streaming")
    .split(body().tokenize(","), new MyOrderStrategy())
    .parallelProcessing()
    .streaming()
    .to("activemq:my.parts")
    .end()
    .to("activemq:all.parts");
```

You can also supply a custom iterator to use with streaming, as follows:

```
// Java
import static org.apache.camel.builder.ExpressionBuilder.beanExpression;
...
from("direct:streaming")
    .split(beanExpression(new MyCustomIteratorFactory(), "iterator"))
    .streaming().to("activemq:my.parts")
```

STREAMING AND XPATH

You cannot use streaming mode in conjunction with XPath. XPath requires the complete DOM XML document in memory.

Stream based processing with XML

If an incoming message is a very large XML file, you can process the message most efficiently using the `tokenizeXML` sub-command in streaming mode.

For example, given a large XML file that contains a sequence of `order` elements, you can split the file into `order` elements using a route like the following:

```
from("file:inbox")
    .split().tokenizeXML("order").streaming()
    .to("activemq:queue:order");
```

You can do the same thing in XML, by defining a route like the following:

```
from("file:inbox")
    .split().tokenize("order").streaming()
    .to("activemq:queue:order");
```
It is often the case that you need access to namespaces that are defined in one of the enclosing (ancestor) elements of the token elements. You can copy namespace definitions from one of the ancestor elements into the token element, by specifying which element you want to inherit namespace definitions from.

In the Java DSL, you specify the ancestor element as the second argument of `tokenizeXML`. For example, to inherit namespace definitions from the enclosing `orders` element:

```java
from("file:inbox")
 .split().tokenizeXML("order", "orders").streaming()
 .to("activemq:queue:order");
```

In the XML DSL, you specify the ancestor element using the `inheritNamespaceTagName` attribute. For example:

```xml
<route>
 <from uri="file:inbox"/>
 <split streaming="true">
  <tokenize token="order" xml="true"
           inheritNamespaceTagName="orders"/>
  <to uri="activemq:queue:order"/>
 </split>
</route>
```

### Options

The `split` DSL command supports the following options:

<table>
<thead>
<tr>
<th>Name</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>strategyRef</code></td>
<td></td>
<td>Refers to an <code>AggregationStrategy</code> to be used to assemble the replies from the sub-messages, into a single outgoing message from the <code>Splitter</code>. See the section titled <code>What does the splitter return</code> below for what's used by default.</td>
</tr>
<tr>
<td>Property</td>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>-------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>parallelProcessing</td>
<td>false</td>
<td>If enables then processing the sub-messages occurs concurrently. Note the caller thread will still wait until all sub-messages has been fully processed, before it continues.</td>
</tr>
<tr>
<td>executorServiceRef</td>
<td></td>
<td>Refers to a custom ThreadPool to be used for parallel processing. Notice if you set this option, then parallel processing is automatic implied, and you do not have to enable that option as well.</td>
</tr>
<tr>
<td>stopOnException</td>
<td>false</td>
<td><strong>Camel 2.2:</strong> Whether or not to stop continue processing immediately when an exception occurred. If disable, then Camel continue splitting and process the sub-messages regardless if one of them failed. You can deal with exceptions in the AggregationStrategy class where you have full control how to handle that.</td>
</tr>
<tr>
<td>streaming</td>
<td>false</td>
<td>If enabled then Camel will split in a streaming fashion, which means it will split the input message in chunks. This reduces the memory overhead. For example if you split big messages its recommended to enable streaming. If streaming is enabled then the sub-message replies will be aggregated out-of-order, eg in the order they come back. If disabled, Camel will process sub-message replies in the same order as they where splitted.</td>
</tr>
</tbody>
</table>
### 7.5. AGGREGATOR

#### Overview

The **aggregator** pattern, shown in Figure 7.5, “Aggregator Pattern”, enables you to combine a batch of related messages into a single message.

**Figure 7.5. Aggregator Pattern**

To control the aggregator's behavior, Apache Camel allows you to specify the properties described in *Enterprise Integration Patterns*, as follows:

- **Correlation expression** — Determines which messages should be aggregated together. The correlation expression is evaluated on each incoming message to produce a correlation key. Incoming messages with the same correlation key are
then grouped into the same batch. For example, if you want to aggregate all incoming messages into a single message, you can use a constant expression.

- **Completeness condition** — Determines when a batch of messages is complete. You can specify this either as a simple size limit or, more generally, you can specify a predicate condition that flags when the batch is complete.

- **Aggregation algorithm** — Combines the message exchanges for a single correlation key into a single message exchange.

For example, consider a stock market data system that receives 30,000 messages per second. You might want to throttle down the message flow if your GUI tool cannot cope with such a massive update rate. The incoming stock quotes can be aggregated together simply by choosing the latest quote and discarding the older prices. (You can apply a delta processing algorithm, if you prefer to capture some of the history.)

**How the aggregator works**

Figure 7.6, “Aggregator Implementation” shows an overview of how the aggregator works, assuming it is fed with a stream of exchanges that have correlation keys such as A, B, C, or D.

**Figure 7.6. Aggregator Implementation**

The incoming stream of exchanges shown in Figure 7.6, “Aggregator Implementation” is processed as follows:

1. The **correlator** is responsible for sorting exchanges based on the correlation key. For each incoming exchange, the correlation expression is evaluated, yielding the correlation key. For example, for the exchange shown in Figure 7.6, “Aggregator Implementation”, the correlation key evaluates to A.

2. The **aggregation strategy** is responsible for merging exchanges with the same correlation key. When a new exchange, A, comes in, the aggregator looks up the corresponding **aggregate exchange**, A’, in the aggregation repository and combines it with the new exchange.

Until a particular aggregation cycle is completed, incoming exchanges are continuously aggregated with the corresponding aggregate exchange. An aggregation cycle lasts until terminated by one of the completion mechanisms.
3. If a completion predicate is specified on the aggregator, the aggregate exchange is tested to determine whether it is ready to be sent to the next processor in the route. Processing continues as follows:

- If complete, the aggregate exchange is processed by the latter part of the route. There are two alternative models for this: synchronous (the default), which causes the calling thread to block, or asynchronous (if parallel processing is enabled), where the aggregate exchange is submitted to an executor thread pool (as shown in Figure 7.6, “Aggregator Implementation”).

- If not complete, the aggregate exchange is saved back to the aggregation repository.

4. In parallel with the synchronous completion tests, it is possible to enable an asynchronous completion test by enabling either the completionTimeout option or the completionInterval option. These completion tests run in a separate thread and, whenever the completion test is satisfied, the corresponding exchange is marked as complete and starts to be processed by the latter part of the route (either synchronously or asynchronously, depending on whether parallel processing is enabled or not).

5. If parallel processing is enabled, a thread pool is responsible for processing exchanges in the latter part of the route. By default, this thread pool contains ten threads, but you have the option of customizing the pool (the section called “Threading options”).

**Java DSL example**

The following example aggregates exchanges with the same StockSymbol header value, using the UseLatestAggregationStrategy aggregation strategy. For a given StockSymbol value, if more than three seconds elapse since the last exchange with that correlation key was received, the aggregated exchange is deemed to be complete and is sent to the mock endpoint.

```java
from("direct:start")
    .aggregate(header("id"), new UseLatestAggregationStrategy())
    .completionTimeout(3000)
    .to("mock:aggregated");
```

**XML DSL example**

The following example shows how to configure the same route in XML:

```xml
<camelContext xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="direct:start"/>
    <aggregate strategyRef="aggregatorStrategy"
               completionTimeout="3000">
      <correlationExpression>
        <simple>header.StockSymbol</simple>
      </correlationExpression>
    </aggregate>
    <to uri="mock:aggregated"/>
  </route>
</camelContext>
```
Specifying the correlation expression

In the Java DSL, the correlation expression is always passed as the first argument to the `aggregate()` DSL command. You are not limited to using the Simple expression language here. You can specify a correlation expression using any of the expression languages or scripting languages, such as XPath, XQuery, SQL, and so on.

For example, to correlate exchanges using an XPath expression, you could use the following Java DSL route:

```java
from("direct:start")
    .aggregate(xpath("/stockQuote/@symbol"), new UseLatestAggregationStrategy())
    .completionTimeout(3000)
    .to("mock:aggregated");
```

If the correlation expression cannot be evaluated on a particular incoming exchange, the aggregator throws a `CamelExchangeException` by default. You can suppress this exception by setting the `ignoreInvalidCorrelationKeys` option. For example, in the Java DSL:

```java
from(...).aggregate(...).ignoreInvalidCorrelationKeys()
```

In the XML DSL, you can set the `ignoreInvalidCorrelationKeys` option is set as an attribute, as follows:

```xml
<aggregate strategyRef="aggregatorStrategy"
    ignoreInvalidCorrelationKeys="true"
    ...>
    ...
</aggregate>
```

Specifying the aggregation strategy

In Java DSL, you can either pass the aggregation strategy as the second argument to the `aggregate()` DSL command or specify it using the `aggregationStrategy()` clause. For example, you can use the `aggregationStrategy()` clause as follows:

```java
from("direct:start")
    .aggregate(header("id"))
    .aggregationStrategy(new UseLatestAggregationStrategy())
    .completionTimeout(3000)
    .to("mock:aggregated");
```

Apache Camel provides the following basic aggregation strategies (where the classes belong to the `org.apache.camel.processor.aggregate` Java package):

- `UseLatestAggregationStrategy`
Return the last exchange for a given correlation key, discarding all earlier exchanges with this key. For example, this strategy could be useful for throttling the feed from a stock exchange, where you just want to know the latest price of a particular stock symbol.

**UseOriginalAggregationStrategy**

Return the first exchange for a given correlation key, discarding all later exchanges with this key. You must set the first exchange by calling `UseOriginalAggregationStrategy.setOriginal()` before you can use this strategy.

**GroupedExchangeAggregationStrategy**

Concatenates all of the exchanges for a given correlation key into a list, which is stored in the `Exchange.GROUPED_EXCHANGE` exchange property. See the section called “Grouped exchanges”.

**Implementing a custom aggregation strategy**

If you want to apply a different aggregation strategy, you can implement one of the following aggregation strategy base interfaces:

**org.apache.camel.processor.aggregate.AggregationStrategy**

The basic aggregation strategy interface.

**org.apache.camel.processor.aggregate.TimeoutAwareAggregationStrategy**

Implement this interface, if you want your implementation to receive a notification when an aggregation cycle times out. The `timeout` notification method has the following signature:

```java
void timeout(Exchange oldExchange, int index, int total, long timeout)
```

**org.apache.camel.processor.aggregate.CompletionAwareAggregationStrategy**

Implement this interface, if you want your implementation to receive a notification when an aggregation cycle completes normally. The notification method has the following signature:

```java
void onCompletion(Exchange exchange)
```

For example, the following code shows two different custom aggregation strategies, `StringAggregationStrategy` and `ArrayListAggregationStrategy`:

```java
//simply combines Exchange String body values using '+' as a delimiter
class StringAggregationStrategy implements AggregationStrategy {

    public Exchange aggregate(Exchange oldExchange, Exchange newExchange) {
        if (oldExchange == null) {
            return newExchange;
        }

        String oldBody = oldExchange.getIn().getBody(String.class);
```

Red Hat JBoss Fuse 6.1 Apache Camel Development Guide
Since Apache Camel 2.0, the `AggregationStrategy.aggregate()` callback method is also invoked for the very first exchange. On the first invocation of the `aggregate` method, the `oldExchange` parameter is `null` and the `newExchange` parameter contains the first incoming exchange.

To aggregate messages using the custom strategy class, `ArrayListAggregationStrategy`, define a route like the following:

```java
String newBody = newExchange.getIn().getBody(String.class);
oldExchange.getIn().setBody(oldBody + "+" + newBody);
return oldExchange;
}
}

// simply combines Exchange body values into an ArrayList<Object>
class ArrayListAggregationStrategy implements AggregationStrategy {
    public Exchange aggregate(Exchange oldExchange, Exchange newExchange) {
        Object newBody = newExchange.getIn().getBody();
        ArrayList<Object> list = null;
        if (oldExchange == null) {
            list = new ArrayList<Object>();
            list.add(newBody);
            newExchange.getIn().setBody(list);
            return newExchange;
        } else {
            list = oldExchange.getIn().getBody(ArrayList.class);
            list.add(newBody);
            return oldExchange;
        }
    }
}
```

from("direct:start")
    .aggregate(header("StockSymbol"), new ArrayListAggregationStrategy())
    .completionTimeout(3000)
    .to("mock:result");

You can also configure a route with a custom aggregation strategy in XML, as follows:

```xml
<camelContext xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="direct:start"/>
    <aggregate strategyRef="aggregatorStrategy" completionTimeout="3000">
      <correlationExpression>
        <simple>header.StockSymbol</simple>
      </correlationExpression>
      <to uri="mock:aggregated"/>
    </aggregate>
  </route>
</camelContext>

NOTE

Since Apache Camel 2.0, the `AggregationStrategy.aggregate()` callback method is also invoked for the very first exchange. On the first invocation of the `aggregate` method, the `oldExchange` parameter is `null` and the `newExchange` parameter contains the first incoming exchange.
Controlling the lifecycle of a custom aggregation strategy

You can implement a custom aggregation strategy so that its lifecycle is aligned with the lifecycle of the enterprise integration pattern that is controlling it. This can be useful for ensuring that the aggregation strategy can shut down gracefully.

To implement an aggregation strategy with lifecycle support, you must implement the `org.apache.camel.Service` interface (in addition to the `AggregationStrategy` interface) and provide implementations of the `start()` and `stop()` lifecycle methods. For example, the following code example shows an outline of an aggregation strategy with lifecycle support:

```java
// Java
import org.apache.camel.processor.aggregate.AggregationStrategy;
import org.apache.camel.Service;
import java.lang.Exception;
...

class MyAggStrategyWithLifecycleControl
    implements AggregationStrategy, Service {

    public Exchange aggregate(Exchange oldExchange, Exchange newExchange) {
        // Implementation not shown...
        ...
    }

    public void start() throws Exception {
        // Actions to perform when the enclosing EIP starts up
        ...
    }

    public void stop() throws Exception {
        // Actions to perform when the enclosing EIP is stopping
        ...
    }
}
```

Exchange properties

The following properties are set on each aggregated exchange:

<table>
<thead>
<tr>
<th>Header</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exchange.AGGREGATED_SIZE</td>
<td>int</td>
<td>The total number of exchanges aggregated into this exchange.</td>
</tr>
</tbody>
</table>
Indicates the mechanism responsible for completing the aggregate exchange. Possible values are: \texttt{predicate}, \texttt{size}, \texttt{timeout}, \texttt{interval}, or \texttt{consumer}.

The following properties are set on exchanges redelivered by the HawtDB aggregation repository (see the section called “Persistent aggregation repository”):

### Table 7.2. Redelivered Exchange Properties

<table>
<thead>
<tr>
<th>Header</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Exchange.REDELIVERY_COUNTER</td>
<td>int</td>
<td>Sequence number of the current redelivery attempt (starting at 1).</td>
</tr>
</tbody>
</table>

**Specifying a completion condition**

It is mandatory to specify \textit{at least one} completion condition, which determines when an aggregate exchange leaves the aggregator and proceeds to the next node on the route. The following completion conditions can be specified:

- **completionPredicate**
  
  Evaluates a predicate after each exchange is aggregated in order to determine completeness. A value of \texttt{true} indicates that the aggregate exchange is complete.

- **completionSize**
  
  Completes the aggregate exchange after the specified number of incoming exchanges are aggregated.

- **completionTimeout**
  
  \textit{(Incompatible with completionInterval)} Completes the aggregate exchange, if no incoming exchanges are aggregated within the specified timeout.

  In other words, the timeout mechanism keeps track of a timeout for \textit{each} correlation key value. The clock starts ticking after the latest exchange with a particular key value is received. If another exchange with the same key value is not received within the specified timeout, the corresponding aggregate exchange is marked complete and sent to the next node on the route.

- **completionInterval**
  
  \textit{(Incompatible with completionTimeout)} Completes all outstanding aggregate exchanges, after each time interval (of specified length) has elapsed.

  The time interval is \textit{not} tailored to each aggregate exchange. This mechanism forces simultaneous completion of all outstanding aggregate exchanges. Hence, in some cases, this mechanism could complete an aggregate exchange immediately after it started.
aggregating.

**completionFromBatchConsumer**

When used in combination with a consumer endpoint that supports the *batch consumer* mechanism, this completion option automatically figures out when the current batch of exchanges is complete, based on information it receives from the consumer endpoint. See the section called “Batch consumer”.

**forceCompletionOnStop**

When this option is enabled, it forces completion of all outstanding aggregate exchanges when the current route context is stopped.

The preceding completion conditions can be combined arbitrarily, except for the *completionTimeout* and *completionInterval* conditions, which cannot be simultaneously enabled. When conditions are used in combination, the general rule is that the first completion condition to trigger is the effective completion condition.

### Specifying the completion predicate

You can specify an arbitrary predicate expression that determines when an aggregated exchange is complete. There are two possible ways of evaluating the predicate expression:

- *On the latest aggregate exchange*—this is the default behavior.
- *On the latest incoming exchange*—this behavior is selected when you enable the *eagerCheckCompletion* option.

For example, if you want to terminate a stream of stock quotes every time you receive an *ALERT* message (as indicated by the value of an *MsgType* header in the latest incoming exchange), you can define a route like the following:

```java
from("direct:start")
 aggregate(
    header("id"),
    new UseLatestAggregationStrategy()
)
 .completionPredicate(
    header("MsgType").isEqualTo("ALERT")
)
 .eagerCheckCompletion()
 .to("mock:result");
```

The following example shows how to configure the same route using XML:

```xml
<camelContext xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="direct:start"/>
    <aggregate strategyRef="aggregatorStrategy" eagerCheckCompletion="true">
      <correlationExpression>
        <simple>header.StockSymbol</simple>
      </correlationExpression>
      <completionExpression>
        <simple>header.MsgType</simple>
        .isEqualTo("ALERT")
      </completionExpression>
    </aggregate>
  </route>
</camelContext>
```
Specifying a dynamic completion timeout

It is possible to specify a dynamic completion timeout, where the timeout value is recalculated for every incoming exchange. For example, to set the timeout value from the `timeout` header in each incoming exchange, you could define a route as follows:

```camelContext
<from("direct:start")
  .aggregate(header("StockSymbol"), new UseLatestAggregationStrategy())
  .completionTimeout(header("timeout"))
  .to("mock:aggregated");
</route>
</camelContext>

You can configure the same route in the XML DSL, as follows:

```camelContext xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="direct:start"/>
    <aggregate strategyRef="aggregatorStrategy">
      <correlationExpression>
        <simple>header.StockSymbol</simple>
      </correlationExpression>
      <completionTimeout>
        <header>timeout</header>
      </completionTimeout>
      <to uri="mock:aggregated"/>
    </aggregate>
  </route>
</camelContext>

<bean id="aggregatorStrategy"
  class="org.apache.camel.processor.UseLatestAggregationStrategy"/>
```

**NOTE**

You can also add a fixed timeout value and Apache Camel will fall back to use this value, if the dynamic value is `null` or `0`.

Specifying a dynamic completion size

It is possible to specify a dynamic completion size, where the completion size is recalculated for every incoming exchange. For example, to set the completion size from the `mySize` header in each incoming exchange, you could define a route as follows:

```camelContext
<simple>$MsgType = 'ALERT'</simple>
</completionPredicate>
<to uri="mock:result"/>
</aggregate>
</route>
</camelContext>
```

```camelContext xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="direct:start"/>
    <aggregate strategyRef="aggregatorStrategy">
      <correlationExpression>
        <simple>header.StockSymbol</simple>
      </correlationExpression>
      <completionTimeout>
        <header>timeout</header>
      </completionTimeout>
      <to uri="mock:aggregated"/>
    </aggregate>
  </route>
</camelContext>

<bean id="aggregatorStrategy"
  class="org.apache.camel.processor.UseLatestAggregationStrategy"/>
```

```xml
<camelContext xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="direct:start"/>
    <aggregate strategyRef="aggregatorStrategy">
      <correlationExpression>
        <simple>header.StockSymbol</simple>
      </correlationExpression>
      <completionTimeout>
        <header>timeout</header>
      </completionTimeout>
      <to uri="mock:aggregated"/>
    </aggregate>
  </route>
</camelContext>
```

<bean id="aggregatorStrategy"
  class="org.apache.camel.processor.UseLatestAggregationStrategy"/>
```
And the same example using Spring XML:

```xml
<camelContext xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="direct:start"/>
    <aggregate strategyRef="aggregatorStrategy">
      <correlationExpression>
        <simple>header.StockSymbol</simple>
      </correlationExpression>
      <completionSize>
        <header>mySize</header>
      </completionSize>
      <to uri="mock:aggregated"/>
    </aggregate>
  </route>
</camelContext>

<bean id="aggregatorStrategy" class="org.apache.camel.processor.UseLatestAggregationStrategy"/>
```

**NOTE**

You can also add a fixed size value and Apache Camel will fall back to use this value, if the dynamic value is `null` or `0`.

**Forcing completion with a special message**

It is possible to force completion of all outstanding aggregate messages, by sending a message with a special header to the route. There are two alternative header settings you can use to force completion:

- **Exchange.AGGREGATION_COMPLETE_ALL_GROUPS**
  
  Set to `true`, to force completion of the current aggregation cycle. This message acts purely as a signal and is *not* included in any aggregation cycle. After processing this signal message, the content of the message is discarded.

- **Exchange.AGGREGATION_COMPLETE_ALL_GROUPS_INCLUSIVE**

  Set to `true`, to force completion of the current aggregation cycle. This message is *included* in the current aggregation cycle.

**Enforcing unique correlation keys**

In some aggregation scenarios, you might want to enforce the condition that the correlation key is unique for each batch of exchanges. In other words, when the aggregate exchange for a particular correlation key completes, you want to make sure that no further aggregate exchanges with that correlation key are allowed to proceed. For example, you might want to enforce this condition, if the latter part of the route expects to process exchanges with unique correlation key values.
Depending on how the completion conditions are configured, there might be a risk of more than one aggregate exchange being generated with a particular correlation key. For example, although you might define a completion predicate that is designed to wait until all the exchanges with a particular correlation key are received, you might also define a completion timeout, which could fire before all of the exchanges with that key have arrived. In this case, the late-arriving exchanges could give rise to a second aggregate exchange with the same correlation key value.

For such scenarios, you can configure the aggregator to suppress aggregate exchanges that duplicate previous correlation key values, by setting the `closeCorrelationKeyOnCompletion` option. In order to suppress duplicate correlation key values, it is necessary for the aggregator to record previous correlation key values in a cache. The size of this cache (the number of cached correlation keys) is specified as an argument to the `closeCorrelationKeyOnCompletion()` DSL command. To specify a cache of unlimited size, you can pass a value of zero or a negative integer. For example, to specify a cache size of 10000 key values:

```java
from("direct:start")
    .aggregate(header("UniqueBatchID"), new MyConcatenateStrategy())
    .completionSize(header("mySize"))
    .closeCorrelationKeyOnCompletion(10000)
    .to("mock:aggregated");
```

If an aggregate exchange completes with a duplicate correlation key value, the aggregator throws a `ClosedCorrelationKeyException` exception.

### Grouped exchanges

You can combine all of the aggregated exchanges in an outgoing batch into a single `org.apache.camel.impl.GroupedExchange` holder class. To enable grouped exchanges, specify the `groupExchanges()` option, as shown in the following Java DSL route:

```java
from("direct:start")
    .aggregate(header("StockSymbol"))
    .completionTimeout(3000)
    .groupExchanges()
    .to("mock:result");
```

The grouped exchange that is sent to `mock:result` contains the list of aggregated exchanges stored in the exchange property, `Exchange.GROUPED_EXCHANGE`. The following line of code shows how a subsequent processor can access the contents of the grouped exchange in the form of a list:

```java
// Java
List<Exchange> grouped = ex.getProperty(Exchange.GROUPED_EXCHANGE, List.class);
```

### NOTE

When you enable the grouped exchanges feature, you must not configure an aggregation strategy (the grouped exchanges feature is itself an aggregation strategy).
**Batch consumer**

The aggregator can work together with the batch consumer pattern to aggregate the total number of messages reported by the batch consumer (a batch consumer endpoint sets the `CamelBatchSize`, `CamelBatchIndex`, and `CamelBatchComplete` properties on the incoming exchange). For example, to aggregate all of the files found by a File consumer endpoint, you could use a route like the following:

```java
from("file://inbox")
 .aggregate(xpath("//order/@customerId"), new
 AggregateCustomerOrderStrategy())
 .completionFromBatchConsumer()
 .to("bean:processOrder");
```

Currently, the following endpoints support the batch consumer mechanism: File, FTP, Mail, iBatis, and JPA.

**Persistent aggregation repository**

If you want pending aggregated exchanges to be stored persistently, you can use either the HawtDB component or the SQL Component for persistence support as a persistent aggregation repository. For example, if using HawtDB, you need to include a dependency on the `camel-hawtdb` component in your Maven POM. You can then configure a route to use the HawtDB aggregation repository as follows:

```java
public void configure() throws Exception {
    HawtDBAggregationRepository repo = new AggregationRepository("repo1",
    "target/data/hawtdb.dat");

    from("direct:start")
        .aggregate(header("id"), new UseLatestAggregationStrategy())
        .completionTimeout(3000)
        .aggregationRepository(repo)
        .to("mock:aggregated");
}
```

The HawtDB aggregation repository has a feature that enables it to recover and retry any failed exchanges (that is, any exchange that raised an exception while it was being processed by the latter part of the route). Figure 7.7, “Recoverable Aggregation Repository” shows an overview of the recovery mechanism.

**Figure 7.7. Recoverable Aggregation Repository**

The recovery mechanism works as follows:
1. The aggregator creates a dedicated recovery thread, which runs in the background, scanning the aggregation repository to find any failed exchanges.

2. Each failed exchange is checked to see whether its current redelivery count exceeds the maximum redelivery limit. If it is under the limit, the recovery task resubmits the exchange for processing in the latter part of the route.

3. If the current redelivery count is over the limit, the failed exchange is passed to the dead letter queue.

For more details about the HawtDB component, see .

**Threading options**

As shown in Figure 7.6, “Aggregator Implementation”, the aggregator is decoupled from the latter part of the route, where the exchanges sent to the latter part of the route are processed by a dedicated thread pool. By default, this pool contains just a single thread. If you want to specify a pool with multiple threads, enable the `parallelProcessing` option, as follows:

```java
from("direct:start")
  .aggregate(header("id"), new UseLatestAggregationStrategy())
  .completionTimeout(3000)
  .parallelProcessing()
  .to("mock:aggregated");
```

By default, this creates a pool with 10 worker threads.

If you want to exercise more control over the created thread pool, specify a custom `java.util.concurrent.ExecutorService` instance using the `executorService` option (in which case it is unnecessary to enable the `parallelProcessing` option).

**Aggregating into a List**

A common aggregation scenario involves aggregating a series of incoming message bodies into a `List` object. To facilitate this scenario, Apache Camel provides the `AbstractListAggregationStrategy` abstract class, which you can quickly extend to create an aggregation strategy for this case. Incoming message bodies of type, `T`, are aggregated into a completed exchange, with a message body of type `List<T>`.

For example, to aggregate a series of `Integer` message bodies into a `List<Integer>` object, you could use an aggregation strategy defined as follows:

```java
import org.apache.camel.processor.aggregate.AbstractListAggregationStrategy;
...
/**
 * Strategy to aggregate integers into a List<Integer>.
 */
public final class MyListOfNumbersStrategy extends AbstractListAggregationStrategy<Integer> {

  @Override
  public Integer getValue(Exchange exchange) {
    // the message body contains a number, so just return that as-is
```
Aggregator options

The aggregator supports the following options:

Table 7.3. Aggregator Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>correlationExpression</td>
<td>Mandatory</td>
<td>Expression which evaluates the correlation key to use for aggregation. The Exchange which has the same correlation key is aggregated together. If the correlation key could not be evaluated an Exception is thrown. You can disable this by using the ignoreBadCorrelationKey option.</td>
</tr>
<tr>
<td>aggregationStrategy</td>
<td>Mandatory</td>
<td>AggregationStrategy which is used to merge the incoming Exchange with the existing already merged exchanges. At first call the oldExchange parameter is null. On subsequent invocations the oldExchange contains the merged exchanges and newExchange is of course the new incoming Exchange. From Camel 2.9.2 onwards, the strategy can optionally be a TimeoutAwareAggregationStrategy implementation, which supports a timeout callback.</td>
</tr>
<tr>
<td>strategyRef</td>
<td></td>
<td>A reference to lookup the AggregationStrategy in the Registry.</td>
</tr>
<tr>
<td>Option</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------</td>
<td>---------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>completionSize</td>
<td></td>
<td>Number of messages aggregated before the aggregation is complete. This option can be set as either a fixed value or using an Expression which allows you to evaluate a size dynamically - will use Integer as result. If both are set Camel will fallback to use the fixed value if the Expression result was null or 0.</td>
</tr>
<tr>
<td>completionTimeout</td>
<td></td>
<td>Time in millis that an aggregated exchange should be inactive before its complete. This option can be set as either a fixed value or using an Expression which allows you to evaluate a timeout dynamically - will use Long as result. If both are set Camel will fallback to use the fixed value if the Expression result was null or 0. You cannot use this option together with completionInterval, only one of the two can be used.</td>
</tr>
<tr>
<td>completionInterval</td>
<td></td>
<td>A repeating period in millis by which the aggregator will complete all current aggregated exchanges. Camel has a background task which is triggered every period. You cannot use this option together with completionTimeout, only one of them can be used.</td>
</tr>
<tr>
<td>completionPredicate</td>
<td></td>
<td>A Predicate to indicate when an aggregated exchange is complete.</td>
</tr>
<tr>
<td>Option</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>---------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>completionFromBatchConsumer</td>
<td>false</td>
<td>This option is if the exchanges are coming from a Batch Consumer. Then when enabled the Aggregator will use the batch size determined by the Batch Consumer in the message header CamelBatchSize. See more details at Batch Consumer. This can be used to aggregate all files consumed from a File endpoint in that given poll.</td>
</tr>
<tr>
<td>eagerCheckCompletion</td>
<td>false</td>
<td>Whether or not to eager check for completion when a new incoming Exchange has been received. This option influences the behavior of the completionPredicate option as the Exchange being passed in changes accordingly. When false the Exchange passed in the Predicate is the aggregated Exchange which means any information you may store on the aggregated Exchange from the AggregationStrategy is available for the Predicate. When true the Exchange passed in the Predicate is the incoming Exchange, which means you can access data from the incoming Exchange.</td>
</tr>
<tr>
<td>forceCompletionOnStop</td>
<td>false</td>
<td>If true, complete all aggregated exchanges when the current route context is stopped.</td>
</tr>
<tr>
<td>Option</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>---------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>groupExchanges</td>
<td>false</td>
<td>If enabled then Camel will group all aggregated Exchanges into a single combined org.apache.camel.impl.GroupedExchange holder class that holds all the aggregated Exchanges. And as a result only one Exchange is being sent out from the aggregator. Can be used to combine many incoming Exchanges into a single output Exchange without coding a custom AggregationStrategy yourself.</td>
</tr>
<tr>
<td>ignoreInvalidCorrelationKeys</td>
<td>false</td>
<td>Whether or not to ignore correlation keys which could not be evaluated to a value. By default Camel will throw an Exception, but you can enable this option and ignore the situation instead.</td>
</tr>
<tr>
<td>closeCorrelationKeyOnCompletion</td>
<td></td>
<td>Whether or not late Exchanges should be accepted or not. You can enable this to indicate that if a correlation key has already been completed, then any new exchanges with the same correlation key be denied. Camel will then throw a closedCorrelationKeyException exception. When using this option you pass in a integer which is a number for a LRUCache which keeps that last X number of closed correlation keys. You can pass in 0 or a negative value to indicate a unbounded cache. By passing in a number you are ensured that cache wont grown too big if you use a log of different correlation keys.</td>
</tr>
<tr>
<td>Option</td>
<td>Default</td>
<td>Description</td>
</tr>
<tr>
<td>------------------------------</td>
<td>---------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>discardOnCompletionTime out</td>
<td>false</td>
<td>Camel 2.5: Whether or not exchanges which complete due to a timeout should be discarded. If enabled, then when a timeout occurs the aggregated message will <strong>not</strong> be sent out but dropped (discarded).</td>
</tr>
<tr>
<td>aggregationRepository</td>
<td></td>
<td>Allows you to plug in your own implementation of <code>org.apache.camel.spi.AggregationRepository</code> which keeps track of the current inflight aggregated exchanges. Camel uses by default a memory-based implementation.</td>
</tr>
<tr>
<td>aggregationRepositoryRef</td>
<td></td>
<td>Reference to lookup a <code>aggregationRepository</code> in the Registry.</td>
</tr>
<tr>
<td>parallelProcessing</td>
<td>false</td>
<td>When aggregated are completed they are being send out of the aggregator. This option indicates whether or not Camel should use a thread pool with multiple threads for concurrency. If no custom thread pool has been specified then Camel creates a default pool with 10 concurrent threads.</td>
</tr>
<tr>
<td>executorService</td>
<td></td>
<td>If using <code>parallelProcessing</code> you can specify a custom thread pool to be used. In fact also if you are not using <code>parallelProcessing</code> this custom thread pool is used to send out aggregated exchanges as well.</td>

<tr>
<td><code>optimisticLocking</code></td>
<td><code>false</code></td>
<td>Turns on optimistic locking, which can be used in combination with an aggregation repository.</td>
</tr>
<tr>
<td><code>optimisticLockRetryPolicy</code></td>
<td></td>
<td>Configures the retry policy for optimistic locking.</td>
</tr>
</tbody>
</table>

## 7.6. RESEQUENCER

### Overview

The resequencer pattern, shown in Figure 7.8, “Resequencer Pattern”, enables you to resequence messages according to a sequencing expression. Messages that generate a low value for the sequencing expression are moved to the front of the batch and messages that generate a high value are moved to the back.

### Figure 7.8. Resequencer Pattern

Apache Camel supports two resequencing algorithms:

- *Batch resequencing* — Collects messages into a batch, sorts the messages and sends them to their output.
Stream resequencing — Re-orders (continuous) message streams based on the detection of gaps between messages.

By default the resequencer does not support duplicate messages and will only keep the last message, in cases where a message arrives with the same message expression. However, in batch mode you can enable the resequencer to allow duplicates.

Batch resequencing

The batch resequencing algorithm is enabled by default. For example, to resequence a batch of incoming messages based on the value of a timestamp contained in the TimeStamp header, you can define the following route in Java DSL:

```java
import org.apache.camel.model.config.BatchResequencerConfig;

RouteBuilder builder = new RouteBuilder() {
    public void configure() {
        from("direct:start").resequence(header("TimeStamp")).to("mock:result");
        from("direct:start").resequence(header("TimeStamp")).batch(new BatchResequencerConfig(300,4000L)).to("mock:result");
    }
};
```

By default, the batch is obtained by collecting all of the incoming messages that arrive in a time interval of 1000 milliseconds (default batch timeout), up to a maximum of 100 messages (default batch size). You can customize the values of the batch timeout and the batch size by appending a batch() DSL command, which takes a BatchResequencerConfig instance as its sole argument. For example, to modify the preceding route so that the batch consists of messages collected in a 4000 millisecond time window, up to a maximum of 300 messages, you can define the Java DSL route as follows:

```java
import org.apache.camel.model.config.BatchResequencerConfig;

RouteBuilder builder = new RouteBuilder() {
    public void configure() {
        from("direct:start").resequence(header("TimeStamp")).batch(new BatchResequencerConfig(300,4000L)).to("mock:result");
    }
};
```

You can also specify a batch resequencer pattern using XML configuration. The following example defines a batch resequencer with a batch size of 300 and a batch timeout of 4000 milliseconds:

```xml
<camelContext id="resequencerBatch"
    xmlns="http://camel.apache.org/schema/spring">
    <route>
        <from uri="direct:start" />
        <resequence>
            <!-- batch-config can be omitted for default (batch) resequencer settings -->
            <batch-config batchSize="300" batchTimeout="4000" />
            <simple>header.TimeStamp</simple>
            <to uri="mock:result" />
        </resequence>
    </route>
</camelContext>
```

Batch options
Table 7.4, “Batch Resequencer Options” shows the options that are available in batch mode only.

### Table 7.4. Batch Resequencer Options

<table>
<thead>
<tr>
<th>Java DSL</th>
<th>XML DSL</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>allowDuplicates()</td>
<td>batch-config/@allowDuplicates</td>
<td>false</td>
<td>If true, do not discard duplicate messages from the batch (where duplicate means that the message expression evaluates to the same value).</td>
</tr>
<tr>
<td>reverse()</td>
<td>batch-config/@reverse</td>
<td>false</td>
<td>If true, put the messages in reverse order (where the default ordering applied to a message expression is based on Java's string lexical ordering, as defined by String.compareTo()).</td>
</tr>
</tbody>
</table>

For example, if you want to resequence messages from JMS queues based on JMSPriority, you would need to combine the options, allowDuplicates and reverse, as follows:

```java
from("jms:queue:foo")
    // sort by JMSPriority by allowing duplicates (message can have same JMSPriority)
    // and use reverse ordering so 9 is first output (most important), and 0 is last
    // use batch mode and fire every 3th second
    .resequence(header("JMSPriority")).batch().timeout(3000).allowDuplicates().reverse()
    .to("mock:result");
```

**Stream resequencing**

To enable the stream resequencing algorithm, you must append stream() to the resequence() DSL command. For example, to resequence incoming messages based on the value of a sequence number in the seqnum header, you define a DSL route as follows:

```java
from("direct:start").resequence(header("seqnum")).stream().to("mock:result");
```

The stream-processing resequencer algorithm is based on the detection of gaps in a message stream, rather than on a fixed batch size. Gap detection, in combination with timeouts, removes the constraint of needing to know the number of messages of a
sequence (that is, the batch size) in advance. Messages must contain a unique sequence number for which a predecessor and a successor is known. For example a message with the sequence number 3 has a predecessor message with the sequence number 2 and a successor message with the sequence number 4. The message sequence 2, 3, 5 has a gap because the successor of 3 is missing. The resequencer therefore must retain message 5 until message 4 arrives (or a timeout occurs).

By default, the stream resequencer is configured with a timeout of 1000 milliseconds, and a maximum message capacity of 100. To customize the stream's timeout and message capacity, you can pass a `StreamResequencerConfig` object as an argument to `stream()`. For example, to configure a stream resequencer with a message capacity of 5000 and a timeout of 4000 milliseconds, you define a route as follows:

```java
// Java
import org.apache.camel.model.config.StreamResequencerConfig;

RouteBuilder builder = new RouteBuilder() {
    public void configure() {
        from("direct:start").resequence(header("seqnum")).stream(new StreamResequencerConfig(5000, 4000L)).to("mock:result");
    }
};
```

If the maximum time delay between successive messages (that is, messages with adjacent sequence numbers) in a message stream is known, the resequencer's timeout parameter should be set to this value. In this case, you can guarantee that all messages in the stream are delivered in the correct order to the next processor. The lower the timeout value that is compared to the out-of-sequence time difference, the more likely it is that the resequencer will deliver messages out of sequence. Large timeout values should be supported by sufficiently high capacity values, where the capacity parameter is used to prevent the resequencer from running out of memory.

If you want to use sequence numbers of some type other than `long`, you would must define a custom comparator, as follows:

```java
// Java
ExpressionResultComparator<Exchange> comparator = new MyComparator();
StreamResequencerConfig config = new StreamResequencerConfig(5000, 4000L, comparator);
from("direct:start").resequence(header("seqnum")).stream(config).to("mock:result");
```

You can also specify a stream resequencer pattern using XML configuration. The following example defines a stream resequencer with a message capacity of 5000 and a timeout of 4000 milliseconds:

```xml
<camelContext id="resequencerStream"
xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="direct:start"/>
    <resequence>
      <stream-config capacity="5000" timeout="4000"/>
      <simple>header.seqnum</simple>
      <to uri="mock:result"/>
  </route>
</camelContext>
```
Ignore invalid exchanges

The resequencer EIP throws a `CamelExchangeException` exception, if the incoming exchange is not valid—that is, if the sequencing expression cannot be evaluated for some reason (for example, due to a missing header). You can use the `ignoreInvalidExchanges` option to ignore these exceptions, which means the resequencer will skip any invalid exchanges.

```camelContext
    from("direct:start")
        .resequence(header("seqno")).batch().timeout(1000)
        // ignore invalid exchanges (they are discarded)
        .ignoreInvalidExchanges()
        .to("mock:result");
```

Reject old messages

The `rejectOld` option can be used to prevent messages being sent out of order, regardless of the mechanism used to resequence messages. When the `rejectOld` option is enabled, the resequencer rejects an incoming message (by throwing a `MessageRejectedException` exception), if the incoming message is older (as defined by the current comparator) than the last delivered message.

```camelContext
    from("direct:start")
        .onException(MessageRejectedException.class).handled(true).to("mock:erro
r").end()
        .resequence(header("seqno")).stream().timeout(1000).rejectOld()
        .to("mock:result");
```

7.7. ROUTING SLIP

Overview

The routing slip pattern, shown in Figure 7.9, “Routing Slip Pattern”, enables you to route a message consecutively through a series of processing steps, where the sequence of steps is not known at design time and can vary for each message. The list of endpoints through which the message should pass is stored in a header field (the `slip`), which Apache Camel reads at run time to construct a pipeline on the fly.
The slip header

The routing slip appears in a user-defined header, where the header value is a comma-separated list of endpoint URIs. For example, a routing slip that specifies a sequence of security tasks—decrypting, authenticating, and de-duplicating a message—might look like the following:

```
cxf:bean:decrypt,cxf:bean:authenticate,cxf:bean:dedup
```

The current endpoint property

From Camel 2.5 the Routing Slip will set a property (Exchange.SLIP_ENDPOINT) on the exchange which contains the current endpoint as it advanced though the slip. This enables you to find out how far the exchange has progressed through the slip.

The Routing Slip will compute the slip beforehand which means, the slip is only computed once. If you need to compute the slip on-the-fly then use the Dynamic Router pattern instead.

Java DSL example

The following route takes messages from the direct:a endpoint and reads a routing slip from the aRoutingSlipHeader header:

```
from("direct:b").routingSlip("aRoutingSlipHeader");
```

You can specify the header name either as a string literal or as an expression.

You can also customize the URI delimiter using the two-argument form of routingSlip(). The following example defines a route that uses the aRoutingSlipHeader header key for the routing slip and uses the # character as the URI delimiter:

```
from("direct:c").routingSlip("aRoutingSlipHeader", ",#");
```

XML configuration example
The following example shows how to configure the same route in XML:

```xml
<camelContext id="buildRoutingSlip"
xmlns="http://camel.apache.org/schema/spring">
   <route>
      <from uri="direct:c"/>
      <routingSlip uriDelimiter="#">
         <headerName>aRoutingSlipHeader</headerName>
      </routingSlip>
   </route>
</camelContext>
```

**Ignore invalid endpoints**

The **Routing Slip** now supports **ignoreInvalidEndpoints**, which the **Recipient List** pattern also supports. You can use it to skip endpoints that are invalid. For example:

```java
from("direct:a").routingSlip("myHeader").ignoreInvalidEndpoints();
```

In Spring XML, this feature is enabled by setting the **ignoreInvalidEndpoints** attribute on the `<routingSlip>` tag:

```xml
<route>
   <from uri="direct:a"/>
   <routingSlip ignoreInvalidEndpoints="true">
      <headerName>myHeader</headerName>
   </routingSlip>
</route>
```

Consider the case where **myHeader** contains the two endpoints, `direct:foo,xxx:bar`. The first endpoint is valid and works. The second is invalid and, therefore, ignored. Apache Camel logs at **INFO** level whenever an invalid endpoint is encountered.

**Options**

The **routingSlip** DSL command supports the following options:

<table>
<thead>
<tr>
<th>Name</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>uriDelimiter</td>
<td>,</td>
<td>Delimiter used if the <strong>Expression</strong> returned multiple endpoints.</td>
</tr>
<tr>
<td>ignoreInvalidEndpoints</td>
<td>false</td>
<td>If an endpoint uri could not be resolved, should it be ignored. Otherwise Camel will throw an exception stating the endpoint uri is not valid.</td>
</tr>
</tbody>
</table>

**7.8. THROTTLER**
Overview

A throttler is a processor that limits the flow rate of incoming messages. You can use this pattern to protect a target endpoint from getting overloaded. In Apache Camel, you can implement the throttler pattern using the `throttle()` Java DSL command.

Video demo

There is a video demo of how to implement the throttler pattern at http://vimeo.com/27592682.

Java DSL example

To limit the flow rate to 100 messages per second, define a route as follows:

```java
from("seda:a").throttle(100).to("seda:b");
```

If necessary, you can customize the time period that governs the flow rate using the `timePeriodMillis()` DSL command. For example, to limit the flow rate to 3 messages per 30000 milliseconds, define a route as follows:

```java
from("seda:a").throttle(3).timePeriodMillis(30000).to("mock:result");
```

XML configuration example

The following example shows how to configure the preceding route in XML:

```xml
<camelContext id="throttleRoute" xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="seda:a"/>
    <!-- throttle 3 messages per 30 sec -->
    <throttle timePeriodMillis="30000">
      <constant>3</constant>
      <to uri="mock:result"/>
    </throttle>
  </route>
</camelContext>
```

Dynamically changing maximum requests per period

Available os of Camel 2.8 Since we use an Expression, you can adjust this value at runtime, for example you can provide a header with the value. At runtime Camel evaluates the expression and converts the result to a `java.lang.Long` type. In the example below we use a header from the message to determine the maximum requests per period. If the header is absent, then the Throttler uses the old value. So that allows you to only provide a header if the value is to be changed:

```xml
<camelContext id="throttleRoute" xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="direct:expressionHeader"/>
    <throttle timePeriodMillis="500"/>
  </route>
</camelContext>
```
Asynchronous delaying

The throttler can enable non-blocking asynchronous delaying, which means that Apache Camel schedules a task to be executed in the future. The task is responsible for processing the latter part of the route (after the throttler). This allows the caller thread to unblock and service further incoming messages. For example:

```xml
from("seda:a").throttle(100).asyncDelayed().to("seda:b");
```

Options

The `throttle` DSL command supports the following options:

<table>
<thead>
<tr>
<th>Name</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>maximumRequestsPerPeriod</td>
<td></td>
<td>Maximum number of requests per period to throttle. This option must be provided and a positive number. Notice, in the XML DSL, from Camel 2.8 onwards this option is configured using an Expression instead of an attribute.</td>
</tr>
<tr>
<td>timePeriodMillis</td>
<td>1000</td>
<td>The time period in millis, in which the throttler will allow at most <code>maximumRequestsPerPeriod</code> number of messages.</td>
</tr>
<tr>
<td>asyncDelayed</td>
<td>false</td>
<td>Camel 2.4: If enabled then any messages which is delayed happens asynchronously using a scheduled thread pool.</td>
</tr>
<tr>
<td>executorServiceRef</td>
<td></td>
<td>Camel 2.4: Refers to a custom Thread Pool to be used if <code>asyncDelay</code> has been enabled.</td>
</tr>
</tbody>
</table>
### 7.9. DELAYER

#### Overview

A *delayer* is a processor that enables you to apply a *relative* time delay to incoming messages.

#### Java DSL example

You can use the `delay()` command to add a *relative* time delay, in units of milliseconds, to incoming messages. For example, the following route delays all incoming messages by 2 seconds:

```java
from("seda:a").delay(2000).to("mock:result");
```

Alternatively, you can specify the time delay using an expression:

```java
from("seda:a").delay(header("MyDelay")).to("mock:result");
```

The DSL commands that follow `delay()` are interpreted as sub-clauses of `delay()`. Hence, in some contexts it is necessary to terminate the sub-clauses of `delay()` by inserting the `end()` command. For example, when `delay()` appears inside an `onException()` clause, you would terminate it as follows:

```java
from("direct:start")
  .onException(Exception.class)
    .maximumRedeliveries(2)
    .backOffMultiplier(1.5)
    .handled(true)
    .delay(1000)
      .log("Halting for some time")
      .to("mock:halt")
    .end()
  .end()
  .to("mock:result");
```

#### XML configuration example

The following example demonstrates the delay in XML DSL:

```xml
<camelContext xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="seda:a”/>
    <delay>
```
Creating a custom delay

You can use an expression combined with a bean to determine the delay as follows:

```java
from("activemq:foo").
    delay().expression().method("someBean", "computeDelay").
    to("activemq:bar");
```

Where the bean class could be defined as follows:

```java
public class SomeBean {
    public long computeDelay() {
        long delay = 0;
        // use java code to compute a delay value in millis
        return delay;
    }
}
```

Asynchronous delaying

You can let the delayer use *non-blocking asynchronous delaying*, which means that Apache Camel schedules a task to be executed in the future. The task is responsible for processing the latter part of the route (after the delayer). This allows the caller thread to unblock and service further incoming messages. For example:

```java
from("activemq:queue:foo")
    .delay(1000)
    .asyncDelayed()
    .to("activemq:aDelayedQueue");
```

The same route can be written in the XML DSL, as follows:

```xml
<route>
    <from uri="activemq:queue:foo"/>
    <delay asyncDelayed="true">
        <constant>1000</constant>
    </delay>
    <to uri="activemq:aDelayedQueue"/>
</route>
```
Options

The delayer pattern supports the following options:

<table>
<thead>
<tr>
<th>Name</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>asyncDelayed</td>
<td>false</td>
<td><strong>Camel 2.4:</strong> If enabled then delayed messages happens asynchronously using a scheduled thread pool.</td>
</tr>
<tr>
<td>executorServiceRef</td>
<td></td>
<td><strong>Camel 2.4:</strong> Refers to a custom Thread Pool to be used if asyncDelay has been enabled.</td>
</tr>
<tr>
<td>callerRunsWhenRejected</td>
<td>true</td>
<td><strong>Camel 2.4:</strong> Is used if asyncDelayed was enabled. This controls if the caller thread should execute the task if the thread pool rejected the task.</td>
</tr>
</tbody>
</table>

7.10. LOAD BALANCER

Overview

The load balancer pattern allows you to delegate message processing to one of several endpoints, using a variety of different load-balancing policies.

Java DSL example

The following route distributes incoming messages between the target endpoints, mock:x, mock:y, mock:z, using a round robin load-balancing policy:

```java
from("direct:start").loadBalance().roundRobin().to("mock:x", "mock:y", "mock:z");
```

XML configuration example

The following example shows how to configure the same route in XML:

```xml
<camelContext xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="direct:start"/>
    <loadBalance>
      <roundRobin/>
      <to uri="mock:x"/>
      <to uri="mock:y"/>
      <to uri="mock:z"/>
    </loadBalance>
  </route>
</camelContext>
```
Load-balancing policies

The Apache Camel load balancer supports the following load-balancing policies:

- Round robin
- Random
- Sticky
- Topic
- the section called “Failover”
- the section called “Weighted round robin and weighted random”
- the section called “Custom Load Balancer”

Round robin

The round robin load-balancing policy cycles through all of the target endpoints, sending each incoming message to the next endpoint in the cycle. For example, if the list of target endpoints is, \texttt{mock:x, mock:y, mock:z}, then the incoming messages are sent to the following sequence of endpoints: \texttt{mock:x, mock:y, mock:z, mock:x, mock:y, mock:z}, and so on.

You can specify the round robin load-balancing policy in Java DSL, as follows:

```java
from("direct:start").loadBalance().roundRobin().to("mock:x", "mock:y", "mock:z");
```

Alternatively, you can configure the same route in XML, as follows:

```xml
<camelContext xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="direct:start"/>
    <loadBalance>
      <roundRobin/>
      <to uri="mock:x"/>
      <to uri="mock:y"/>
      <to uri="mock:z"/>
    </loadBalance>
  </route>
</camelContext>
```

Random

The random load-balancing policy chooses the target endpoint randomly from the specified list.
You can specify the random load-balancing policy in Java DSL, as follows:

```java
from("direct:start").loadBalance().random().to("mock:x", "mock:y", "mock:z");
```

Alternatively, you can configure the same route in XML, as follows:

```xml
<camelContext xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="direct:start"/>
    <loadBalance>
      <random/>
      <to uri="mock:x"/>
      <to uri="mock:y"/>
      <to uri="mock:z"/>
    </loadBalance>
  </route>
</camelContext>
```

### Sticky

The sticky load-balancing policy directs the *In* message to an endpoint that is chosen by calculating a hash value from a specified expression. The advantage of this load-balancing policy is that expressions of the same value are always sent to the same server. For example, by calculating the hash value from a header that contains a username, you ensure that messages from a particular user are always sent to the same server. Another useful approach is to specify an expression that extracts the session ID from an incoming message. This ensures that all messages belonging to the same session are sent to the same target endpoint.

You can specify the sticky load-balancing policy in Java DSL, as follows:

```java
from("direct:start").loadBalance().sticky(header("username")).to("mock:x", "mock:y", "mock:z");
```

Alternatively, you can configure the same route in XML, as follows:

```xml
<camelContext xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="direct:start"/>
    <loadBalance>
      <sticky>
        <expression>
          <simple>header.username</simple>
        </expression>
      </sticky>
      <to uri="mock:x"/>
      <to uri="mock:y"/>
      <to uri="mock:z"/>
    </loadBalance>
  </route>
</camelContext>
```
**Topic**

The topic load-balancing policy sends a copy of each *in* message to *all* of the listed destination endpoints (effectively broadcasting the message to all of the destinations, like a JMS topic).

You can use the Java DSL to specify the topic load-balancing policy, as follows:

```java
from("direct:start").loadBalance().topic().to("mock:x", "mock:y", "mock:z");
```

Alternatively, you can configure the same route in XML, as follows:

```xml
<camelContext xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="direct:start"/>
    <loadBalance>
      <topic/>
      <to uri="mock:x"/>
      <to uri="mock:y"/>
      <to uri="mock:z"/>
    </loadBalance>
  </route>
</camelContext>
```

**Failover**

*Available as of Apache Camel 2.0* The failover load balancer is capable of trying the next processor in case an Exchange failed with an *exception* during processing. You can configure the failover with a list of specific exceptions that trigger failover. If you do not specify any exceptions, failover is triggered by any exception. The failover load balancer uses the same strategy for matching exceptions as the *onException* exception clause.

---

**ENABLE STREAM CACHING IF USING STREAMS**

If you use streaming, you should enable *Stream Caching* when using the failover load balancer. This is needed so the stream can be re-read when failing over.

The failover load balancer supports the following options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Type</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
</table>

---
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Type</th>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>inheritErrorHandler</code></td>
<td>boolean</td>
<td><code>true</code></td>
<td>Camel 2.3: Specifies whether to use the <code>errorHandler</code> configured on the route. If you want to fail over immediately to the next endpoint, you should disable this option (value of <code>false</code>). If you enable this option, Apache Camel will first attempt to process the message using the <code>errorHandler</code>. For example, the <code>errorHandler</code> might be configured to redeliver messages and use delays between attempts. Apache Camel will initially try to redeliver to the original endpoint, and only fail over to the next endpoint when the <code>errorHandler</code> is exhausted.</td>
</tr>
<tr>
<td><code>maximumFailoverAttempts</code></td>
<td>int</td>
<td><code>-1</code></td>
<td>Camel 2.3: Specifies the maximum number of attempts to fail over to a new endpoint. The value, <code>0</code>, implies that no failover attempts are made and the value, <code>-1</code>, implies an infinite number of failover attempts.</td>
</tr>
</tbody>
</table>
The following example is configured to fail over, only if an `IOException` exception is thrown:

```java
from("direct:start")
// here we will load balance if IOException was thrown
// any other kind of exception will result in the Exchange as failed
// to failover over any kind of exception we can just omit the
exception
// in the failOver DSL
.loadBalance().failover(IOException.class)
  .to("direct:x", "direct:y", "direct:z");
```

You can optionally specify multiple exceptions to fail over, as follows:

```java
// enable redelivery so failover can react
errorHandler(defaultErrorHandler().maximumRedeliveries(5));
from("direct:foo")
  .loadBalance()
  .failover(IOException.class, MyOtherException.class)
  .to("direct:a", "direct:b");
```

You can configure the same route in XML, as follows:

```xml
<route errorHandlerRef="myErrorHandler">
<from uri="direct:foo"/>
<loadBalance>
  <failover>
    <exception>java.io.IOException</exception>
    <exception>com.mycompany.MyOtherException</exception>
  </failover>
</loadBalance>
</route>
```
Weighted round robin and weighted random

In many enterprise environments, where server nodes of unequal processing power are hosting services, it is usually preferable to distribute the load in accordance with the individual server processing capacities. A weighted round robin algorithm or a weighted random algorithm can be used to address this problem.

The weighted load balancing policy allows you to specify a processing load distribution ratio for each server with respect to the others. You can specify this value as a positive processing weight for each server. A larger number indicates that the server can handle a larger load. The processing weight is used to determine the payload distribution ratio of each processing endpoint with respect to the others.

The parameters that can be used are

<table>
<thead>
<tr>
<th>Option</th>
<th>Type</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
</table>

You can configure the same route in XML, as follows:

```xml
<from uri="direct:start"/>
<loadBalance>
  <!-- failover using stateful round robin, which will keep retrying the 4 endpoints indefinitely. You can set the maximumFailoverAttempt to break out after X attempts -->
  <failover roundRobin="true"/>
  <to uri="direct:bad"/>
  <to uri="direct:bad2"/>
  <to uri="direct:good"/>
  <to uri="direct:good2"/>
</loadBalance>
</route>
```
The default value for round-robin is false. In the absence of this setting or parameter, the load-balancing algorithm used is random.

The `distributionRatioDelimiter` is the delimiter used to specify the `distributionRatio`. If this attribute is not specified, comma, is the default delimiter.

The following Java DSL examples show how to define a weighted round-robin route and a weighted random route:

```
// Java
// round-robin
from("direct:start")
  .loadBalance().weighted(true, "4:2:1" distributionRatioDelimiter=":")
  .to("mock:x", "mock:y", "mock:z");

//random
from("direct:start")
  .loadBalance().weighted(false, "4,2,1")
  .to("mock:x", "mock:y", "mock:z");
```

You can configure the round-robin route in XML, as follows:

```
<route>
  <from uri="direct:start"/>
  <loadBalance>
    <weighted roundRobin="true" distributionRatio="4:2:1"
      distributionRatioDelimiter=":"/>
    <to uri="mock:x"/>
    <to uri="mock:y"/>
    <to uri="mock:z"/>
  </loadBalance>
</route>
```

### Custom Load Balancer

You can use a custom load balancer (eg your own implementation) also.

An example using Java DSL:
And the same example using XML DSL:

```xml
<bean id="myBalancer"
     class="org.apache.camel.processor.CustomLoadBalanceTest$MyLoadBalancer"/>

<camelContext xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="direct:start"/>
    <loadBalance>
      <!-- refer to my custom load balancer -->
      <custom ref="myBalancer"/>
      <!-- these are the endpoints to balancer -->
      <to uri="mock:x"/>
      <to uri="mock:y"/>
      <to uri="mock:z"/>
    </loadBalance>
  </route>
</camelContext>
```

Notice in the XML DSL above we use `<custom>` which is only available in Camel 2.8 onwards. In older releases you would have to do as follows instead:

```xml
<loadBalance ref="myBalancer">
  <!-- these are the endpoints to balancer -->
  <to uri="mock:x"/>
  <to uri="mock:y"/>
  <to uri="mock:z"/>
</loadBalance>
```

To implement a custom load balancer you can extend some support classes such as `LoadBalancerSupport` and `SimpleLoadBalancerSupport`. The former supports the asynchronous routing engine, and the latter does not. Here is an example:

```java
public static class MyLoadBalancer extends LoadBalancerSupport {
    public boolean process(Exchange exchange, AsyncCallback callback) {
        String body = exchange.getIn().getBody(String.class);
        try {
            if ("x".equals(body)) {
                getProcessors().get(0).process(exchange);
            } else if ("y".equals(body)) {
                getProcessors().get(1).process(exchange);
            } else {
                getProcessors().get(2).process(exchange);
            }
        } catch (Throwable e) {
            exchange.setException(e);
        }
        callback.done(true);
    }
}
```
7.11. MULTICAST

Overview

The multicast pattern, shown in Figure 7.10, “Multicast Pattern”, is a variation of the recipient list with a fixed destination pattern, which is compatible with the InOut message exchange pattern. This is in contrast to recipient list, which is only compatible with the InOnly exchange pattern.

Figure 7.10. Multicast Pattern

Multicast with a custom aggregation strategy

Whereas the multicast processor receives multiple Out messages in response to the original request (one from each of the recipients), the original caller is only expecting to receive a single reply. Thus, there is an inherent mismatch on the reply leg of the message exchange, and to overcome this mismatch, you must provide a custom aggregation strategy to the multicast processor. The aggregation strategy class is responsible for aggregating all of the Out messages into a single reply message.

Consider the example of an electronic auction service, where a seller offers an item for sale to a list of buyers. The buyers each put in a bid for the item, and the seller automatically selects the bid with the highest price. You can implement the logic for distributing an offer to a fixed list of buyers using the multicast() DSL command, as follows:

```java
from("cxf:bean:offer").multicast(new HighestBidAggregationStrategy()).to("cxf:bean:Buyer1", "cxf:bean:Buyer2", "cxf:bean:Buyer3");
```

Where the seller is represented by the endpoint, cxf:bean:offer, and the buyers are represented by the endpoints, cxf:bean:Buyer1, cxf:bean:Buyer2, cxf:bean:Buyer3. To consolidate the bids received from the various buyers, the multicast processor uses the aggregation strategy, HighestBidAggregationStrategy. You can implement the HighestBidAggregationStrategy in Java, as follows:

```java
// Java
```
Parallel processing

By default, the multicast processor invokes each of the recipient endpoints one after another (in the order listed in the to() command). In some cases, this might cause unacceptably long latency. To avoid these long latency times, you have the option of enabling parallel processing by adding the parallelProcessing() clause. For example, to enable parallel processing in the electronic auction example, define the route as follows:

```java
from("cxf:bean:offer")
    .multicast(new HighestBidAggregationStrategy())
    .parallelProcessing()
    .to("cxf:bean:Buyer1", "cxf:bean:Buyer2", "cxf:bean:Buyer3");
```

Where the multicast processor now invokes the buyer endpoints, using a thread pool that has one thread for each of the endpoints.

If you want to customize the size of the thread pool that invokes the buyer endpoints, you can invoke the executorService() method to specify your own custom executor service. For example:

```java
from("cxf:bean:offer")
    .multicast(new HighestBidAggregationStrategy())
    .executorService(MyExecutor)
    .to("cxf:bean:Buyer1", "cxf:bean:Buyer2", "cxf:bean:Buyer3");
```

Where MyExecutor is an instance of java.util.concurrent.ExecutorService type.

When the exchange has an InOut pattern, an aggregation strategy is used to aggregate reply messages. The default aggregation strategy takes the latest reply message and discards earlier replies. For example, in the following route, the custom strategy, MyAggregationStrategy, is used to aggregate the replies from the endpoints direct:a, direct:b, and direct:c:

```java
from("direct:start")
    .multicast(new MyAggregationStrategy())
    .parallelProcessing()
    .timeout(500)
```

Where it is assumed that the buyers insert the bid price into a header named, Bid. For more details about custom aggregation strategies, see Section 7.5, “Aggregator”.

```java
import org.apache.camel.processor.aggregate.AggregationStrategy;
import org.apache.camel.Exchange;

public class HighestBidAggregationStrategy implements AggregationStrategy {
    public Exchange aggregate(Exchange oldExchange, Exchange newExchange) {
        float oldBid = oldExchange.getOut().getHeader("Bid", Float.class);
        float newBid = newExchange.getOut().getHeader("Bid", Float.class);
        return (newBid > oldBid) ? newExchange : oldExchange;
    }
}
```
XML configuration example

The following example shows how to configure a similar route in XML, where the route uses a custom aggregation strategy and a custom thread executor:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<beans xmlns="http://www.springframework.org/schema/beans"
      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xsi:schemaLocation="http://www.springframework.org/schema/beans
                           http://www.springframework.org/schema/beans/spring-beans-3.0.xsd
                           http://camel.apache.org/schema/spring
                           http://camel.apache.org/schema/spring/camel-spring.xsd">
  <camelContext xmlns="http://camel.apache.org/schema/spring">
    <route>
      <from uri="cxf:bean:offer"/>
      <multicast strategyRef="highestBidAggregationStrategy"
                 parallelProcessing="true"
                 threadPoolRef="myThreadExcutor">
        <to uri="cxf:bean:Buyer1"/>
        <to uri="cxf:bean:Buyer2"/>
        <to uri="cxf:bean:Buyer3"/>
      </multicast>
    </route>
  </camelContext>

  <bean id="highestBidAggregationStrategy" class="com.acme.example.HighestBidAggregationStrategy"/>
  <bean id="myThreadExcutor" class="com.acme.example.MyThreadExcutor"/>
</beans>
```

Where both the `parallelProcessing` attribute and the `threadPoolRef` attribute are optional. It is only necessary to set them if you want to customize the threading behavior of the multicast processor.

Apply custom processing to the outgoing messages

Before multicast sends a message to one of the recipient endpoints, it creates a message replica, which is a shallow copy of the original message. If you want to perform some custom processing on each message replica before the replica is sent to its endpoint, you can invoke the `onPrepare` DSL command in the `multicast` clause. The `onPrepare` command inserts a custom processor just after the message has been shallow-copied and just before the message is dispatched to its endpoint. For example, in the following route, the `CustomProc` processor is invoked on the message sent to `direct:a` and the `CustomProc` processor is also invoked on the message sent to `direct:b`.

```java
from("direct:start")
  .multicast().onPrepare(new CustomProc())
"
A common use case for the onPrepare DSL command is to perform a deep copy of some or all elements of a message. For example, the following CustomProc processor class performs a deep copy of the message body, where the message body is presumed to be of type, BodyType, and the deep copy is performed by the method BodyType.deepCopy().

```java
// Java
import org.apache.camel.*;
...
public class CustomProc implements Processor {

    public void process(Exchange exchange) throws Exception {
        BodyType body = exchange.getIn().getBody(BodyType.class);

        // Make a _deep_ copy of of the body object
        BodyType clone = BodyType.deepCopy();
        exchange.getIn().setBody(clone);

        // Headers and attachments have already been
        // shallow-copied. If you need deep copies,
        // add some more code here.
    }
}
```

**NOTE**

Although the multicast syntax allows you to invoke the process DSL command in the multicast clause, this does not make sense semantically and it does not have the same effect as onPrepare (in fact, in this context, the process DSL command has no effect).

**Using onPrepare to execute custom logic when preparing messages**

The Multicast will copy the source Exchange and multicast each copy. However the copy is a shallow copy, so in case you have mutable message bodies, then any changes will be visible by the other copied messages. If you want to use a deep clone copy then you need to use a custom onPrepare which allows you to do this using the Processor interface.

Notice the onPrepare can be used for any kind of custom logic which you would like to execute before the Exchange is being multicasted.

**NOTE**

Its best practice to design for immutable objects.

For example if you have a mutable message body as this Animal class:

```java
public class Animal implements Serializable {
    private int id;
    private String name;
    public Animal() {
```
Then we can create a deep clone processor which clones the message body:

```java
public class AnimalDeepClonePrepare implements Processor {
    public void process(Exchange exchange) throws Exception {
        Animal body = exchange.getIn().getBody(Animal.class);
        // do a deep clone of the body which wont affect when doing multicasting
        Animal clone = body.deepClone();
        exchange.getIn().setBody(clone);
    }
}
```

Then we can use the AnimalDeepClonePrepare class in the Multicast route using the **onPrepare** option as shown:

```java
public class AnimalDeepClonePrepare implements Processor {
    public void process(Exchange exchange) throws Exception {
        Animal body = exchange.getIn().getBody(Animal.class);
        // do a deep clone of the body which wont affect when doing multicasting
        Animal clone = body.deepClone();
        exchange.getIn().setBody(clone);
    }
}
```
And the same example in XML DSL

```
<camelContext xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="direct:start"/>
    <!-- use on prepare with multicast -->
    <multicast onPrepareRef="animalDeepClonePrepare">
      <to uri="direct:a"/>
      <to uri="direct:b"/>
    </multicast>
  </route>

  <route>
    <from uri="direct:a"/>
    <process ref="processorA"/>
    <to uri="mock:a"/>
  </route>

  <route>
    <from uri="direct:b"/>
    <process ref="processorB"/>
    <to uri="mock:b"/>
  </route>
</camelContext>
```

<!-- the on prepare Processor which performs the deep cloning -->
<bean id="animalDeepClonePrepare" class="org.apache.camel.processor.AnimalDeepClonePrepare"/>

<!-- processors used for the last two routes, as part of unit test -->
<bean id="processorA" class="org.apache.camel.processor.MulticastOnPrepareTest$ProcessorA"/>
<bean id="processorB" class="org.apache.camel.processor.MulticastOnPrepareTest$ProcessorB"/>

**Options**

The **multicast** DSL command supports the following options:

<table>
<thead>
<tr>
<th>Name</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>strategyRef</td>
<td></td>
<td>Refers to an <a href="https://camel.apache.org/manual40/strategy.html">AggregationStrategy</a> to be used to assemble the replies from the multicasts, into a single outgoing message from the Multicast. By default Camel will use the last reply as the outgoing message.</td>
</tr>
<tr>
<td>Parameter</td>
<td>Value</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------</td>
<td>-------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>parallelProcessing</td>
<td>false</td>
<td>If enables then sending messages to the multicasts occurs concurrently. Note the caller thread will still wait until all messages has been fully processed, before it continues. Its only the sending and processing the replies from the multicasts which happens concurrently.</td>
</tr>
<tr>
<td>executorServiceRef</td>
<td></td>
<td>Refers to a custom Thread Pool to be used for parallel processing. Notice if you set this option, then parallel processing is automatic implied, and you do not have to enable that option as well.</td>
</tr>
<tr>
<td>stopOnException</td>
<td>false</td>
<td><strong>Camel 2.2:</strong> Whether or not to stop continue processing immediately when an exception occurred. If disable, then Camel will send the message to all multicasts regardless if one of them failed. You can deal with exceptions in the AggregationStrategy class where you have full control how to handle that.</td>
</tr>
<tr>
<td>streaming</td>
<td>false</td>
<td>If enabled then Camel will process replies out-of-order, eg in the order they come back. If disabled, Camel will process replies in the same order as multicasted.</td>
</tr>
<tr>
<td>timeout</td>
<td></td>
<td><strong>Camel 2.5:</strong> Sets a total timeout specified in millis. If the Multicast hasn't been able to send and process all replies within the given timeframe, then the timeout triggers and the Multicast breaks out and continues. Notice if you provide a TimeoutAwareAggregationStrategy then the timeout method is invoked before breaking out.</td>
</tr>
</tbody>
</table>
7.12. COMPOSED MESSAGE PROCESSOR

Composed Message Processor

The composed message processor pattern, as shown in Figure 7.11, “Composed Message Processor Pattern”, allows you to process a composite message by splitting it up, routing the sub-messages to appropriate destinations, and then re-aggregating the responses back into a single message.

Figure 7.11. Composed Message Processor Pattern

Java DSL example

The following example checks that a multipart order can be filled, where each part of the order requires a check to be made at a different inventory:

```java
// split up the order so individual OrderItems can be validated by the appropriate bean
from("direct:start")
    .split().body()
    .choice()
        .when().method("orderItemHelper", "isWidget")
            .to("bean:widgetInventory")
        .otherwise()
            .to("bean:gadgetInventory")
```
The preceding route can also be written in XML DSL, as follows:

```xml
<route>
  <from uri="direct:start"/>
  <split>
    <simple>body</simple>
    <choice>
      <when>
        <method bean="orderItemHelper" method="isWidget"/>
        <to uri="bean:widgetInventory"/>
      </when>
      <otherwise>
        <to uri="bean:gadgetInventory"/>
      </otherwise>
    </choice>
    <to uri="seda:aggregate"/>
  </split>
</route>

<route>
  <from uri="seda:aggregate"/>
  <aggregate strategyRef="myOrderAggregatorStrategy" completionTimeout="1000">
    <correlationExpression>
      <simple>header.orderId</simple>
    </correlationExpression>
    <to uri="mock:result"/>
  </aggregate>
</route>
```

**Processing steps**

Processing starts by splitting the order, using a **Splitter**. The **Splitter** then sends individual **OrderItems** to a **Content Based Router**, which routes messages based on the item type. **Widget** items get sent for checking in the **widgetInventory** bean and **gadget** items get sent to the **gadgetInventory** bean. Once these **OrderItems** have been validated by the appropriate bean, they are sent on to the **Aggregator** which collects and re-assembles the validated **OrderItems** into an order again.

Each received order has a header containing an **order ID**. We make use of the order ID during the aggregation step: the `.header("orderId")` qualifier on the `aggregate()` DSL command instructs the aggregator to use the header with the key, **orderId**, as the correlation expression.
For full details, check the example source here:

## 7.13. SCATTER-GATHER

### Scatter-Gather

The scatter-gather pattern, as shown in Figure 7.12, "Scatter-Gather Pattern", enables you to route messages to a number of dynamically specified recipients and re-aggregate the responses back into a single message.

### Figure 7.12. Scatter-Gather Pattern

![Scatter-Gather Pattern Diagram]

### Dynamic scatter-gather example

The following example outlines an application that gets the best quote for beer from several different vendors. The examples uses a dynamic Recipient List to request a quote from all vendors and an Aggregator to pick the best quote out of all the responses. The routes for this application are defined as follows:

```xml
<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="direct:start"/>
    <recipientList>
      <header>listOfVendors</header>
    </recipientList>
  </route>
  <route>
    <from uri="seda:quoteAggregator"/>
    <aggregate strategyRef="aggregatorStrategy" completionTimeout="1000">
      <correlationExpression>
        <header>quoteRequestId</header>
      </correlationExpression>
      <to uri="mock:result"/>
    </aggregate>
  </route>
</camelContext>
```

In the first route, the Recipient List looks at the **listOfVendors** header to obtain the list of
recipients. Hence, the client that sends messages to this application needs to add a \texttt{listOfVendors} header to the message. Example 7.1, “Messaging Client Sample” shows some sample code from a messaging client that adds the relevant header data to outgoing messages.

**Example 7.1. Messaging Client Sample**

```java
Map<String, Object> headers = new HashMap<String, Object>();
headers.put("listOfVendors", "bean:vendor1, bean:vendor2,
bean:vendor3");
headers.put("quoteRequestId", "quoteRequest-1");
template.sendBodyAndHeaders("direct:start", "<quote_request
item="beer"/">", headers);
```

The message would be distributed to the following endpoints: \texttt{bean:vendor1}, \texttt{bean:vendor2}, and \texttt{bean:vendor3}. These beans are all implemented by the following class:

```java
public class MyVendor {
    private int beerPrice;
    @Produce(uri = "seda:quoteAggregator")
    private ProducerTemplate quoteAggregator;

    public MyVendor(int beerPrice) {
        this.beerPrice = beerPrice;
    }

    public void getQuote(@XPath("/quote_request/@item") String item,
    Exchange exchange) throws Exception {
        if ("beer".equals(item)) {
            exchange.getIn().setBody(beerPrice);
            quoteAggregator.send(exchange);
        } else {
            throw new Exception("No quote available for " + item);
        }
    }
}
```

The bean instances, \texttt{vendor1}, \texttt{vendor2}, and \texttt{vendor3}, are instantiated using Spring XML syntax, as follows:

```xml
<bean id="aggregatorStrategy"
    class="org.apache.camel.spring.processor.scattergather.LowestQuoteAggregationStrategy"/>

<bean id="vendor1"
    class="org.apache.camel.spring.processor.scattergather.MyVendor">
    <constructor-arg>
        <value>1</value>
    </constructor-arg>
</bean>

<bean id="vendor2"
    class="org.apache.camel.spring.processor.scattergather.MyVendor">
```

```
```
Each bean is initialized with a different price for beer (passed to the constructor argument). When a message is sent to each bean endpoint, it arrives at the `MyVendor.getQuote` method. This method does a simple check to see whether this quote request is for beer and then sets the price of beer on the exchange for retrieval at a later step. The message is forwarded to the next step using **POJO Producing** (see the `@Produce` annotation).

At the next step, we want to take the beer quotes from all vendors and find out which one was the best (that is, the lowest). For this, we use an **Aggregator** with a custom aggregation strategy. The **Aggregator** needs to identify which messages are relevant to the current quote, which is done by correlating messages based on the value of the `quoteRequestId` header (passed to the `correlationExpression`). As shown in Example 7.1, “Messaging Client Sample”, the correlation ID is set to `quoteRequest-1` (the correlation ID should be unique). To pick the lowest quote out of the set, you can use a custom aggregation strategy like the following:

```java
class LowestQuoteAggregationStrategy implements AggregationStrategy {
    public Exchange aggregate(Exchange oldExchange, Exchange newExchange) {
        // the first time we only have the new exchange
        if (oldExchange == null) {
            return newExchange;
        }

        if (oldExchange.getIn().getBody(int.class) <
            newExchange.getIn().getBody(int.class)) {
            return oldExchange;
        } else {
            return newExchange;
        }
    }
}
```

**Static scatter-gather example**

You can specify the recipients explicitly in the scatter-gather application by employing a static **Recipient List**. The following example shows the routes you would use to implement a static scatter-gather scenario:

```xml
<constructor-arg>
    <value>2</value>
</constructor-arg>
</bean>

<bean id="vendor3"
    class="org.apache.camel.spring.processor.scattergather.MyVendor">
    <constructor-arg>
        <value>3</value>
    </constructor-arg>
</bean>

public class LowestQuoteAggregationStrategy implements AggregationStrategy {
    public Exchange aggregate(Exchange oldExchange, Exchange newExchange) {
        // the first time we only have the new exchange
        if (oldExchange == null) {
            return newExchange;
        }

        if (oldExchange.getIn().getBody(int.class) <
            newExchange.getIn().getBody(int.class)) {
            return oldExchange;
        } else {
            return newExchange;
        }
    }
}

from("direct:start").multicast().to("seda:vendor1").to("seda:vendor2").to("seda:vendor3");
from("seda:vendor1").to("bean:vendor1").to("seda:quoteAggregator");
```
Loop
The loop pattern enables you to process a message multiple times. It is used mainly for testing.

**DEFAULT MODE**
Notice by default the loop uses the same exchange throughout the looping. So the result from the previous iteration is used for the next (eg Pipes and Filters). From Camel 2.8 onwards you can enable copy mode instead. See the options table for more details.

Exchange properties
On each loop iteration, two exchange properties are set, which can optionally be read by any processors included in the loop.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CamelLoopSize</td>
<td>Apache Camel 2.0: Total number of loops</td>
</tr>
<tr>
<td>CamelLoopIndex</td>
<td>Apache Camel 2.0: Index of the current iteration (0 based)</td>
</tr>
</tbody>
</table>

Java DSL examples
The following examples show how to take a request from the direct:x endpoint and then send the message repeatedly to mock:result. The number of loop iterations is specified either as an argument to loop() or by evaluating an expression at run time, where the expression must evaluate to an int (or else a RuntimeCamelException is thrown).

The following example passes the loop count as a constant:

```java
from("direct:a").loop(8).to("mock:result");
```

The following example evaluates a simple expression to determine the loop count:

```java
from("direct:b").loop(header("loop")).to("mock:result");
```

The following example evaluates an XPath expression to determine the loop count:

```java
from("direct:c").loop().xpath("/hello/@times").to("mock:result");
```
XML configuration example

You can configure the same routes in Spring XML.

The following example passes the loop count as a constant:

```xml
<route>
   <from uri="direct:a"/>
   <loop>
      <constant>8</constant>
      <to uri="mock:result"/>
   </loop>
</route>
```

The following example evaluates a simple expression to determine the loop count:

```xml
<route>
   <from uri="direct:b"/>
   <loop>
      <header>loop</header>
      <to uri="mock:result"/>
   </loop>
</route>
```

Using copy mode

Now suppose we send a message to `direct:start` endpoint containing the letter A. The output of processing this route will be that, each `mock:loop` endpoint will receive AB as message.

```java
from("direct:start")
   // instruct loop to use copy mode, which mean it will use a copy of
   // the input exchange
   // for each loop iteration, instead of keep using the same exchange
   all over
      .loop(3).copy()
      .transform(body().append("B"))
      .to("mock:loop")
   .end()
   .to("mock:result");
```

However if we do not enable copy mode then `mock:loop` will receive AB, ABB, ABBB messages.

```java
from("direct:start")
   // by default loop will keep using the same exchange so on the 2nd
   // and 3rd iteration its
   // the same exchange that was previous used that are being looped all
   over
   .loop(3)
      .transform(body().append("B"))
      .to("mock:loop")
   .end()
```
The equivalent example in XML DSL in copy mode is as follows:

```xml
<route>
  <from uri="direct:start"/>
  <!-- enable copy mode for loop eip -->
  <loop copy="true">
    <constant>3</constant>
    <transform>
      <simple>${body}B</simple>
    </transform>
    <to uri="mock:loop"/>
  </loop>
  <to uri="mock:result"/>
</route>
```

### Options

The **loop** DSL command supports the following options:

<table>
<thead>
<tr>
<th>Name</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>copy</td>
<td>false</td>
<td><strong>Camel 2.8:</strong> Whether or not copy mode is used. If <strong>false</strong> then the same Exchange is being used throughout the looping. So the result from the previous iteration will be <strong>visible</strong> for the next iteration. Instead you can enable copy mode, and then each iteration is <strong>restarting</strong> with a fresh copy of the input Exchange.</td>
</tr>
</tbody>
</table>

### 7.15. SAMPLING

#### Sampling Throttler

A sampling throttler allows you to extract a sample of exchanges from the traffic through a route. It is configured with a sampling period during which only a **single** exchange is allowed to pass through. All other exchanges will be stopped.

By default, the sample period is 1 second.

#### Java DSL example

Use the **sample()** DSL command to invoke the sampler as follows:

```java
// Sample with default sampling period (1 second)
from("direct:sample")
 .sample()
```
In Spring XML, use the `sample` element to invoke the sampler, where you have the option of specifying the sampling period using the `samplePeriod` and `units` attributes:

```
<route>
  <from uri="direct:sample"/>
  <sample samplePeriod="1" units="seconds">
    <to uri="mock:result"/>
  </sample>
</route>

<route>
  <from uri="direct:sample-messageFrequency"/>
  <sample messageFrequency="10">
    <to uri="mock:result"/>
  </sample>
</route>

<route>
  <from uri="direct:sample-messageFrequency-via-dsl"/>
  <sample messageFrequency="5">
    <to uri="mock:result"/>
  </sample>
</route>
```

### Options

The `sample` DSL command supports the following options:

<table>
<thead>
<tr>
<th>Name</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>samplePeriod</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>units</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td>messageFrequency</td>
<td>Samples the message every N'th message. You can only use either frequency or period.</td>
<td></td>
</tr>
<tr>
<td>------------------</td>
<td>--------------------------------------------------------------------------------------------------</td>
<td></td>
</tr>
<tr>
<td>samplePeriod</td>
<td>1</td>
<td>Samples the message every N'th period. You can only use either frequency or period.</td>
</tr>
<tr>
<td>units</td>
<td>SECOND</td>
<td>Time unit as an enum of <code>java.util.concurrent.TimeUnit</code> from the JDK.</td>
</tr>
</tbody>
</table>

### 7.16. DYNAMIC ROUTER

**Dynamic Router**

The Dynamic Router pattern, as shown in Figure 7.13, "Dynamic Router Pattern", enables you to route a message consecutively through a series of processing steps, where the sequence of steps is not known at design time. The list of endpoints through which the message should pass is calculated dynamically at run time. Each time the message returns from an endpoint, the dynamic router calls back on a bean to discover the next endpoint in the route.

**Figure 7.13. Dynamic Router Pattern**

In Camel 2.5 we introduced a `dynamicRouter` in the DSL, which is like a dynamicRouteSlip that evaluates the slip on-the-fly.
BEWARE

You must ensure the expression used for the `dynamicRouter` (such as a bean), returns `null` to indicate the end. Otherwise, the `dynamicRouter` will continue in an endless loop.

Dynamic Router in Camel 2.5 onwards

From Camel 2.5, the Dynamic Router updates the exchange property, `Exchange.SLIP_ENDPOINT`, with the current endpoint as it advances through the slip. This enables you to find out how far the exchange has progressed through the slip. (It's a slip because the Dynamic Router implementation is based on Routing Slip).

Java DSL

In Java DSL you can use the `dynamicRouter` as follows:

```java
from("direct:start")
    // use a bean as the dynamic router
    .dynamicRouter(bean(DynamicRouterTest.class, "slip"));
```

Which will leverage a Bean to compute the slip on-the-fly, which could be implemented as follows:

```java
// Java
/**
 * Use this method to compute dynamic where we should route next.
 * @param body the message body
 * @return endpoints to go, or <tt>null</tt> to indicate the end
 */
public String slip(String body) {
    bodies.add(body);
    invoked++;

    if (invoked == 1) {
        return "mock:a";
    } else if (invoked == 2) {
        return "mock:b, mock:c";
    } else if (invoked == 3) {
        return "direct:foo";
    } else if (invoked == 4) {
        return "mock:result";
    }

    // no more so return null
    return null;
}
```
NOTE

The preceding example is not thread safe. You would have to store the state on the Exchange to ensure thread safety.

**Spring XML**

The same example in Spring XML would be:

```xml
<bean id="mySlip" class="org.apache.camel.processor.DynamicRouterTest"/>
<camelContext xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="direct:start"/>
    <dynamicRouter>
      <!-- use a method call on a bean as dynamic router -->
      <method ref="mySlip" method="slip"/>
    </dynamicRouter>
  </route>

  <route>
    <from uri="direct:foo"/>
    <transform><constant>Bye World</constant></transform>
    <to uri="mock:foo"/>
  </route>
</camelContext>
```

**Options**

The `dynamicRouter` DSL command supports the following options:

<table>
<thead>
<tr>
<th>Name</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>uriDelimiter</td>
<td>,</td>
<td>Delimiter used if the Expression returned multiple endpoints.</td>
</tr>
<tr>
<td>ignoreInvalidEndpoints</td>
<td>false</td>
<td>If an endpoint uri could not be resolved, should it be ignored. Otherwise Camel will throw an exception stating the endpoint uri is not valid.</td>
</tr>
</tbody>
</table>

**@DynamicRouter annotation**

You can also use the `@DynamicRouter` annotation. For example:

```java
// Java
public class MyDynamicRouter {

    @Consume(uri = "activemq:foo")
```
The route method is invoked repeatedly as the message progresses through the slip. The idea is to return the endpoint URI of the next destination. Return null to indicate the end. You can return multiple endpoints if you like, just as the Routing Slip, where each endpoint is separated by a delimiter.

```java
@DynamicRouter
public String route(@XPath("/customer/id") String customerId,
@Header("Location") String location, Document body) {
    // query a database to find the best match of the endpoint based
    // on the input parameters
    // return the next endpoint uri, where to go. Return null to
    indicate the end.
    }
}
CHAPTER 8. MESSAGE TRANSFORMATION

Abstract

The message transformation patterns describe how to modify the contents of messages for various purposes.

8.1. CONTENT ENRICHER

Overview

The content enricher pattern describes a scenario where the message destination requires more data than is present in the original message. In this case, you would use a content enricher to pull in the extra data from an external resource.

Models of content enrichment

Apache Camel supports two kinds of content enricher, as follows:

- **enrich()**—obtains additional data from the resource by sending a copy of the current exchange to a producer endpoint and then using the data from the resulting reply (the exchange created by the enricher is always an InOut exchange).

- **pollEnrich()**—obtains the additional data by polling a consumer endpoint for data. Effectively, the consumer endpoint from the main route and the consumer endpoint in pollEnrich() are coupled, such that exchanges incoming on the main route trigger a poll of the pollEnrich() endpoint.

Content enrichment using enrich()

```java
AggregationStrategy aggregationStrategy = ...

from("direct:start")
    .enrich("direct:resource", aggregationStrategy)
    .to("direct:result");
```
The content enricher (enrich) retrieves additional data from a resource endpoint in order to enrich an incoming message (contained in the original exchange). An aggregation strategy combines the original exchange and the resource exchange. The first parameter of the AggregationStrategy.aggregate(Exchange, Exchange) method corresponds to the original exchange, and the second parameter corresponds to the resource exchange. The results from the resource endpoint are stored in the resource exchange's Out message.

Here is a sample template for implementing your own aggregation strategy class:

```java
public class ExampleAggregationStrategy implements AggregationStrategy {

    public Exchange aggregate(Exchange original, Exchange resource) {
        Object originalBody = original.getIn().getBody();
        Object resourceResponse = resource.getOut().getBody();
        Object mergeResult = ... // combine original body and resource response
        if (original.getPattern().isOutCapable()) {
            original.getOut().setBody(mergeResult);
        } else {
            original.getIn().setBody(mergeResult);
        }
        return original;
    }
}
```

Using this template, the original exchange can have any exchange pattern. The resource exchange created by the enricher is always an InOut exchange.

**Spring XML enrich example**

The preceding example can also be implemented in Spring XML:

```xml
<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="direct:start"/>
    <enrich uri="direct:resource" strategyRef="aggregationStrategy"/>
    <to uri="direct:result"/>
  </route>
  <route>
    <from uri="direct:resource"/>
    ...
  </route>
</camelContext>

<bean id="aggregationStrategy" class="..." />
```

**Default aggregation strategy**

The aggregation strategy is optional. If you do not provide it, Apache Camel will use the body obtained from the resource by default. For example:
In the preceding route, the message sent to the `direct:result` endpoint contains the output from the `direct:resource`, because this example does not use any custom aggregation.

In XML DSL, just omit the `strategyRef` attribute, as follows:

```xml
<route>
  <from uri="direct:start"/>
  <enrich uri="direct:resource"/>
  <to uri="direct:result"/>
</route>
```

**Enrich Options**

The `enrich` DSL command supports the following options:

<table>
<thead>
<tr>
<th>Name</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>uri</code></td>
<td></td>
<td>The endpoint uri for the external service to enrich from. You must use either <code>uri</code> or <code>ref</code>.</td>
</tr>
<tr>
<td><code>ref</code></td>
<td></td>
<td>Refers to the endpoint for the external service to enrich from. You must use either <code>uri</code> or <code>ref</code>.</td>
</tr>
<tr>
<td><code>strategyRef</code></td>
<td></td>
<td>Refers to an <code>AggregationStrategy</code> to be used to merge the reply from the external service, into a single outgoing message. By default Camel will use the reply from the external service as outgoing message.</td>
</tr>
</tbody>
</table>

**Content enrich using `pollEnrich`**

The `pollEnrich` command treats the resource endpoint as a consumer. Instead of sending an exchange to the resource endpoint, it polls the endpoint. By default, the poll returns immediately, if there is no exchange available from the resource endpoint. For example, the following route reads a file whose name is extracted from the header of an incoming JMS message:

```java
from("activemq:queue:order")
  .pollEnrich("file://order/data/additional?fileName=orderId")
  .to("bean:processOrder");
```
And if you want to wait at most 20 seconds for the file to be ready, you can use a timeout as follows:

```java
from("activemq:queue:order")
    .pollEnrich("file://order/data/additional?fileName=orderId", 20000) //
        timeout is in milliseconds
    .to("bean:processOrder");
```

You can also specify an aggregation strategy for `pollEnrich`, as follows:

```java
.pollEnrich("file://order/data/additional?fileName=orderId", 20000, aggregationStrategy)
```

**NOTE**

The resource exchange passed to the aggregation strategy's `aggregate()` method might be `null`, if the poll times out before an exchange is received.

**DATA FROM CURRENT EXCHANGE NOT USED**

`pollEnrich` does not access any data from the current Exchange, so that, when polling, it cannot use any of the existing headers you may have set on the Exchange. For example, you cannot set a filename in the `Exchange.FILE_NAME` header and use `pollEnrich` to consume only that file. For that, you must set the filename in the endpoint URI.

### Polling methods used by `pollEnrich()`

In general, the `pollEnrich()` enricher polls the consumer endpoint using one of the following polling methods:

- `receiveNoWait()` *(used by default)*
- `receive()`
- `receive(long timeout)`

The `pollEnrich()` command's timeout argument (specified in milliseconds) determines which method gets called, as follows:

- Timeout is 0 or not specified, `receiveNoWait` is called.
- Timeout is negative, `receive` is called.
- Otherwise, `receive(timeout)` is called.

### `pollEnrich` example

```java
from("activemq:queue:order")
    .pollEnrich("file://order/data/additional?fileName=orderId", 20000) //
        timeout is in milliseconds
    .to("bean:processOrder");
```
In this example we enrich the message by loading the content from the file named inbox/data.txt.

```java
from("direct:start")
    .pollEnrich("file:inbox?fileName=data.txt")
    .to("direct:result");
```

And in XML DSL you do:

```xml
<route>
    <from uri="direct:start"/>
    <pollEnrich uri="file:inbox?fileName=data.txt"/>
    <to uri="direct:result"/>
</route>
```

If there is no file then the message is empty. We can use a timeout to either wait (potential forever) until a file exists, or use a timeout to wait a period. For example to wait up til 5 seconds you can do:

```xml
<route>
    <from uri="direct:start"/>
    <pollEnrich uri="file:inbox?fileName=data.txt" timeout="5000"/>
    <to uri="direct:result"/>
</route>
```

**PollEnrich Options**

The `pollEnrich` DSL command supports the following options:

<table>
<thead>
<tr>
<th>Name</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>uri</code></td>
<td></td>
<td>The endpoint uri for the external service to enrich from. You must use either <code>uri</code> or <code>ref</code>.</td>
</tr>
<tr>
<td><code>ref</code></td>
<td></td>
<td>Refers to the endpoint for the external service to enrich from. You must use either <code>uri</code> or <code>ref</code>.</td>
</tr>
<tr>
<td><code>strategyRef</code></td>
<td></td>
<td>Refers to an <code>AggregationStrategy</code> to be used to merge the reply from the external service, into a single outgoing message. By default Camel will use the reply from the external service as outgoing message.</td>
</tr>
</tbody>
</table>
8.2. CONTENT FILTER

Overview

The content filter pattern describes a scenario where you need to filter out extraneous content from a message before delivering it to its intended recipient. For example, you might employ a content filter to strip out confidential information from a message.

Figure 8.2. Content Filter Pattern

A common way to filter messages is to use an expression in the DSL, written in one of the supported scripting languages (for example, XSLT, XQuery or JoSQL).

Implementing a content filter

A content filter is essentially an application of a message processing technique for a particular purpose. To implement a content filter, you can employ any of the following message processing techniques:

- Message translator—see message translators.
- Processors—see Chapter 41, Implementing a Processor.
- Bean integration.

XML configuration example

The following example shows how to configure the same route in XML:

```xml
<camelContext xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="activemq:My.Queue"/>
    <to uri="xslt:classpath:com/acme/content_filter.xsl"/>
    <to uri="activemq:Another.Queue"/>
  </route>
</camelContext>
```
Using an XPath filter

You can also use XPath to filter out part of the message you are interested in:

```xml
<route>
    <from uri="activemq:Input"/>
    <setBody><xpath resultType="org.w3c.dom.Document">//foo:bar</xpath>
    </setBody>
    <to uri="activemq:Output"/>
</route>
```

8.3. NORMALIZER

Overview

The normalizer pattern is used to process messages that are semantically equivalent, but arrive in different formats. The normalizer transforms the incoming messages into a common format.

In Apache Camel, you can implement the normalizer pattern by combining a content-based router, which detects the incoming message's format, with a collection of different message translators, which transform the different incoming formats into a common format.

Figure 8.3. Normalizer Pattern

Java DSL example

This example shows a Message Normalizer that converts two types of XML messages into a common format. Messages in this common format are then filtered.

Using the Fluent Builders

```java
// we need to normalize two types of incoming messages
from("direct:start")
    .choice()
        .when().xpath("/employee").to("bean:normalizer?
method=employeeToPerson")
        .when().xpath("/customer").to("bean:normalizer?
```

![Diagram of Normalizer Pattern](image-url)
In this case we're using a Java bean as the normalizer. The class looks like this

```java
public class MyNormalizer {
    public void employeeToPerson(Exchange exchange,
            @XPath("/employee/name/text()") String name) {
        exchange.getOut().setBody(createPerson(name));
    }

    public void customerToPerson(Exchange exchange,
            @XPath("/customer/@name") String name) {
        exchange.getOut().setBody(createPerson(name));
    }

    private String createPerson(String name) {
        return "<person name=" + name + "/>";
    }
}
```

The same example in the XML DSL

```xml
<camelContext xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="direct:start"/>
    <choice>
      <when>
        <xpath>/employee</xpath>
        <to uri="bean:normalizer?method=employeeToPerson"/>
      </when>
      <when>
        <xpath>/customer</xpath>
        <to uri="bean:normalizer?method=customerToPerson"/>
      </when>
    </choice>
    <to uri="mock:result"/>
  </route>
</camelContext>

<bean id="normalizer" class="org.apache.camel.processor.MyNormalizer"/>
```

### 8.4. CLAIM CHECK

#### Claim Check

The claim check pattern, shown in Figure 8.4, "Claim Check Pattern", allows you to replace message content with a claim check (a unique key), which can be used to retrieve the message content at a later time. The message content is stored temporarily in a persistent
store like a database or file system. This pattern is very useful when message content is very large (thus it would be expensive to send around) and not all components require all information.

It can also be useful in situations where you cannot trust the information with an outside party; in this case, you can use the Claim Check to hide the sensitive portions of data.

**Figure 8.4. Claim Check Pattern**

Java DSL example

The following example shows how to replace a message body with a claim check and restore the body at a later step.

```java
def from("direct:start").to("bean:checkLuggage", "mock:testCheckpoint", "bean:dataEnricher", "mock:result");
```

The next step in the pipeline is the `mock:testCheckpoint` endpoint, which checks that the message body has been removed, the claim check added, and so on.

XML DSL example

The preceding example can also be written in XML, as follows:

```xml
<route>
    <from uri="direct:start"/>
    <pipeline>
        <to uri="bean:checkLuggage"/>
        <to uri="mock:testCheckpoint"/>
        <to uri="bean:dataEnricher"/>
        <to uri="mock:result"/>
    </pipeline>
</route>
```

**checkLuggage bean**

The message is first sent to the `checkLuggage` bean which is implemented as follows:

```java
public static final class CheckLuggageBean {
```
This bean stores the message body into the data store, using the custId as the claim check. In this example, we are using a HashMap to store the message body; in a real application you would use a database or the file system. The claim check is added as a message header for later use and, finally, we remove the body from the message and pass it down the pipeline.

**testCheckpoint endpoint**

The example route is just a Pipeline. In a real application, you would substitute some other steps for the mock:testCheckpoint endpoint.

**dataEnricher bean**

To add the message body back into the message, we use the dataEnricher bean, which is implemented as follows:

```java
public static final class DataEnricherBean {
    public void addDataBackIn(Exchange exchange, @Header("claimCheck") String claimCheck) {
        // query the data store using the claim check as the key and add the data
        // back into the message body
        exchange.getIn().setBody(dataStore.get(claimCheck));
        // remove the message data from the data store
        dataStore.remove(claimCheck);
        // remove the claim check header
        exchange.getIn().removeHeader("claimCheck");
    }
}
```

This bean queries the data store, using the claim check as the key, and then adds the recovered data back into the message body. The bean then deletes the message data from the data store and removes the claimCheck header from the message.

**8.5. SORT**

**Sort**

The sort pattern is used to sort the contents of a message body, assuming that the message body contains a list of items that can be sorted.

By default, the contents of the message are sorted using a default comparator that handles
numeric values or strings. You can provide your own comparator and you can specify an
equation that returns the list to be sorted (the expression must be convertible to
\texttt{java.util.List}).

**Java DSL example**

The following example generates the list of items to sort by tokenizing on the line break
character:

```java
from("file://inbox").sort(body().tokenize("\n")).to("bean:MyServiceBean.processLine");
```

You can pass in your own comparator as the second argument to \texttt{sort()}:

```java
from("file://inbox").sort(body().tokenize("\n"), new MyReverseComparator()).to("bean:MyServiceBean.processLine");
```

**XML configuration example**

You can configure the same routes in Spring XML.

The following example generates the list of items to sort by tokenizing on the line break
character:

```xml
<route>
  <from uri="file://inbox"/>
  <sort>
    <simple>body</simple>
  </sort>
  <beanRef ref="myServiceBean" method="processLine"/>
</route>
```

And to use a custom comparator, you can reference it as a Spring bean:

```xml
<route>
  <from uri="file://inbox"/>
  <sort comparatorRef="myReverseComparator">
    <simple>body</simple>
  </sort>
  <beanRef ref="MyServiceBean" method="processLine"/>
</route>
```

```xml
<bean id="myReverseComparator" class="com.mycompany.MyReverseComparator"/>
```

Besides \texttt{<simple>}, you can supply an expression using any language you like, so long as it
returns a list.

**Options**

The \texttt{sort} DSL command supports the following options:

<table>
<thead>
<tr>
<th>Name</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
comparatorRef

| comparatorRef | Refers to a custom java.util.Comparator to use for sorting the message body. Camel will by default use a comparator which does a A..Z sorting. |

8.6. VALIDATE

Overview

The validate pattern provides a convenient syntax to check whether the content of a message is valid. The validate DSL command takes a predicate expression as its sole argument: if the predicate evaluates to true, the route continues processing normally; if the predicate evaluates to false, a PredicateValidationException is thrown.

Java DSL example

The following route validates the body of the current message using a regular expression:

```java
from("jms:queue:incoming")
 .validate(body(String.class).regex("^\\w{10},\d{2},\\w{24}\$"))
 .to("bean:MyServiceBean.processLine");
```

You can also validate a message header—for example:

```java
from("jms:queue:incoming")
 .validate(header("bar").isGreaterThan(100))
 .to("bean:MyServiceBean.processLine");
```

And you can use validate with the simple expression language:

```java
from("jms:queue:incoming")
 .validate(simple("${in.header.bar} == 100"))
 .to("bean:MyServiceBean.processLine");
```

XML DSL example

To use validate in the XML DSL, the recommended approach is to use the simple expression language:

```xml
<route>
 <from uri="jms:queue:incoming"/>
 <validate>
  <simple>${body} regex ^\w{10},\d{2},\w{24}$</simple>
 </validate>
 <beanRef ref="myServiceBean" method="processLine"/>
</route>
```

```
<bean id="myServiceBean" class="com.mycompany.MyServiceBean"/>
```
You can also validate a message header—for example:

```xml
<route>
  <from uri="jms:queue:incoming"/>
  <validate>
    <simple>${in.header.bar} == 100</simple>
  </validate>
  <beanRef ref="myServiceBean" method="processLine"/>
</route>

<bean id="myServiceBean" class="com.mycompany.MyServiceBean"/>
```
CHAPTER 9. MESSAGING ENDPOINTS

Abstract

The messaging endpoint patterns describe various features and qualities of service that can be configured on an endpoint.

9.1. MESSAGING MAPPER

Overview

The **messaging mapper** pattern describes how to map domain objects to and from a canonical message format, where the message format is chosen to be as platform neutral as possible. The chosen message format should be suitable for transmission through a message bus, where the message bus is the backbone for integrating a variety of different systems, some of which might not be object-oriented.

Many different approaches are possible, but not all of them fulfill the requirements of a messaging mapper. For example, an obvious way to transmit an object is to use **object serialization**, which enables you to write an object to a data stream using an unambiguous encoding (supported natively in Java). However, this is *not* a suitable approach to use for the messaging mapper pattern, however, because the serialization format is understood only by Java applications. Java object serialization creates an impedance mismatch between the original application and the other applications in the messaging system.

The requirements for a messaging mapper can be summarized as follows:

- The canonical message format used to transmit domain objects should be suitable for consumption by non-object oriented applications.
- The mapper code should be implemented separately from both the domain object code and the messaging infrastructure. Apache Camel helps fulfill this requirement by providing hooks that can be used to insert mapper code into a route.
- The mapper might need to find an effective way of dealing with certain object-oriented concepts such as inheritance, object references, and object trees. The complexity of these issues varies from application to application, but the aim of the mapper implementation must always be to create messages that can be processed effectively by non-object-oriented applications.

Finding objects to map

You can use one of the following mechanisms to find the objects to map:

- **Find a registered bean.** — For singleton objects and small numbers of objects, you could use the **CamelContext** registry to store references to beans. For example, if a bean instance is instantiated using Spring XML, it is automatically entered into the registry, where the bean is identified by the value of its `id` attribute.

- **Select objects using the JoSQL language.** — If all of the objects you want to access are already instantiated at runtime, you could use the JoSQL language to locate a specific object (or objects). For example, if you have a class,
org.apache.camel.builder.sql.Person, with a name bean property and the incoming message has a UserName header, you could select the object whose name property equals the value of the UserName header using the following code:

```java
import static org.apache.camel.builder.sql.SqlBuilder.sql;
import org.apache.camel.Expression;
...
Expression expression = sql("SELECT * FROM org.apache.camel.builder.sql.Person where name = :UserName");
Object value = expression.evaluate(exchange);
```

Where the syntax, :HeaderName, is used to substitute the value of a header in a JoSQL expression.

- **Dynamic** — For a more scalable solution, it might be necessary to read object data from a database. In some cases, the existing object-oriented application might already provide a finder object that can load objects from the database. In other cases, you might have to write some custom code to extract objects from a database, and in these cases the JDBC component and the SQL component might be useful.

### 9.2. EVENT DRIVEN CONSUMER

#### Overview

The event-driven consumer pattern, shown in Figure 9.1, “Event Driven Consumer Pattern”, is a pattern for implementing the consumer endpoint in a Apache Camel component, and is only relevant to programmers who need to develop a custom component in Apache Camel. Existing components already have a consumer implementation pattern hard-wired into them.

![Figure 9.1. Event Driven Consumer Pattern](image)

Consumers that conform to this pattern provide an event method that is automatically called by the messaging channel or transport layer whenever an incoming message is received. One of the characteristics of the event-driven consumer pattern is that the consumer endpoint itself does not provide any threads to process the incoming messages. Instead, the underlying transport or messaging channel implicitly provides a processor thread when it invokes the exposed event method (which blocks for the duration of the message processing).

For more details about this implementation pattern, see Section 44.1.3, “Consumer Patterns and Threading” and Chapter 47, Consumer Interface.
9.3. POLLING CONSUMER

Overview

The polling consumer pattern, shown in Figure 9.2, “Polling Consumer Pattern”, is a pattern for implementing the consumer endpoint in an Apache Camel component, so it is only relevant to programmers who need to develop a custom component in Apache Camel. Existing components already have a consumer implementation pattern hard-wired into them.

Consumers that conform to this pattern expose polling methods, `receive()`, `receive(long timeout)`, and `receiveNoWait()` that return a new exchange object, if one is available from the monitored resource. A polling consumer implementation must provide its own thread pool to perform the polling.

For more details about this implementation pattern, see Section 44.1.3, “Consumer Patterns and Threading”, Chapter 47, Consumer Interface, and Section 43.2, “Using the Consumer Template”.

Figure 9.2. Polling Consumer Pattern

Scheduled poll consumer

Many of the Apache Camel consumer endpoints employ a scheduled poll pattern to receive messages at the start of a route. That is, the endpoint appears to implement an event-driven consumer interface, but internally a scheduled poll is used to monitor a resource that provides the incoming messages for the endpoint.

See Section 47.2, “Implementing the Consumer Interface” for details of how to implement this pattern.

Quartz component

You can use the quartz component to provide scheduled delivery of messages using the Quartz enterprise scheduler. See and Quartz Component for details.

9.4. COMPETING CONSUMERS

Overview

The competing consumers pattern, shown in Figure 9.3, “Competing Consumers Pattern”, enables multiple consumers to pull messages from the same queue, with the guarantee that each message is consumed once only. This pattern can be used to replace serial
message processing with concurrent message processing (bringing a corresponding reduction in response latency).

**Figure 9.3. Competing Consumers Pattern**

The following components demonstrate the competing consumers pattern:

- the section called “JMS based competing consumers”
- the section called “SEDA based competing consumers”

**JMS based competing consumers**

A regular JMS queue implicitly guarantees that each message can only be consumed at once. Hence, a JMS queue automatically supports the competing consumers pattern. For example, you could define three competing consumers that pull messages from the JMS queue, `HighVolumeQ`, as follows:

```java
from("jms:HighVolumeQ").to("cxf:bean:replica01");
from("jms:HighVolumeQ").to("cxf:bean:replica02");
from("jms:HighVolumeQ").to("cxf:bean:replica03");
```

Where the CXF (Web services) endpoints, `replica01`, `replica02`, and `replica03`, process messages from the `HighVolumeQ` queue in parallel.

Alternatively, you can set the JMS query option, `concurrentConsumers`, to create a thread pool of competing consumers. For example, the following route creates a pool of three competing threads that pick messages from the specified queue:
And the `concurrentConsumers` option can also be specified in XML DSL, as follows:

```
<route>
  <from uri="jms:HighVolumeQ?concurrentConsumers=3"/>
  <to uri="cxf:bean:replica01"/>
</route>
```

**NOTE**

JMS topics *cannot* support the competing consumers pattern. By definition, a JMS topic is intended to send multiple copies of the same message to different consumers. Therefore, it is not compatible with the competing consumers pattern.

**SEDA based competing consumers**

The purpose of the SEDA component is to simplify concurrent processing by breaking the computation into stages. A SEDA endpoint essentially encapsulates an in-memory blocking queue (implemented by `java.util.concurrent.BlockingQueue`). Therefore, you can use a SEDA endpoint to break a route into stages, where each stage might use multiple threads. For example, you can define a SEDA route consisting of two stages, as follows:

```
// Stage 1: Read messages from file system.
from("file://var/messages").to("seda:fanout");

// Stage 2: Perform concurrent processing (3 threads).
from("seda:fanout").to("cxf:bean:replica01");
from("seda:fanout").to("cxf:bean:replica02");
from("seda:fanout").to("cxf:bean:replica03");
```

Where the first stage contains a single thread that consumes message from a file endpoint, `file://var/messages`, and routes them to a SEDA endpoint, `seda:fanout`. The second stage contains three threads: a thread that routes exchanges to `cxf:bean:replica01`, a thread that routes exchanges to `cxf:bean:replica02`, and a thread that routes exchanges to `cxf:bean:replica03`. These three threads compete to take exchange instances from the SEDA endpoint, which is implemented using a blocking queue. Because the blocking queue uses locking to prevent more than one thread from accessing the queue at a time, you are guaranteed that each exchange instance can only be consumed once.

For a discussion of the differences between a SEDA endpoint and a thread pool created by `thread()`, see.

**9.5. MESSAGE DISPATCHER**

**Overview**

The *message dispatcher* pattern, shown in Figure 9.4, “Message Dispatcher Pattern”, is used to consume messages from a channel and then distribute them locally to *performers*, which are responsible for processing the messages. In an Apache Camel application, performers are usually represented by in-process endpoints, which are used to transfer messages to another section of the route.
You can implement the message dispatcher pattern in Apache Camel using one of the following approaches:

- the section called “JMS selectors”
- the section called “JMS selectors in ActiveMQ”
- the section called “Content-based router”

### JMS selectors

If your application consumes messages from a JMS queue, you can implement the message dispatcher pattern using **JMS selectors**. A JMS selector is a predicate expression involving JMS headers and JMS properties. If the selector evaluates to **true**, the JMS message is allowed to reach the consumer, and if the selector evaluates to **false**, the JMS message is blocked. In many respects, a JMS selector is like a **filter processor**, but it has the additional advantage that the filtering is implemented inside the JMS provider. This means that a JMS selector can block messages before they are transmitted to the Apache Camel application. This provides a significant efficiency advantage.

In Apache Camel, you can define a JMS selector on a consumer endpoint by setting the **selector** query option on a JMS endpoint URI. For example:

```java
from("jms:dispatcher?selector=CountryCode='US'").to("cxf:bean:replica01");
from("jms:dispatcher?selector=CountryCode='IE'").to("cxf:bean:replica02");
from("jms:dispatcher?selector=CountryCode='DE'").to("cxf:bean:replica03");
```

Where the predicates that appear in a selector string are based on a subset of the SQL92 conditional expression syntax (for full details, see the **JMS specification**). The identifiers
appearing in a selector string can refer either to JMS headers or to JMS properties. For example, in the preceding routes, the sender sets a JMS property called `CountryCode`.

If you want to add a JMS property to a message from within your Apache Camel application, you can do so by setting a message header (either on `In` message or on `Out` messages). When reading or writing to JMS endpoints, Apache Camel maps JMS headers and JMS properties to, and from, its native message headers.

Technically, the selector strings must be URL encoded according to the `application/x-www-form-urlencoded` MIME format (see the HTML specification). In practice, the `&` (ampersand) character might cause difficulties because it is used to delimit each query option in the URI. For more complex selector strings that might need to embed the `&` character, you can encode the strings using the `java.net.URLEncoder` utility class. For example:

```java
from("jms:dispatcher?selector=" +
    java.net.URLEncoder.encode("CountryCode='US'", "UTF-8"))
    .to("cxf:bean:replica01");
```

Where the UTF-8 encoding must be used.

**JMS selectors in ActiveMQ**

You can also define JMS selectors on ActiveMQ endpoints. For example:

```java
from("activemq:dispatcher?
    selector=CountryCode='US'").to("cxf:bean:replica01");
from("activemq:dispatcher?
    selector=CountryCode='IE'").to("cxf:bean:replica02");
from("activemq:dispatcher?
    selector=CountryCode='DE'").to("cxf:bean:replica03");
```

For more details, see [ActiveMQ: JMS Selectors](#) and [ActiveMQ Message Properties](#).

**Content-based router**

The essential difference between the content-based router pattern and the message dispatcher pattern is that a content-based router dispatches messages to physically separate destinations (remote endpoints), and a message dispatcher dispatches messages locally, within the same process space. In Apache Camel, the distinction between these two patterns is determined by the target endpoint. The same router logic is used to implement both a content-based router and a message dispatcher. When the target endpoint is remote, the route defines a content-based router. When the target endpoint is in-process, the route defines a message dispatcher.

For details and examples of how to use the content-based router pattern see [Section 7.1, “Content-Based Router”](#).

**9.6. SELECTIVE CONSUMER**

**Overview**
The *selective consumer* pattern, shown in **Figure 9.5, “Selective Consumer Pattern”**, describes a consumer that applies a filter to incoming messages, so that only messages meeting specific selection criteria are processed.

![Figure 9.5. Selective Consumer Pattern](image)

You can implement the selective consumer pattern in Apache Camel using one of the following approaches:

- the section called “JMS selector”
- the section called “JMS selector in ActiveMQ”
- the section called “Message filter”

**JMS selector**

A JMS selector is a predicate expression involving JMS headers and JMS properties. If the selector evaluates to `true`, the JMS message is allowed to reach the consumer, and if the selector evaluates to `false`, the JMS message is blocked. For example, to consume messages from the queue, *selective*, and select only those messages whose country code property is equal to *US*, you can use the following Java DSL route:

```java
to("cxf:bean:replica01");
```

Where the selector string, `CountryCode='US'`, must be URL encoded (using UTF-8 characters) to avoid trouble with parsing the query options. This example presumes that the JMS property, `CountryCode`, is set by the sender. For more details about JMS selectors, see the section called "JMS selectors".

**NOTE**

If a selector is applied to a JMS queue, messages that are not selected remain on the queue and are potentially available to other consumers attached to the same queue.

**JMS selector in ActiveMQ**

You can also define JMS selectors on ActiveMQ endpoints. For example:

```java
to("cxf:bean:replica01");
```
For more details, see ActiveMQ: JMS Selectors and ActiveMQ Message Properties.

**Message filter**

If it is not possible to set a selector on the consumer endpoint, you can insert a filter processor into your route instead. For example, you can define a selective consumer that processes only messages with a US country code using Java DSL, as follows:

```java
from("seda:a").filter(header("CountryCode").isEqualTo("US")).process(myProcessor);
```

The same route can be defined using XML configuration, as follows:

```xml
<camelContext id="buildCustomProcessorWithFilter" xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="seda:a"/>
    <filter>
      <xpath>$CountryCode = 'US'</xpath>
      <process ref="#myProcessor"/>
    </filter>
  </route>
</camelContext>
```

For more information about the Apache Camel filter processor, see Message Filter.

---

**WARNING**

Be careful about using a message filter to select messages from a JMS queue. When using a filter processor, blocked messages are simply discarded. Hence, if the messages are consumed from a queue (which allows each message to be consumed only once—see Section 9.4, “Competing Consumers”), then blocked messages are not processed at all. This might not be the behavior you want.

---

**9.7. DURABLE SUBSCRIBER**

**Overview**

A **durable subscriber**, as shown in Figure 9.6, “Durable Subscriber Pattern”, is a consumer that wants to receive all of the messages sent over a particular publish-subscribe channel, including messages sent while the consumer is disconnected from the messaging system. This requires the messaging system to store messages for later replay to the disconnected consumer. There also has to be a mechanism for a consumer to indicate that it wants to establish a durable subscription. Generally, a publish-subscribe channel (or topic) can have both durable and non-durable subscribers, which behave as follows:

- **non-durable subscriber**—Can have two states: connected and disconnected. While a non-durable subscriber is connected to a topic, it receives all of the topic's
messages in real time. However, a non-durable subscriber never receives messages sent to the topic while the subscriber is disconnected.

- **durable subscriber**—Can have two states: **connected** and **inactive**. The inactive state means that the durable subscriber is disconnected from the topic, but wants to receive the messages that arrive in the interim. When the durable subscriber reconnects to the topic, it receives a replay of all the messages sent while it was inactive.

**Figure 9.6. Durable Subscriber Pattern**

![Diagram of Durable Subscriber Pattern]

**JMS durable subscriber**

The JMS component implements the durable subscriber pattern. In order to set up a durable subscription on a JMS endpoint, you must specify a **client ID**, which identifies this particular connection, and a **durable subscription name**, which identifies the durable subscriber. For example, the following route sets up a durable subscription to the JMS topic, **news**, with a client ID of **conn01** and a durable subscription name of **John.Doe**:

```java
from("jms:topic:news?clientId=conn01&durableSubscriptionName=John.Doe").
to("cxf:bean:newsprocessor");
```

You can also set up a durable subscription using the ActiveMQ endpoint:

```java
from("activemq:topic:news?
  clientId=conn01&durableSubscriptionName=John.Doe").
to("cxf:bean:newsprocessor");
```

If you want to process the incoming messages concurrently, you can use a SEDA endpoint to fan out the route into multiple, parallel segments, as follows:

```java
from("jms:topic:news?clientId=conn01&durableSubscriptionName=John.Doe").
to("seda:fanout");
from("seda:fanout").to("cxf:bean:newsproc01");
from("seda:fanout").to("cxf:bean:newsproc02");
```
Where each message is processed only once, because the SEDA component supports the competing consumers pattern.

**Alternative example**

Another alternative is to combine the Message Dispatcher or Content-Based Router with File component or JPA component components for durable subscribers then something like SEDA component for non-durable.

Here is a simple example of creating durable subscribers to a topic

**Using the Fluent Builders**

```java
from("direct:start").to("activemq:topic:foo");

from("activemq:topic:foo?clientId=1&durableSubscriptionName=bar1").to("mock:result1");

from("activemq:topic:foo?clientId=2&durableSubscriptionName=bar2").to("mock:result2");
```

**Using the Spring XML Extensions**

```xml
<route>
    <from uri="direct:start"/> 
    <to uri="activemq:topic:foo"/>
</route>

<route>
    <from uri="activemq:topic:foo?clientId=1&durableSubscriptionName=bar1"/>
    <to uri="mock:result1"/>
</route>

<route>
    <from uri="activemq:topic:foo?clientId=2&durableSubscriptionName=bar2"/>
    <to uri="mock:result2"/>
</route>
```

Here is another example of JMS durable subscribers, but this time using virtual topics (recommended by AMQ over durable subscriptions)

**Using the Fluent Builders**

```java
from("direct:start").to("activemq:topic:VirtualTopic.foo");

from("activemq:queue:Consumer.1.VirtualTopic.foo").to("mock:result1");

from("activemq:queue:Consumer.2.VirtualTopic.foo").to("mock:result2");
```

**Using the Spring XML Extensions**

```xml
```
9.8. IDEMPOTENT CONSUMER

Overview

The **idempotent consumer** pattern is used to filter out duplicate messages. For example, consider a scenario where the connection between a messaging system and a consumer endpoint is abruptly lost due to some fault in the system. If the messaging system was in the middle of transmitting a message, it might be unclear whether or not the consumer received the last message. To improve delivery reliability, the messaging system might decide to redeliver such messages as soon as the connection is re-established. Unfortunately, this entails the risk that the consumer might receive duplicate messages and, in some cases, the effect of duplicating a message may have undesirable consequences (such as debiting a sum of money twice from your account). In this scenario, an idempotent consumer could be used to weed out undesired duplicates from the message stream.

Camel provides the following Idempotent Consumer implementations:

- MemoryIdempotentRepository
- File
- HazelcastIdempotentRepository
- JdbcMessageIdRepository
- JpaMessageIdRepository

**Idempotent consumer with in-memory cache**

In Apache Camel, the idempotent consumer pattern is implemented by the `idempotentConsumer()` processor, which takes two arguments:

- **messageIdExpression** — An expression that returns a message ID string for the current message.
- **messageIdRepository** — A reference to a message ID repository, which stores the IDs of all the messages received.

As each message comes in, the idempotent consumer processor looks up the current
message ID in the repository to see if this message has been seen before. If yes, the message is discarded; if no, the message is allowed to pass and its ID is added to the repository.

The code shown in Example 9.1, “Filtering Duplicate Messages with an In-memory Cache” uses the TransactionID header to filter out duplicates.

**Example 9.1. Filtering Duplicate Messages with an In-memory Cache**

```java
import static org.apache.camel.processor.idempotent.MemoryMessageIdRepository.memoryMessageIdRepository;
...
RouteBuilder builder = new RouteBuilder() {
  public void configure() {
    from("seda:a")
      .idempotentConsumer(
        header("TransactionID"),
        memoryMessageIdRepository(200)
      ).to("seda:b");
  }
};
```

Where the call to `memoryMessageIdRepository(200)` creates an in-memory cache that can hold up to 200 message IDs.

You can also define an idempotent consumer using XML configuration. For example, you can define the preceding route in XML, as follows:

```xml
<camelContext id="buildIdempotentConsumer"
  xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="seda:a"/>
    <idempotentConsumer messageIdRepositoryRef="MsgIDRepos">
      <simple>header.TransactionID</simple>
      <to uri="seda:b"/>
    </idempotentConsumer>
  </route>
</camelContext>

<bean id="MsgIDRepos"
  class="org.apache.camel.processor.idempotent.MemoryMessageIdRepository">
  <!-- Specify the in-memory cache size. -->
  <constructor-arg type="int" value="200"/>
</bean>
```

**Idempotent consumer with JPA repository**

The in-memory cache suffers from the disadvantages of easily running out of memory and not working in a clustered environment. To overcome these disadvantages, you can use a Java Persistent API (JPA) based repository instead. The JPA message ID repository uses an object-oriented database to store the message IDs. For example, you can define a route that uses a JPA repository for the idempotent consumer, as follows:
The JPA message ID repository is initialized with two arguments:

- **JpaTemplate** instance—Provides the handle for the JPA database.
- processor name—Identifies the current idempotent consumer processor.

The **SpringRouteBuilder.bean()** method is a shortcut that references a bean defined in the Spring XML file. The **JpaTemplate** bean provides a handle to the underlying JPA database. See the JPA documentation for details of how to configure this bean.

For more details about setting up a JPA repository, see JPA Component documentation, the Spring JPA documentation, and the sample code in the Camel JPA unit test.

### Spring XML example

The following example uses the **myMessageId** header to filter out duplicates:

```xml
<!-- repository for the idempotent consumer -->
<bean id="myRepo" class="org.apache.camel.processor.idempotent.MemoryIdempotentRepository"/>

<camelContext xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="direct:start"/>
    <idempotentConsumer messageIdRepositoryRef="myRepo">
      <!-- use the messageId header as key for identifying duplicate messages -->
      <header>messageId</header>
      <!-- if not a duplicate send it to this mock endpoint -->
      <to uri="mock:result"/>
    </idempotentConsumer>
  </route>
</camelContext>
```

### Idempotent consumer with JDBC repository

A JDBC repository is also supported for storing message IDs in the idempotent consumer pattern. The implementation of the JDBC repository is provided by the SQL component, so if
You are using the Maven build system, add a dependency on the `camel-sql` artifact.

You can use the `SingleConnectionDataSource` JDBC wrapper class from the Spring persistence API in order to instantiate the connection to a SQL database. For example, to instantiate a JDBC connection to a HyperSQL database instance, you could define the following JDBC data source:

```xml
<bean id="dataSource"
      class="org.springframework.jdbc.datasource.SingleConnectionDataSource">
  <property name="driverClassName" value="org.hsqldb.jdbcDriver"/>
  <property name="url" value="jdbc:hsqldb:mem:camel_jdbc"/>
  <property name="username" value="sa"/>
  <property name="password" value=""/>
</bean>
```

**NOTE**

The preceding JDBC data source uses the HyperSQL `mem` protocol, which creates a memory-only database instance. This is a toy implementation of the HyperSQL database which is not actually persistent.

Using the preceding data source, you can define an idempotent consumer pattern that uses the JDBC message ID repository, as follows:

```xml
<bean id="messageIdRepository"
      class="org.apache.camel.processor.idempotent.jdbc.JdbcMessageIdRepository">
  <constructor-arg ref="dataSource" />
  <constructor-arg value="myProcessorName" />
</bean>

<camel:camelContext>
  <camel:errorHandler id="deadLetterChannel" type="DeadLetterChannel" deadLetterUri="mock:error">
    <camel:redeliveryPolicy maximumRedeliveries="0" maximumRedeliveryDelay="0" logStackTrace="false" />  
  </camel:errorHandler>

  <camel:route id="JdbcMessageIdRepositoryTest" errorHandlerRef="deadLetterChannel">
    <camel:from uri="direct:start" />
    <camel:idempotentConsumer messageIdRepositoryRef="messageIdRepository">
      <camel:header>messageId</camel:header>
      <camel:to uri="mock:result" />
    </camel:idempotentConsumer>
  </camel:route>
</camel:camelContext>
```

**How to handle duplicate messages in the route**

**Available as of Camel 2.8**

You can now set the `skipDuplicate` option to `false` which instructs the idempotent consumer to route duplicate messages as well. However the duplicate message has been
marked as duplicate by having a property on the Exchange set to true. We can leverage this fact by using a Content-Based Router or Message Filter to detect this and handle duplicate messages.

For example in the following example we use the Message Filter to send the message to a duplicate endpoint, and then stop continue routing that message.

```camel
from("direct:start")
    // instruct idempotent consumer to not skip duplicates as we will filter then our self
    .idempotentConsumer(header("messageId"), messageIdRepository(repo).skipDuplicate(false)
        .filter(property(Exchange.DUPLICATE_MESSAGE).isEqualTo(true))
        // filter out duplicate messages by sending them to someplace
    else and then stop
        .to("mock:duplicate")
        .stop()
    // and here we process only new messages (no duplicates)
    .to("mock:result");
```

The sample example in XML DSL would be:

```xml
<bean id="myRepo" class="org.apache.camel.processor.idempotent.MemoryIdempotentRepository"/>
<camelContext xmlns="http://camel.apache.org/schema/spring">
    <route>
        <!-- we do not want to skip any duplicate messages -->
        <idempotentConsumer messageIdRepositoryRef="myRepo" skipDuplicate="false">
            <!-- use the messageId header as key for identifying duplicate messages -->
            <header>messageId</header>
            <!-- we will to handle duplicate messages using a filter -->
            <filter>
                <!-- the filter will only react on duplicate messages, if this property is set on the Exchange -->
                <property>CamelDuplicateMessage</property>
                <!-- and send the message to this mock, due its part of an unit test -->
                <!-- but you can of course do anything as its part of the route -->
                <to uri="mock:duplicate"/>
                <!-- and then stop -->
                <stop/>
            </filter>
        </idempotentConsumer>
    </route>
</camelContext>
```
How to handle duplicate message in a clustered environment with a data grid

If you have running Camel in a clustered environment, a in memory idempotent repository doesn't work (see above). You can setup either a central database or use the idempotent consumer implementation based on the Hazelcast data grid. Hazelcast finds the nodes over multicast (which is default - configure Hazelcast for tcp-ip) and creates automatically a map based repository:

```java
HazelcastIdempotentRepository idempotentRepo = new HazelcastIdempotentRepository("myrepo");
from("direct:in").idempotentConsumer(header("messageId"), idempotentRepo).to("mock:out");
```

You have to define how long the repository should hold each message id (default is to delete it never). To avoid that you run out of memory you should create an eviction strategy based on the Hazelcast configuration. For additional information see camel-hazelcast.

See this little tutorial, how setup such an idempotent repository on two cluster nodes using Apache Karaf.

Options

The Idempotent Consumer has the following options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>eager</td>
<td>true</td>
<td><strong>Camel 2.0:</strong> Eager controls whether Camel adds the message to the repository before or after the exchange has been processed. If enabled before then Camel will be able to detect duplicate messages even when messages are currently in progress. By disabling Camel will only detect duplicates when a message has successfully been processed.</td>
</tr>
<tr>
<td>messageIdRepositoryRef</td>
<td>null</td>
<td>A reference to a IdempotentRepository to lookup in the registry. This option is mandatory when using XML DSL.</td>
</tr>
</tbody>
</table>
### 9.9. TRANSACTIONAL CLIENT

#### Overview

The *transactional client* pattern, shown in Figure 9.7, “Transactional Client Pattern”, refers to messaging endpoints that can participate in a transaction. Apache Camel supports transactions using Spring transaction management.

![Figure 9.7. Transactional Client Pattern](image)

**Transaction oriented endpoints**

Not all Apache Camel endpoints support transactions. Those that do are called *transaction oriented endpoints* (or TOEs). For example, both the JMS component and the ActiveMQ component support transactions.

To enable transactions on a component, you must perform the appropriate initialization before adding the component to the `CamelContext`. This entails writing code to initialize your transactional components explicitly.

#### References

The details of configuring transactions in Apache Camel are beyond the scope of this guide. For full details of how to use transactions, see the Apache Camel *Transaction Guide*.

### 9.10. MESSAGING GATEWAY

#### Overview
The *messaging gateway* pattern, shown in Figure 9.8, “Messaging Gateway Pattern”, describes an approach to integrating with a messaging system, where the messaging system’s API remains hidden from the programmer at the application level. One of the more common examples is when you want to translate synchronous method calls into request/reply message exchanges, without the programmer being aware of this.

**Figure 9.8. Messaging Gateway Pattern**

The following Apache Camel components provide this kind of integration with the messaging system:

- 
- 

### 9.11. SERVICE ACTIVATOR

**Overview**

The *service activator* pattern, shown in Figure 9.9, “Service Activator Pattern”, describes the scenario where a service’s operations are invoked in response to an incoming request message. The service activator identifies which operation to call and extracts the data to use as the operation’s parameters. Finally, the service activator invokes an operation using the data extracted from the message. The operation invocation can be either oneway (request only) or two-way (request/reply).

**Figure 9.9. Service Activator Pattern**
In many respects, a service activator resembles a conventional remote procedure call (RPC), where operation invocations are encoded as messages. The main difference is that a service activator needs to be more flexible. An RPC framework standardizes the request and reply message encodings (for example, Web service operations are encoded as SOAP messages), whereas a service activator typically needs to improvise the mapping between the messaging system and the service’s operations.

**Bean integration**

The main mechanism that Apache Camel provides to support the service activator pattern is bean integration. Bean integration provides a general framework for mapping incoming messages to method invocations on Java objects. For example, the Java fluent DSL provides the processors `bean()` and `beanRef()` that you can insert into a route to invoke methods on a registered Java bean. The detailed mapping of message data to Java method parameters is determined by the bean binding, which can be implemented by adding annotations to the bean class.

For example, consider the following route which calls the Java method, `BankBean.getUserAccBalance()`, to service requests incoming on a JMS/ActiveMQ queue:

```java
from("activemq:BalanceQueries")
  .setProperty("userid", xpath("/Account/BalanceQuery/UserID").stringResult())
  .beanRef("bankBean", "getUserAccBalance")
  .to("velocity:file:src/scripts/acc_balance.vm")
  .to("activemq:BalanceResults");
```

The messages pulled from the ActiveMQ endpoint, `activemq:BalanceQueries`, have a simple XML format that provides the user ID of a bank account. For example:

```xml
<?xml version='1.0' encoding='UTF-8'?>
<Account>
  <BalanceQuery>
    <UserID>James.Strachan</UserID>
  </BalanceQuery>
</Account>
```

The first processor in the route, `setProperty()`, extracts the user ID from the `In` message and stores it in the `userid` exchange property. This is preferable to storing it in a header, because the `In` headers are not available after invoking the bean.

The service activation step is performed by the `beanRef()` processor, which binds the incoming message to the `getUserAccBalance()` method on the Java object identified by the `bankBean` bean ID. The following code shows a sample implementation of the `BankBean` class:

```java
package tutorial;

import org.apache.camel.language.XPath;

public class BankBean {
    public int getUserAccBalance(@XPath("/Account/BalanceQuery/UserID") String user) {
        if (user.equals("James.Strachan")) {
            return 1200;
        }
    }
}
```
Where the binding of message data to method parameter is enabled by the @XPath annotation, which injects the content of the UserID XML element into the user method parameter. On completion of the call, the return value is inserted into the body of the Out message which is then copied into the In message for the next step in the route. In order for the bean to be accessible to the beanRef() processor, you must instantiate an instance in Spring XML. For example, you can add the following lines to the META-INF/spring/camel-context.xml configuration file to instantiate the bean:

```xml
<bean id="bankBean" class="tutorial.BankBean"/>
```

Where the bean ID, bankBean, identifies this bean instance in the registry.

The output of the bean invocation is injected into a Velocity template, to produce a properly formatted result message. The Velocity endpoint, velocity:file:src/scripts/acc_balance.vm, specifies the location of a velocity script with the following contents:

```xml
<?xml version='1.0' encoding='UTF-8'?>
<Account>
  <BalanceResult>
    <UserID>${exchange.getProperty("userid")}</UserID>
    <Balance>${body}</Balance>
  </BalanceResult>
</Account>
```

The exchange instance is available as the Velocity variable, exchange, which enables you to retrieve the userid exchange property, using ${exchange.getProperty("userid")}. The body of the current in message, ${body}, contains the result of the getUserAccBalance() method invocation.
CHAPTER 10. SYSTEM MANAGEMENT

Abstract

The system management patterns describe how to monitor, test, and administer a messaging system.

10.1. DETOUR

Detour

The Detour from the Introducing Enterprise Integration Patterns allows you to send messages through additional steps if a control condition is met. It can be useful for turning on extra validation, testing, debugging code when needed.

Example

In this example we essentially have a route like from("direct:start").to("mock:result") with a conditional detour to the mock:detour endpoint in the middle of the route..

```java
from("direct:start").choice()
  .when().method("controlBean", "isDetour").to("mock:detour").end()
  .to("mock:result");
```

Using the Spring XML Extensions

```xml
<route>
  <from uri="direct:start"/>
  <choice>
    <when>
      <method bean="controlBean" method="isDetour"/>
    </when>
    <to uri="mock:detour"/>
  </choice>
  <to uri="mock:result"/>
</route>
```
whether the detour is turned on or off is decided by the ControlBean. So, when the detour is on the message is routed to mock:detour and then mock:result. When the detour is off, the message is routed to mock:result.

For full details, check the example source here:

camel-core/src/test/java/org/apache/camel/processor/DetourTest.java

10.2. LOGEIP

Overview

Apache Camel provides several ways to perform logging in a route:

- Using the log DSL command.
- Using the Log component, which can log the message content.
- Using the Tracer, which traces message flow.
- Using a Processor or a Bean endpoint to perform logging in Java.

DIFFERENCE BETWEEN THE LOG DSL COMMAND AND THE LOG COMPONENT

The log DSL is much lighter and meant for logging human logs such as Starting to do .... It can only log a message based on the Simple language. In contrast, the Log component is a fully featured logging component. The Log component is capable of logging the message itself and you have many URI options to control the logging.

Java DSL example

Since Apache Camel 2.2, you can use the log DSL command to construct a log message at run time using the Simple expression language. For example, you can create a log message within a route, as follows:

```java
from("direct:start").log("Processing ${id}").to("bean:foo");
```

This route constructs a String format message at run time. The log message will by logged at INFO level, using the route ID as the log name. By default, routes are named consecutively, route-1, route-2 and so on. But you can use the DSL command, routeId("myCoolRoute"), to specify a custom route ID.

The log DSL also provides variants that enable you to set the logging level and the log name explicitly. For example, to set the logging level explicitly to LoggingLevel.DEBUG, you can invoke the log DSL as follows:

```java
from("direct:start").log(LoggingLevel.DEBUG, "Processing ${id}").to("bean:foo");
```

To set the log name to fileRoute, you can invoke the log DSL as follows:
XML DSL example

In XML DSL, the log DSL is represented by the `log` element and the log message is specified by setting the `message` attribute to a Simple expression, as follows:

```xml
<route id="foo">
  <from uri="direct:foo"/>
  <log message="Got ${body}"/>
  <to uri="mock:foo"/>
</route>
```

The `log` element supports the `message`, `loggingLevel` and `logName` attributes. For example:

```xml
<route id="baz">
  <from uri="direct:baz"/>
  <log message="Me Got ${body}" loggingLevel="FATAL" logName="cool"/>
  <to uri="mock:baz"/>
</route>
```

10.3. WIRE TAP

Wire Tap

The wire tap pattern, as shown in Figure 10.1, "Wire Tap Pattern", enables you to route a copy of the message to a separate tap location, while the original message is forwarded to the ultimate destination.

Figure 10.1. Wire Tap Pattern

STREAMS

If you Wire Tap a stream message body, you should consider enabling Stream Caching to ensure the message body can be re-read. See more details at Stream Caching

WireTap node
Apache Camel 2.0 introduces the `wireTap` node for doing wire taps. The `wireTap` node copies the original exchange to a tapped exchange, whose exchange pattern is set to `InOnly`, because the tapped exchange should be propagated in `oneway` style. The tapped exchange is processed in a separate thread, so that it can run concurrently with the main route.

The `wireTap` supports two different approaches to tapping an exchange:

- Tap a copy of the original exchange.
- Tap a new exchange instance, enabling you to customize the tapped exchange.

### Tap a copy of the original exchange

Using the Java DSL:

```java
from("direct:start")
  .to("log:foo")
  .wireTap("direct:tap")
  .to("mock:result");
```

Using Spring XML extensions:

```xml
<route>
  <from uri="direct:start"/>
  <to uri="log:foo"/>
  <wireTap uri="direct:tap"/>
  <to uri="mock:result"/>
</route>
```

### Tap and modify a copy of the original exchange

Using the Java DSL, Apache Camel supports using either a processor or an expression to modify a copy of the original exchange. Using a processor gives you full power over how the exchange is populated, because you can set properties, headers and so on. The expression approach can only be used to modify the `In` message body.

For example, to modify a copy of the original exchange using the `processor` approach:

```java
from("direct:start")
  .wireTap("direct:foo", new Processor() {
      public void process(Exchange exchange) throws Exception {
          exchange.getIn().setHeader("foo", "bar");
      }
  }).to("mock:result");

from("direct:foo").to("mock:foo");
```

And to modify a copy of the original exchange using the `expression` approach:

```java
from("direct:start")
  .wireTap("direct:foo", constant("Bye World"))
```
Using the Spring XML extensions, you can modify a copy of the original exchange using the processor approach, where the processorRef attribute references a spring bean with the myProcessor ID:

```xml
<route>
  <from uri="direct:start2"/>
  <wireTap uri="direct:foo" processorRef="myProcessor"/>
  <to uri="mock:result"/>
</route>
```

And to modify a copy of the original exchange using the expression approach:

```xml
<route>
  <from uri="direct:start"/>
  <wireTap uri="direct:foo">
    <body>
      <constant>Bye World</constant>
    </body>
  </wireTap>
  <to uri="mock:result"/>
</route>
```

**Tap a new exchange instance**

You can define a wiretap with a new exchange instance by setting the copy flag to `false` (the default is `true`). In this case, an initially empty exchange is created for the wiretap.

For example, to create a new exchange instance using the processor approach:

```java
from("direct:start")
  .wireTap("direct:foo", false, new Processor() {
    public void process(Exchange exchange) throws Exception {
      exchange.getIn().setBody("Bye World");
      exchange.getIn().setHeader("foo", "bar");
    }
  }).to("mock:result");
```

Where the second wireTap argument sets the copy flag to `false`, indicating that the original exchange is *not* copied and an empty exchange is created instead.

To create a new exchange instance using the expression approach:

```java
from("direct:start")
  .wireTap("direct:foo", false, constant("Bye World"))
  .to("mock:result");
from("direct:foo").to("mock:foo");
```
Using the Spring XML extensions, you can indicate that a new exchange is to be created by setting the `wireTap` element's `copy` attribute to `false`.

To create a new exchange instance using the `processor` approach, where the `processorRef` attribute references a spring bean with the `myProcessor` ID, as follows:

```xml
<route>
  <from uri="direct:start2"/>
  <wireTap uri="direct:foo" processorRef="myProcessor" copy="false"/>
  <to uri="mock:result"/>
</route>
```

And to create a new exchange instance using the `expression` approach:

```xml
<route>
  <from uri="direct:start"/>
  <wireTap uri="direct:foo" copy="false">
    <body><constant>Bye World</constant></body>
  </wireTap>
  <to uri="mock:result"/>
</route>
```

**Sending a new Exchange and set headers in DSL**

**Available as of Camel 2.8**

If you send a new messages using the Wire Tap then you could only set the message body using an Expression from the DSL. If you also need to set new headers you would have to use a Processor for that. So in Camel 2.8 onwards we have improved this situation so you can now set headers as well in the DSL.

The following example sends a new message which has

- "Bye World" as message body
- a header with key "id" with the value 123
- a header with key "date" which has current date as value

**Java DSL**

```java
from("direct:start")
  // tap a new message and send it to direct:tap
  // the new message should be Bye World with 2 headers
  .wireTap("direct:tap")
    // create the new tap message body and headers
    .newExchangeBody(constant("Bye World"))
    .newExchangeHeader("id", constant(123))
    .newExchangeHeader("date", simple("${date:now:yyyyMMdd}"))
  .end()
  // here we continue routing the original messages
  .to("mock:result");
```
// this is the tapped route
from("direct:tap")
  .to("mock:tap");

XML DSL

The XML DSL is slightly different than Java DSL as how you configure the message body and headers. In XML you use <body> and <setHeader> as shown:

```xml
<route>
  <from uri="direct:start"/>
  <!-- tap a new message and send it to direct:tap -->
  <!-- the new message should be Bye World with 2 headers -->
  <wireTap uri="direct:tap">
    <!-- create the new tap message body and headers -->
    <body><constant>Bye World</constant></body>
    <setHeader headerName="id"><constant>123</constant></setHeader>
    <setHeader headerName="date"><simple>${date:now:yyyyMMdd}</simple></setHeader>
  </wireTap>
  <!-- here we continue routing the original message -->
  <to uri="mock:result"/>
</route>
```

Using `onPrepare` to execute custom logic when preparing messages

Available as of Camel 2.8

For details, see Multicast.

Options

The `wireTap` DSL command supports the following options:

<table>
<thead>
<tr>
<th>Name</th>
<th>Default Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>uri</td>
<td></td>
<td>The endpoint uri where to send the wire tapped message. You should use either <code>uri</code> or <code>ref</code>.</td>
</tr>
<tr>
<td>ref</td>
<td></td>
<td>Refers to the endpoint where to send the wire tapped message. You should use either <code>uri</code> or <code>ref</code>.</td>
</tr>
<tr>
<td>executorServiceRef</td>
<td></td>
<td>Refers to a custom Thread Pool to be used when processing the wire tapped messages. If not set then Camel uses a default thread pool.</td>
</tr>
<tr>
<td>processorRef</td>
<td></td>
<td>Refers to a custom Processor to be used for creating a new message (eg the send a new message mode). See below.</td>
</tr>
<tr>
<td>copy</td>
<td>true</td>
<td><strong>Camel 2.3</strong>: Should a copy of the Exchange to used when wire tapping the message.</td>
</tr>
<tr>
<td>onPrepareRef</td>
<td></td>
<td><strong>Camel 2.8</strong>: Refers to a custom Processor to prepare the copy of the Exchange to be wire tapped. This allows you to do any custom logic, such as deep-cloning the message payload if that's needed etc.</td>
</tr>
</tbody>
</table>
APPENDIX A. MIGRATING FROM SERVICEMIX EIP

Abstract

If you are currently an Apache ServiceMix 3.x user, you might already have implemented some Enterprise Integration Patterns using the ServiceMix EIP module. It is recommended that you migrate these legacy patterns to Apache Camel, which has more extensive support for Enterprise Integration Patterns. After migrating, you can deploy your patterns into a Red Hat JBoss Fuse container.

A.1. MIGRATING ENDPOINTS

Overview

A typical ServiceMix EIP route exposes a service that consumes exchanges from the NMR. The route also defines one or more target destinations, to which exchanges are sent. In the Apache Camel environment, the exposed ServiceMix service maps to a consumer endpoint and the ServiceMix target destinations map to producer endpoints. The Apache Camel consumer endpoints and producer endpoints are both defined using endpoint URIs.

When migrating endpoints from ServiceMix EIP to Apache Camel, you must express the ServiceMix services/endpoints as Apache Camel endpoint URIs. You can adopt one of the following approaches:

- Connect to an existing ServiceMix service/endpoint through the ServiceMix Camel module (which integrates Apache Camel with the NMR).
- If the existing ServiceMix service/endpoint represents a ServiceMix binding component, you can replace the ServiceMix binding component with an equivalent Apache Camel component (thus bypassing the NMR).

The ServiceMix Camel module

The integration between Apache Camel and ServiceMix is provided by the servicemix-camel module. This module is provided with ServiceMix, but actually implements a plug-in for the Apache Camel product: the JBI component (see JBI Component).

To access the JBI component from Apache Camel, make sure that the servicemix-camel JAR file is included on your Classpath or, if you are using Maven, include a dependency on the servicemix-camel artifact in your project POM. You can then access the JBI component by defining Apache Camel endpoint URIs with the jbi: component prefix.

Translating ServiceMix URIs into Apache Camel endpoint URIs

ServiceMix defines a flexible format for defining URIs, which is described in detail in ServiceMix URIs. To translate a ServiceMix URI into a Apache Camel endpoint URI, perform the following steps:

1. If the ServiceMix URI contains a namespace prefix, replace the prefix by its corresponding namespace.

2. Modify the separator character, depending on what kind of namespace appears in the URI:

   - If the namespace starts with `http://`, use the `/` character as the separator between namespace, service name, and endpoint name (if present).

     For example, the URI, `service:http://progress.com/demos/test:messageFilter`, would be modified to `service:http://progress.com/demos/test/messageFilter`.

   - If the namespace starts with `urn:`, use the `:` character as the separator between namespace, service name, and endpoint name (if present).

     For example, `service:urn:progress:com:demos:test:messageFilter`.

3. Create a JBI endpoint URI by adding the `jbi:` prefix.

   For example, `jbi:service:http://progress.com/demos/test/messageFilter`.

### Example of mapping ServiceMix URIs

For example, consider the following configuration of the `static recipient list` pattern in ServiceMix EIP. The `eip:exchange-target` elements define some targets using the ServiceMix URI format.

```xml
<beans xmlns:sm="http://servicemix.apache.org/config/1.0"
      xmlns:eip="http://servicemix.apache.org/eip/1.0"
      xmlns:test="http://progress.com/demos/test" >
  ...
  <eip:static-recipient-list service="test:recipients"
                               endpoint="endpoint">
    <eip:recipients>
      <eip:exchange-target uri="service:test:messageFilter" />
      <eip:exchange-target uri="service:test:trace4" />
    </eip:recipients>
  </eip:static-recipient-list>
  ...
</beans>
```

When the preceding ServiceMix configuration is mapped to an equivalent Apache Camel configuration, you get the following route:

```xml
<route>
  <from uri="jbi:endpoint:http://progress.com/demos/test/recipients/endpoint"/>
  <to uri="jbi:service:http://progress.com/demos/test/messageFilter"/>
  <to uri="jbi:service:http://progress.com/demos/test/trace4"/>
</route>
```

### Replacing ServiceMix bindings with Apache Camel components
Instead of using the Apache Camel JBI component to route all your messages through the ServiceMix NMR, you can use one of the many supported Apache Camel components to connect directly to a consumer or a producer endpoint. In particular, when sending messages to an external endpoint, it is more efficient to send the messages directly through a Apache Camel component than sending them through the NMR and a ServiceMix binding.

For details of all the Apache Camel components that are available, see and Apache Camel Components.

### A.2. COMMON ELEMENTS

#### Overview

When configuring ServiceMix EIP patterns in a ServiceMix configuration file, there are some common elements that occur in many of the pattern schemas. This section provides a brief overview of these common elements and explains how they can be mapped to equivalent constructs in Apache Camel.

#### Exchange target

All of the patterns supported by ServiceMix EIP use the `eip:exchange-target` element to specify JBI target endpoints. Table A.1, “Mapping the Exchange Target Element” shows examples of how to map sample `eip:exchange-target` elements to Apache Camel endpoint URIs, where it is assumed that the `test` prefix maps to the `http://progress.com/demos/test` namespace.

<table>
<thead>
<tr>
<th>ServiceMix EIP Target</th>
<th>Apache Camel Endpoint URI</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>&lt;eip:exchange-target interface=&quot;HelloWorld&quot; /&gt;</code></td>
<td><code>jbi:interface:HelloWorld</code></td>
</tr>
</tbody>
</table>

#### Predicates

The ServiceMix EIP component allows you to define predicate expressions in the XPath language. For example, XPath predicates can appear in `eip:xpath-predicate` elements or in `eip:xpath-splitter` elements, where the XPath predicate is specified using an `xpath` attribute.
ServiceMix XPath predicates can easily be migrated to equivalent constructs in Apache Camel: that is, either the `xpath` element (in XML configuration) or the `xpath()` command (in Java DSL). For example, the message filter pattern in Apache Camel can incorporate an XPath predicate as follows:

```xml
<route>
  <from uri="jbi:endpoint:http://progress.com/demos/test/messageFilter/endpoint">
    <filter>
      <xpath>count(/test:world) = 1</xpath>
      <to uri="jbi:service:http://progress.com/demos/test/trace3"/>
    </filter>
  </from>
</route>
```

Where the `xpath` element specifies that only messages containing the `test:world` element will pass through the filter.

**NOTE**

Apache Camel also supports a wide range of other scripting languages including XQuery, PHP, Python, and Ruby, which can be used to define predicates. For details of all the supported predicate languages, see Expression and Predicate Languages.

**Namespace contexts**

When using XPath predicates in the ServiceMix EIP configuration, it is necessary to define a namespace context using the `eip:namespace-context` element. The namespace is then referenced using a `namespaceContext` attribute.

When ServiceMix EIP configuration is migrated to Apache Camel, there is no need to define namespace contexts, because Apache Camel allows you to define XPath predicates without referencing a namespace context. You can simply drop the `eip:namespace-context` elements when you migrate to Apache Camel.

**A.3. SERVICEMIX EIP PATTERNS**

The patterns supported by ServiceMix EIP are shown in Table A.2, “ServiceMix EIP Patterns”.

<table>
<thead>
<tr>
<th>Content-Based Router</th>
<th>How we handle a situation where the implementation of a single logical function (e.g., inventory check) is spread across multiple physical systems.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Content Enricher</td>
<td>How we communicate with another system if the message originator does not have all the required data items available.</td>
</tr>
</tbody>
</table>
### A.4. CONTENT-BASED ROUTER

**Overview**

A *content-based router* enables you to route messages to the appropriate destination, where the routing decision is based on the message contents. This pattern maps to the corresponding *content-based router* pattern in Apache Camel.

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Message Filter</td>
<td>How a component avoids receiving uninteresting messages.</td>
</tr>
<tr>
<td>Pipeline</td>
<td>How we perform complex processing on a message while maintaining independence and flexibility.</td>
</tr>
<tr>
<td>Resequencer</td>
<td>How we get a stream of related but out-of-sequence messages back into the correct order.</td>
</tr>
<tr>
<td>Static Recipient List</td>
<td>How we route a message to a list of specified recipients.</td>
</tr>
<tr>
<td>Static Routing Slip</td>
<td>How we route a message consecutively through a series of processing steps.</td>
</tr>
<tr>
<td>Wire Tap</td>
<td>How you inspect messages that travel on a point-to-point channel.</td>
</tr>
<tr>
<td>XPath Splitter</td>
<td>How we process a message if it contains multiple elements, each of which may have to be processed in a different way.</td>
</tr>
</tbody>
</table>
Example ServiceMix EIP route

Example A.1, “ServiceMix EIP Content-based Route” shows how to define a content-based router using the ServiceMix EIP component. If a test:echo element is present in the message body, the message is routed to the http://test/pipeline/endpoint endpoint. Otherwise, the message is routed to the test:recipients endpoint.

Example A.1. ServiceMix EIP Content-based Route

```xml
<eip:content-based-router service="test:router" endpoint="endpoint">
  <eip:rules>
    <eip:routing-rule>
      <eip:predicate>
        <eip:xpath-predicate xpath="count(/test:echo) = 1" namespaceContext="#nsContext" />
      </eip:predicate>
      <eip:target>
        <eip:exchange-target uri="endpoint:test:pipeline:endpoint" />
      </eip:target>
    </eip:routing-rule>
    <eip:routing-rule>
      <!-- There is no predicate, so this is the default destination -->
      <eip:target>
        <eip:exchange-target service="test:recipients" />
      </eip:target>
    </eip:routing-rule>
  </eip:rules>
</eip:content-based-router>
```

Equivalent Apache Camel XML route

Example A.2. Apache Camel Content-based Router Using XML Configuration

```xml
<route>
  <from
    uri="jbi:endpoint:http://progress.com/demos/test/router/endpoint"/>
  <choice>
    <when>
```
Equivalent Apache Camel Java DSL route

Example A.3, “Apache Camel Content-based Router Using Java DSL” shows how to define an equivalent route using the Apache Camel Java DSL.

```xml
from("jbi:endpoint:http://progress.com/demos/test/router/endpoint").
    choice().when(xpath("count(/test:echo) = 1")).to("jbi:endpoint:http://progress.com/demos/test/pipeline/endpoint")
    .otherwise().to("jbi:service:http://progress.com/demos/test/recipients");
```

A.5. CONTENT ENRICHER

Overview

A content enricher, shown in Figure A.2, “Content Enricher Pattern”, is a pattern for augmenting a message with missing information. The ServiceMix EIP content enricher is roughly equivalent to a pipeline that adds missing data as the message passes through an enricher target. Consequently, when migrating to Apache Camel, you can re-implement the ServiceMix content enricher as a Apache Camel pipeline.
Example ServiceMix EIP route

Example A.4, “ServiceMix EIP Content Enricher” shows how to define a content enricher using the ServiceMix EIP component. Incoming messages pass through the enricher target, `test:additionalInformationExtractor`, which adds missing data to the message. The message is then sent on to its ultimate destination, `test:myTarget`.

Example A.4. ServiceMix EIP Content Enricher

```xml
<eip:content-enricher service="test:contentEnricher" endpoint="endpoint">
  <eip:enricherTarget>
    <eip:exchange-target service="test:additionalInformationExtractor"/>
  </eip:enricherTarget>
  <eip:target>
    <eip:exchange-target service="test:myTarget"/>
  </eip:target>
</eip:content-enricher>
```

Equivalent Apache Camel XML route

Example A.5, “Apache Camel Content Enricher using XML Configuration” shows how to define an equivalent route using Apache Camel XML configuration.

Example A.5. Apache Camel Content Enricher using XML Configuration

```xml
<route>
  <from uri="jbi:endpoint:http://progress.com/demos/test/contentEnricher/endpoint"/>
  <to uri="jbi:service:http://progress.com/demos/test/additionalInformationExtractor"/>
  <to uri="jbi:service:http://progress.com/demos/test/myTarget"/>
</route>
```

Equivalent Apache Camel Java DSL route

Example A.6, “Apache Camel Content Enricher using Java DSL” shows how to define an equivalent route using the Apache Camel Java DSL:

Example A.6. Apache Camel Content Enricher using Java DSL

```java
from("jbi:endpoint:http://progress.com/demos/test/contentEnricher/endpoint").

to("jbi:service:http://progress.com/demos/test/additionalInformationExtractor").
  to("jbi:service:http://progress.com/demos/test/myTarget");
```
A.6. MESSAGE FILTER

Overview

A message filter, shown in Figure A.3, “Message Filter Pattern”, is a processor that eliminates undesired messages based on specific criteria. Filtering is controlled by specifying a predicate in the filter: when the predicate is true, the incoming message is allowed to pass; otherwise, it is blocked. This pattern maps to the corresponding message filter pattern in Apache Camel.

Figure A.3. Message Filter Pattern

Example ServiceMix EIP route

Example A.7, “ServiceMix EIP Message Filter” shows how to define a message filter using the ServiceMix EIP component. Incoming messages are passed through a filter mechanism that blocks messages that lack a test:world element.

Example A.7. ServiceMix EIP Message Filter

```xml
<eip:message-filter service="test:messageFilter" endpoint="endpoint">
    <eip:target>
        <eip:exchange-target service="test:trace3" />
    </eip:target>
    <eip:filter>
        <eip:xpath-predicate xpath="count(/test:world) = 1" namespaceContext="#nsContext"/>
    </eip:filter>
</eip:message-filter>
```

Equivalent Apache Camel XML route

Example A.8, “Apache Camel Message Filter Using XML” shows how to define an equivalent route using Apache Camel XML configuration.

Example A.8. Apache Camel Message Filter Using XML

```xml
<route>
    <from uri="jbi:endpoint:http://progress.com/demos/test/messageFilter/endpoint"/>
    <filter>
        <xpath>count(/test:world) = 1</xpath>
    </filter>
</route>
```
Equivalent Apache Camel Java DSL route

Example A.9, “Apache Camel Message Filter Using Java DSL” shows how to define an equivalent route using the Apache Camel Java DSL.

```java
from("jbi:endpoint:http://progress.com/demos/test/messageFilter/endpoint").
  filter(xpath("count(/test:world) = 1")).
  to("jbi:service:http://progress.com/demos/test/trace3");
```

A.7. PIPELINE

Overview

The ServiceMix EIP pipeline pattern, shown in Figure A.4, “Pipes and Filters Pattern”, is used to pass messages through a single transformer endpoint, where the transformer's input is taken from the source endpoint and the transformer's output is routed to the target endpoint. This pattern is thus a special case of the more general Apache Camel pipes and filters pattern, which enables you to pass an In message through multiple transformer endpoints.

Figure A.4. Pipes and Filters Pattern

Example ServiceMix EIP route

Example A.10, “ServiceMix EIP Pipeline” shows how to define a pipeline using the ServiceMix EIP component. Incoming messages are passed into the transformer endpoint, test:decrypt, and the output from the transformer endpoint is then passed into the target endpoint, test:plaintextOrder.

```xml
<eip:pipeline service="test:pipeline" endpoint="endpoint">
  <eip:transformer>
    <eip:exchange-target service="test:decrypt" />
  </eip:transformer>
  <eip:target>
```

278
Equivalent Apache Camel XML route

Example A.11, “Apache Camel Pipeline Using XML” shows how to define an equivalent route using Apache Camel XML configuration.

Example A.11. Apache Camel Pipeline Using XML

```xml
<route>
  <from uri="jbi:endpoint:http://progress.com/demos/test/pipeline/endpoint"/>
  <to uri="jbi:service:http://progress.com/demos/test/decrypt"/>
  <to uri="jbi:service:http://progress.com/demos/test/plaintextOrder"/>
</route>
```

Equivalent Apache Camel Java DSL route

Example A.12, “Apache Camel Pipeline Using Java DSL” shows how to define an equivalent route using the Apache Camel Java DSL.

Example A.12. Apache Camel Pipeline Using Java DSL

```java
from("jbi:endpoint:http://progress.com/demos/test/pipeline/endpoint").
    pipeline("jbi:service:http://progress.com/demos/test/decrypt",
        "jbi:service:http://progress.com/demos/test/plaintextOrder");
```

A.8. RESEQUENCER

Overview

The resequencer pattern, shown in Figure A.5, “Resequencer Pattern”, enables you to resequence messages according to the sequence number stored in an NMR property. The ServiceMix EIP resequencer pattern maps to the Apache Camel resequencer configured with the stream resequencing algorithm.

Figure A.5. Resequencer Pattern
Sequence number property

The sequence of messages emitted from the resequencer is determined by the value of the sequence number property: messages with a low sequence number are emitted first and messages with a higher number are emitted later. By default, the sequence number is read from the org.apache.servicemix.eip.sequence.number property in ServiceMix, but you can customize the name of this property using the eip:default-comparator element in ServiceMix.

The equivalent concept in Apache Camel is a sequencing expression, which can be any message-dependent expression. When migrating from ServiceMix EIP, you normally define an expression that extracts the sequence number from a header (a Apache Camel header is equivalent to an NMR message property). For example, to extract a sequence number from a seqnum header, you can use the simple expression header.seqnum.

Example ServiceMix EIP route

Example A.13, “ServiceMix EIP Resequencer” shows how to define a resequencer using the ServiceMix EIP component.

Example A.13. ServiceMix EIP Resequencer

<eip:resequencer
  service="sample:Resequencer"
  endpoint="ResequencerEndpoint"
  comparator="#comparator"
  capacity="100"
  timeout="2000">
  <eip:target>
    <eip:exchange-target service="sample:SampleTarget" />
  </eip:target>
</eip:resequencer>

<!-- Configure default comparator with custom sequence number property -->

<eip:default-comparator xml:id="comparator"
  sequenceNumberKey="seqnum"/>

Equivalent Apache Camel XML route

Example A.14, “Apache Camel Resequencer Using XML” shows how to define an equivalent route using Apache Camel XML configuration.

<route>
  <from uri="jbi:endpoint:sample:Resequencer:ResequencerEndpoint"/>
  <resequencer>
    <simple>header.seqnum</simple>
    <to uri="jbi:service:sample:SampleTarget"/>
    <stream-config capacity="100" timeout="2000"/>
  </resequencer>
</route>
Equivalent Apache Camel Java DSL route

Example A.15, “Apache Camel Resequencer Using Java DSL” shows how to define an equivalent route using the Apache Camel Java DSL.

```
from("jbi:endpoint:sample:Resequencer:ResequencerEndpoint").
    resequencer(header("seqnum")).
    stream(new StreamResequencerConfig(100, 2000L)).
    to("jbi:service:sample:SampleTarget");
```

A.9. STATIC RECIPIENT LIST

Overview

A recipient list, shown in Figure A.6, “Static Recipient List Pattern”, is a type of router that sends each incoming message to multiple different destinations. The ServiceMix EIP recipient list is restricted to processing InOnly and RobustInOnly exchange patterns. Moreover, the list of recipients must be static. This pattern maps to the recipient list with fixed destination pattern in Apache Camel.

Figure A.6. Static Recipient List Pattern

Example ServiceMix EIP route

Example A.16, “ServiceMix EIP Static Recipient List” shows how to define a static recipient list using the ServiceMix EIP component. Incoming messages are copied to the test:messageFilter endpoint and to the test:trace4 endpoint.

```
<eip:static-recipient-list service="test:recipients"
    endpoint="endpoint">
    <eip:recipients>
        <eip:recipient service="A"/>
        <eip:recipient service="B"/>
        <eip:recipient service="C"/>
        <eip:recipient service="D"/>
    </eip:recipients>
</eip:static-recipient-list>
```
Equivalent Apache Camel XML route

Example A.17, “Apache Camel Static Recipient List Using XML” shows how to define an equivalent route using Apache Camel XML configuration.

```xml
<route>
    <from uri="jbi:endpoint:http://progress.com/demos/test/recipients/endpoint"/>
    <to uri="jbi:service:http://progress.com/demos/test/messageFilter"/>
    <to uri="jbi:service:http://progress.com/demos/test/trace4"/>
</route>
```

**NOTE**

The preceding route configuration appears to have the same syntax as a Apache Camel pipeline pattern. The key difference is that the preceding route is intended for processing *InOnly* message exchanges, which are processed in a different way. See Section 4.4, “Pipes and Filters” for more details.

Equivalent Apache Camel Java DSL route

Example A.18, “Apache Camel Static Recipient List Using Java DSL” shows how to define an equivalent route using the Apache Camel Java DSL.

```java
from("jbi:endpoint:http://progress.com/demos/test/recipients/endpoint").
to("jbi:service:http://progress.com/demos/test/messageFilter",
    "jbi:service:http://progress.com/demos/test/trace4");
```

### A.10. STATIC ROUTING SLIP

**Overview**

The *static routing slip* pattern in the ServiceMix EIP component is used to route an *InOut* message exchange through a series of endpoints. Semantically, it is equivalent to the *pipeline* pattern in Apache Camel.

**Example ServiceMix EIP route**

Example A.19, “ServiceMix EIP Static Routing Slip” shows how to define a static routing slip
using the ServiceMix EIP component. Incoming messages pass through each of the endpoints, test:procA, test:procB, and test:procC, where the output of each endpoint is connected to the input of the next endpoint in the chain. The final endpoint, test:procC, sends its output (Out message) back to the caller.

**Example A.19. ServiceMix EIP Static Routing Slip**

```xml
<eip:static-routing-slip service="test:routingSlip" endpoint="endpoint">
  <eip:targets>
    <eip:exchange-target service="test:procA" />
    <eip:exchange-target service="test:procB" />
    <eip:exchange-target service="test:procC" />
  </eip:targets>
</eip:static-routing-slip>
```

**Equivalent Apache Camel XML route**

**Example A.20. Apache Camel Static Routing Slip Using XML**

```xml
<route>
  <to uri="jbi:service:http://progress.com/demos/test/procA"/>
  <to uri="jbi:service:http://progress.com/demos/test/procB"/>
  <to uri="jbi:service:http://progress.com/demos/test/procC"/>
</route>
```

**Equivalent Apache Camel Java DSL route**

Example A.21, “Apache Camel Static Routing Slip Using Java DSL” shows how to define an equivalent route using the Apache Camel Java DSL.

**Example A.21. Apache Camel Static Routing Slip Using Java DSL**

```java
from("jbi:endpoint:http://progress.com/demos/test/routingSlip/endpoint")
           "jbi:service:http://progress.com/demos/test/procC");
```

**A.11. WIRE TAP**

**Overview**
The **wire tap** pattern, shown in Figure A.7, “Wire Tap Pattern”, allows you to route messages to a separate tap location before it is forwarded to the ultimate destination. The ServiceMix EIP wire tap pattern maps to the **wire tap** pattern in Apache Camel.

**Figure A.7. Wire Tap Pattern**

![Wire Tap Pattern Diagram]

**Example ServiceMix EIP route**

Example A.22, “ServiceMix EIP Wire Tap” shows how to define a wire tap using the ServiceMix EIP component. The **In** message from the source endpoint is copied to the **In**-listener endpoint, before being forwarded on to the target endpoint. If you want to monitor any returned **Out** messages or **Fault** messages from the target endpoint, you also must define an **Out** listener (using the **eip:outListener** element) and a **Fault** listener (using the **eip:faultListener** element).

**Example A.22. ServiceMix EIP Wire Tap**

```xml
<eip:wire-tap service="test:wireTap" endpoint="endpoint">
  <eip:target>
    <eip:exchange-target service="test:target" />
  </eip:target>
  <eip:inListener>
    <eip:exchange-target service="test:trace1" />
  </eip:inListener>
</eip:wire-tap>
```

**Equivalent Apache Camel XML route**

**Example A.23. Apache Camel Wire Tap Using XML**

```xml
<route>
  <from uri="jbi:endpoint:http://progress.com/demos/test/wireTap/endpoint"/>
  <to uri="jbi:service:http://progress.com/demos/test/trace1"/>
  <to uri="jbi:service:http://progress.com/demos/test/target"/>
</route>
```
Equivalent Apache Camel Java DSL route

Example A.24, “Apache Camel Wire Tap Using Java DSL” shows how to define an equivalent route using the Apache Camel Java DSL.

```
from("jbi:endpoint:http://progress.com/demos/test/wireTap/endpoint")
  .to("jbi:service:http://progress.com/demos/test/tracel",
      "jbi:service:http://progress.com/demos/test/target");
```

A.12. XPATH SPLITTER

Overview

A splitter, shown in Figure A.8, “XPath Splitter Pattern”, is a type of router that splits an incoming message into a series of outgoing messages, where each of the messages contains a piece of the original message. The ServiceMix EIP XPath splitter pattern is restricted to using the InOnly and RobustInOnly exchange patterns. The expression that defines how to split up the original message is defined in the XPath language. The XPath splitter pattern maps to the splitter pattern in Apache Camel.

**Figure A.8. XPath Splitter Pattern**

Forwarding NMR attachments and properties

The `eip:xpath-splitter` element supports a `forwardAttachments` attribute and a `forwardProperties` attribute, either of which can be set to `true`, if you want the splitter to copy the incoming message’s attachments or properties to the outgoing messages. The corresponding splitter pattern in Apache Camel does not support any such attributes. By default, the incoming message’s headers are copied to each of the outgoing messages by the Apache Camel splitter.

Example ServiceMix EIP route

Example A.25, “ServiceMix EIP XPath Splitter” shows how to define a splitter using the ServiceMix EIP component. The specified XPath expression, `/*/*`, causes an incoming message to split at every occurrence of a nested XML element (for example, the `/foo/bar` and `/foo/car` elements are split into distinct messages).
Example A.25. ServiceMix EIP XPath Splitter

```
<eip:xpath-splitter service="test:xpathSplitter"
  endpoint="endpoint"
  xpath="/*/*"
  namespaceContext="#nsContext">
  <eip:target>
    <eip:exchange-target uri="service:http://test/router" />
  </eip:target>
</eip:xpath-splitter>
```

Equivalent Apache Camel XML route

Example A.26, “Apache Camel XPath Splitter Using XML” shows how to define an equivalent route using Apache Camel XML configuration.

Example A.26. Apache Camel XPath Splitter Using XML

```
<route>
  <from uri="jbi:endpoint:http://progress.com/demos/test/xpathSplitter/endpoint" />
  <splitter>
    <xpath>/*/*</xpath>
    <to uri="jbi:service:http://test/router"/>
  </splitter>
</route>
```

Equivalent Apache Camel Java DSL route

Example A.27, “Apache Camel XPath Splitter Using Java DSL” shows how to define an equivalent route using the Apache Camel Java DSL.

Example A.27. Apache Camel XPath Splitter Using Java DSL

```
from("jbi:endpoint:http://progress.com/demos/test/xpathSplitter/endpoint ").
  splitter(xpath("/*/*")).to("jbi:service:http://test/router");
```
PART II. ROUTING EXPRESSION AND PREDICATE LANGUAGES

Abstract

This guide describes the basic syntax used by the evaluative languages supported by Apache Camel.
CHAPTER 11. INTRODUCTION

Abstract

This chapter provides an overview of all the expression languages supported by Apache Camel.

11.1. OVERVIEW OF THE LANGUAGES

Table of expression and predicate languages

Table 11.1, “Expression and Predicate Languages” gives an overview of the different syntaxes for invoking expression and predicate languages.

Table 11.1. Expression and Predicate Languages

<table>

</tbody>
</table>
### 11.2. HOW TO INVOKE AN EXPRESSION LANGUAGE

#### Prerequisites

Before you can use a particular expression language, you must ensure that the required JAR files are available on the classpath. If the language you want to use is not included in the Apache Camel core, you must add the relevant JARs to your classpath.

If you are using the Maven build system, you can modify the build-time classpath simply by adding the relevant dependency to your POM file. For example, if you want to use the Ruby language, add the following dependency to your POM file:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-script</artifactId>
  <!-- Use the same version as your Camel core version -->
  <version>${camel.version}</version>
</dependency>
```

If you are going to deploy your application in a Red Hat JBoss Fuse OSGi container, you also...
need to ensure that the relevant language features are installed (features are named after the corresponding Maven artifact). For example, to use the Groovy language in the OSGi container, you must first install the camel-groovy feature by entering the following OSGi console command:

```
karaf@root> features:install camel-groovy
```

### Approaches to invoking

As shown in Table 11.1, “Expression and Predicate Languages”, there are several different syntaxes for invoking an expression language, depending on the context in which it is used. You can invoke an expression language:

- the section called “As a static method”.
- the section called “As a fluent DSL method”.
- the section called “As an XML element”.
- the section called “As an annotation”.

### As a static method

Most of the languages define a static method that can be used in any context where an org.apache.camel.Expression type or an org.apache.camel.Predicate type is expected. The static method takes a string expression (or predicate) as its argument and returns an Expression object (which is usually also a Predicate object).

For example, to implement a content-based router that processes messages in XML format, you could route messages based on the value of the /order/address/countryCode element, as follows:

```java
from("SourceURL")
  .choice
    .when(xpath("/order/address/countryCode = 'us'"))
      .to("file://countries/us/")
    .when(xpath("/order/address/countryCode = 'uk'"))
      .to("file://countries/uk/")
    .otherwise()
      .to("file://countries/other/")
  .to("TargetURL");
```

### As a fluent DSL method

The Java fluent DSL supports another style of invoking expression languages. Instead of providing the expression as an argument to an Enterprise Integration Pattern (EIP), you can provide the expression as a sub-clause of the DSL command. For example, instead of invoking an XPath expression as `filter(xpath("Expression"))`, you can invoke the expression as, `filter().xpath("Expression")`.

For example, the preceding content-based router can be re-implemented in this style of invocation, as follows:

```java
from("SourceURL")
```

290
As an XML element

You can also invoke an expression language in XML, by putting the expression string inside the relevant XML element.

For example, the XML element for invoking XPath in XML is `xpath` (which belongs to the standard Apache Camel namespace). You can use XPath expressions in a XML DSL content-based router, as follows:

```xml
<from uri="file://input/orders"/>
<choice>
  <when>
    <xpath>/order/address/countryCode = 'us'</xpath>
    <to uri="file://countries/us"/>
  </when>
  <when>
    <xpath>/order/address/countryCode = 'uk'</xpath>
    <to uri="file://countries/uk"/>
  </when>
  <otherwise>
    <to uri="file://countries/other"/>
  </otherwise>
</choice>
```

Alternatively, you can specify a language expression using the `language` element, where you specify the name of the language in the `language` attribute. For example, you can define an XPath expression using the `language` element as follows:

```xml
<language language="xpath">/order/address/countryCode = 'us'</language>
```

As an annotation

Language annotations are used in the context of bean integration (see Section 2.4, “Bean Integration”). The annotations provide a convenient way of extracting information from a message or header and then injecting the extracted data into a bean's method parameters.

For example, consider the bean, `myBeanProc`, which is invoked as a predicate of the `filter()` EIP. If the bean's `checkCredentials` method returns `true`, the message is allowed to proceed; but if the method returns `false`, the message is blocked by the filter. The filter pattern is implemented as follows:

```java
// Java
MyBeanProcessor myBeanProc = new MyBeanProcessor();
```
The implementation of the `MyBeanProcessor` class exploits the `@XPath` annotation to extract the `username` and `password` from the underlying XML message, as follows:

```java
import org.apache.camel.language.XPath;

public class MyBeanProcessor {
    boolean void checkCredentials(
        @XPath("/credentials/username/text()") String user,
        @XPath("/credentials/password/text()") String pass
    ) {
        // Check the user/pass credentials...
    }
}
```

The `@XPath` annotation is placed just before the parameter into which it gets injected. Notice how the XPath expression explicitly selects the text node, by appending `text()` to the path, which ensures that just the content of the element is selected, not the enclosing tags.

**As a Camel endpoint URI**

Using the Camel Language component, you can invoke a supported language in an endpoint URI. There are two alternative syntaxes.

To invoke a language script stored in a file (or other resource type defined by `Scheme`), use the following URI syntax:

```
language://LanguageName:resource:Scheme:Location[?Options]
```

Where the scheme can be `file:`, `classpath:`, or `http:`.

For example, the following route executes the `mysimplescript.txt` from the classpath:

```
from("direct:start")
    .to("language:simple:classpath:org/apache/camel/component/language/mysimplescript.txt")
    .to("mock:result");
```

To invoke an embedded language script, use the following URI syntax:

```
language://LanguageName[::Script][?Options]
```

For example, to run the Simple language script stored in the `script` string:

```
String script = URLEncoder.encode("Hello ${body}", "UTF-8");
from("direct:start")
    .to("language:simple:" + script)
```
CHAPTER 12. CONSTANT

OVERVIEW

The constant language is a trivial built-in language that is used to specify a plain text string. This makes it possible to provide a plain text string in any context where an expression type is expected.

XML EXAMPLE

In XML, you can set the `username` header to the value, Jane Doe as follows:

```xml
<camelContext>
    <route>
        <from uri="SourceURL"/>
        <setHeader headerName="username">
            <constant>Jane Doe</constant>
        </setHeader>
        <to uri="TargetURL"/>
    </route>
</camelContext>
```

JAVA EXAMPLE

In Java, you can set the `username` header to the value, Jane Doe as follows:

```java
from("SourceURL")
    .setHeader("username", constant("Jane Doe"))
    .to("TargetURL");
```
Chapter 13. EL

Overview

The Unified Expression Language (EL) was originally specified as part of the JSP 2.1 standard (JSR-245), but it is now available as a standalone language. Apache Camel integrates with JUEL (http://juel.sourceforge.net/), which is an open source implementation of the EL language.

Adding JUEL Package

To use EL in your routes you need to add a dependency on camel-juel to your project as shown in Example 13.1, “Adding the camel-juel dependency”.

Example 13.1. Adding the camel-juel dependency

```xml
<properties>
  <camel-version>2.12.0.redhat-610379</camel-version>
  ...
</properties>
<dependencies>
  ...
  <dependency>
    <groupId>org.apache.camel</groupId>
    <artifactId>camel-juel</artifactId>
    <version>${camel-version}</version>
  </dependency>
  ...
</dependencies>
```

Static Import

To use the el() static method in your application code, include the following import statement in your Java source files:

```java
import static org.apache.camel.language.juel.JuelExpression.el;
```

Variables

Table 13.1, “EL variables” lists the variables that are accessible when using EL.

Table 13.1. EL variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Type</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>exchange</td>
<td>org.apache.camel.Exchange</td>
<td>The current Exchange</td>
</tr>
</tbody>
</table>
### Variable Table

<table>
<thead>
<tr>
<th>Variable</th>
<th>Type</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>in</td>
<td>org.apache.camel.Message</td>
<td>The IN message</td>
</tr>
<tr>
<td>out</td>
<td>org.apache.camel.Message</td>
<td>The OUT message</td>
</tr>
</tbody>
</table>

### EXAMPLE

Example 13.2, “Routes using EL” shows two routes that use EL.

**Example 13.2. Routes using EL**

```xml
<camelContext>
    <route>
        <from uri="seda:foo"/>
        <filter>
            <language language="el">${in.headers.foo == 'bar'}</language>
            <to uri="seda:bar"/>
        </filter>
    </route>
    <route>
        <from uri="seda:foo2"/>
        <filter>
            <language language="el">${in.headers['My Header'] == 'bar'}</language>
            <to uri="seda:bar"/>
        </filter>
    </route>
</camelContext>
```
Abstract

The file language is an extension to the simple language, not an independent language in its own right. But the file language extension can only be used in conjunction with File or FTP endpoints.

14.1. WHEN TO USE THE FILE LANGUAGE

Overview

The file language is an extension to the simple language which is not always available. You can use it under the following circumstances:

- the section called “In a File or FTP consumer endpoint”
- the section called “On exchanges created by a File or FTP consumer”

NOTE

The escape character, \\, is not available in the file language.

In a File or FTP consumer endpoint

There are several URI options that you can set on a File or FTP consumer endpoint, which take a file language expression as their value. For example, in a File consumer endpoint URI you can set the fileName, move, preMove, moveFailed, and sortBy options using a file expression.

In a File consumer endpoint, the fileName option acts as a filter, determining which file will actually be read from the starting directory. If a plain text string is specified (for example, fileName=report.txt), the File consumer reads the same file each time it is updated. You can make this option more dynamic, however, by specifying a simple expression. For example, you could use a counter bean to select a different file each time the File consumer polls the starting directory, as follows:

```
file://target/filelanguage/bean/?
fileName=${bean:counter.next}.txt&delete=true
```

Where the ${bean:counter.next} expression invokes the next() method on the bean registered under the ID, counter.

The move option is used to move files to a backup location after they have been read by a File consumer endpoint. For example, the following endpoint moves files to a backup directory, after they have been processed:

```
file://target/filelanguage/?
move=backup/${date:now:yyyyMMdd}/${file:name.noext}.bak&recursive=false
```

Where the ${file:name.noext}.bak expression modifies the original file name, replacing the file extension with .bak.
You can use the `sortBy` option to specify the order in which file should be processed. For example, to process files according to the alphabetical order of their file name, you could use the following File consumer endpoint:

```text
file://target/filelanguage/?sortBy=file:name
```

To process file according to the order in which they were last modified, you could use the following File consumer endpoint:

```text
file://target/filelanguage/?sortBy=file:modified
```

You can reverse the order by adding the `reverse:` prefix—for example:

```text
file://target/filelanguage/?sortBy=reverse:file:modified
```

### On exchanges created by a File or FTP consumer

When an exchange originates from a File or FTP consumer endpoint, it is possible to apply file language expressions to the exchange throughout the route (as long as the original message headers are not erased). For example, you could define a content-based router, which routes messages according to their file extension, as follows:

```xml
<from uri="file://input/orders"/>
<choice>
  <when>
    <simple>${file:ext} == 'txt'</simple>
    <to uri="bean:orderService?method=handleTextFiles"/>
  </when>
  <when>
    <simple>${file:ext} == 'xml'</simple>
    <to uri="bean:orderService?method=handleXmlFiles"/>
  </when>
  <otherwise>
    <to uri="bean:orderService?method=handleOtherFiles"/>
  </otherwise>
</choice>
```

## 14.2. FILE VARIABLES

### Overview

File variables can be used whenever a route starts with a File or FTP consumer endpoint, which implies that the underlying message body is of `java.io.File` type. The file variables enable you to access various parts of the file pathname, almost as if you were invoking the methods of the `java.io.File` class (in fact, the file language extracts the information it needs from message headers that have been set by the File or FTP endpoint).

### Starting directory

Some of file variables return paths that are defined relative to a starting directory, which is just the directory that is specified in the File or FTP endpoint. For example, the following File consumer endpoint has the starting directory, `.filetransfer` (a relative path):

```text
file://target/filelanguage/?sortBy=file:name
```
file:filetransfer

The following FTP consumer endpoint has the starting directory, ./ftptransfer (a relative path):

ftp://myhost:2100/ftptransfer

### Naming convention of file variables

In general, the file variables are named after corresponding methods on the java.io.File class. For example, the file:absolute variable gives the value that would be returned by the java.io.File.getAbsolutePath() method.

**NOTE**

This naming convention is not strictly followed, however. For example, there is no such method as java.io.File.getSize().

### Table of variables

Table 14.1, “Variables for the File Language” shows all of the variable supported by the file language.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file:name</td>
<td>String</td>
<td>The pathname relative to the starting directory.</td>
</tr>
<tr>
<td>file:name.ext</td>
<td>String</td>
<td>The file extension (characters following the last . character in the pathname).</td>
</tr>
<tr>
<td>file:name.noext</td>
<td>String</td>
<td>The pathname relative to the starting directory, omitting the file extension.</td>
</tr>
<tr>
<td>file:onlyname</td>
<td>String</td>
<td>The final segment of the pathname. That is, the file name without the parent directory path.</td>
</tr>
<tr>
<td>file:onlyname.noext</td>
<td>String</td>
<td>The final segment of the pathname, omitting the file extension.</td>
</tr>
<tr>
<td>file:ext</td>
<td>String</td>
<td>The file extension (same as file:name.ext).</td>
</tr>
</tbody>
</table>
### 14.3. EXAMPLES

#### Relative pathname

Consider a File consumer endpoint, where the starting directory is specified as a relative pathname. For example, the following File endpoint has the starting directory, .\filelanguage:

```
file://filelanguage
```

Now, while scanning the filelanguage directory, suppose that the endpoint has just consumed the following file:

```
./filelanguage/test/hello.txt
```

And, finally, assume that the filelanguage directory itself has the following absolute location:

```
/workspace/camel/camel-core/target/filelanguage
```

Given the preceding scenario, the file language variables return the following values, when applied to the current exchange:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file:parent</td>
<td>String</td>
<td>The pathname of the parent directory, including the starting directory in the path.</td>
</tr>
<tr>
<td>file:path</td>
<td>String</td>
<td>The file pathname, including the starting directory in the path.</td>
</tr>
<tr>
<td>file:absolute</td>
<td>Boolean</td>
<td>true, if the starting directory was specified as an absolute path; false, otherwise.</td>
</tr>
<tr>
<td>file:absolute.path</td>
<td>String</td>
<td>The absolute pathname of the file.</td>
</tr>
<tr>
<td>file:length</td>
<td>Long</td>
<td>The size of the referenced file.</td>
</tr>
<tr>
<td>file:size</td>
<td>Long</td>
<td>Same as file:length.</td>
</tr>
<tr>
<td>file:modified</td>
<td>java.util.Date</td>
<td>Date last modified.</td>
</tr>
</tbody>
</table>
Absolute pathname

Consider a File consumer endpoint, where the starting directory is specified as an absolute pathname. For example, the following File endpoint has the starting directory, 
file:///workspace/camel/camel-core/target/filelanguage:

file:///workspace/camel/camel-core/target/filelanguage

Now, while scanning the filelanguage directory, suppose that the endpoint has just consumed the following file:

./filelanguage/test/hello.txt

Given the preceding scenario, the file language variables return the following values, when applied to the current exchange:

<table>
<thead>
<tr>
<th>Expression</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>file:name</td>
<td>test/hello.txt</td>
</tr>
<tr>
<td>file:name.ext</td>
<td>txt</td>
</tr>
<tr>
<td>file:name.noext</td>
<td>test/hello</td>
</tr>
<tr>
<td>file:onlyname</td>
<td>hello.txt</td>
</tr>
<tr>
<td>file:onlyname.noext</td>
<td>hello</td>
</tr>
<tr>
<td>file:ext</td>
<td>txt</td>
</tr>
<tr>
<td>file:parent</td>
<td>filelanguage/test</td>
</tr>
<tr>
<td>file:path</td>
<td>filelanguage/test/hello.txt</td>
</tr>
<tr>
<td>file:absolute</td>
<td>false</td>
</tr>
<tr>
<td>file:absolute.path</td>
<td>/workspace/camel/camel-core/target/filelanguage/test/hello.txt</td>
</tr>
<tr>
<td>Expression</td>
<td>Result</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>---------------------------------------------</td>
</tr>
<tr>
<td>file:onlyname</td>
<td>hello.txt</td>
</tr>
<tr>
<td>file:onlyname.noext</td>
<td>hello</td>
</tr>
<tr>
<td>file:ext</td>
<td>txt</td>
</tr>
<tr>
<td>file:parent</td>
<td>/workspace/camel/camel-core/target/filelanguage/test</td>
</tr>
<tr>
<td>file:path</td>
<td>/workspace/camel/camel-core/target/filelanguage/test/hello.txt</td>
</tr>
<tr>
<td>file:absolute</td>
<td>true</td>
</tr>
<tr>
<td>file:absolute.path</td>
<td>/workspace/camel/camel-core/target/filelanguage/test/hello.txt</td>
</tr>
</tbody>
</table>
CHAPTER 15. GROOVY

OVERVIEW

Groovy is a Java-based scripting language that allows quick parsing of objects. The Groovy support is part of the camel-script module.

ADDING THE SCRIPT MODULE

To use Groovy in your routes you need to add a dependency on camel-script to your project as shown in Example 15.1, “Adding the camel-script dependency”.

Example 15.1. Adding the camel-script dependency

```xml
<properties>
    <camel-version>2.12.0.redhat-610379</camel-version>
    ...
</properties>

<dependencies>
    ...
    <dependency>
        <groupId>org.apache.camel</groupId>
        <artifactId>camel-script</artifactId>
        <version>${camel-version}</version>
    </dependency>
    ...
</dependencies>
```

STATIC IMPORT

To use the `groovy()` static method in your application code, include the following import statement in your Java source files:

```java
import static org.apache.camel.builder.camel.script.ScriptBuilder.*;
```

BUILT-IN ATTRIBUTES

Table 15.1, “Groovy attributes” lists the built-in attributes that are accessible when using Groovy.

Table 15.1. Groovy attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Type</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>context</td>
<td>org.apache.camel.CamelContext</td>
<td>The Camel Context</td>
</tr>
</tbody>
</table>
The attributes all set at ENGINE_SCOPE.

EXAMPLE

Example 15.2, “Routes using Groovy” shows two routes that use Groovy scripts.

Example 15.2. Routes using Groovy

```xml
<camelContext>
  <route>
    <from uri="mock:mock0" />
    <filter>
      <language language="groovy">request.lineItems.any { i -> i.value > 100 } </language>
    </filter>
  </route>
  <route>
    <from uri="direct:in"/>
    <setHeader headerName="firstName">
      <language language="groovy">$user.firstName $user.lastName </language>
    </setHeader>
    <to uri="seda:users"/>
  </route>
</camelContext>
```

USING THE PROPERTIES COMPONENT

To access a property value from the properties component, invoke the resolve method on the built-in properties attribute, as follows:

```java
.setHeader("myHeader").groovy("properties.resolve(PropKey)")
```
Where PropKey is the key of the property you want to resolve, where the key value is of String type.

For more details about the properties component, see .
CHAPTER 16. HEADER

OVERVIEW

The header language provides a convenient way of accessing header values in the current message. When you supply a header name, the header language performs a case-insensitive lookup and returns the corresponding header value.

The header language is part of camel-core.

XML EXAMPLE

For example, to resequence incoming exchanges according to the value of a SequenceNumber header (where the sequence number must be a positive integer), you can define a route as follows:

```xml
<camelContext xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="SourceURL"/>
    <resequence>
      <language language="header">SequenceNumber</language>
    </resequence>
    <to uri="TargetURL"/>
  </route>
</camelContext>
```

JAVA EXAMPLE

The same route can be defined in Java, as follows:

```java
from("SourceURL")
  .resequence(header("SequenceNumber"))
  .to("TargetURL");
```
CHAPTER 17. JAVASCRIPT

OVERVIEW

JavaScript, also known as ECMAScript is a Java-based scripting language that allows quick parsing of objects. The JavaScript support is part of the camel-script module.

ADDING THE SCRIPT MODULE

To use JavaScript in your routes you need to add a dependency on camel-script to your project as shown in Example 17.1, “Adding the camel-script dependency”.

Example 17.1. Adding the camel-script dependency

```xml
<!-- Maven POM File -->
<properties>
  <camel-version>2.12.0.redhat-610379</camel-version>
  ...
</properties>

<dependencies>
  ...
  <dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-script</artifactId>
  <version>${camel-version}</version>
  </dependency>
  ...
</dependencies>
```

STATIC IMPORT

To use the `javaScript()` static method in your application code, include the following import statement in your Java source files:

```java
import static org.apache.camel.builder.camel.script.ScriptBuilder.*;
```

BUILT-IN ATTRIBUTES

Table 17.1, “JavaScript attributes” lists the built-in attributes that are accessible when using JavaScript.

Table 17.1. JavaScript attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Type</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>context</td>
<td><code>org.apache.camel.CamelContext</code></td>
<td>The Camel Context</td>
</tr>
</tbody>
</table>
The attributes all set at `ENGINE_SCOPE`.

**EXAMPLE**

**Example 17.2, “Route using JavaScript”** shows a route that uses JavaScript.

**Example 17.2. Route using JavaScript**

```xml
<camelContext>
  <route>
    <from uri="direct:start"/>
    <choice>
      <when>
        <language language="javaScript">request.headers.get('user') == 'admin'</language>
        <to uri="seda:adminQueue"/>
      </when>
      <otherwise>
        <to uri="seda:regularQueue"/>
      </otherwise>
    </choice>
  </route>
</camelContext>
```

**USING THE PROPERTIES COMPONENT**

To access a property value from the properties component, invoke the `resolve` method on the built-in `properties` attribute, as follows:

```java
.setHeader("myHeader").javaScript("properties.resolve(PropKey)")
```

Where `PropKey` is the key of the property you want to resolve, where the key value is of `String` type.
For more details about the properties component, see.
CHAPTER 18. JOSQL

OVERVIEW

The JoSQL (SQL for Java objects) language enables you to evaluate predicates and expressions in Apache Camel. JoSQL employs a SQL-like query syntax to perform selection and ordering operations on data from in-memory Java objects—however, JoSQL is not a database. In the JoSQL syntax, each Java object instance is treated like a table row and each object method is treated like a column name. Using this syntax, it is possible to construct powerful statements for extracting and compiling data from collections of Java objects. For details, see http://josql.sourceforge.net/.

ADDING THE JOSQL MODULE

To use JoSQL in your routes you need to add a dependency on camel-josql to your project as shown in Example 18.1, “Adding the camel-josql dependency”.

Example 18.1. Adding the camel-josql dependency

```xml
<!-- Maven POM File -->
...
<dependencies>
...
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-josql</artifactId>
  <version>${camel-version}</version>
</dependency>
...
</dependencies>
```

STATIC IMPORT

To use the `sql()` static method in your application code, include the following import statement in your Java source files:

```java
import static org.apache.camel.builder.sql.SqlBuilder.sql;
```

VARIABLES

Table 18.1, “SQL variables” lists the variables that are accessible when using JoSQL.

Table 18.1. SQL variables

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>exchange</td>
<td>org.apache.camel.Exchange</td>
<td>The current Exchange</td>
</tr>
</tbody>
</table>
### Name | Type | Description
--- | --- | ---
in | `org.apache.camel.Message` | The IN message
out | `org.apache.camel.Message` | The OUT message
property | `Object` | the Exchange property whose key is `property`
helper | `Object` | the IN message header whose key is `header`
variable | `Object` | the variable whose key is `variable`

---

**EXAMPLE**

Example 18.2, “Route using JoSQL” shows a route that uses JoSQL.

**Example 18.2. Route using JoSQL**

```xml
<camelContext>
  <route>
    <from uri="direct:start"/>
    <setBody>
      <language language="sql">select * from MyType</language>
    </setBody>
    <to uri="seda:regularQueue"/>
  </route>
</camelContext>
```
CHAPTER 19. JXPATH

OVERVIEW

The JXPath language enables you to invoke Java beans using the Apache Commons JXPath language. The JXPath language has a similar syntax to XPath, but instead of selecting element or attribute nodes from an XML document, it invokes methods on an object graph of Java beans. If one of the bean attributes returns an XML document (a DOM/JDOM instance), however, the remaining portion of the path is interpreted as an XPath expression and is used to extract an XML node from the document. In other words, the JXPath language provides a hybrid of object graph navigation and XML node selection.

ADDING JXPATH PACKAGE

To use JXPath in your routes you need to add a dependency on camel-jxpath to your project as shown in Example 19.1, "Adding the camel-jxpath dependency".

Example 19.1. Adding the camel-jxpath dependency

```xml
<!-- Maven POM File -->
<properties>
    <camel-version>2.12.0.redhat-610379</camel-version>
    ...
</properties>

<dependencies>
    ...
    <dependency>
        <groupId>org.apache.camel</groupId>
        <artifactId>camel-jxpath</artifactId>
        <version>${camel-version}</version>
    </dependency>
    ...
</dependencies>
```

VARIABLES

Table 19.1, "JXPath variables" lists the variables that are accessible when using JXPath.

Table 19.1. JXPath variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Type</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>this</td>
<td>org.apache.camel.Exchange</td>
<td>The current Exchange</td>
</tr>
<tr>
<td>in</td>
<td>org.apache.camel.Message</td>
<td>The IN message</td>
</tr>
</tbody>
</table>
**EXAMPLE**

Example 19.2, “Routes using JXPath” shows a route that use JXPath.

**Example 19.2. Routes using JXPath**

```xml
<camelContext>
  <route>
    <from uri="activemq:MyQueue"/>
    <filter>
      <jxpath>in/body/name = 'James'</jxpath>
      <to uri="mqseries:SomeOtherQueue"/>
    </filter>
  </route>
</camelContext>
```
CHAPTER 20. MVEL

OVERVIEW

MVEL (http://mvel.codehaus.org/) is a Java-based dynamic language that is similar to OGNL, but is reported to be much faster. The MVEL support is in the camel-mvel module.

SYNTAX

You use the MVEL dot syntax to invoke Java methods, for example:

```java
getRequest().getBody().getFamilyName()
```

Because MVEL is dynamically typed, it is unnecessary to cast the message body instance (of `Object` type) before invoking the `getFamilyName()` method. You can also use an abbreviated syntax for invoking bean attributes, for example:

```java
request.body.familyName
```

ADDING THE MVEL MODULE

To use MVEL in your routes you need to add a dependency on camel-mvel to your project as shown in Example 20.1, “Adding the camel-mvel dependency”.

Example 20.1. Adding the camel-mvel dependency

```xml
<dependencies>
  ...  
  <dependency>
    <groupId>org.apache.camel</groupId>
    <artifactId>camel-mvel</artifactId>
    <version>${camel-version}</version>
  </dependency>
  ...  
</dependencies>
```

BUILT-IN VARIABLES

Table 20.1, “MVEL variables” lists the built-in variables that are accessible when using MVEL.

Table 20.1. MVEL variables
<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>this</td>
<td>org.apache.camel.Exchange</td>
<td>The current Exchange</td>
</tr>
<tr>
<td>exchange</td>
<td>org.apache.camel.Exchange</td>
<td>The current Exchange</td>
</tr>
<tr>
<td>exception</td>
<td>Throwable</td>
<td>the Exchange exception (if any)</td>
</tr>
<tr>
<td>exchangeID</td>
<td>String</td>
<td>the Exchange ID</td>
</tr>
<tr>
<td>fault</td>
<td>org.apache.camel.Message</td>
<td>The Fault message (if any)</td>
</tr>
<tr>
<td>request</td>
<td>org.apache.camel.Message</td>
<td>The IN message</td>
</tr>
<tr>
<td>response</td>
<td>org.apache.camel.Message</td>
<td>The OUT message</td>
</tr>
<tr>
<td>properties</td>
<td>Map</td>
<td>The Exchange properties</td>
</tr>
<tr>
<td>property(name)</td>
<td>Object</td>
<td>The value of the named Exchange property</td>
</tr>
<tr>
<td>property(name, type)</td>
<td>Type</td>
<td>The typed value of the named Exchange property</td>
</tr>
</tbody>
</table>

### EXAMPLE

Example 20.2, “Route using MVEL” shows a route that uses MVEL.

**Example 20.2. Route using MVEL**

```xml
<camelContext>
  <route>
    <from uri="seda:foo"/>
    <filter>
      <language language="mvel">request.headers.foo == 'bar'</language>
      <to uri="seda:bar"/>
    </filter>
  </route>
</camelContext>
```
CHAPTER 21. THE OBJECT-GRAPH NAVIGATION LANGUAGE (OGNL)

OVERVIEW

OGNL (http://www.opensymphony.com/ognl/) is an expression language for getting and setting properties of Java objects. You use the same expression for both getting and setting the value of a property. The OGNL support is in the camel-ognl module.

ADDING THE OGNL MODULE

To use OGNL in your routes you need to add a dependency on camel-ognl to your project as shown in Example 21.1, “Adding the camel-ognl dependency”.

Example 21.1. Adding the camel-ognl dependency

```xml
<dependencies>
  ...
  <dependency>
    <groupId>org.apache.camel</groupId>
    <artifactId>camel-ognl</artifactId>
    <version>${camel-version}</version>
  </dependency>
  ...
</dependencies>
```

STATIC IMPORT

To use the ognl() static method in your application code, include the following import statement in your Java source files:

```java
import static org.apache.camel.language.ognl.OgnlExpression.ognl;
```

BUILT-IN VARIABLES

Table 21.1, “OGNL variables” lists the built-in variables that are accessible when using OGNL.

Table 21.1. OGNL variables

<table>
<thead>
<tr>
<th>Name</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>this</td>
<td>org.apache.camel.Exchange</td>
<td>The current Exchange</td>
</tr>
<tr>
<td>exchange</td>
<td>org.apache.camel.Exchange</td>
<td>The current Exchange</td>
</tr>
<tr>
<td>Name</td>
<td>Type</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------------</td>
<td>------------------------------------------------------------------</td>
</tr>
<tr>
<td>exception</td>
<td>Throwable</td>
<td>the Exchange exception (if any)</td>
</tr>
<tr>
<td>exchangeID</td>
<td>String</td>
<td>the Exchange ID</td>
</tr>
<tr>
<td>fault</td>
<td>org.apache.camel.Message</td>
<td>The Fault message(if any)</td>
</tr>
<tr>
<td>request</td>
<td>org.apache.camel.Message</td>
<td>The IN message</td>
</tr>
<tr>
<td>response</td>
<td>org.apache.camel.Message</td>
<td>The OUT message</td>
</tr>
<tr>
<td>properties</td>
<td>Map</td>
<td>The Exchange properties</td>
</tr>
<tr>
<td>property(name)</td>
<td>Object</td>
<td>The value of the named Exchange property</td>
</tr>
<tr>
<td>property(name, type)</td>
<td>Type</td>
<td>The typed value of the named Exchange property</td>
</tr>
</tbody>
</table>

**EXAMPLE**

Example 21.2, “Route using OGNL” shows a route that uses OGNL.

**Example 21.2. Route using OGNL**

```xml
<camelContext>
  <route>
    <from uri="seda:foo"/>
    <filter>
      <language langauge="ognl">request.headers.foo == 'bar'</language>
      <to uri="seda:bar"/>
    </filter>
  </route>
</camelContext>
```
CHAPTER 22. PHP

OVERVIEW

PHP is a widely-used general-purpose scripting language that is especially suited for Web development. The PHP support is part of the camel-script module.

ADDING THE SCRIPT MODULE

To use PHP in your routes you need to add a dependency on camel-script to your project as shown in Example 22.1, “Adding the camel-script dependency”.

Example 22.1. Adding the camel-script dependency

```xml
<!-- Maven POM File -->
...
<dependencies>
  ...
  <dependency>
    <groupId>org.apache.camel</groupId>
    <artifactId>camel-script</artifactId>
    <version>${camel-version}</version>
  </dependency>
  ...
</dependencies>
```

STATIC IMPORT

To use the `php()` static method in your application code, include the following import statement in your Java source files:

```java
import static org.apache.camel.builder.camel.script.ScriptBuilder.*;
```

BUILT-IN ATTRIBUTES

Table 22.1, “PHP attributes” lists the built-in attributes that are accessible when using PHP.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Type</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>context</td>
<td>org.apache.camel.CamelContext</td>
<td>The Camel Context</td>
</tr>
<tr>
<td>exchange</td>
<td>org.apache.camel.Exchange</td>
<td>The current Exchange</td>
</tr>
<tr>
<td>request</td>
<td>org.apache.camel.Message</td>
<td>The IN message</td>
</tr>
</tbody>
</table>
The attributes all set at **ENGINE_SCOPE**.

### EXAMPLE

Example 22.2, “Route using PHP” shows a route that uses PHP.

#### Example 22.2. Route using PHP

```xml
<camelContext>
  <route>
    <from uri="direct:start"/>
    <choice>
      <when>
        <language language="php">strpos(request.headers.get('user'), 'admin')!== FALSE</language>
        <to uri="seda:adminQueue"/>
      </when>
      <otherwise>
        <to uri="seda:regularQueue"/>
      </otherwise>
    </choice>
  </route>
</camelContext>
```

### USING THE PROPERTIES COMPONENT

To access a property value from the properties component, invoke the `resolve` method on the built-in `properties` attribute, as follows:

```
.setHeader("myHeader").php("properties.resolve(PropKey)")
```

Where `PropKey` is the key of the property you want to resolve, where the key value is of `String` type.

For more details about the properties component, see .
CHAPTER 23. PROPERTY

OVERVIEW

The property language provides a convenient way of accessing exchange properties. When you supply a key that matches one of the exchange property names, the property language returns the corresponding value.

The property language is part of camel-core.

XML EXAMPLE

For example, to implement the recipient list pattern when the listOfEndpoints exchange property contains the recipient list, you could define a route as follows:

```xml
<camelContext>
  <route>
    <from uri="direct:a"/>
    <recipientList>
      <property>listOfEndpoints</property>
    </recipientList>
  </route>
</camelContext>
```

JAVA EXAMPLE

The same recipient list example can be implemented in Java as follows:

```java
from("direct:a").recipientList(property("listOfEndpoints"));
```
CHAPTER 24. PYTHON

OVERVIEW

Python is a remarkably powerful dynamic programming language that is used in a wide variety of application domains. Python is often compared to Tcl, Perl, Ruby, Scheme or Java. The Python support is part of the camel-script module.

ADDING THE SCRIPT MODULE

To use Python in your routes you need to add a dependency on camel-script to your project as shown in Example 24.1, “Adding the camel-script dependency”.

Example 24.1. Adding the camel-script dependency

```xml
<!-- Maven POM File -->
...
<dependencies>
...
  <dependency>
    <groupId>org.apache.camel</groupId>
    <artifactId>camel-script</artifactId>
    <version>${camel-version}</version>
  </dependency>
...
</dependencies>
```

STATIC IMPORT

To use the python() static method in your application code, include the following import statement in your Java source files:

```java
import static org.apache.camel.builder.camel.script.ScriptBuilder.*;
```

BUILT-IN ATTRIBUTES

Table 24.1, “Python attributes” lists the built-in attributes that are accessible when using Python.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Type</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>context</td>
<td>org.apache.camel.CamelContext</td>
<td>The Camel Context</td>
</tr>
<tr>
<td>exchange</td>
<td>org.apache.camel.Exchange</td>
<td>The current Exchange</td>
</tr>
<tr>
<td>Attribute</td>
<td>Type</td>
<td>Value</td>
</tr>
<tr>
<td>--------------</td>
<td>-----------------------------------------------</td>
<td>----------------------------------------------------------------------</td>
</tr>
<tr>
<td>request</td>
<td>org.apache.camel.Message</td>
<td>The IN message</td>
</tr>
<tr>
<td>response</td>
<td>org.apache.camel.Message</td>
<td>The OUT message</td>
</tr>
<tr>
<td>properties</td>
<td>org.apache.camel.builder.script.PropertiesFunction</td>
<td>Function with a <code>resolve</code> method to make it easier to use the properties component inside scripts.</td>
</tr>
</tbody>
</table>

The attributes all set at `ENGINE_SCOPE`.

**EXAMPLE**

Example 24.2, “Route using Python” shows a route that uses Python.

**Example 24.2. Route using Python**

```xml
<camelContext>
  <route>
    <from uri="direct:start"/>
    <choice>
      <when>
        <language language="python">if request.headers.get('user') = 'admin'</language>
        <to uri="seda:adminQueue"/>
      </when>
      <otherwise>
        <to uri="seda:regularQueue"/>
      </otherwise>
    </choice>
  </route>
</camelContext>
```

**USING THE PROPERTIES COMPONENT**

To access a property value from the properties component, invoke the `resolve` method on the built-in `properties` attribute, as follows:

```java
.setHeader("myHeader").python("properties.resolve(PropKey)")
```

Where `PropKey` is the key of the property you want to resolve, where the key value is of `String` type.

For more details about the properties component, see .
CHAPTER 25. REF

OVERVIEW

The Ref expression language is really just a way to look up a custom Expression from the Registry. This is particularly convenient to use in the XML DSL.

The Ref language is part of camel-core.

STATIC IMPORT

To use the Ref language in your Java application code, include the following import statement in your Java source files:

```java
import static org.apache.camel.language.simple.RefLanguage.ref;
```

XML EXAMPLE

For example, the splitter pattern can reference a custom expression using the Ref language, as follows:

```xml
<beans ...>
  <bean id="myExpression" class="com.mycompany.MyCustomExpression"/>
  ...
  <camelContext>
    <route>
      <from uri="seda:a"/>
      <split>
        <ref>myExpression</ref>
        <to uri="mock:b"/>
      </split>
    </route>
  </camelContext>
</beans>
```

JAVA EXAMPLE

The preceding route can also be implemented in the Java DSL, as follows:

```java
from("seda:a")
  .split().ref("myExpression")
  .to("seda:b");
```
CHAPTER 26. RUBY

OVERVIEW

Ruby is a dynamic, open source programming language with a focus on simplicity and productivity. It has an elegant syntax that is natural to read and easy to write. The Ruby support is part of the camel-script module.

ADDING THE SCRIPT MODULE

To use Ruby in your routes you need to add a dependency on camel-script to your project as shown in Example 26.1, “Adding the camel-script dependency”.

Example 26.1. Adding the camel-script dependency

```xml
<dependencies>
  ...
  <dependency>
    <groupId>org.apache.camel</groupId>
    <artifactId>camel-script</artifactId>
    <version>${camel-version}</version>
  </dependency>
  ...
</dependencies>
```

STATIC IMPORT

To use the ruby() static method in your application code, include the following import statement in your Java source files:

```java
import static org.apache.camel.builder.camel.script.ScriptBuilder.*;
```

BUILT-IN ATTRIBUTES

Table 26.1, “Ruby attributes” lists the built-in attributes that are accessible when using Ruby.

Table 26.1. Ruby attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Type</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>context</td>
<td>org.apache.camel.CamelContext</td>
<td>The Camel Context</td>
</tr>
<tr>
<td>exchange</td>
<td>org.apache.camel.Exchange</td>
<td>The current Exchange</td>
</tr>
</tbody>
</table>
The attributes all set at `ENGINE_SCOPE`.

**EXAMPLE**

Example 26.2, “Route using Ruby” shows a route that uses Ruby.

```xml
<camelContext>
  <route>
    <from uri="direct:start"/>
    <choice>
      <when>
        <language langauge="ruby">$request.headers['user'] == 'admin'</language>
        <to uri="seda:adminQueue"/>
      </when>
      <otherwise>
        <to uri="seda:regularQueue"/>
      </otherwise>
    </choice>
  </route>
</camelContext>
```

**USING THE PROPERTIES COMPONENT**

To access a property value from the properties component, invoke the `resolve` method on the built-in `properties` attribute, as follows:

```java
.setHeader("myHeader").ruby("properties.resolve(PropKey)")
```

Where `PropKey` is the key of the property you want to resolve, where the key value is of `String` type.

For more details about the properties component, see .
CHAPTER 27. THE SIMPLE LANGUAGE

Abstract

The simple language is a language that was developed in Apache Camel specifically for the purpose of accessing and manipulating the various parts of an exchange object. The language is not quite as simple as when it was originally created and it now features a comprehensive set of logical operators and conjunctions.

27.1. JAVA DSL

Simple expressions in Java DSL

In the Java DSL, there are two styles for using the simple() command in a route. You can either pass the simple() command as an argument to a processor, as follows:

```java
from("seda:order")
  .filter(simple("${in.header.foo}"))
  .to("mock:fooOrders");
```

Or you can call the simple() command as a sub-clause on the processor, for example:

```java
from("seda:order")
  .filter()
  .simple("${in.header.foo}")
  .to("mock:fooOrders");
```

Embedding in a string

If you are embedding a simple expression inside a plain text string, you must use the placeholder syntax, `$Expression$`. For example, to embed the `in.header.name` expression in a string:

```java
simple("Hello ${in.header.name}, how are you?")
```

Customizing the start and end tokens

From Java, you can customize the start and end tokens ({} and }, by default) by calling the changeFunctionStartToken static method and the changeFunctionEndToken static method on the SimpleLanguage object.

For example, you can change the start and end tokens to [ and ] in Java, as follows:

```java
// Java
import org.apache.camel.language.simple.SimpleLanguage;
...
SimpleLanguage.changeFunctionStartToken("[");
SimpleLanguage.changeFunctionEndToken("]");
```
27.2. XML DSL

Simple expressions in XML DSL

In the XML DSL, you can use a simple expression by putting the expression inside a `simple` element. For example, to define a route that performs filtering based on the contents of the `foo` header:

```xml
<route id="simpleExample">
  <from uri="seda:orders"/>
  <filter>
    <simple>${in.header.foo}</simple>
    <to uri="mock:fooOrders"/>
  </filter>
</route>
```

Alternative placeholder syntax

Sometimes—for example, if you have enabled Spring property placeholders or OSGi blueprint property placeholders—you might find that the `${Expression}` syntax clashes with another property placeholder syntax. In this case, you can disambiguate the placeholder using the alternative syntax, `$simple{Expression}`, for the simple expression. For example:

```xml
<simple>Hello $simple{in.header.name}, how are you?</simple>
```

Customizing the start and end tokens

From XML configuration, you can customize the start and end tokens ({} and {}, by default) by overriding the `SimpleLanguage` instance. For example, to change the start and end tokens to [ ] and ], define a new `SimpleLanguage` bean in your XML configuration file, as follows:

```xml
<bean id="simple" class="org.apache.camel.language.simple.SimpleLanguage">
  <constructor-arg name="functionStartToken" value="["/>
  <constructor-arg name="functionEndToken" value="]"/>
</bean>
```

NOTE

Customizing the start and end tokens affects all Apache Camel applications that share the same camel-core library on their classpath. For example, in an OSGi server this might affect many applications; whereas in a Web application (WAR file) it would affect only the Web application itself.
Whitespace and auto-trim in XML DSL

By default, whitespace preceding and following a simple expression is automatically trimmed in XML DSL. So this expression with surrounding whitespace:

```xml
<transform>
  <simple>
    data=${body}
  </simple>
</transform>
```

is automatically trimmed, so that it is equivalent to this expression (no surrounding whitespace):

```xml
<transform>
  <simple data=${body} />
</transform>
```

If you want to include newlines before or after the expression, you can either explicitly add a newline character, as follows:

```xml
<transform>
  <simple data=${body} \n />
</transform>
```

or you can switch off auto-trimming, by setting the trim attribute to false, as follows:

```xml
<transform trim="false">
  <simple data=${body} />
</simple>
</transform>
```

27.3. INVOKING AN EXTERNAL SCRIPT

Overview

It is possible to execute Simple scripts that are stored in an external resource, as described here.

Syntax for script resource

Use the following syntax to access a Simple script that is stored as an external resource:

```xml
resource:Scheme:Location
```

Where the Scheme can be either classpath:, file:, or http:.

For example, to read the mysimple.txt script from the classpath,

```xml
simple("resource:classpath:mysimple.txt")
```
27.4. EXPRESSIONS

Overview

The simple language provides various elementary expressions that return different parts of a message exchange. For example, the expression, `simple("${header.timeOfDay}"), would return the contents of a header called `timeOfDay` from the incoming message.

**NOTE**

Since Apache Camel 2.9, you must *always* use the placeholder syntax, `${Expression}`, to return a variable value. It is never permissible to omit the enclosing tokens (`{$` and `}`).

Contents of a single variable

You can use the simple language to define string expressions, based on the variables provided. For example, you can use a variable of the form, `in.header.HeaderName`, to obtain the value of the `HeaderName` header, as follows:

```java
simple("${in.header.foo}"
```

Variables embedded in a string

You can embed simple variables in a string expression—for example:

```java
simple("Received a message from ${in.header.user} on
${(date:in.header.date:yyyyMMdd)."
```

date and bean variables

As well as providing variables that access all of the different parts of an exchange (see Table 27.1, “Variables for the Simple Language”), the simple language also provides special variables for formatting dates, `date:command:pattern`, and for calling bean methods, `bean:beanRef`. For example, you can use the date and the bean variables as follows:

```java
simple("Todays date is ${date:now:yyyyMMdd}"
simple("The order type is ${bean:orderService?method=getOrderType}"
```

Specifying the result type

You can specify the result type of an expression explicitly. This is mainly useful for converting the result type to a boolean or numerical type.

In the Java DSL, specify the result type as an extra argument to `simple()`. For example, to return a boolean result, you could evaluate a simple expression as follows:

```java
... .setHeader("cool", simple("true", Boolean.class))
```

In the XML DSL, specify the result type using the `resultType` attribute. For example:
Nested expressions

Simple expressions can be nested—for example:

```xml
<setHeader headerName="cool">
  <!-- use resultType to indicate that the type should be a java.lang.Boolean -->
  <simple resultType="java.lang.Boolean">true</simple>
</setHeader>
```

Accessing constants or enums

You can access a bean's constant or enum fields using the following syntax:

```java
type:ClassName.Field
```

For example, consider the following Java enum type:

```java
package org.apache.camel.processor;
...
public enum Customer {
  GOLD, SILVER, BRONZE
}
```

You can access the Customer enum fields, as follows:

```java
from("direct:start")
  .choice()
    .when().simple("${header.customer} == ${type:org.apache.camel.processor.Customer.GOLD}")
      .to("mock:gold")
    .when().simple("${header.customer} == ${type:org.apache.camel.processor.Customer.SILVER}")
      .to("mock:silver")
    .otherwise()
      .to("mock:other");
```

OGNL expressions

The Object Graph Navigation Language (OGNL) is a notation for invoking bean methods in a chain-like fashion. If a message body contains a Java bean, you can easily access its bean properties using OGNL notation. For example, if the message body is a Java object with a `getAddress()` accessor, you can access the Address object and the Address object's properties as follows:

```java
simple("${body.address}")
simple("${body.address.street}")
simple("${body.address.zip}")
simple("${body.address.city}")
```
Where the notation, \( $\{\text{body.address.street}\} \), is shorthand for \( $\{\text{body.getAddress.getStreet}\} \).

**OGNL null-safe operator**

You can use the null-safe operator, \( ? \), to avoid encountering null-pointer exceptions, in case the body does not have an address. For example:

```java
simple("$\{\text{body?.address?.street}\}"")
```

If the body is a `java.util.Map` type, you can look up a value in the map with the key `foo`, using the following notation:

```java
simple("$\{\text{body[foo]?.name}\}"")
```

**OGNL list element access**

You can also use square brackets notation, \([k]\), to access the elements of a list. For example:

```java
simple("$\{\text{body.address.lines[0]}\}"")
simple("$\{\text{body.address.lines[1]}\}"")
simple("$\{\text{body.address.lines[2]}\}"")
```

The `last` keyword returns the index of the last element of a list. For example, you can access the second last element of a list, as follows:

```java
simple("$\{\text{body.address.lines[last-1]}\}"")
```

You can use the `size` method to query the size of a list, as follows:

```java
simple("$\{\text{body.address.lines.size}\}"")
```

**OGNL array length access**

You can access the length of a Java array through the `length` method, as follows:

```java
String[] lines = new String[]{"foo", "bar", "cat"};
exchange.getIn().setBody(lines);
simple("There are $\{\text{body.length} \ lines\}"")
```

### 27.5. PREDICATES

**Overview**

You can construct predicates by testing expressions for equality. For example, the predicate, \( \text{simple("$\{\text{header.timeOfDay} \} == \ '14:30'\}"") } \), tests whether the `timeOfDay` header in the incoming message is equal to **14:30**.
Syntax

You can also test various parts of an exchange (headers, message body, and so on) using simple predicates. Simple predicates have the following general syntax:

\[ \text{$\{LHSVariable\} \, Op \, RHSValue} \]

Where the variable on the left hand side, \textit{LHSVariable}, is one of the variables shown in Table 27.1, “Variables for the Simple Language” and the value on the right hand side, \textit{RHSValue}, is one of the following:

- Another variable, \textit{$\{RHSVariable\}$}.
- A string literal, enclosed in single quotes, ‘ ’.
- A numeric constant, enclosed in single quotes, ‘ ’.
- The null object, \texttt{null}.

The simple language always attempts to convert the RHS value to the type of the LHS value.

**NOTE**

While the simple language will attempt to convert the RHS, depending on the operator the LHS may need to be cast into the appropriate Type before the comparison is made.

Examples

For example, you can perform simple string comparisons and numerical comparisons as follows:

```java
simple("${in.header.user} == 'john'")
simple("${in.header.number} > '100'")  // String literal can be converted to integer
```

You can test whether the left hand side is a member of a comma-separated list, as follows:

```java
simple("${in.header.type} in 'gold,silver'")
```

You can test whether the left hand side matches a regular expression, as follows:

```java
simple("${in.header.number} regex '\d{4}'")
```

You can test the type of the left hand side using the \texttt{is} operator, as follows:

```java
simple("${in.header.type} is 'java.lang.String'")
simple("${in.header.type} is 'String'") // You can abbreviate java.lang. types
```

You can test whether the left hand side lies in a specified numerical range (where the range is inclusive), as follows:
Conjunctions

You can also combine predicates using the logical conjunctions, `&&` and `||`.

For example, here is an expression using the `&&` conjunction (logical and):

```text
simple("${in.header.title} contains 'Camel' && ${in.header.type} == 'gold'")
```

And here is an expression using the `||` conjunction (logical inclusive or):

```text
simple("${in.header.title} contains 'Camel' || ${in.header.type} == 'gold'")
```

### 27.6. VARIABLE REFERENCE

#### Table of variables

Table 27.1, “Variables for the Simple Language” shows all of the variables supported by the simple language.

**Table 27.1. Variables for the Simple Language**

<table>

</tbody>
</table>
CHAPTER 28. SPEL

OVERVIEW

The Spring Expression Language (SpEL) is an object graph navigation language provided with Spring 3, which can be used to construct predicates and expressions in a route. A notable feature of SpEL is the ease with which you can access beans from the registry.

SYNTAX

The SpEL expressions must use the placeholder syntax, `{SpelExpression}`, so that they can be embedded in a plain text string (in other words, SpEL has expression templating enabled).

SpEL can also look up beans in the registry (typically, the Spring registry), using the `@BeanID` syntax. For example, given a bean with the ID `headerUtils`, and the method, `count()` (which counts the number of headers on the current message), you could use the `headerUtils` bean in an SpEL predicate, as follows:

```java
#{@headerUtils.count > 4}
```

ADDING SPEL PACKAGE

To use SpEL in your routes you need to add a dependency on `camel-spring` to your project as shown in Example 28.1, “Adding the camel-spring dependency”.

```xml
<dependencies>
  ...  
  <dependency>
    <groupId>org.apache.camel</groupId>
    <artifactId>camel-spring</artifactId>
    <version>${camel-version}</version>
  </dependency>
</dependencies>
```

VARIABLES

Table 28.1, “SpEL variables” lists the variables that are accessible when using SpEL.

Table 28.1. SpEL variables
<table>
<thead>
<tr>
<th>Variable</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>this</td>
<td>Exchange</td>
<td>The current exchange is the root object.</td>
</tr>
<tr>
<td>exchange</td>
<td>Exchange</td>
<td>The current exchange.</td>
</tr>

</tbody>
</table>

**XML EXAMPLE**

For example, to select only those messages whose **Country** header has the value **USA**, you can use the following SpEL expression:

```xml
<route>
  <from uri="SourceURL"/>
  <filter>
    <spel>#{request.headers['Country'] == 'USA'}}</spel>
  <to uri="TargetURL"/>
</filter>
</route>
```

**JAVA EXAMPLE**

You can define the same route in the Java DSL, as follows:

```java
from("SourceURL")
  .filter().spel("#{request.headers['Country'] == 'USA'}")
  .to("TargetURL");
```
The following example shows how to embed SpEL expressions within a plain text string:

```java
from("SourceURL")
  .setBody(spel("Hello #{request.body}! What a beautiful #
  {request.headers['dayOrNight']}"))
  .to("TargetURL");
```
CHAPTER 29. THE XPATH LANGUAGE

Abstract

When processing XML messages, the XPath language enables you to select part of a message, by specifying an XPath expression that acts on the message's Document Object Model (DOM). You can also define XPath predicates to test the contents of an element or an attribute.

29.1. JAVA DSL

Basic expressions

You can use `xpath("Expression")` to evaluate an XPath expression on the current exchange (where the XPath expression is applied to the body of the current In message). The result of the `xpath()` expression is an XML node (or node set, if more than one node matches).

For example, to extract the contents of the `/person/name` element from the current In message body and use it to set a header named `user`, you could define a route like the following:

```java
from("queue:foo")
    .setHeader("user", xpath("/person/name/text()"))
    .to("direct:tie");
```

Instead of specifying `xpath()` as an argument to `setHeader()`, you can use the fluent builder `xpath()` command—for example:

```java
from("queue:foo")
    .setHeader("user").xpath("/person/name/text()")
    .to("direct:tie");
```

If you want to convert the result to a specific type, specify the result type as the second argument of `xpath()`. For example, to specify explicitly that the result type is `String`:

```java
xpath("/person/name/text()", String.class)
```

Namespaces

Typically, XML elements belong to a schema, which is identified by a namespace URI. When processing documents like this, it is necessary to associate namespace URIs with prefixes, so that you can identify element names unambiguously in your XPath expressions. Apache Camel provides the helper class, `org.apache.camel.builder.xml.Namespaces`, which enables you to define associations between namespaces and prefixes.

For example, to associate the prefix, `cust`, with the namespace, `http://acme.com/customer/record`, and then extract the contents of the element, `/cust:person/cust:name`, you could define a route like the following:

```java
import org.apache.camel.builder.xml.Namespaces;
Where you make the namespace definitions available to the `xpath()` expression builder by passing the `Namespaces` object, `ns`, as an additional argument. If you need to define multiple namespaces, use the `Namespace.add()` method, as follows:

```java
import org.apache.camel.builder.xml.Namespaces;

Namespaces ns = new Namespaces("cust", "http://acme.com/customer/record");
ns.add("inv", "http://acme.com/invoice");
ns.add("xsi", "http://www.w3.org/2001/XMLSchema-instance");
```

If you need to specify the result type and define namespaces, you can use the three-argument form of `xpath()`, as follows:

```java
xpath("/person/name/text()", String.class, ns)
```

### Auditing namespaces

One of the most frequent problems that can occur when using XPath expressions is that there is a mismatch between the namespaces appearing in the incoming messages and the namespaces used in the XPath expression. To help you troubleshoot this kind of problem, the XPath language supports an option to dump all of the namespaces from all of the incoming messages into the system log.

To enable namespace logging at the `INFO` log level, enable the `logNamespaces` option in the Java DSL, as follows:

```java
xpath("/foo:person/@id", String.class).logNamespaces()
```

Alternatively, you could configure your logging system to enable `TRACE` level logging on the `org.apache.camel.builder.xml.XPathBuilder` logger.

When namespace logging is enabled, you will see log messages like the following for each processed message:

```
2012-01-16 13:23:45,878 [stSaxonWithFlag] INFO  XPathBuilder  -
Namespaces discovered in message: {xmlns:a=[http://apache.org/camel],
DEFAULT=[http://apache.org/default],
```

### 29.2. XML DSL

#### Basic expressions

To evaluate an XPath expression in the XML DSL, put the XPath expression inside an `xpath` element. The XPath expression is applied to the body of the current `In` message and returns an XML node (or node set). Typically, the returned XML node is automatically converted to
a string.

For example, to extract the contents of the /person/name element from the current message body and use it to set a header named user, you could define a route like the following:

```xml
<beans ...>
  <camelContext xmlns="http://camel.apache.org/schema/spring">
    <route>
      <from uri="queue:foo"/>
      <setHeader headerName="user">
        <xpath>/person/name/text()</xpath>
      </setHeader>
      <to uri="direct:tie"/>
    </route>
  </camelContext>
</beans>
```

If you want to convert the result to a specific type, specify the result type by setting the resultType attribute to a Java type name (where you must specify the fully-qualified type name). For example, to specify explicitly that the result type is java.lang.String (you can omit the java.lang. prefix here):

```xml
<xpath resultType="String">/person/name/text()</xpath>
```

**Namespaces**

When processing documents whose elements belong to one or more XML schemas, it is typically necessary to associate namespace URIs with prefixes, so that you can identify element names unambiguously in your XPath expressions. It is possible to use the standard XML mechanism for associating prefixes with namespace URIs. That is, you can set an attribute like this: xmlns:Prefix="NamespaceURI".

For example, to associate the prefix, cust, with the namespace, http://acme.com/customer/record, and then extract the contents of the element, /cust:person/cust:name, you could define a route like the following:

```xml
<beans ...>
  <camelContext xmlns="http://camel.apache.org/schema/spring"
    xmlns:cust="http://acme.com/customer/record">
    <route>
      <from uri="queue:foo"/>
      <setHeader headerName="user">
        <xpath>/cust:person/cust:name/text()</xpath>
      </setHeader>
      <to uri="direct:tie"/>
    </route>
  </camelContext>
</beans>
```
**Auditing namespaces**

One of the most frequent problems that can occur when using XPath expressions is that there is a mismatch between the namespaces appearing in the incoming messages and the namespaces used in the XPath expression. To help you troubleshoot this kind of problem, the XPath language supports an option to dump all of the namespaces from all of the incoming messages into the system log.

To enable namespace logging at the **INFO** log level, enable the `logNamespaces` option in the XML DSL, as follows:

```xml
<xpath logNamespaces="true" resultType="String">/foo:person/@id</xpath>
```

Alternatively, you could configure your logging system to enable **TRACE** level logging on the `org.apache.camel.builder.xml.XPathBuilder` logger.

When namespace logging is enabled, you will see log messages like the following for each processed message:

```
2012-01-16 13:23:45,878 [stSaxonWithFlag] INFO  XPathBuilder  -
Namespaces discovered in message: {xmlns:a=[http://apache.org/camel],
DEFAULT=[http://apache.org/default],
```

**29.3. XPATH INJECTION**

**Parameter binding annotation**

When using Apache Camel bean integration to invoke a method on a Java bean, you can use the `@XPath` annotation to extract a value from the exchange and bind it to a method parameter.

For example, consider the following route fragment, which invokes the `credit` method on an `AccountService` object:

```java
from("queue:payments")
  .beanRef("accountService","credit")
  ...
```

The `credit` method uses parameter binding annotations to extract relevant data from the message body and inject it into its parameters, as follows:

```java
public class AccountService {
  ...
  public void credit(
    @XPath("/transaction/transfer/receiver/text()") String name,
    @XPath("/transaction/transfer/amount/text()") String amount
  )
  {
    ...
  }
  ...
}
```
For more information about bean integration, see Section 2.4, “Bean Integration”.

**Namespaces**

Table 29.1, “Predefined Namespaces for @XPath” shows the namespaces that are predefined for XPath. You can use these namespace prefixes in the XPath expression that appears in the @XPath annotation.

**Table 29.1. Predefined Namespaces for @XPath**

<table>
<thead>
<tr>
<th>Namespace URI</th>
<th>Prefix</th>
</tr>
</thead>
<tbody>
<tr>
<td><a href="http://www.w3.org/2001/XMLSchema">http://www.w3.org/2001/XMLSchema</a></td>
<td>xsd</td>
</tr>
<tr>
<td><a href="http://www.w3.org/2003/05/soap-envelope">http://www.w3.org/2003/05/soap-envelope</a></td>
<td>soap</td>
</tr>
</tbody>
</table>

**Custom namespaces**

You can use the @NamespacePrefix annotation to define custom XML namespaces. Invoke the @NamespacePrefix annotation to initialize the namespaces argument of the @XPath annotation. The namespaces defined by @NamespacePrefix can then be used in the @XPath annotation’s expression value.

For example, to associate the prefix, `ex`, with the custom namespace, `http://fusesource.com/examples`, invoke the @XPath annotation as follows:

```java
public class AccountService {

    public void credit(  
        @XPath(  
            value = "/ex:transaction/ex:transfer/ex:receiver/text()",  
            namespaces = @NamespacePrefix(  
                prefix = "ex",  
                uri = "http://fusesource.com/examples"  
            )  
        ) String name,  
        @XPath(  
            value = "/ex:transaction/ex:transfer/ex:amount/text()",  
            namespaces = @NamespacePrefix(  
                prefix = "ex",  
                uri = "http://fusesource.com/examples"  
            )  
        ) String amount,  
    ) {  
        ...  
    }  
}
```

**29.4. XPATH BUILDER**
Overview

The `org.apache.camel.builder.xml.XPathBuilder` class enables you to evaluate XPath expressions independently of an exchange. That is, if you have an XML fragment from any source, you can use `XPathBuilder` to evaluate an XPath expression on the XML fragment.

Matching expressions

Use the `matches()` method to check whether one or more XML nodes can be found that match the given XPath expression. The basic syntax for matching an XPath expression using `XPathBuilder` is as follows:

```java
boolean matches = XPathBuilder
    .xpath("Expression")
    .matches(CamelContext, "XMLString");
```

Where the given expression, `Expression`, is evaluated against the XML fragment `XMLString`, and the result is true, if at least one node is found that matches the expression. For example, the following example returns `true`, because the XPath expression finds a match in the `xyz` attribute.

```java
boolean matches = XPathBuilder
    .xpath("/foo/bar/@xyz")
    .matches(getContext(), "<foo><bar xyz='cheese'/>
          </foo>");
```

Evaluating expressions

Use the `evaluate()` method to return the contents of the first node that matches the given XPath expression. The basic syntax for evaluating an XPath expression using `XPathBuilder` is as follows:

```java
String nodeValue = XPathBuilder
    .xpath("Expression")
    .evaluate(CamelContext, "XMLString");
```

You can also specify the result type by passing the required type as the second argument to `evaluate()`—for example:

```java
String name = XPathBuilder
    .xpath("foo/bar")
    .evaluate(context, "<foo><bar>cheese</bar></foo>",
    String.class);
Integer number = XPathBuilder
    .xpath("foo/bar")
    .evaluate(context, "<foo><bar>123</bar></foo>",
    Integer.class);
Boolean bool = XPathBuilder
    .xpath("foo/bar")
    .evaluate(context, "<foo><bar>true</bar></foo>",
    Boolean.class);
```

29.5. ENABLING SAXON
Prerequisites
A prerequisite for using the Saxon parser is that you add a dependency on the camel-saxon artifact (either adding this dependency to your Maven POM, if you use Maven, or adding the camel-saxon-6.1.0.redhat-379.jar file to your classpath, otherwise).

Using the Saxon parser in Java DSL
In Java DSL, the simplest way to enable the Saxon parser is to call the saxon() fluent builder method. For example, you could invoke the Saxon parser as shown in the following example:

```java
// Java
// create a builder to evaluate the xpath using saxon
XPathBuilder builder = XPathBuilder.xpath("tokenize(/foo/bar, '_') [2]").saxon();

// evaluate as a String result
String result = builder.evaluate(context, "<foo><bar>abc_def_ghi</bar></foo>");
```

Using the Saxon parser in XML DSL
In XML DSL, the simplest way to enable the Saxon parser is to set the saxon attribute to true in the xpath element. For example, you could invoke the Saxon parser as shown in the following example:

```xml
<xpath saxon="true" resultType="java.lang.String">current-dateTime()</xpath>
```

Programming with Saxon
If you want to use the Saxon XML parser in your application code, you can create an instance of the Saxon transformer factory explicitly using the following code:

```java
// Java
import javax.xml.transform.TransformerFactory;
import net.sf.saxon.TransformerFactoryImpl;
...
TransformerFactory saxonFactory = new net.sf.saxon.TransformerFactoryImpl();
```

On the other hand, if you prefer to use the generic JAXP API to create a transformer factory instance, you must first set the javax.xml.transform.TransformerFactory property in the ESBInstall/etc/system.properties file, as follows:

```
javax.xml.transform.TransformerFactory=net.sf.saxon.TransformerFactoryImpl
```

You can then instantiate the Saxon factory using the generic JAXP API, as follows:

```java
// Java
import javax.xml.transform.TransformerFactory;
...
```
TransformerFactory factory = TransformerFactory.newInstance();

If your application depends on any third-party libraries that use Saxon, it might be necessary to use the second, generic approach.

NOTE
The Saxon library must be installed in the container as the OSGi bundle, net.sf.saxon/saxon9he (normally installed by default). In versions of Fuse ESB prior to 7.1, it is not possible to load Saxon using the generic JAXP API.

29.6. EXPRESSIONS

Result type
By default, an XPath expression returns a list of one or more XML nodes, of org.w3c.dom.NodeList type. You can use the type converter mechanism to convert the result to a different type, however. In the Java DSL, you can specify the result type in the second argument of the xpath() command. For example, to return the result of an XPath expression as a String:

```java
xpath("/person/name/text()", String.class)
```

In the XML DSL, you can specify the result type in the resultType attribute, as follows:

```xml
<xpath resultType="java.lang.String">/person/name/text()</xpath>
```

Patterns in location paths
You can use the following patterns in XPath location paths:

/people/person

The basic location path specifies the nested location of a particular element. That is, the preceding location path would match the person element in the following XML fragment:

```xml
<people>
    <person>...</person>
</people>
```

Note that this basic pattern can match multiple nodes—for example, if there is more than one person element inside the people element.

/name/text()

If you just want to access the text inside by the element, append/text() to the location path, otherwise the node includes the element's start and end tags (and these tags would be included when you convert the node to a string).

/person/telephone/@isDayTime

To select the value of an attribute, AttributeName, use the syntax @AttributeName. For example, the preceding location path returns true when applied to the following XML fragment:
A wildcard that matches all elements in the specified scope. For example, 
/people/person/* matches all the child elements of person.

@*
A wildcard that matches all attributes of the matched elements. For example, 
/person/name/@* matches all attributes of every matched name element.

//
Match the location path at every nesting level. For example, the //name pattern matches every name element highlighted in the following XML fragment:

```
<invoice>
  <person>
    <name .../>
  </person>
</invoice>
```

Selects the parent of the current context node. Not normally useful in the Apache Camel XPath language, because the current context node is the document root, which has no parent.

default (node())
Match any kind of node.

text()
Match a text node.

comment()
Match a comment node.

processing-instruction()
Match a processing-instruction node.

**Predicate filters**

You can filter the set of nodes matching a location path by appending a predicate in square brackets, [Predicate]. For example, you can select the $N^{th}$ node from the list of matches by appending \([N]\) to a location path. The following expression selects the first matching person element:
The following expression selects the second-last `person` element:

```
/people/person[1]
```

You can test the value of attributes in order to select elements with particular attribute values. The following expression selects the `name` elements, whose `surname` attribute is either Strachan or Davies:

```
/person/name[@surname="Strachan" or @surname="Davies"]
```

You can combine predicate expressions using any of the conjunctions `and`, `or`, `not()`, and you can compare expressions using the comparators, `=`, `!=`, `>`, `>=`, `<`, `<=` (in practice, the less-than symbol must be replaced by the `&lt;` entity). You can also use XPath functions in the predicate filter.

### Axes

When you consider the structure of an XML document, the root element contains a sequence of children, and some of those child elements contain further children, and so on. Looked at in this way, where nested elements are linked together by the `child-of` relationship, the whole XML document has the structure of a tree. Now, if you choose a particular node in this element tree (call it the `context node`), you might want to refer to different parts of the tree relative to the chosen node. For example, you might want to refer to the children of the context node, to the parent of the context node, or to all of the nodes that share the same parent as the context node (`sibling nodes`).

An XPath axis is used to specify the scope of a node match, restricting the search to a particular part of the node tree, relative to the current context node. The axis is attached as a prefix to the node name that you want to match, using the syntax, `AxisType::MatchingNode`. For example, you can use the `child::` axis to search the children of the current context node, as follows:

```
/invoice/items/child::item
```

The context node of `child::item` is the `items` element that is selected by the path, `/invoice/items`. The `child::` axis restricts the search to the children of the context node, `items`, so that `child::item` matches the children of `items` that are named `item`. As a matter of fact, the `child::` axis is the default axis, so the preceding example can be written equivalently as:

```
/invoice/items/item
```

But there several other axes (13 in all), some of which you have already seen in abbreviated form: `@` is an abbreviation of `attribute::`, and `//` is an abbreviation of `descendant-or-self::`. The full list of axes is as follows (for details consult the reference below):

- `ancestor`
- `ancestor-or-self`
Functions

XPath provides a small set of standard functions, which can be useful when evaluating predicates. For example, to select the last matching node from a node set, you can use the last() function, which returns the index of the last node in a node set, as follows:

```
/people/person[last()]
```

Where the preceding example selects the last `person` element in a sequence (in document order).

For full details of all the functions that XPath provides, consult the reference below.

Reference

For full details of the XPath grammar, see the XML Path Language, Version 1.0 specification.

29.7. PREDICATES

Basic predicates

You can use `xpath` in the Java DSL or the XML DSL in a context where a predicate is expected—for example, as the argument to a `filter()` processor or as the argument to a `when()` clause.

For example, the following route filters incoming messages, allowing a message to pass, only if the `/person/city` element contains the value, London:

```
from("direct:tie")
  .filter().xpath("/person/city = 'London'").to("file:target/messages/uk");
```
The following route evaluates the XPath predicate in a `when()` clause:

```
from("direct:tie")
 .choice()
   .when(xpath("/person/city = 'London'"))
     .to("file:target/messages/uk")
   .otherwise().to("file:target/messages/others");
```

**XPath predicate operators**

The XPath language supports the standard XPath predicate operators, as shown in Table 29.2, “Operators for the XPath Language”.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>=</code></td>
<td>Equals.</td>
</tr>
<tr>
<td><code>!=</code></td>
<td>Not equal to.</td>
</tr>
<tr>
<td><code>&gt;</code></td>
<td>Greater than.</td>
</tr>
<tr>
<td><code>&gt;=</code></td>
<td>Greater than or equals.</td>
</tr>
<tr>
<td><code>&lt;</code></td>
<td>Less than.</td>
</tr>
<tr>
<td><code>&lt;=</code></td>
<td>Less than or equals.</td>
</tr>
<tr>
<td><code>or</code></td>
<td>Combine two predicates with logical \textit{and}.</td>
</tr>
<tr>
<td><code>and</code></td>
<td>Combine two predicates with logical \textit{inclusive or}.</td>
</tr>
<tr>
<td><code>not()</code></td>
<td>Negate predicate argument.</td>
</tr>
</tbody>
</table>

29.8. USING VARIABLES AND FUNCTIONS

**Evaluating variables in a route**

When evaluating XPath expressions inside a route, you can use XPath variables to access the contents of the current exchange, as well as O/S environment variables and Java system properties. The syntax to access a variable value is `\textdollar\textit{VarName}` or `\textdollar\textit{Prefix:VarName}`, if the variable is accessed through an XML namespace.

For example, you can access the \textit{In} message's body as `\textdollar\textit{in:body}` and the \textit{In} message's header value as `\textdollar\textit{in:HeaderName}`. O/S environment variables can be accessed as `\textdollar\textit{env:EnvVar}` and Java system properties can be accessed as `\textdollar\textit{system:SysVar}`.

In the following example, the first route extracts the value of the \textit{/person/city} element
and inserts it into the `city` header. The second route filters exchanges using the XPath expression, `$in:city = 'London'`, where the `$in:city` variable is replaced by the value of the `city` header.

```java
from("file:src/data?noop=true")
  .setHeader("city").xpath("/person/city/text()")
  .to("direct:tie");

from("direct:tie")
  .filter().xpath("$in:city = 'London'").to("file:target/messages/uk");
```

### Evaluating functions in a route

In addition to the standard XPath functions, the XPath language defines additional functions. These additional functions (which are listed in Table 29.4, “XPath Custom Functions”) can be used to access the underlying exchange, to evaluate a simple expression or to look up a property in the Apache Camel property placeholder component.

For example, the following example uses the `in:header()` function and the `in:body()` function to access a head and the body from the underlying exchange:

```java
from("direct:start").choice()
  .when().xpath("in:header('foo') = 'bar'").to("mock:x")
  .when().xpath("in:body() = '<two/>'").to("mock:y")
  .otherwise().to("mock:z");
```

Notice the similarity between these functions and the corresponding `in:HeaderName` or `in:body` variables. The functions have a slightly different syntax however: `in:header('HeaderName')` instead of `in:HeaderName`; and `in:body()` instead of `in:body`.

### Evaluating variables in XPathBuilder

You can also use variables in expressions that are evaluated using the `XPathBuilder` class. In this case, you cannot use variables such as `$in:body` or `$in:HeaderName`, because there is no exchange object to evaluate against. But you can use variables that are defined inline using the `variable(Name, Value)` fluent builder method.

For example, the following XPathBuilder construction evaluates the `$test` variable, which is defined to have the value, `London`:

```java
String var = XPathBuilder.xpath("$test")
  .variable("test", "London")
  .evaluate(getContext(), "<name>foo</name>");
```

Note that variables defined in this way are automatically entered into the global namespace (for example, the variable, `$test`, uses no prefix).

### 29.9. VARIABLE NAMESPACES

#### Table of namespaces

Table 29.3, “XPath Variable Namespaces” shows the namespace URIs that are associated with the various namespace prefixes.
### Table 29.3. XPath Variable Namespaces

<table>
<thead>
<tr>
<th>Namespace URI</th>
<th>Prefix</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><a href="http://camel.apache.org/schema/spring">http://camel.apache.org/schema/spring</a></td>
<td>None</td>
<td>Default namespace (associated with variables that have no namespace prefix).</td>
</tr>
<tr>
<td><a href="http://camel.apache.org/xml/in/">http://camel.apache.org/xml/in/</a></td>
<td>in</td>
<td>Used to reference header or body of the current exchange's In message.</td>
</tr>
<tr>
<td><a href="http://camel.apache.org/xml/out/">http://camel.apache.org/xml/out/</a></td>
<td>out</td>
<td>Used to reference header or body of the current exchange's Out message.</td>
</tr>
<tr>
<td><a href="http://camel.apache.org/xml/functions/">http://camel.apache.org/xml/functions/</a></td>
<td>functions</td>
<td>Used to reference some custom functions.</td>
</tr>
<tr>

<td>Looks up a property with the key, <code>PropKey</code> (see Section 2.7, “Property Placeholders”).</td>
</tr>
<tr>
<td><code>function:simple(SimpleExp)</code></td>
<td>Evaluates the specified simple expression, <code>SimpleExp</code>.</td>
</tr>
</tbody>
</table>
CHAPTER 30. XQUERY

OVERVIEW

XQuery was originally devised as a query language for data stored in XML form in a database. The XQuery language enables you to select parts of the current message, when the message is in XML format. XQuery is a superset of the XPath language; hence, any valid XPath expression is also a valid XQuery expression.

JAVA SYNTAX

You can pass an XQuery expression to `xquery()` in several ways. For simple expressions, you can pass the XQuery expressions as a string (`java.lang.String`). For longer XQuery expressions, you might prefer to store the expression in a file, which you can then reference by passing a `java.io.File` argument or a `java.net.URL` argument to the overloaded `xquery()` method. The XQuery expression implicitly acts on the message content and returns a node set as the result. Depending on the context, the return value is interpreted either as a predicate (where an empty node set is interpreted as false) or as an expression.

ADDING THE SAXON MODULE

To use XQuery in your routes you need to add a dependency on `camel-saxon` to your project as shown in Example 30.1, “Adding the camel-saxon dependency”.

Example 30.1. Adding the camel-saxon dependency

```xml
<!-- Maven POM File -->
...
<dependencies>
...
  <dependency>
    <groupId>org.apache.camel</groupId>
    <artifactId>camel-saxon</artifactId>
    <version>${camel-version}</version>
  </dependency>
...
</dependencies>
```

STATIC IMPORT

To use the `xquery()` static method in your application code, include the following import statement in your Java source files:

```java
import static org.apache.camel.builder.saxon.XQueryBuilder.xquery;
```

VARIABLES

Table 30.1, “XQuery variables” lists the variables that are accessible when using XQuery.
Table 30.1. XQuery variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>exchange</td>
<td>Exchange</td>
<td>The current Exchange</td>
</tr>
<tr>
<td>in.body</td>
<td>Object</td>
<td>The body of the IN message</td>
</tr>
<tr>
<td>out.body</td>
<td>Object</td>
<td>The body of the OUT message</td>
</tr>
<tr>
<td>in.headers.key</td>
<td>Object</td>
<td>The IN message header whose key is key</td>
</tr>
<tr>
<td>out.headers.key</td>
<td>Object</td>
<td>The OUT message header whose key is key</td>
</tr>
<tr>
<td>key</td>
<td>Object</td>
<td>The Exchange property whose key is key</td>
</tr>
</tbody>
</table>

EXAMPLE

Example 30.2, “Route using XQuery” shows a route that uses XQuery.

```xml
<camelContext>
  <route>
    <from uri="activemq:MyQueue"/>
    <filter>
      <language langauge="xquery">/foo:person[@name='James']</language>
      <to uri="mqseries:SomeOtherQueue"/>
    </filter>
  </route>
</camelContext>
```
PART III. WEB SERVICES AND ROUTING WITH CAMEL CXF

Abstract

This guide describes how to use Apache Camel's CXF component to create Web services or wrap existing functionality in Web service facades.
CHAPTER 31. DEMONSTRATION CODE FOR CAMEL/CXF

Abstract
This chapter explains how to install, build, and run the demonstrations that accompany this guide.

31.1. DOWNLOADING AND INSTALLING THE DEMONSTRATIONS

Overview
Most of the examples discussed in this guide are based on working demonstrations, which you can download and try out for yourself. The examples can easily be run by deploying them into a Red Hat JBoss Fuse container, as described here.

Prerequisites
For building and running the demonstration code, you must have the following prerequisites installed:

- **Java platform**—the demonstrations can run on Java 6 or Java 7.
- **Apache Maven build tool**—to build the demonstration, you require Apache Maven 3.0.4.
- **Internet connection**—Maven requires an Internet connection in order to download required dependencies from remote repositories while performing a build.
- **Red Hat JBoss Fuse**—the demonstrations are deployed into the JBoss Fuse container.

**NOTE**
For more details of the requirements for installing and working with JBoss Fuse, see "Installation Guide".

Downloading the demonstration package
The source code for the demonstrations is packaged as a Zip file, `cxf-webinars-jboss-fuse-6.1.zip`, and is available from the following location:

- `https://github.com/FuseByExample/cxf-webinars/archive/jboss-fuse-6.1.zip`

31.2. RUNNING THE DEMONSTRATIONS

Building the demonstrations
Use Apache Maven to build the demonstrations. Open a new command prompt, change directory to `cxf-webinars-jboss-fuse-6.1`, and enter the following commands:
The first invocation of `mvn install` is to install the parent POM in your local Maven repository (so that it is available for the main build step).

The second invocation of `mvn install` is the main build step. This command builds all of the demonstrations under the `cxf-webinars-jboss-fuse-6.1` directory (where the demonstrations are defined to be submodules of the `cxf-webinars-jboss-fuse-6.1/pom.xml` project). While Maven is building the demonstration code, it downloads whatever dependencies it needs from the Internet and installs them in the local Maven repository.

### Starting and configuring the Red Hat JBoss Fuse container

Start and configure the Red Hat JBoss Fuse container as follows:

1. *(Optional)* If your local Maven repository is in a non-standard location, you might need to edit the JBoss Fuse configuration to specify your custom location. Edit the `InstallDir/etc/org.ops4j.pax.url.mvn.cfg` file and set the `org.ops4j.pax.url.mvn.localRepository` property to the location of your local Maven repository:

   ```
   # Path to the local maven repository which is used to avoid downloading artifacts when they already exist locally.
   # The value of this property will be extracted from the settings.xml file
   # above, or defaulted to:
   #      System.getProperty( "user.home" ) + "/.m2/repository"
   #
   #org.ops4j.pax.url.mvn.localRepository=org.ops4j.pax.url.mvn.localRepository=file:E:/Data/.m2/repository
   
   ./fuse
   ```

2. Launch the JBoss Fuse container. Open a new command prompt, change directory to `InstallDir/bin`, and enter the following command:

   ```bash
   ./fuse
   ```

### Running the customer-ws-osgi-bundle demonstration

It is now a relatively straightforward task to run each of the demonstrations by installing the relevant OSGi bundles.

For example, to start up the WSDL-first Web service (discussed in Chapter 33, *WSDL-First Service Implementation*), enter the following console commands:

```bash
JBossFuse:karaf@root> install -s mvn:com.fusesource.byexample.cxf-webinars/customer-ws-osgi-bundle
```
To see the Web service in action, start up the sample Web service client (discussed in Chapter 34, *Implementing a WS Client*), by entering the following console command:

```
JBossFuse:karaf@root> install -s mvn:com.fusesource.byexample.cxf-webinars/customer-ws-client
```

The bundle creates a thread that invokes the Web service once a second and logs the response. View the log by entering the following console command:

```
JBossFuse:karaf@root> log:tail -n 4
```

You should see log output like the following:

```
18:03:58,609 | INFO  | qtp5581640-231   | CustomerServiceImpl
| ?                                   ? |
| 218 - org.fusesource.sparks.fuse-webinars.cxf-webinars.customer-ws-osgi-bundle - 1.1.4 | Getting status for customer 1234
18:03:58,687 | INFO  |  invoker thread. | ClientInvoker
| ?                                   ? |
| 219 - org.fusesource.sparks.fuse-webinars.cxf-webinars.customer-ws-client
- 1.1.4 | Got back: status = Active, statusMessage = In the park, playing with my frisbee.
18:04:00,687 | INFO  | qtp5581640-232   | CustomerServiceImpl
| ?                                   ? |
| 218 - org.fusesource.sparks.fuse-webinars.cxf-webinars.customer-ws-osgi-bundle - 1.1.4 | Getting status for customer 1234
18:04:00,703 | INFO  |  invoker thread. | ClientInvoker
| ?                                   ? |
| 219 - org.fusesource.sparks.fuse-webinars.cxf-webinars.customer-ws-client
- 1.1.4 | Got back: status = Active, statusMessage = In the park, playing with my frisbee.
```

To stop viewing the log, type the interrupt character (usually Ctrl-C).

To stop the client, first discover the client's bundle ID using the `osgi:list` console command. For example:

```
JBossFuse:karaf@root> list | grep customer-ws-client
[ 219] [Active     ] [            ] [Started] [   60] customer-ws-client (1.1.4)
```

You can then stop the client using the `osgi:stop` console command. For example:

```
JBossFuse:karaf@root> stop 219
```

To shut down the container completely, enter the following console command:

```
JBossFuse:karaf@root> shutdown -f
```

**Running the other demonstrations**
The remaining demonstrations are all based on the Camel CXF component. You can only run one of these demonstrations at a time, because they all use the same Web service port and would clash, if started at the same time:

- customer-ws-camel-cxf-pojo
- customer-ws-camel-cxf-payload
- customer-ws-camel-cxf-provider

The preceding demonstrations all require the Camel CXF component and some of them require the Camel Velocity component as well. Before you run the demonstrations, you must install the requisite features for these Camel components, as follows:

```
JBossFuse:karaf@root> features:install camel-cxf
JBossFuse:karaf@root> features:install camel-velocity
```

You can test these demonstrations using the provided `customer-ws-client` client or using the third-party SoapUI utility.
CHAPTER 32. JAVA-FIRST SERVICE IMPLEMENTATION

32.1. JAVA-FIRST OVERVIEW

Overview

The Java-first approach is a convenient way to get started with Web services, if you are unfamiliar with WSDL syntax. Using this approach, you can define the Web service interface using an ordinary Java interface and then use the provided Apache CXF utilities to generate the corresponding WSDL contract from the Java interface.

NOTE

There is no demonstration code to accompany this example.

Service Endpoint Interface (SEI)

An SEI is an ordinary Java interface. In order to use the standard JAX-WS frontend, the SEI must be annotated with the `@WebService` annotation.[1]

In the Java-first approach, the SEI is the starting point for implementing the Web service and it plays a central role in the development of the Web service implementation. The SEI is used in the following ways:

- **Base type of the Web service implementation (server side)—**you define the Web service by implementing the SEI.
- **Proxy type (client side)—**on the client side, you use the SEI to invoke operations on the client proxy object.
- **Basis for generating the WSDL contract—**in the Java-first approach, you generate the WSDL contract by converting the SEI to WSDL.

WSDL contract

The WSDL contract is a platform-neutral and language-neutral description of the Web service interface. When you want to make the Web service available to third-party clients, you should publish the WSDL contract to some well-known location. The WSDL contract contains all of the metadata required by WS clients.

The CustomerService demonstration

Figure 32.1, “Building a Java-First Web Service” shows an overview of the files required to implement and build the CustomerService Web service using the Java-first approach.
Implementing and building the service

To implement and build the Java-first example shown in Figure 32.1, “Building a Java-First Web Service”, you would perform the following steps:

1. Implement the SEI, which constitutes the basic definition of the Web service's interface.

2. Annotate the SEI (you can use the annotations to influence the ultimate form of the generated WSDL contract).

3. Implement any other requisite Java classes. In particular, implement the following:
   - Any data types referenced by the SEI—for example, the Customer class.
   - The implementation of the SEI, CustomerServiceImpl.

4. Instantiate the Web service endpoint, by adding the appropriate code to a Spring XML file.

5. Generate the WSDL contract using a Java-to-WSDL converter.

32.2. DEFINE SEI AND RELATED CLASSES

Overview

The Service Endpoint Interface (SEI) is the starting point for implementing a Web service in the Java-first approach. The SEI represents the Web service in Java and it is ultimately used as the basis for generating the WSDL contract. This section describes how to create a sample SEI, the CustomerService interface, which enables you to access the details of a customer’s account.

The CustomerService SEI

A JAX-WS service endpoint interface (SEI) is essentially an ordinary Java interface, augmented by certain annotations (which are discussed in the next section). For example, consider the following CustomerService interface, which defines methods for accessing the Customer data type:
After adding the requisite annotations to the `CustomerService` interface, this interface provides the basis for defining the `CustomerService` Web service.

**javax.xml.ws.Holder<?> types**

The `getCustomerStatus` method from the `CustomerService` interface has parameters declared to be of `javax.xml.ws.Holder<String>` type. These so-called holder types are needed in order to declare the OUT or INOUT parameters of a WSDL operation.

The syntax of WSDL operations allows you to define any number of OUT or INOUT parameters, which means that the parameters are used to return a value to the caller. This kind of parameter passing is not natively supported by the Java language. Normally, the only way that Java allows you to return a value is by declaring it as the return value of a method. You can work around this language limitation, however, by declaring parameters to be holder types.

For example, consider the definition of the following method, `getStringValues()`, which takes a holder type as its second parameter:

```java
// Java
public void getStringValues(
    String wrongWay,
    javax.xml.ws.Holder<String> rightWay
) {
    wrongWay = "Caller will never see this string!";
    rightWay.value = "But the caller *can* see this string.";
}
```

The caller can access the value of the returned `rightWay` string as `rightWay.value`. For example:

```java
// Java
String wrongWay = "This string never changes";
javax.xml.ws.Holder<String> rightWay.value = "This value *can* change.";
```
It is, perhaps, slightly unnatural to use `Holder<>` types in a Java-first example, because this is not a normal Java idiom. But it is interesting to include OUT parameters in the example, so that you can see how a Web service processes this kind of parameter.

**Related classes**

When you run the Java-to-WSDL compiler on the SEI, it converts not only the SEI, but also the classes referenced as parameters or return values. The parameter types must be convertible to XML, otherwise it would not be possible for WSDL operations to send or to receive those data types. In fact, when you run the Java-to-WSDL compiler, it is typically necessary to convert an entire tree of related classes to XML using the standard JAX-B encoding.

Normally, as long as the related classes do not require any exotic language features, the JAX-B encoding should be quite straightforward.

**Default constructor for related classes**

There is one simple rule, however, that you need to keep in mind when implementing related classes: each related class must have a default constructor (that is, a constructor without arguments). If you do not define any constructor for a class, the Java language automatically adds a default constructor. But if you define a class's constructors explicitly, you must ensure that one of them is a default constructor.

**The Customer class**

For example, the `Customer` class appears as a related class in the definition of the `CustomerService` SEI (the section called “The CustomerService SEI”). The `Customer` class consists of a collection of `String` fields and the only special condition it needs to satisfy is that it includes a default constructor:

```java
// Java
package com.fusesource.demo.customer;

public class Customer {
    protected String firstName;
    protected String lastName;
    protected String phoneNumber;
    protected String id;

    // Default constructor, required by JAX-WS
    public Customer() { }

    public Customer(String firstName, String lastName, String phoneNumber, String id) {
        super();
        this.firstName = firstName;
        this.lastName = lastName;
        this.phoneNumber = phoneNumber;
    }
}
```
32.3. ANNOTATE SEI FOR JAX-WS

Overview

To use the JAX-WS frontend, an SEI must be annotated using standardised JAX-WS annotations. The annotations signal to the Web services tooling that the SEI uses JAX-WS and the annotations are also used to customize the mapping from Java to WSDL. Here we only cover the most basic annotations—for complete details of JAX-WS annotations, see Developing Applications Using JAX-WS from the Apache CXF library.

NOTE

It sometimes makes sense also to annotate the service implementation class (the class that implements the SEI)—for example, if you want to associate an implementation class with a specific WSDL serviceName and portName (there can be more than one implementation of a given SEI).

Minimal annotation

```java
    this.id = id;
}
public String getFirstName() {
    return firstName;
}
public void setFirstName(String value) {
    this.firstName = value;
}
public String getLastName() {
    return lastName;
}
public void setLastName(String value) {
    this.lastName = value;
}
public String getPhoneNumber() {
    return phoneNumber;
}
public void setPhoneNumber(String value) {
    this.phoneNumber = value;
}
public String getId() {
    return id;
}
public void setId(String value) {
    this.id = value;
}
```
The minimal annotation required for an SEI using the JAX-WS frontend is to prefix the interface declaration with `@WebService`. For example, the `CustomerService` SEI could be minimally annotated as follows:

```java
// Java
package com.fusesource.demo.wsdldemoservice;

import javax.jws.WebService;

@WebService
public interface CustomerService {
    ...
}
```

If you run the Java-to-WSDL utility on this interface, it will generate a complete WSDL contract using the standard default style of code conversion.

**@WebService annotation**

Although it is sufficient to specify the `@WebService` annotation without any attributes, it is usually better to specify some attributes to provide a more descriptive WSDL service name and WSDL port name. You will also usually want to specify the XML target namespace. For this, you can specify the following optional attributes of the `@WebService` annotation:

- **name**
  - Specifies the name of the WSDL contract (appearing in the `wsdl:definitions` element).

- **serviceName**
  - Specifies the name of the WSDL service (a SOAP service is defined by default in the generated contract).

- **portName**
  - Specifies the name of the WSDL port (a SOAP/HTTP port is defined by default in the generated contract).

- **targetNamespace**
  - The XML schema namespace that is used, by default, to qualify the elements and types defined in the contract.

**@WebParam annotation**

You can add the `@WebParam` annotation to method arguments in the SEI. The `@WebParam` annotation is optional, but there are a couple of good reasons for adding it:

- By default, JAX-WS maps Java arguments to parameters with names like `arg0`, `...`, `argN`. Messages are much easier to read, however, when the parameters have meaningful names.

- It is a good idea to define parameter elements without a namespace. This makes the XML encoding of requests and responses more compact.

- To enable support for WSDL OUT and INOUT parameters.
You can add `@WebParam` annotations with the following attributes:

**name**

Specifies the mapped name of the parameter.

**targetNamespace**

 Specifies the namespace of the mapped parameter. Set this to a blank string for a more compact XML encoding.

**mode**

Can have one of the following values:

- `WebParam.Mode.IN`—*(default)* parameter is passed from client to service (in request).
- `WebParam.Mode.INOUT`—parameter is passed from client to service (request) and from the service back to the client (in reply).
- `WebParam.Mode.OUT`—parameter is passed from service back to the client (in reply).

### OUT and INOUT parameters

In WSDL, OUT and INOUT parameters represent values that can be sent from the service back to the client (where the INOUT parameter is sent in both directions).

In Java syntax, the only value that can ordinarily be returned from a method is the method's return value. In order to support OUT or INOUT parameters in Java (which are effectively like additional return values), you must:

- Declare the corresponding Java argument using a `javax.xml.ws.Holder<ParamType>` type, where `ParamType` is the type of the parameter you want to send.

- Annotate the Java argument with `@WebParam`, setting either `mode = WebParam.Mode.OUT` or `mode = WebParam.Mode.INOUT`.

### Annotated CustomerService SEI

The following example shows the `CustomerService` SEI after it has been annotated. Many other annotations are possible, but this level of annotation is usually adequate for a WSDL-first project.

```java
// Java
package com.fusesource.demo.wsdl.customerservice;

import javax.jws.WebParam;
import javax.jws.WebService;

@WebService(targetNamespace = "http://demo.fusesource.com/wsdl/CustomerService/",
            name = "CustomerService",
            serviceName = "CustomerService",
            ...)
32.4. INSTANTIATE THE WS ENDPOINT

Overview

In Apache CXF, you create a WS endpoint by defining a `jaxws:endpoint` element in XML. The WS endpoint is effectively the runtime representation of the Web service: it opens an IP port to listen for SOAP/HTTP requests, is responsible for marshalling and unmarshalling messages (making use of the generated Java stub code), and routes incoming requests to the relevant methods on the implementor class.

In other words, creating a Web service in Spring XML consists essentially of the following two steps:

1. Create an instance of the implementor class, using the Spring `bean` element.
2. Create a WS endpoint, using the `jaxws:endpoint` element.

The `jaxws:endpoint` element

You can instantiate a WS endpoint using the `jaxws:endpoint` element in a Spring file, where the `jaxws:` prefix is associated with the `http://cxf.apache.org/jaxws` namespace.
NOTE

Take care not to confuse the `jaxws:endpoint` element with the `cxf:cxfEndpoint` element, which you meet later in this guide: the `jaxws:endpoint` element is used to integrate a WS endpoint with a Java implementation class; whereas the `cxf:cxfEndpoint` is used to integrate a WS endpoint with a Camel route.

Define JAX-WS endpoint in XML

The following sample Spring file shows how to define a JAX-WS endpoint in XML, using the `jaxws:endpoint` element.

```xml
<?xml version="1.0" encoding="UTF-8"?>
<beans xmlns="http://www.springframework.org/schema/beans"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xmlns:jaxws="http://cxf.apache.org/jaxws"
    xmlns:soap="http://cxf.apache.org/bindings/soap"
    xsi:schemaLocation="
        http://www.springframework.org/schema/beans
        http://www.springframework.org/schema/beans/spring-beans.xsd
        http://cxf.apache.org/bindings/soap
        http://cxf.apache.org/schemas/configuration/soap.xsd
    <jaxws:endpoint
        id="customerService"
        address="/Customer"
        serviceName="customer:CustomerService"
        endpointName="customer:SOAPOverHTTP"
        implementor="#customerServiceImpl">
    </jaxws:endpoint>

    <bean id="customerServiceImpl"
         class="com.fusesource.customer.ws.CustomerServiceImpl"/>
</beans>
```

Address for the Jetty container

Apache CXF deploys the WS endpoint into a Jetty servlet container instance and the `address` attribute of `jaxws:endpoint` is therefore used to configure the addressing information for the endpoint in the Jetty container.

Apache CXF supports the notion of a default servlet container instance. The way the default servlet container is initialized and configured depends on the particular mode of deployment that you choose. For example the Red Hat JBoss Fuse container and Web containers (such as Tomcat) provide a default servlet container.

There are two different syntaxes you can use for the endpoint address, where the syntax that you use effectively determines whether or not the endpoint is deployed into the default servlet container, as follows:

- **Address syntax for default servlet container**—to use the default servlet container,
specify only the servlet context for this endpoint. Do not specify the protocol, host, and IP port in the address. For example, to deploy the endpoint to the /Customers servlet context in the default servlet container:

- Address syntax for custom servlet container—to instantiate a custom Jetty container for the endpoint, specify a complete HTTP URL, including the host and IP port (the value of the IP port effectively identifies the target Jetty container). Typically, for a Jetty container, you specify the host as `0.0.0.0`, which is interpreted as a wildcard that matches every IP network interface on the local machine (that is, if deployed on a multi-homed host, Jetty opens a listening port on every network card). For example, to deploy the endpoint to the custom Jetty container listening on IP port, 8083:

- Address syntax for custom servlet container

```java
address="/Customers"
```

- Address syntax for custom servlet container

```java
address="http://0.0.0.0:8083/Customers"
```

**NOTE**

If you want to configure a secure endpoint (secured by SSL), you would specify the `https:` scheme in the address.

### Referencing the service implementation

The `implementor` attribute of the `jaxws:endpoint` element references the implementation of the WS service. The value of this attribute can either be the name of the implementation class or (as in this example) a bean reference in the format, `#BeanID`, where the `#` character indicates that the following identifier is the name of a bean in the bean registry.

### 32.5. JAVA-TO-WSDL MAVEN PLUG-IN

#### Overview

To generate a WSDL contract from your SEI, you can use either the `java2ws` command-line utility or the `cxf-java2ws-plugin` Maven plug-in. The plug-in approach is ideal for Maven-based projects: after you paste the requisite plug-in configuration into your POM file, the WSDL code generation step is integrated into your build.

#### Configure the Java-to-WSDL Maven plug-in

Configuring the Java-to-WSDL Maven plug-in is relatively easy, because most of the default configuration settings can be left as they are. After copying and pasting the sample `plugin` element into your project's POM file, there are just a few basic settings that need to be customized, as follows:

- **CXF version**—make sure that the plug-in's dependencies are using the latest version of Apache CXF.

- **SEI class name**—specify the fully-qualified class name of the SEI in the `configuration/className` element.

- **Location of output**—specify the location of the generated WSDL file in the `configuration/outputFile` element.
For example, the following POM fragment shows how to configure the `cxf-java2ws-plugin` plug-in to generate WSDL from the CustomerService SEI:

```xml
<project ...>
  ...
  <properties>
    <cxf.version>2.7.0.redhat-610379</cxf.version>
  </properties>

  <build>
    <defaultGoal>install</defaultGoal>
    <plugins>
      ...
      <plugin>
        <groupId>org.apache.cxf</groupId>
        <artifactId>cxf-java2ws-plugin</artifactId>
        <version>${cxf.version}</version>
        <dependencies>
          <dependency>
            <groupId>org.apache.cxf</groupId>
            <artifactId>cxf-rt-frontend-jaxws</artifactId>
            <version>${cxf.version}</version>
          </dependency>
          <dependency>
            <groupId>org.apache.cxf</groupId>
            <artifactId>cxf-rt-frontend-simple</artifactId>
            <version>${cxf.version}</version>
          </dependency>
        </dependencies>
        <executions>
          <execution>
            <id>process-classes</id>
            <phase>process-classes</phase>
            <configuration>
              <className>org.fusesource.demo.camelcxf.ws.server.CustomerService</className>
              <outputFile>${basedir}/../src/main/resources/wsdl/CustomerService.wsdl</outputFile>
              <genWsdl>true</genWsdl>
              <verbose>true</verbose>
            </configuration>
            <goals>
              <goal>java2ws</goal>
            </goals>
          </execution>
        </executions>
      </plugin>
    </plugins>
  </build>
</project>

**Generated WSDL**
When using the Java-first approach to defining a Web service, there are typically other parts of your application (for example, WS clients) that depend on the generated WSDL file. For this reason, it is generally a good idea to output the generated WSDL file to a common location, which is accessible to other projects in your application, using the `outputFile` configuration element.

If you do not specify the `outputFile` configuration element, the generated WSDL is sent to the following location, by default:

```
BaseDir/target/generated/wso2/SEIClassName.wsdl
```

Reference

For full details of how to configure the Java-to-WSDL plug-in, see the Maven [Java2WS plug-in reference page](#).

[1] If the SEI is left without annotations, Apache CXF defaults to using the simple frontend. This is a non-standard frontend, which is not recommended for most applications.
33.1. WSDL-FIRST OVERVIEW

Overview

If you are familiar with the syntax of WSDL and you want to have ultimate control over the layout and conventions applied to the WSDL contract, you will probably prefer to develop your Web service using the WSDL-first approach. In this approach, you start with the WSDL contract and then use the provided Apache CXF utilities to generate the requisite Java stub files from the WSDL contract.

Demonstration location

The code presented in this chapter is taken from the following demonstration:

```
cxf-webinars-jboss-fuse-6.1/customer-ws-osgi-bundle
```

For details of how to download and install the demonstration code, see Chapter 31, Demonstration Code for Camel/CXF

WSDL contract

The WSDL contract is a platform-neutral and language-neutral description of the Web service interface. In the WSDL-first approach, the WSDL contract is the starting point for implementing the Web service. You can use it to generate Java stub code, which provides the basis for implementing the Web service on the server side.

Service Endpoint Interface (SEI)

The most important piece of the generated stub code is the SEI, which is an ordinary Java interface that represents the Web service interface in the Java language.

The SEI is used in the following ways:

- **Base type of the Web service implementation (server side)**—you define the Web service by implementing the SEI.

- **Proxy type (client side)**—on the client side, you use the SEI to invoke operations on the client proxy object.

The CustomerService demonstration

Figure 33.1, “Building a WSDL-First Web Service” shows an overview of the files required to implement and build the CustomerService Web service using the WSDL-first approach.
Implementing and building the service

To implement and build the WSDL-first example shown in Figure 33.1, “Building a WSDL-First Web Service”, starting from scratch, you would perform the following steps:

1. Create the WSDL contract.

2. Generate the Java stub code from the WSDL contract using a WSDL-to-Java converter, \texttt{ws2java}. This gives you the SEI, \texttt{CustomerService}, and its related classes, such as \texttt{Customer}.

3. Write the implementation of the SEI, \texttt{CustomerServiceImpl}.

4. Instantiate the Web service endpoint, by adding the appropriate code to a Spring XML file.

33.2. CUSTOMERSERVICE WSDL CONTRACT

Sample WSDL contract

The WSDL contract used in this demonstration is the \texttt{CustomerService} WSDL contract, which is available in the following location:

\texttt{cxf-webinars-jboss-fuse-6.1/src/main/resources}

Because the WSDL contract is a fairly verbose format, it is not shown in here in full. The main point you need to be aware of is that the \texttt{CustomerService} WSDL contract exposes the following operations:

\textbf{lookupCustomer}

Given a customer ID, the operation returns the corresponding \texttt{Customer} data object.

\textbf{updateCustomer}

Stores the given \texttt{Customer} data object against the given customer ID.
getCustomerStatus

Returns the status of the customer with the given customer ID.

Parts of the WSDL contract

A WSDL contract has the following main parts:

- the section called “Port type”.
- the section called “WSDL binding”.
- the section called “WSDL port”.

Port type

The port type is defined in the WSDL contract by the \texttt{wsdl:portType} element. It is analogous to an interface and it defines the operations that can be invoked on the Web service.

For example, the following WSDL fragment shows the \texttt{wsdl:portType} definition from the CustomerService WSDL contract:

```xml
<wsdl:definitions name="CustomerService"
    targetNamespace="http://demo.fusesource.com/wSDL/CustomerService/"
    ...>
    ...
    <wsdl:portType name="CustomerService">
        <wsdl:operation name="lookupCustomer">
            <wsdl:input message="tns:lookupCustomer"></wsdl:input>
            <wsdl:output message="tns:lookupCustomerResponse"></wsdl:output>
        </wsdl:operation>
        <wsdl:operation name="updateCustomer">
            <wsdl:input message="tns:updateCustomer"></wsdl:input>
            <wsdl:output message="tns:updateCustomerResponse"></wsdl:output>
        </wsdl:operation>
        <wsdl:operation name="getCustomerStatus">
            <wsdl:input message="tns:getCustomerStatus"></wsdl:input>
            <wsdl:output message="tns:getCustomerStatusResponse"></wsdl:output>
        </wsdl:operation>
    </wsdl:portType>
    ...
</wsdl:definitions>
```

WSDL binding

A WSDL binding describes how to \textit{encode} all of the operations and data types associated with a particular port type. A binding is specific to a particular protocol—for example, SOAP or JMS.
**WSDL port**

A WSDL port specifies the transport protocol and contains addressing data that enables clients to locate and connect to a remote server endpoint.

For example, the CustomerService WSDL contract defines the following WSDL port:

```xml
<wsdl:definitions ...>
  ...
  <wsdl:port name="SOAPOverHTTP" binding="tns:CustomerServiceSOAP">
    <soap:address location="http://0.0.0.0:8183/CustomerService"/>
  </wsdl:port>
</wsdl:definitions>
```

The address specified by the soap:address element's location attribute in the original WSDL contract is typically overridden at run time, however.

**The getCustomerStatus operation**

Because a WSDL contract is fairly verbose, it can be a bit difficult to see what the parameters of an operation are. Typically, for each operation, you can find data types in the XML schema section that represent the operation request and the operation response. For example, the getCustomerStatus operation has its request parameters (IN parameters) encoded by the getCustomerStatus element and its response parameters (OUT parameters) encoded by the getCustomerStatusResponse element, as follows:

```xml
  ...
  <wsdl:types>
    <xsd:schema ...
      ...>
        <xsd:element name="getCustomerStatus">
          <xsd:complexType>
            <xsd:sequence>
              <xsd:element name="customerId" type="xsd:string"/>
            </xsd:sequence>
          </xsd:complexType>
        </xsd:element>
        <xsd:element name="getCustomerStatusResponse">
          <xsd:complexType>
            <xsd:sequence>
              <xsd:element name="status" type="xsd:string"/>
              <xsd:element name="statusMessage" type="xsd:string"/>
            </xsd:sequence>
          </xsd:complexType>
        </xsd:element>
      </xsd:schema>
    </wsdl:types>
</wsdl:definitions>
```
References

For more details about the format of WSDL contracts and how to create your own WSDL contracts, see *Writing WSDL Contracts* and the *Eclipse JAX-WS Tools Component*.

### 33.3. WSDL-TO-JAVA MAVEN PLUG-IN

#### Overview

In contrast to the Java-first approach, which starts with a Java interface and then generates the WSDL contract, the WSDL-first approach needs to generate Java stub code from the WSDL contract.

To generate Java stub code from the WSDL contract, you can use either the `ws2java` command-line utility or the `cxf-codegen-plugin` Maven plug-in. The plug-in approach is ideal for Maven-based projects: after you paste the requisite plug-in configuration into your POM file, the WSDL-to-Java code generation step is integrated into your build.

#### Configure the WSDL-to-Java Maven plug-in

Configuring the WSDL-to-Java Maven plug-in is relatively easy, because most of the default configuration settings can be left as they are. After copying and pasting the sample `plugin` element into your project's POM file, there are just a few basic settings that need to be customized, as follows:

- **CXF version**—make sure that the plug-in's dependencies are using the latest version of Apache CXF.
- **WSDL file location**—specify the WSDL file location in the `configuration/wsdlOptions/wsdlOption/wsdl` element.
- **Location of output**—specify the root directory of the generated Java source files in the `configuration/sourceRoot` element.

For example, the following POM fragment shows how to configure the `cxf-codegen-plugin` plug-in to generate Java stub code from the `CustomerService.wsdl` WSDL file:

```xml
<project ...
...
<parent>
  <groupId>com.fusesource.byexample.cxf-webinars</groupId>
  <artifactId>cxf-webinars</artifactId>
  <version>1.0-SNAPSHOT</version>
</parent>

<build>
  <defaultGoal>install</defaultGoal>
  <plugins>
    ...
    <plugin>
With the sample configuration shown here, the generated Java source code is written under the `target/generated-sources/jaxws` directory. Note that the Web service implementation is dependent on this generated stub code—for example, the service implementation class must implement the generated `CustomerService` SEI.

### Adding the generated source to an IDE

If you are using an IDE such as Eclipse or Intellij’s IDEA, you need to make sure that the IDE is aware of the generated Java code. For example, in Eclipse it is necessary to add the `target/generated-sources/jaxws` directory to the project as a source code directory.

### Compiling the generated code

You must ensure that the generated Java code is compiled and added to the deployment package. By convention, Maven automatically compiles any source files that it finds under the following directory:

```
<groupId>org.apache.cxf</groupId>
<artifactId>cxf-codegen-plugin</artifactId>
<version>${cxf-version}</version>
<executions>
  <execution>
    <id>generate-sources</id>
    <phase>generate-sources</phase>
    <configuration>
      <!-- Maven auto-compiles any source files under target/generated-sources/ -->
      <sourceRoot>${basedir}/target/generated-sources/jaxws</sourceRoot>
      <wsdlOptions>
        <wsdlOption>
          <wsdl>${basedir}/../src/main/resources/wsdl/CustomerService.wsdl</wsdl>
        </wsdlOption>
      </wsdlOptions>
    </configuration>
    <goals>
      <goal>wsdl2java</goal>
    </goals>
  </execution>
</executions>
</plugin>
</plugins>
</build>
</project>
```

Hence, if you configure the output directory as shown in the preceding POM fragment, the generated code is automatically compiled by Maven.
Reference

For full details of how to configure the Java-to-WSDL plug-in, see the Maven cxf-codegen-plugin reference page.

33.4. INSTANTIATE THE WS ENDPOINT

Overview

In Apache CXF, you create a WS endpoint by defining a jaxws:endpoint element in XML. The WS endpoint is effectively the runtime representation of the Web service: it opens an IP port to listen for SOAP/HTTP requests, is responsible for marshalling and unmarshalling messages (making use of the generated Java stub code), and routes incoming requests to the relevant methods on the implementor class.

In other words, creating a Web service in Spring XML consists essentially of the following two steps:

1. Create an instance of the implementor class, using the Spring bean element.
2. Create a WS endpoint, using the jaxws:endpoint element.

Define JAX-WS endpoint in XML

The following sample Spring file shows how to define a JAX-WS endpoint in XML, using the jaxws:endpoint element.

```xml
<beans xmlns="http://www.springframework.org/schema/beans"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xmlns:jaxws="http://cxf.apache.org/jaxws"
    xmlns:soap="http://cxf.apache.org/bindings/soap"
    xsi:schemaLocation="http://www.springframework.org/schema/beans
    http://www.springframework.org/schema/beans/spring-beans.xsd
    http://cxf.apache.org/bindings/soap
    http://cxf.apache.org/schemas/configuration/soap.xsd

    <import resource="classpath:META-INF/cxf/cxf.xml" />

    <jaxws:endpoint
        id="customerService"
        address="/Customer"
        serviceName="customer:CustomerService"
        endpointName="customer:SOAPOverHTTP"
        implementor="#customerServiceImpl">
    </jaxws:endpoint>

    <bean id="customerServiceImpl"
        class="com.fusesource.customer.ws.CustomerServiceImpl"/>

</beans>
```
Address for the Jetty container

In the preceding example, the address attribute of the jaxws:endpoint element specifies the servlet context for this endpoint, relative to the Jetty container in which it is deployed.

For more details about the options for specifying the endpoint address, see the section called “Address for the Jetty container”.

Referencing the service implementation

The implementor attribute of the jaxws:endpoint element is used to reference the implementation of the WS service. The value of this attribute can either be the name of the implementation class or (as in this example) a bean reference in the format, #BeanID, where the # character indicates that the following identifier is the name of a bean in the bean registry.

33.5. DEPLOY TO AN OSGI CONTAINER

Overview

One of the options for deploying the Web service is to package it as an OSGi bundle and deploy it into an OSGi container such as Red Hat JBoss Fuse. Some of the advantages of an OSGi deployment include:

- Bundles are a relatively lightweight deployment option (because dependencies can be shared between deployed bundles).
- OSGi provides sophisticated dependency management, ensuring that only version-consistent dependencies are added to the bundle's classpath.

Using the Maven bundle plug-in

The Maven bundle plug-in is used to package your project as an OSGi bundle, in preparation for deployment into the OSGi container. There are two essential modifications to make to your project's pom.xml file:

1. Change the packaging type to bundle (by editing the value of the project/packaging element in the POM).
2. Add the Maven bundle plug-in to your POM file and configure it as appropriate.

Configuring the Maven bundle plug-in is quite a technical task (although the default settings are often adequate). For full details of how to customize the plug-in configuration, consult Deploying into the OSGi Container and Managing OSGi Dependencies.

Sample bundle plug-in configuration

The following POM fragment shows a sample configuration of the Maven bundle plug-in, which is appropriate for the current example.

```xml
<groupId>com.fusesource.byexample.cxf-webinars</groupId>
Dynamic imports

The Java packages from Apache CXF and the Spring API are imported using dynamic imports (specified using the `DynamicImport-Package` element). This is a pragmatic way of dealing with the fact that Spring XML files are not terribly well integrated with the Maven bundle plug-in. At build time, the Maven bundle plug-in is not able to figure out which Java classes are required by the Spring XML code. By listing wildcarded package names in the `DynamicImport-Package` element, however, you allow the OSGi container to figure out which Java classes are needed by the Spring XML code at run time.
NOTE

In general, using DynamicImport-Package headers is not recommended in OSGi, because it short-circuits OSGi version checking. Normally, what should happen is that the Maven bundle plug-in lists the Java packages used at build time, along with their versions, in the Import-Package header. At deploy time, the OSGi container then checks that the available Java packages are compatible with the build-time versions listed in the Import-Package header. With dynamic imports, this version checking cannot be performed.

Build and deploy the service bundle

After you have configured the POM file, you can build the Maven project and install it in your local repository by entering the following command:

```bash
mvn install
```

To deploy the service bundle, enter the following command at the command console:

```bash
karaf@root> install -s mvn:com.fusesource.byexample.cxf-webinars/customer-ws-osgi-bundle
```

NOTE

If your local Maven repository is stored in a non-standard location, you might need to customize the value of the org.ops4j.pax.url.mvn.localRepository property in the $EsbInstallDir/etc/org.ops4j.pax.url.mvn.cfg file, before you can use the mvn: scheme to access Maven artifacts.

Red Hat JBoss Fuse default servlet container

Red Hat JBoss Fuse has a default Jetty container which, by default, listens for HTTP requests on port 8181. Moreover, WS endpoints in this container are implicitly deployed under the servlet context cxf/. Hence, any WS endpoint whose address attribute is configured in the jaxws:element as /EndpointContext will have the following effective address:

```text
http://Hostname:8181/cxf/EndpointContext
```

You can optionally customize the default servlet container by editing settings in the following file:

```text
InstallDir/etc/org.ops4j.pax.web.cfg
```

Full details of the properties you can set in this file are given in the Ops4j Pax Web configuration reference..

Check that the service is running

A simple way of checking that the service is running is to point your browser at the following URL:

```text
```
This query should return a copy of the WS endpoint's WSDL contract.
CHAPTER 34. IMPLEMENTING A WS CLIENT

34.1. WS CLIENT OVERVIEW

Overview

The key object in a WS client is the WS client proxy object, which enables you to access the remote Web service by invoking methods on the SEI. The proxy object itself can easily be instantiated using the `jaxws:client` element in Spring XML.

Demonstration location

The code presented in this chapter is taken from the following demonstration:

```
xrf-webinars-jboss-fuse-6.1/customer-ws-client
```

For details of how to download and install the demonstration code, see Chapter 31, *Demonstration Code for Camel/CXF*.

WSDL contract

The WSDL contract is a platform-neutral and language-neutral description of the Web service interface. It contains all of the metadata that a client needs to find a Web service and invoke its operations. You can generate Java stub code from the WSDL contract, which provides an API that makes it easy to invoke the remote WSDL operations.

Service Endpoint Interface (SEI)

The most important piece of the generated stub code is the SEI, which is an ordinary Java interface that represents the Web service interface in the Java language.

WS client proxy

The WS client proxy is an object that converts Java method invocations to remote procedure calls, sending and receiving messages to a remote instance of the Web service across the network. The methods of the proxy are exposed through the SEI.

NOTE

The proxy type is generated *dynamically* by Apache CXF at run time. That is, there is no class in the stub code that corresponds to the implementation of the proxy (the only relevant entity is the SEI, which defines the proxy’s interface).

The CustomerService client

To take a specific example, consider the `customer-ws-client` demonstration, which is available from the following location:

```
xrf-webinars-jboss-fuse-6.1/customer-ws-client
```

Figure 34.1, “Building a WS Client” shows an overview of the files required to implement
and build the WS client.

**Figure 34.1. Building a WS Client**

Implementing and building the WS client

To implement and build the sample WS client shown in Figure 34.1, “Building a WS Client”, starting from scratch, you would perform the following steps:

1. Obtain a copy of the WSDL contract.

2. Generate the Java stub code from the WSDL contract using a WSDL-to-Java converter, `ws2java`. This gives you the SEI, `CustomerService`, and its related classes, such as `Customer`.

3. Implement the main client class, `ClientInvoker`, which invokes the Web service operations. In this class define a bean property of type, `CustomerService`, so that the client class can receive a reference to the WS client proxy by property injection.

4. In a Spring XML file, instantiate the WS client proxy and inject it into the main client class, `ClientInvoker`.

### 34.2. WSDL-TO-JAVA MAVEN PLUG-IN

**Overview**

To generate Java stub code from the WSDL contract, you can use either the `ws2java` command-line utility or the `cxf-codegen-plugin` Maven plug-in. When using Maven, the plug-in approach is ideal: after you paste the requisite plug-in configuration into your POM file, the WSDL-to-Java code generation step is integrated into your build.

**Configure the WSDL-to-Java Maven plug-in**

Configuring the WSDL-to-Java Maven plug-in is relatively easy, because most of the default configuration settings can be left as they are. After copying and pasting the sample `plugin` element into your project's POM file, there are just a few basic settings that need to be customized, as follows:

- **CXF version**—make sure that the plug-in's dependencies are using the latest version
of Apache CXF.

- **WSDL file location**—specify the WSDL file location in the `configuration/wsdlOptions/wsdlOption/wsdl` element.

- **Location of output**—specify the root directory of the generated Java source files in the `configuration/sourceRoot` element.

For example, the following POM fragment shows how to configure the `cxf-codegen-plugin` plug-in to generate Java stub code from the `CustomerService.wsdl` WSDL file:

```xml
<project ...>
...
<parent>
<groupId>com.fusesource.byexample.cxf-webinars</groupId>
<artifactId>cxf-webinars</artifactId>
<version>1.0-SNAPSHOT</version>
</parent>

<build>
<defaultGoal>install</defaultGoal>
<plugins>
 ...
 <plugin>
 <groupId>org.apache.cxf</groupId>
 <artifactId>cxf-codegen-plugin</artifactId>
 <version>${cxf-version}</version>
 <executions>
 <execution>
 <id>generate-sources</id>
 <phase>generate-sources</phase>
 <configuration>
 <sourceRoot>${basedir}/target/generated-sources/jaxws</sourceRoot>
 <wsdl0ptions>
 <wsdlOption>
 <wsdl>${basedir}/../src/main/resources/wsdl/CustomerService.wsdl</wsdl>
 </wsdlOption>
 </wsdl0ptions>
 </configuration>
 <goals>
 <goal>wsdl2java</goal>
 </goals>
 </execution>
 </executions>
</plugin>

</plugins>
</build>

</project>

Generated Java source code
With the sample configuration shown here, the generated Java source code is written under the `target/generated-sources/jaxws` directory. Note that the client implementation is dependent on this generated stub code—for example, the client invokes the proxy using the generated `CustomerService` SEI.

**Add generated source to IDE**

If you are using an IDE such as Eclipse or Intellij's IDEA, you need to make sure that the IDE is aware of the generated Java code. For example, in Eclipse it is necessary to add the `target/generated-sources/jaxws` directory to the project as a source code directory.

**Compiling the generated code**

You must ensure that the generated Java code is compiled and added to the deployment package. By convention, Maven automatically compiles any source files that it finds under the following directory:

```
BaseDir/target/generated-sources/
```

Hence, if you configure the output directory as shown in the preceding POM fragment, the generated code is automatically compiled by Maven.

**Reference**

For full details of how to configure the Java-to-WSDL plug-in, see the Maven cxf-codegen-plugin reference page.

### 34.3. INSTANTIATE THE WS CLIENT PROXY

**Overview**

The WS client proxy is the most important kind of object in a WS client, because it provides a simple way of invoking operations on a remote Web service. The proxy enables you to access a Web service by invoking methods locally on a Java interface. The methods invoked on the proxy object are then translated into remote procedure calls on the Web service.

You can instantiate a WS client proxy straightforwardly using the `jaxws:client` element.

**Define the WS client in XML**

The following Spring XML fragment shows how to instantiate a client proxy bean using the `jaxws:client` element.
The **jaxws:client** element

The **jaxws:client** element creates a client proxy _dynamically_ (that is, there is no dedicated class that represents a proxy implementation in the Java stub code). The following attributes are used to define the proxy:

**id**

The ID that you specify here is entered in the bean registry and can be used to reference the proxy instance from other beans.

**address**

The full address of the remote Web service that this proxy connects to.

**serviceClass**

The fully-qualified class name of the Web service's SEI (you invoke methods on the proxy through the SEI).

### Injecting with the proxy reference

To access the proxy instance, simply inject the proxy into one or more other beans defined in XML. Given that the proxy ID has the value, **customerServiceProxy**, you can inject it into a bean property using the Spring **property** element, as follows:

```xml
<bean id="customerServiceClient"
     class="com.fusesource.customer.client.ClientInvoker"
     init-method="init" destroy-method="destroy">
     <property name="customerService" ref="customerServiceProxy"/>
</bean>
```

The bean class that is being injected must have a corresponding **setCustomerService** setter method—for example:

```java
// Java
...
public class ClientInvoker implements Runnable {
```
34.4. INVOKE WS OPERATIONS

Proxy interface is SEI interface

The proxy implements the SEI. Hence, to make remote procedure calls on the Web service, simply invoke the SEI methods on the proxy instance.

Invoking the lookupCustomer operation

For example, the `CustomerService` SEI exposes the `lookupCustomer` method, which takes a customer ID as its argument and returns a `Customer` data object. Using the proxy instance, `customerService`, you can invoke the `lookupCustomer` operation as follows:

```java
// Java
com.fusesource.demo.customer.Customer response = customerService.lookupCustomer("1234");
log.info("Got back " + response.getFirstName() + " " + response.getLastName() + ", ph:" + response.getPhoneNumber() );
```

The ClientInvoker class

In the `cxf-webinars-jboss-fuse-6.1/customer-ws-client` project, there is a `ClientInvoker` class (located in `src/main/java/com/fusesource/customer/client`), which defines a continuous loop that invokes the `lookupCustomer` operation.

When you are experimenting with the demonstration code in the latter chapters of this guide, you might need to modify the `ClientInvoker` class, possibly adding operation invocations.

34.5. DEPLOY TO AN OSGI CONTAINER

Overview

One of the options for deploying the WS client is to package it as an OSGi bundle and deploy it into an OSGi container such as Red Hat JBoss Fuse. Some of the advantages of an OSGi deployment include:

- Bundles are a relatively lightweight deployment option (because dependencies can be shared between deployed bundles).
- OSGi provides sophisticated dependency management, ensuring that only version-consistent dependencies are added to the bundle's classpath.
Using the Maven bundle plug-in

The Maven bundle plug-in is used to package your project as an OSGi bundle, in preparation for deployment into the OSGi container. There are two essential modifications to make to your project's pom.xml file:

1. Change the packaging type to bundle (by editing the value of the project/packaging element in the POM).

2. Add the Maven bundle plug-in to your POM file and configure it as appropriate.

Configuring the Maven bundle plug-in is quite a technical task (although the default settings are often adequate). For full details of how to customize the plug-in configuration, consult Deploying into the OSGi Container and Managing OSGi Dependencies.

Sample bundle plug-in configuration

The following POM fragment shows a sample configuration of the Maven bundle plug-in, which is appropriate for the current example.

```xml
<?xml version="1.0"?>
<project ...
...
<groupId>com.fusesource.byexample.cxf-webinars</groupId>
<artifactId>customer-ws-client</artifactId>
<name>customer-ws-client</name>
<packaging>bundle</packaging>
...
<build>
<plugins>
...
<plugin>
    <groupId>org.apache.felix</groupId>
    <artifactId>maven-bundle-plugin</artifactId>
    <extensions>true</extensions>
    <configuration>
        <instructions>
            <Export-Package>
                !com.fusesource.customer.client,
                !com.fusesource.demo.customer,
                !com.fusesource.demo.wsdl.customerservice
            </Export-Package>
            <Import-Package>
                META-INF.cxf,
                *
            </Import-Package>
            <DynamicImport-Package>
                org.apache.cxf.*,
                org.springframework.beans.*
            </DynamicImport-Package>
        </instructions>
    </configuration>
</plugin>
...
```
Dynamic imports

The Java packages from Apache CXF and the Spring API are imported using dynamic imports (specified using the `DynamicImport-Package` element). This is a pragmatic way of dealing with the fact that Spring XML files are not terribly well integrated with the Maven bundle plug-in. At build time, the Maven bundle plug-in is not able to figure out which Java classes are required by the Spring XML code. By listing wildcarded package names in the `DynamicImport-Package` element, however, you allow the OSGi container to figure out which Java classes are needed by the Spring XML code at run time.

**NOTE**

In general, using `DynamicImport-Package` headers is not recommended in OSGi, because it short-circuits OSGi version checking. Normally, what should happen is that the Maven bundle plug-in lists the Java packages used at build time, along with their versions, in the `Import-Package` header. At deploy time, the OSGi container then checks that the available Java packages are compatible with the build time versions listed in the `Import-Package` header. With dynamic imports, this version checking cannot be performed.

Build and deploy the client bundle

After you have configured the POM file, you can build the Maven project and install it in your local repository by entering the following command:

```
mvn install
```

To deploy the client bundle, enter the following command at the containers command console:

```
karaf@root> install -s maven:com.fusesource.byexample.cxf-webinars/customer-ws-client
```

**NOTE**

If your local Maven repository is stored in a non-standard location, you might need to customize the value of the `org.ops4j.pax.url.mvn.localRepository` property in the `EsbInstallDir/etc/org.ops4j.pax.url.mvn.cfg` file, before you can use the `mvn:` scheme to access Maven artifacts.

Check that the client is running

Assuming that you have already deployed the corresponding Web service into the OSGi container, you can verify that the client is successfully invoking WSDL operations by checking the log, as follows:

```
karaf@root> log:display -n 10
```
The client invokes an operation on the Web service once every second.
CHAPTER 35. POJO-BASED ROUTE

35.1. PROCESSING MESSAGES IN POJO FORMAT

Overview

By default, the Camel CXF component marshals incoming Web service requests into the POJO data form, where the In message body is encoded as a list of Java objects (one for each operation parameter). The POJO data format has advantages and disadvantages, as follows:

- The big advantage of the POJO data format is that the operation parameters are encoded using the JAX-B standard, which makes them easy to manipulate in Java.

- The downside of the POJO data format, on the other hand, is that it requires that the WSDL metadata is converted to Java in advance (as defined by the JAX-WS and JAX-B mappings) and compiled into your application. This means that a POJO-based route is not very dynamic.

Demonstration location

The code presented in this chapter is taken from the following demonstration:

cxf-webinars-jboss-fuse-6.1/customer-ws-camel-cxf-pojo

For details of how to download and install the demonstration code, see Chapter 31, Demonstration Code for Camel/CXF

Camel CXF component

The Camel CXF component is an Apache CXF component that integrates Web services with routes. You can use it either to instantiate consumer endpoints (at the start of a route), which behave like Web service instances, or to instantiate producer endpoints (at any other points in the route), which behave like WS clients.

NOTE

Camel CXF endpoints—which are instantiated using the cxf:cxfEndpoint XML element and are implemented by the Apache Camel project—are not to be confused with the Apache CXF JAX-WS endpoints—which are instantiated using the jaxws:endpoint XML element and are implemented by the Apache CXF project.

POJO data format

POJO data format is the default data format used by the Camel CXF component and it has the following characteristics:

- JAX-WS and JAX-B stub code (as generated from the WSDL contract) must be provided.

- The SOAP body is marshalled into a list of Java objects.
One Java object for each part or parameter of the corresponding WSDL operation.

- The type of the message body is `org.apache.cxf.message.MessageContentsList`.

- The SOAP headers are converted into headers in the exchange's In message.

### Implementing and building a POJO route

To implement and build the demonstration POJO-based route, starting from scratch, you would perform the following steps:

1. Obtain a copy of the WSDL contract that is to be integrated into the route.
2. Generate the Java stub code from the WSDL contract using a WSDL-to-Java converter. This gives you the SEI, `CustomerService`, and its related classes, such as `Customer`.
3. Instantiate the Camel CXF endpoint in Spring, using the `cxf:cxfEndpoint` element.
4. Implement the route in XML, where you can use the content-based router to sort requests by operation name.
5. Implement the operation processor beans, which are responsible for processing each operation. When implementing these beans, the message contents must be accessed in POJO data format.

### Sample POJO route

Figure 35.1, “Sample POJO Route” shows an outline of the route that is used to process the operations of the `CustomerService` Web service using the POJO data format. After sorting the request messages by operation name, an operation-specific processor bean reads the incoming request parameters and then generates a response in the POJO data format.

**Figure 35.1. Sample POJO Route**

![Sample POJO Route Diagram](image)

### 35.2. WSDL-TO-JAVA MAVEN PLUG-IN
Overview

To generate Java stub code from the WSDL contract, you can use either the ws2java command-line utility or the cxf-codegen-plugin Maven plug-in. When using Maven, the plug-in approach is ideal: after you paste the requisite plug-in configuration into your POM file, the WSDL-to-Java code generation step is integrated into your build.

Configure the WSDL-to-Java Maven plug-in

Configuring the WSDL-to-Java Maven plug-in is relatively easy, because most of the default configuration settings can be left as they are. After copying and pasting the sample plugin element into your project's POM file, there are just a few basic settings that need to be customized, as follows:

- **CXF version**—make sure that the plug-in's dependencies are using the latest version of Apache CXF.
- **WSDL file location**—specify the WSDL file location in the configuration/wsdlOptions/wsdlOption/wsdl element.
- **Location of output**—specify the root directory of the generated Java source files in the configuration/sourceRoot element.

For example, the following POM fragment shows how to configure the cxf-codegen-plugin plug-in to generate Java stub code from the CustomerService.wsdl WSDL file:

```xml
<project ...>
  ...<parent>
    <groupId>com.fusesource.byexample.cxf-webinars</groupId>
    <artifactId>cxf-webinars</artifactId>
    <version>1.0-SNAPSHOT</version>
  </parent>
  <build>
    <defaultGoal>install</defaultGoal>
    <plugins>
      ...
      <plugin>
        <groupId>org.apache.cxf</groupId>
        <artifactId>cxf-codegen-plugin</artifactId>
        <version>${cxf-version}</version>
        <executions>
          <execution>
            <id>generate-sources</id>
            <phase>generate-sources</phase>
            <configuration>
              <sourceRoot>${basedir}/target/generated-sources/jaxws</sourceRoot>
              <wsdlOptions>
                <wsdlOption>
                  <wsdl>${basedir}/../src/main/resources/wsdl/CustomerService.wsdl</wsdl>
                </wsdlOption>
              </wsdlOptions>
            </configuration>
          </execution>
        </executions>
      </plugin>
    </plugins>
  </build>
</project>
```
Generated Java source code

With the sample configuration shown here, the generated Java source code is written under the target/generated-sources/jaxws directory. Note that the route is dependent on this generated stub code—for example, when processing the POJO parameters, the parameter processor uses the Customer data type from the stub code.

Add generated code to IDE

If you are using an IDE such as Eclipse or Intellij's IDEA, you need to make sure that the IDE is aware of the generated Java code. For example, in Eclipse it is necessary to add the target/generated-sources/jaxws directory to the project as a source code directory.

Compiling the generated code

You must ensure that the generated Java code is compiled and added to the deployment package. By convention, Maven automatically compiles any source files that it finds under the following directory:

BaseDir/target/generated-sources/

Hence, if you configure the output directory as shown in the preceding POM fragment, the generated code is automatically compiled by Maven.

Reference

For full details of how to configure the Java-to-WSDL plug-in, see the Maven cxf-codegen-plugin reference page.

35.3. INSTANTIATE THE WS ENDPOINT

Overview

In Apache Camel, the Camel CXF component is the key to integrating routes with Web services. You can use the Camel CXF component to create a CXF endpoint, which can be used in either of the following ways:

- **Consumer**—(at the start of a route) represents a Web service instance, which integrates with the route. The type of payload injected into the route depends on the value of the endpoint's dataFormat option.
Producer—(at other points in the route) represents a WS client proxy, which converts the current exchange object into an operation invocation on a remote Web service. The format of the current exchange must match the endpoint's dataFormat setting.

In the current demonstration, we are interested in creating a Camel CXF consumer endpoint, with the dataFormat option set to POJO.

**Maven dependency**

The Camel CXF component requires you to add a dependency on the camel-cxf component in your Maven POM. For example, the pom.xml file from the customer-ws-camel-cxf-pojo demonstration project includes the following dependency:

```xml
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-cxf</artifactId>
  <version>${camel-version}</version>
</dependency>
```

**The cxf:bean: URI syntax**

The cxf:bean: URI is used to bind an Apache CXF endpoint to a route and has the following general syntax:

```
     cxf:bean:CxfEndpointID[?Options]
```

Where CxfEndpointID is the ID of a bean created using the cxf:cxfEndpoint element, which configures the details of the WS endpoint. You can append options to this URI (where the options are described in detail in ). If you do not specify any additional options, the endpoint uses the POJO data format by default.

For example, to start a route with a Apache CXF endpoint that is configured by the bean with ID, customer-ws, define the route as follows:

```
<route>
  <from uri="cxf:bean:customer-ws"/>
  ...
</route>
```

**NOTE**

There is an alternative URI syntax, cxf://WsAddress[?Options], which enables you to specify all of the WS endpoint details in the URI (so there is no need to reference a bean instance). This typically results in a long and cumbersome URI, but is useful in some cases.

**The cxf:cxfEndpoint element**

The cxf:cxfEndpoint element is used to define a WS endpoint that binds either to the start (consumer endpoint) or the end (producer endpoint) of a route. For example, to define the customer-ws WS endpoint referenced in the preceding route, you would define a cxf:cxfEndpoint element as follows:
IMPORTANT

Remember that the cxf:cxfEndpoint element and the jaxws:endpoint element use different XML schemas (although the syntax looks superficially similar). These elements bind a WS endpoint in different ways: the cxf:cxfEndpoint element instantiates and binds a WS endpoint to an Apache Camel route, whereas the jaxws:endpoint element instantiates and binds a WS endpoint to a Java class using the JAX-WS mapping.

Address for the Jetty container

Apache CXF deploys the WS endpoint into a Jetty servlet container instance and the address attribute of cxf:cxfEndpoint is therefore used to configure the addressing information for the endpoint in the Jetty container.

Apache CXF supports the notion of a default servlet container instance. The way the default servlet container is initialized and configured depends on the particular mode of deployment that you choose. For example the Red Hat JBoss Fuse container and Web containers (such as Tomcat) provide a default servlet container.

There are two different syntaxes you can use for the endpoint address, where the syntax that you use effectively determines whether or not the endpoint is deployed into the default servlet container, as follows:

- **Address syntax for default servlet container**—to use the default servlet container, specify only the servlet context for this endpoint. Do not specify the protocol, host, and IP port in the address. For example, to deploy the endpoint to the /Customer servlet context in the default servlet container:

  address="/Customer"

- **Address syntax for custom servlet container**—to instantiate a custom Jetty container for this endpoint, specify a complete HTTP URL, including the host and IP port (the value of the IP port effectively identifies the target Jetty container). Typically, for a Jetty container, you specify the host as 0.0.0.0, which is interpreted as a wildcard that matches every IP network interface on the local machine (that is, if deployed on a multi-homed host, Jetty opens a listening port on every network card). For example, to deploy the endpoint to the custom Jetty container listening on IP port, 8083:
NOTE

If you want to configure a secure endpoint (secured by SSL), you would specify the https: scheme in the address.

Referencing the SEI

The serviceClass attribute of the cxf:cxfEndpoint element references the SEI of the Web service, which in this case is the CustomerService interface.

35.4. SORT MESSAGES BY OPERATION NAME

The operationName header

When the WS endpoint parses an incoming operation invocation in POJO mode, it automatically sets the operationName header to the name of the invoked operation. You can then use this header to sort messages by operation name.

Sorting by operation name

For example, the customer-ws-camel-cxf-pojo demonstration defines the following route, which uses the content-based router pattern to sort incoming messages, based on the operation name. The when predicates check the value of the operationName header using simple language expressions, sorting messages into invocations on the updateCustomer operation, the lookupCustomer operation, or the getCustomerStatus operation.

```
<beans ...>
  ... 
  <camelContext id="camel"
    xmlns="http://camel.apache.org/schema/spring">
    <route>
      <from uri="cxf:bean:customer-ws"/>
      <choice>
        <when>
          <simple>${in.header.operationName} == 'updateCustomer'</simple>
          <to uri="updateCustomer"/>
        </when>
        <when>
          <simple>${in.header.operationName} == 'lookupCustomer'</simple>
          <to uri="lookupCustomer"/>
        </when>
        <when>
          <simple>${in.header.operationName} == 'getCustomerStatus'</simple>
          <to uri="getCustomerStatus"/>
        </when>
      </choice>
    </route>
  </camelContext>
```
Beans as endpoints

Note how the preceding route uses a convenient shortcut to divert each branch of the choice DSL to a different processor bean. The DSL for sending exchanges to producer endpoints (for example, `<to uri="Destination"/>`) is integrated with the bean registry: if the Destination does not resolve to an endpoint or a component, the Destination is used as a bean ID to look up the bean registry. In this example, the exchange is routed to processor beans (which implement the org.apache.camel.Processor interface).

35.5. PROCESS OPERATION PARAMETERS

Overview

The most important characteristic of using Camel CXF in POJO mode is that the exchange's message body contains a list of Java objects, representing the parameters of the WSDL operation. The types of the Java objects are defined by the standard JAX-B mapping and the implementations of these parameter types are provided by the Java stub code.

Contents of request message body

In POJO mode, the body of the request message is an org.apache.cxf.message.MessageContentsList object. You can also obtain the message body as an Object[] array (where type conversion is automatic).

When the body is obtained as an Object[] array, the array contains the list of all the operation's IN, INOUT, and OUT parameters in exactly the same order as defined in the WSDL contract (and in the same order as the corresponding operation signature of the SEI). The parameter mode affects the content as follows:

IN
   Contains a parameter value from the client.

INOUT
   Contains a Holder object containing a parameter value from the client.

OUT
   Contains an empty Holder object, which is a placeholder for the response.
NOTE

Unlike OUT parameters, there is no placeholder in the request's Object[] array to represent a return value.

Contents of response message body

In POJO mode, the body of the response message can be either an org.apache.cxf.message.MessageContentsList object or an Object[] array.

When setting the response body as an Object[] array, the array should contain only the operation's INOUT and OUT parameters in the same order as defined in the WSDL contract, omitting the IN parameters. The parameter mode affects the content as follows:

INOUT

Contains a Holder object, which you must set to a response value. The Holder object used here must be exactly the Holder object for the corresponding parameter that was extracted from the request Object[] array. Creating and inserting a new Holder object into the Object[] array does not work.

OUT

Contains a Holder object, which you must initialize with a response value. The Holder object used here must be exactly the Holder object for the corresponding parameter that was extracted from the request Object[] array. Creating and inserting a new Holder object into the Object[] array does not work.

NOTE

If you defined the Web service interface using the Java-first approach, note that the return value (if any) must be set as the first element in the response's Object[] array. The return type is set as a plain object: it does not use a Holder object.

Example: getCustomerStatus operation

For example, the getCustomerStatus operation takes three parameters: IN, OUT, and OUT, respectively. The corresponding method signature in the SEI is, as follows:

```
// Java
public void getCustomerStatus(
    @WebParam(name = "customerId", targetNamespace = "")
    java.lang.String customerId,

    @WebParam(mode = WebParam.Mode.OUT, name = "status", targetNamespace = ")
    javax.xml.ws.Holder<java.lang.String> status,

    @WebParam(mode = WebParam.Mode.OUT, name = "statusMessage",
    targetNamespace = ")
    javax.xml.ws.Holder<java.lang.String> statusMessage
);```
**Example: request and response bodies**

For the `getCustomerStatus` operation, the bodies of the request message and the response message have the following contents:

- **Request message**—as an `Object[]` array type, the contents are: `{ String customerId, Holder<String> status, Holder<String> statusMessage }`.

- **Response message**—as an `Object[]` array type, the contents are: `{ Holder<String> status, Holder<String> statusMessage }`

**Example: processing getCustomerStatus**

The `GetCustomerStatusProcessor` class is responsible for processing incoming `getCustomerStatus` invocations. The following sample implementation for POJO mode shows how to read the request parameters from the `In` message body and then set the response parameters in the `Out` message body.

```java
// Java
package com.fusesource.customerwscamelcxfpojo;

import javax.xml.ws.Holder;
import org.apache.camel.Exchange;
import org.apache.camel.Processor;
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;

public class GetCustomerStatusProcessor implements Processor {
    public static final Logger log = LoggerFactory.getLogger(GetCustomerStatusProcessor.class);

    public void process(Exchange exchng) throws Exception {
        Object[] args = exchng.getIn().getBody(Object[].class);
        String id = (String) args[0];
        Holder<String> status = (Holder<String>) args[1];
        Holder<String> statusMsg = (Holder<String>) args[2];

        log.debug("Getting status for customer "+ id + ":");

        // This is where you'd actually do the work! Setting
        // the holder values to constants for the sake of brevity.
        //
        status.value = "Offline";
        statusMsg.value = "Going to sleep now!";

        exchng.getOut().setBody(new Object[] {status , statusMsg});
    }
}
```

**35.6. DEPLOY TO OSGI**
Overview

One of the options for deploying the POJO-based route is to package it as an OSGi bundle and deploy it into an OSGi container such as Red Hat JBoss Fuse. Some of the advantages of an OSGi deployment include:

- Bundles are a relatively lightweight deployment option (because dependencies can be shared between deployed bundles).
- OSGi provides sophisticated dependency management, ensuring that only version-consistent dependencies are added to the bundle's classpath.

Using the Maven bundle plug-in

The Maven bundle plug-in is used to package your project as an OSGi bundle, in preparation for deployment into the OSGi container. There are two essential modifications to make to your project's pom.xml file:

1. Change the packaging type to bundle (by editing the value of the project/packaging element in the POM).
2. Add the Maven bundle plug-in to your POM file and configure it as appropriate.

Configuring the Maven bundle plug-in is quite a technical task (although the default settings are often adequate). For full details of how to customize the plug-in configuration, consult Deploying into the OSGi Container and Managing OSGi Dependencies.

Sample bundle plug-in configuration

The following POM fragment shows a sample configuration of the Maven bundle plug-in, which is appropriate for the current example.

```xml
<?xml version="1.0"?>
<project ...>
  ...
  <groupId>com.fusesource.byexample.cxf-webinars</groupId>
  <artifactId>customer-ws-camel-cxf-pojo</artifactId>
  <name>customer-ws-camel-cxf-pojo</name>
  <packaging>bundle</packaging>
  ...
  <build>
    <plugins>
      ...
      <plugin>
        <groupId>org.apache.felix</groupId>
        <artifactId>maven-bundle-plugin</artifactId>
        <extensions>true</extensions>
        <configuration>
          <instructions>
            <Import-Package>
              META-INF.cxf,
              META-INF.cxf.osgi,
              *
            </Import-Package>
            <DynamicImport-Package>
```
Dynamic imports

The Java packages from Apache CXF and the Spring API are imported using dynamic imports (specified using the `<DynamicImport-Package>` element). This is a pragmatic way of dealing with the fact that Spring XML files are not terribly well integrated with the Maven bundle plug-in. At build time, the Maven bundle plug-in is not able to figure out which Java classes are required by the Spring XML code. By listing wildcarded package names in the `<DynamicImport-Package>` element, however, you allow the OSGi container to figure out which Java classes are needed by the Spring XML code at run time.

NOTE

In general, using `<DynamicImport-Package>` headers is not recommended in OSGi, because it short-circuits OSGi version checking. Normally, what should happen is that the Maven bundle plug-in lists the Java packages used at build time, along with their versions, in the `<Import-Package>` header. At deploy time, the OSGi container then checks that the available Java packages are compatible with the build time versions listed in the `<Import-Package>` header. With dynamic imports, this version checking cannot be performed.

Build and deploy the POJO route bundle

After you have configured the POM file, you can build the Maven project and install it in your local repository by entering the following command:

```
mvn install
```

To deploy the route bundle, enter the following command at the JBoss Fuse console:

```
karaf@root> install -s mvn:com.fusesource.byexample.cxf-webinars/customer-ws-camel-cxf-pojo
```

NOTE

If your local Maven repository is stored in a non-standard location, you might need to customize the value of the `org.ops4j.pax.url.mvn.localRepository` property in the `EsbInstallDir/etc/org.ops4j.pax.url.mvn.cfg` file, before you can use the `mvn:` scheme to access Maven artifacts.
CHAPTER 36. PAYLOAD-BASED ROUTE

36.1. PROCESSING MESSAGES IN PAYLOAD FORMAT

Overview

Select the PAYLOAD format, if you want to access the SOAP message body in XML format, encoded as a DOM object (that is, of \texttt{org.w3c.dom.Node} type). One of the advantages of the PAYLOAD format is that no JAX-WS and JAX-B stub code is required, which allows your application to be dynamic, potentially handling many different WSDL interfaces.

Having a message body in XML format enables you to parse the request using XML languages such as XPath and to generate responses using templating languages, such as Velocity.

\textbf{NOTE}

The DOM format is not the optimal type to use for large XML message bodies. For large messages, consider using the techniques described in Chapter 37, \textit{Provider-Based Route}.

Demonstration location

The code presented in this chapter is taken from the following demonstration:

\texttt{cxr-webinars-jboss-fuse-6.1/customer-ws-camel-cxf-payload}

For details of how to download and install the demonstration code, see Chapter 31, \textit{Demonstration Code for Camel/CXF}

Camel CXF component

The Camel CXF component is an Apache CXF component that integrates Web services with routes. You can use it either to instantiate \textit{consumer endpoints} (at the start of a route), which behave like Web service instances, or to instantiate \textit{producer endpoints} (at any other points in the route), which behave like WS clients.

\textbf{NOTE}

Camel CXF endpoints—which are instantiated using the \texttt{cxf:cxfEndpoint} XML element and are implemented by the Apache Camel project—are not to be confused with the Apache CXF JAX-WS endpoints—which are instantiated using the \texttt{jaxws:endpoint} XML element and are implemented by the Apache CXF project.

PAYLOAD data format

The PAYLOAD data format is selected by setting the \texttt{dataFormat=PAYLOAD} option on a Camel CXF endpoint URI and it has the following characteristics:

- Enables you to access the message body as a DOM object (XML payload).
- No JAX-WS or JAX-B stub code required.
The SOAP body is marshalled as follows:

- The message body is effectively an XML payload of `org.w3c.dom.Node` type (wrapped in a `CxfPayload` object).
- The type of the message body is `org.apache.camel.component.cxf.CxfPayload`.
- The SOAP headers are converted into headers in the exchange's `In` message, of `org.apache.cxf.binding.soap.SoapHeader` type.

### Implementing and building a PAYLOAD route

To implement and build the demonstration PAYLOAD-based route, starting from scratch, you would perform the following steps:

1. Instantiate the Camel CXF endpoint in Spring, using the `cxf:cxfEndpoint` element.
2. Implement the route in XML, where you can use the content-based router to sort requests by operation name.
3. For each operation, define a processor bean to process the request.
4. Define velocity templates for generating the response messages.

### Sample PAYLOAD route

Figure 36.1, “Sample PAYLOAD Route” shows an outline of the route that is used to process the operations of the `CustomerService` Web service using the PAYLOAD data format. After sorting the request messages by operation name, an operation-specific processor bean reads the incoming request parameters. Finally, the response messages are generated using Velocity templates.

### 36.2. INSTANTIATE THE WS ENDPOINT

#### Overview

In Apache Camel, the CXF component is the key to integrating routes with Web services. You can use the CXF component to create two different kinds of endpoint:
Consumer endpoint—(at the start of a route) represents a Web service instance, which integrates with the route. The type of payload injected into the route depends on the value of the endpoint’s dataFormat option.

Producer endpoint—represents a special kind of WS client proxy, which converts the current exchange object into an operation invocation on a remote Web service. The format of the current exchange must match the endpoint’s dataFormat setting.

The cxf:bean: URI syntax

The cxf:bean: URI is used to bind an Apache CXF endpoint to a route and has the following general syntax:

```
cxf:bean:CxfEndpointID[?Options]
```

Where CxfEndpointID is the ID of a bean created using the cxf:cxfEndpoint element, which configures the details of the WS endpoint. You can append options to this URI (where the options are described in detail in ). To enable payload mode, you must set the URI option, dataFormat=PAYLOAD.

For example, to start a route with an endpoint in PAYLOAD mode, where the endpoint is configured by the customer-ws bean, define the route as follows:

```xml
<route>
  <from uri="cxf:bean:customer-ws?dataFormat=PAYLOAD"/>
  ...
</route>
```

The cxf:cxfEndpoint element

The cxf:cxfEndpoint element is used to define a WS endpoint that binds either to the start (consumer endpoint) or the end (producer endpoint) of a route. For example, to define the customer-ws WS endpoint in PAYLOAD mode, you define cxf:cxfEndpoint element as follows:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<beans ...>
  ...
  <cxf:cxfEndpoint id="customer-ws" address="/Customer"
   endpointName="c:SOAPOverHTTP"
   serviceName="c:CustomerService"
   wsdlURL="wsdl/CustomerService.wSDL"
  ...
</beans>
```

NOTE

In the case of PAYLOAD mode, you do not need to reference the SEI and you must specify the WSDL location instead. In fact, in PAYLOAD mode, you do not require any Java stub code at all.
Address for the Jetty container

Apache CXF deploys the WS endpoint into a Jetty servlet container instance and the address attribute of cxf:cxfEndpoint is therefore used to configure the addressing information for the endpoint in the Jetty container.

Apache CXF supports the notion of a default servlet container instance. The way the default servlet container is initialized and configured depends on the particular mode of deployment that you choose. For example the OSGi container and Web containers (such as Tomcat) provide a default servlet container.

There are two different syntaxes you can use for the endpoint address, where the syntax that you use effectively determines whether or not the endpoint is deployed into the default servlet container, as follows:

- **Address syntax for default servlet container**—to use the default servlet container, specify only the servlet context for this endpoint. Do not specify the protocol, host, and IP port in the address. For example, to deploy the endpoint to the /Customer servlet context in the default servlet container:

  address="/Customer"

- **Address syntax for custom servlet container**—to instantiate a custom Jetty container for this endpoint, specify a complete HTTP URL, including the host and IP port (the value of the IP port effectively identifies the target Jetty container). Typically, for a Jetty container, you specify the host as 0.0.0.0, which is interpreted as a wildcard that matches every IP network interface on the local machine (that is, if deployed on a multi-homed host, Jetty opens a listening port on every network card). For example, to deploy the endpoint to the custom Jetty container listening on IP port, 8083:

  address="http://0.0.0.0:8083/Customer"

**NOTE**

If you want to configure a secure endpoint (secured by SSL), you would specify the https: scheme in the address.

Specifying the WSDL location

The wsdlURL attribute of the cxf:cxfEndpoint element is used to specify the location of the WSDL contract for this endpoint. The WSDL contract is used exclusively as the source of metadata for this endpoint: there is need to specify an SEI in PAYLOAD mode.

36.3. SORT MESSAGES BY OPERATION NAME

The operationName header

When the WS endpoint parses an incoming operation invocation in PAYLOAD mode, it automatically sets the operationName header to the name of the invoked operation. You can then use this header to sort messages by operation name.

Sorting by operation name
For example, the customer-ws-camel-cxf-payload demonstration defines the following route, which uses the content-based router pattern to sort incoming messages, based on the operation name. The when predicates check the value of the operationName header using simple language expressions, sorting messages into invocations on the updateCustomer operation, the lookupCustomer operation, or the getCustomerStatus operation.

```xml
<beans ...>
...
  <camelContext id="camel"
xmlns="http://camel.apache.org/schema/spring">
    <route>
      <from uri="cxf:bean:customer-ws?dataFormat=PAYLOAD"/>
      <choice>
        <when>
          <simple>${in.header.operationName} == 'updateCustomer'</simple>
          ...
        </when>
        <when>
          <simple>${in.header.operationName} == 'lookupCustomer'</simple>
          ...
        </when>
        <when>
          <simple>${in.header.operationName} == 'getCustomerStatus'</simple>
          ...
        </when>
      </choice>
    </route>
  </camelContext>
</beans>
```

### 36.4. SOAP/HTTP-TO-JMS BRIDGE USE CASE

**Overview**

In this section, we consider a SOAP/HTTP-to-JMS bridge use case: that is, you want to create a route that transforms a synchronous operation invocation (over SOAP/HTTP) into an asynchronous message delivery (by pushing the message onto a JMS queue). In this way, it becomes possible to process the incoming operation invocations at a later time, by pulling messages off the JMS queue.

Of course, an alternative solution would be to modify the WSDL contract directly to declare the operation as OneWay, thus making the operation asynchronous. Unfortunately, it is often impractical to modify existing WSDL contracts in the real world, because this can have an impact on third-party applications.

Figure 36.2, “SOAP/HTTP-to-JMS Bridge” shows the general outline of a bridge that can transform synchronous SOAP/HTTP invocations into asynchronous JMS message deliveries.
As shown in Figure 36.2, “SOAP/HTTP-to-JMS Bridge”, the route for transforming synchronous SOAP/HTTP to asynchronous JMS works as follows:

1. The WS client invokes a synchronous operation on the Camel CXF endpoint at the start of the route. The Camel CXF endpoint then creates an initial InOut exchange at the start of the route, where the body of the exchange message contains a payload in XML format.

2. The inOnly DSL command pushes a copy of the XML payload onto a JMS queue, so that it can be processed offline at some later time.

3. The transform DSL command constructs an immediate response to send back to the client, where the response has the form of an XML string.

4. The Camel CXF component supports implicit type conversion of the XML string to payload format.

5. The response is sent back to the WS client, thus completing the synchronous operation invocation.

Evidently, this transformation can only work, if the original operation invocation has no return value. Otherwise, it would be impossible to generate a response message before the request has been processed.

Creating a broker instance

You can use Apache ActiveMQ as the JMS implementation. A convenient approach to use in this demonstration is to embed the Apache ActiveMQ broker in the bridge bundle. Simply define an amq:broker element in the Spring XML file, as follows:

```xml
<beans xmlns="http://www.springframework.org/schema/beans"
... xmlns:amq="http://activemq.apache.org/schema/core"
...>
<amq:broker brokerName="CxPayLoadDemo" persistent="false"/>
```
This broker instance is created with the persistent attribute set to false, so that the messages are stored only in memory.

**Configuring the JMS component**

Because the broker is co-located with the bridge route (in the same JVM), the most efficient way to connect to the broker is to use the VM (Virtual Machine) transport. Configure the Apache ActiveMQ component as follows, to connect to the co-located broker using the VM protocol:

```xml
<beans ...
  ...
  <bean id="activemq"
    class="org.apache.activemq.camel.component.ActiveMQComponent">
    <property name="brokerURL" value="vm:local"/>
  </bean>
  ...
</beans>
```

**NOTE**

By defining the bean with an id value of activemq, you are implicitly overriding the component associated with the endpoint URI prefix, activemq:. In other words, your custom ActiveMQComponent instance is used instead of the default ActiveMQComponent instance from the camel-activemq JAR file.

**Sample SOAP/HTTP-to-JMS route**

For example, you could define a route that implements the SOAP/HTTP-to-JMS bridge specifically for the updateCustomer operation from the CustomerService SEI, as follows:

```xml
<when>
  <simple>${in.header.operationName} == 'updateCustomer'</simple>
  <log message="Placing update customer message onto queue."/>
  <inOnly uri="activemq:queue:CustomerUpdates?jmsMessageType=Text"/>
  <transform>
    <constant>
      <![CDATA[
      <ns2:updateCustomerResponse
      ]]>
Sending to the JMS endpoint in inOnly mode

Note how the message payload is sent to the JMS queue using the `inOnly` DSL command instead of the `to` DSL command. When you send a message using the `to` DSL command, the default behavior is to use the same invocation mode as the current exchange. But the current exchange has an `InOut` MEP, which means that the `to` DSL command would wait forever for a response message from JMS.

The invocation mode we want to use when sending the payload to the JMS queue is `InOnly` (asynchronous), and we can force this mode by inserting the `inOnly` DSL command into the route.

NOTE

By specifying the option, `jmsMessageType=Text`, Camel CXF implicitly converts the message payload to an XML string before pushing it onto the JMS queue.

Returning a literal response value

The `transform` DSL command uses an expression to set the body of the exchange’s `Out` message and this message is then used as the response to the client. Your first impulse when defining a response in XML format might be to use a DOM API, but in this example, the response is specified as a string literal. This approach has the advantage of being both efficient and very easy to program.

The final step of processing, which consists of converting the XML string to a DOM object, is performed by Apache Camel’s implicit type conversion mechanism.

36.5. GENERATING RESPONSES USING TEMPLATES

Overview

One of the simplest and quickest approaches to generating a response message is to use a velocity template. Figure 36.3, “Response Generated by Velocity” shows the outline of a general template-based route. At the start of the route is a Camel CXF endpoint in PAYLOAD mode, which is the appropriate mode to use for processing the message as an XML document. After doing the work required to process the message and stashing some intermediate results in message headers, the route generates the response message using a Velocity template.

Figure 36.3. Response Generated by Velocity
Sample template-based route

For example, you could define a template-based route specifically for the `getCustomerStatus` operation, as follows:

```camelContext
...<bean id="getCustomerStatus" class="com.fusesource.customerwscamelcxfpayload.GetCustomerStatus"/>
...<route>
  ...<when>
     <simple>${in.header.operationName} == 'getCustomerStatus'</simple>
     <convertBodyTo type="org.w3c.dom.Node"/>
     <setHeader headerName="customerId">
       <xpath>/cus:getCustomerStatus/customerId/text()</xpath>
     </setHeader>
     <to uri="getCustomerStatus"/>
     <to uri="velocity:getCustomerStatusResponse.vm"/>
   </when>
  </choice>
</route>
...</camelContext>
```

Route processing steps

Given the preceding route definition, any message whose operation name matches `getCustomerStatus` would be processed as follows:

1. To facilitate processing the payload body, the first step uses `convertBodyTo` to convert the body type from `org.apache.camel.component.cxf.CxfPayload` (the default payload type) to `org.w3c.dom.Node`.

2. The route then applies an XPath expression to the message in order to extract the customer ID value and then stashes it in the `customerId` header.

3. The next step sends the message to the `getCustomerStatus` bean, which does whatever processing is required to get the customer status for the specified customer ID. The results from this step are stashed in message headers.

4. Finally, a response is generated using a velocity template.

NOTE

A common pattern when implementing Apache Camel routes is to use message headers as a temporary stash to hold intermediate results (you could also use exchange properties in the same way).

Converting XPath result to a string

Because the default return type of XPath is a node list, you must explicitly convert the result to a string, if you want to obtain the string contents of an element. There are two alternative ways of obtaining the string value of an element:

- Specify the result type explicitly using the `resultType` attribute, as follows:
Modify the expression so that it returns a text() node, which automatically converts to string:

```xml
<xpath resultType="java.lang.String">/cus:getCustomerStatus/customerId</xpath>
```

- Modify the expression so that it returns a text() node, which automatically converts to string:

```xml
<xpath>/cus:getCustomerStatus/customerId/text()</xpath>
```

getCustomerStatus processor bean

The `getCustomerStatus` processor bean is an instance of the `GetCustomerStatus` processor class, which is defined as follows:

```java
// Java
cpyackage com.fusesource.customerwscamelcxfpayload;

import org.apache.camel.Exchange;
import org.apache.camel.Processor;

public class GetCustomerStatus implements Processor {
    public void process(Exchange exchng) throws Exception {
        String id = exchng.getIn().getHeader("customerId", String.class);

        // Maybe do some kind of lookup here!

        exchng.getIn().setHeader("status", "Away");
        exchng.getIn().setHeader("statusMessage", "Going to sleep.");
    }
}
```

The implementation shown here is just a placeholder. In a realistic application you would perform some sort of checks or database lookup to obtain the customer status. In the demonstration code, however, the `status` and `statusMessage` are simply set to constant values and stashed in message headers.

In the preceding code, we make the modifications directly to the In message. When the exchange's Out message is `null`, the next processor in the route gets a copy of the current In message instead.

**NOTE**

An exceptional case occurs when the message exchange pattern is `inOnly`, in which case the Out message value is always copied into the In message, even if it is `null`.

getCustomerStatusResponse.vm Velocity template

You can generate a response message very simply using a Velocity template. The Velocity template consists of a message in plain text, where specific pieces of data can be inserted using expressions—for example, the expression `${header.HeaderName}` substitutes the value of a named header.
The Velocity template for generating the `getCustomerStatus` response is located in the `customer-ws-camel-cxf-payload/src/main/resources` directory and it contains the following template script:

```xml
<ns2:getCustomerStatusResponse
  <status>${headers.status}</status>
  <statusMessage>${headers.statusMessage}</statusMessage>
</ns2:getCustomerStatusResponse>
```

### 36.6. TYPECONVERTER FOR CXFPAYLOAD

**Overview**

Apache Camel supports a type converter mechanism, which is used to perform implicit and explicit type conversions of message bodies and message headers. The payload demonstration requires a customer type converter that can convert `String` objects to `CXFPayload` objects. This type converter automatically gets invoked at the end of the Camel route, when the generated response message (which is a `String` type) gets converted into a `CXFPayload` object.

**String to CXFPayload type converter**

The `String` to `CXFPayload` type converter is implemented in the `AdditionalCxfPayloadConverters` class, as follows:

```java
// Java
package com.fusesource.customerwscamelcxfpayload;
import java.io.ByteArrayInputStream;
import java.io.StringWriter;
import java.util.ArrayList;
import java.util.List;
import javax.xml.transform.OutputKeys;
import javax.xml.transform.Transformer;
import javax.xml.transform.TransformerFactory;
import javax.xml.transform.dom.DOMSource;
import javax.xml.transform.stream.StreamResult;
import org.apache.camel.Converter;
import org.apache.camel.component.cxf.CxfPayload;
import org.apache.cxf.binding.soap.SoapHeader;
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import org.w3c.dom.Document;
import org.w3c.dom.Element;
import org.w3c.dom.Node;

@Converter
public class AdditionalCxfPayloadConverters {
  // ...

  @Converter
  public static CxfPayload<SoapHeader> toCxfPayload(String xml) {
    // System.out.println("To CxfPayload "+ xml);
    List<Element> elements = new ArrayList<Element>();
    ...
36.7. DEPLOY TO OSGI

Overview

One of the options for deploying the payload-based route is to package it as an OSGi bundle and deploy it into an OSGi container such as Red Hat JBoss Fuse. Some of the advantages of an OSGi deployment include:

- Bundles are a relatively lightweight deployment option (because dependencies can be shared between deployed bundles).
- OSGi provides sophisticated dependency management, ensuring that only version-consistent dependencies are added to the bundle's classpath.

Using the Maven bundle plug-in

The Maven bundle plug-in is used to package your project as an OSGi bundle, in preparation for deployment into the OSGi container. There are two essential modifications to make to your project's `pom.xml` file:

1. Change the packaging type to `bundle` (by editing the value of the `project/packaging` element in the POM).

2. Add the Maven bundle plug-in to your POM file and configure it as appropriate.

Configuring the Maven bundle plug-in is quite a technical task (although the default settings are often adequate). For full details of how to customize the plug-in configuration, consult Deploying into the OSGi Container and Managing OSGi Dependencies.

Sample bundle plug-in configuration

```java
try {
    Document doc = b.newDocumentBuilder().parse(new
            ByteArrayInputStream(xml.getBytes()));
    elements.add(doc.getDocumentElement());
} catch (Exception ex) {
    log.warn("Exception while converting String payload to
            CxfPayload; resulting payload will be empty.");
    // The CxfPayload is changed to use Source object under layer, the
            elements API only work if we already setup the list before creating the
            CxfPayload
    CxfPayload<SoapHeader> ret = new CxfPayload<SoapHeader>(null,
            elements);
    return ret;
}
...
The following POM fragment shows a sample configuration of the Maven bundle plug-in, which is appropriate for the current example.

```xml
<?xml version="1.0"?>
<project ...>
  ...
  <groupId>com.fusesource.byexample.cxf-webinars</groupId>
  <artifactId>customer-ws-camel-cxf-payload</artifactId>
  <name>customer-ws-camel-cxf-payload</name>
  <packaging>bundle</packaging>
  ...
  <build>
    <plugins>
      ...
      <plugin>
        <groupId>org.apache.felix</groupId>
        <artifactId>maven-bundle-plugin</artifactId>
        <extensions>true</extensions>
        <configuration>
          <instructions>
            <Import-Package>
              org.apache.camel.component.velocity,
              META-INF.cxf,
              META-INF.cxf.osgi,
              javax.jws,
              javax.wsdl,
              javax.xml.bind,
              javax.xml.bind.annotation,
              javax.xml.namespace,
              javax.xml.ws,
              org.w3c.dom,
              <!-- Workaround to access DOM XPathFactory -->
              org.apache.xpath.jaxp,
              *
            </Import-Package>
            <DynamicImport-Package>
              org.apache.cxf.*,
              org.springframework.beans.*
            </DynamicImport-Package>
          </instructions>
        </configuration>
      </plugin>
      ...
    </plugins>
  </build>
</project>
```

**Dynamic imports**

The Java packages from Apache CXF and the Spring API are imported using dynamic imports (specified using the `DynamicImport-Package` element). This is a pragmatic way of dealing with the fact that Spring XML files are not terribly well integrated with the Maven bundle plug-in. At build time, the Maven bundle plug-in is not able to figure out which Java
classes are required by the Spring XML code. By listing wildcarded package names in the `DynamicImport-Package` element, however, you allow the OSGi container to figure out which Java classes are needed by the Spring XML code at run time.

**NOTE**

In general, using `DynamicImport-Package` headers is not recommended in OSGi, because it short-circuits OSGi version checking. Normally, what should happen is that the Maven bundle plug-in lists the Java packages used at build time, along with their versions, in the `Import-Package` header. At deploy time, the OSGi container then checks that the available Java packages are compatible with the build time versions listed in the `Import-Package` header. With dynamic imports, this version checking cannot be performed.

### Build and deploy the client bundle

After you have configured the POM file, you can build the Maven project and install it in your local repository by entering the following command:

```
mvn install
```

Install the `camel-velocity` feature, which is needed for this example:

```
karaf@root> features:install camel-velocity
```

To deploy the route bundle, enter the following command at the console:

```
karaf@root> install -s mvn:com.fusesource.byexample.cxf-webinars/customer-ws-camel-cxf-payload
```

**NOTE**

If your local Maven repository is stored in a non-standard location, you might need to customize the value of the `org.ops4j.pax.url.mvn.localRepository` property in the `InstallDir/etc/org.ops4j.pax.url.mvn.cfg` file, before you can use the `mvn:` scheme to access Maven artifacts.
CHAPTER 37. PROVIDER-BASED ROUTE

37.1. PROVIDER-BASED JAX-WS ENDPOINT

Overview

Use the provider-based approach, if you need to process very large Web services messages. The provider-based approach is a variant of the PAYLOAD data format that enables you to encode the message body as an XML streaming type, such as SAXSource. Since the XML streaming types are more efficient than DOM objects, the provider-based approach is ideal for large XML messages.

Demonstration location

The code presented in this chapter is taken from the following demonstration:

`cxfr-webinars-jboss-fuse-6.1/customer-ws-camel-cxf-provider`

For details of how to download and install the demonstration code, see Chapter 31, Demonstration Code for Camel/CXF

Camel CXF component

The Camel CXF component is an Apache CXF component that integrates Web services with routes. You can use it either to instantiate consumer endpoints (at the start of a route), which behave like Web service instances, or to instantiate producer endpoints (at any other points in the route), which behave like WS clients.

**NOTE**

Came CXF endpoints—which are instantiated using the `cxf:cxfEndpoint` XML element and are implemented by the Apache Camel project—are not to be confused with the Apache CXF JAX-WS endpoints—which are instantiated using the `jaxws:endpoint` XML element and are implemented by the Apache CXF project.

Provider-based approach and the PAYLOAD data format

The provider-based approach is a variant of the PAYLOAD data format, which is enabled as follows:

- Define a custom `javax.xml.ws.Provider<StreamType>` class, where the `StreamType` type is an XML streaming type, such as SAXSource.
- The PAYLOAD data format is selected by an annotation on the custom `Provider<?>` class (see the section called “The SAXSourceService provider class”).
- The custom `Provider<?>` class is referenced by setting the `serviceClass` attribute of the `cxf:cxfEndpoint` element in XML configuration.

The provider-based approach has the following characteristics:
- Enables you to access the message body as a streamed XML type—for example, `javax.xml.transform.sax.SAXSource`.

- No JAX-WS or JAX-B stub code required.

- The SOAP body is marshalled into a stream-based `SAXSource` type.

- The SOAP headers are converted into headers in the exchange's `In` message, of `org.apache.cxf.binding.soap.SoapHeader` type.

**Implementing and building a provider-based route**

To implement and build the demonstration provider-based route, starting from scratch, you would perform the following steps:

1. Define a custom `javax.xml.ws.Provider<StreamType>` class (the current demonstration uses `SAXSource` as the `StreamType` type).

2. Instantiate the Camel CXF endpoint in Spring, using the `cxf:cxfEndpoint` element and reference the custom provider class (using the `serviceClass` attribute).

3. Implement the route in XML, where you can use the content-based router to sort requests by operation name.

4. For each operation, define a processor bean to process the request.

5. Define velocity templates for generating the response messages.

6. Define a custom type converter, to support converting a `String` message body to a `SAXSource` message body.

**Sample provider-based route**

*Figure 37.1, “Sample Provider-Based Route”* shows an outline of the route that is used to process the operations of the `CustomerService` Web service using the provider-based approach. After sorting the request messages by operation name, an operation-specific processor bean reads the incoming request parameters. Finally, the response messages are generated using Velocity templates.

*Figure 37.1. Sample Provider-Based Route*
37.2. CREATE A PROVIDER<?> IMPLEMENTATION CLASS

Overview

The fundamental prerequisite for using provider mode is to define a custom `Provider<>` class that implements the `invoke()` method. In fact, the sole purpose of this class is to provide runtime type information for Apache CXF: the `invoke()` method never gets called!

By implementing the provider class in the way shown here, you are merely indicating to the Apache CXF runtime that the WS endpoint should operate in PAYLOAD mode and the type of the message PAYLOAD should be `SAXSource`.

The SAXSourceService provider class

The definition of the provider class is relatively short and the complete definition of the customer provider class, `SAXSourceService`, is as follows:

```java
// Java
package com.fusesource.customerwscamelcxprovider;

import javax.xml.transform.sax.SAXSource;
import javax.xml.ws.Provider;
import javax.xml.ws.Service.Mode;
import javax.xml.ws.ServiceMode;
import javax.xml.ws.WebServiceProvider;

@WebServiceProvider()
@ServiceMode(Mode.PAYLOAD)
public class SAXSourceService implements Provider<SAXSource> {
    public SAXSource invoke(SAXSource t) {
        throw new UnsupportedOperationException("Not supported yet.");
    }
}
```

The customer provider class, `SAXSourceService`, must be annotated by the `@WebServiceProvider` annotation to mark it as a provider class and can be optionally annotated by the `@ServiceMode` annotation to select PAYLOAD mode.

37.3. INSTANTIATE THE WS ENDPOINT

Overview

In Apache Camel, the CXF component is the key to integrating routes with Web services. You can use the CXF component to create two different kinds of endpoint:

- Consumer endpoint—(at the start of a route) represents a Web service instance, which integrates with the route. The type of payload injected into the route depends on the value of the endpoint's `dataFormat` option.

- Producer endpoint—represents a special kind of WS client proxy, which converts the current exchange object into an operation invocation on a remote Web service. The format of the current exchange must match the endpoint's `dataFormat` setting.
The cxf:bean: URI syntax

The cxf:bean: URI is used to bind an Apache CXF endpoint to a route and has the following general syntax:

```
cxf:bean:CxfEndpointID[?Options]
```

Where CxfEndpointID is the ID of a bean created using the cxf:cxfEndpoint element, which configures the details of the WS endpoint. You can append options to this URI (where the options are described in detail in ). Provider mode is essentially a variant of PAYLOAD mode: you could specify this mode on the URI (by setting dataFormat=PAYLOAD), but this is not necessary, because PAYLOAD mode is already selected by the @ServiceMode annotation on the custom Provider class.

For example, to start a route with an endpoint in provider mode, where the endpoint is configured by the customer-ws bean, define the route as follows:

```xml
<route>
    <from uri="cxf:bean:customer-ws"/>
    ...
</route>
```

The cxf:cxfEndpoint element

The cxf:cxfEndpoint element is used to define a WS endpoint that binds either to the start (consumer endpoint) or the end (producer endpoint) of a route. For example, to define the customer-ws WS endpoint in provider mode, you define acxf:cxfEndpoint element as follows:

```xml
<beans ...>
    ...
    <cxf:cxfEndpoint id="customer-ws"
        address="/Customer"
        endpointName="c:SOAPOverHTTP"
        serviceName="c:CustomerService"
        wsdlURL="wsdl/CustomerService.wsdl"
        serviceClass="com.fusesource.customerwscamelcxfprovider.SAXSourceService"
    ...
</beans>
```

Specifying the WSDL location

The wsdlURL attribute of the cxf:cxfEndpoint element is used to specify the location of the WSDL contract for this endpoint. The WSDL contract is used as the source of metadata for this endpoint.

Specifying the service class

A key difference between provider mode and ordinary PAYLOAD mode is that the serviceClass attribute must be set to the provider class, SAXSourceService.
37.4. SORT MESSAGES BY OPERATION NAME

The operationName header

When the WS endpoint parses an incoming operation invocation in PROVIDER mode, it automatically sets the operationName header to the name of the invoked operation. You can then use this header to sort messages by operation name.

Sorting by operation name

For example, the customer-ws-camel-cxf-provider demonstration defines the following route, which uses the content-based router pattern to sort incoming messages, based on the operation name. The when predicates check the value of the operationName header using simple language expressions, sorting messages into invocations on the updateCustomer operation, the lookupCustomer operation, or the getCustomerStatus operation.

```xml
<beans ...
   ...
   <camelContext id="camel"
xmlns="http://camel.apache.org/schema/spring">
   <route>
      <from uri="cxf:bean:customer-ws"/>
      <choice>
         <when>
            <simple>${in.header.operationName} == 'updateCustomer'</simple>
            ...
         </when>
         <when>
            <simple>${in.header.operationName} == 'lookupCustomer'</simple>
            ...
         </when>
         <when>
            <simple>${in.header.operationName} == 'getCustomerStatus'</simple>
            ...
         </when>
      </choice>
   </route>
   </camelContext>
   ...
</beans>
```

37.5. SOAP/HTTP-TO-JMS BRIDGE USE CASE

Overview

In this section, we consider a SOAP/HTTP-to-JMS bridge use case: that is, you want to create a route that transforms a synchronous operation invocation (over SOAP/HTTP) into an asynchronous message delivery (by pushing the message onto a JMS queue). In this way, it
becomes possible to process the incoming operation invocations at a later time, by pulling messages off the JMS queue.

Figure 37.2, “SOAP/HTTP-to-JMS Bridge” shows the general outline of a bridge that can transform synchronous SOAP/HTTP invocations into asynchronous JMS message deliveries.

**Figure 37.2. SOAP/HTTP-to-JMS Bridge**

![Diagram of SOAP/HTTP-to-JMS Bridge]

**Transforming RPC operations to One Way**

As shown in Figure 37.2, “SOAP/HTTP-to-JMS Bridge”, the route for transforming synchronous SOAP/HTTP to asynchronous JMS works as follows:

1. The WS client invokes a synchronous operation on the Camel CXF endpoint at the start of the route. The Camel CXF endpoint then creates an initial InOut exchange at the start of the route, where the body of the exchange message contains a payload in XML format.

2. The inOnly DSL command pushes a copy of the XML payload onto a JMS queue, so that it can be processed offline at some later time.

3. The transform DSL command constructs an immediate response to send back to the client, where the response has the form of an XML string.

4. The route explicitly converts the XML string to the javax.xml.transform.sax.SAXSource type.

5. The response is sent back to the WS client, thus completing the synchronous operation invocation.

Evidently, this transformation can only work, if the original operation invocation has no return value. Otherwise, it would be impossible to generate a response message before the request has been processed.

**Creating a broker instance**

You can use Apache ActiveMQ as the JMS implementation. A convenient approach to use in this demonstration is to embed the Apache ActiveMQ broker in the bridge bundle. Simply define an amq:broker element in the Spring XML file, as follows:
This broker instance is created with the persistent attribute set to false, so that the messages are stored only in memory.

Configuring the JMS component

Because the broker is co-located with the bridge route (in the same JVM), the most efficient way to connect to the broker is to use the VM (Virtual Machine) transport. Configure the Apache ActiveMQ component as follows, to connect to the co-located broker using the VM protocol:

```xml
<beans xmlns="http://www.springframework.org/schema/beans"
       xmlns:amq="http://activemq.apache.org/schema/core">
    <amq:broker brokerName="CxfPayloadDemo" persistent="false">
        <amq:transportConnectors>
            <amq:transportConnector name="openwire" uri="tcp://localhost:51616"/>
            <amq:transportConnector name="vm" uri="vm:local"/>
        </amq:transportConnectors>
    </amq:broker>
</beans>
```

NOTE

By defining the bean with an id value of activemq, you are implicitly overriding the component associated with the endpoint URI prefix, activemq:. In other words, your custom ActiveMQComponent instance is used instead of the default ActiveMQComponent instance from the camel-activemq JAR file.

Sample SOAP/HTTP-to-JMS route

For example, you could define a route that implements the SOAP/HTTP-to-JMS bridge specifically for the updateCustomer operation from the CustomerService SEI, as follows:

```xml
<when>
    <simple>${in.header.operationName} == 'updateCustomer'</simple>
    <log message="Placing update customer message onto queue."/>
    <inOnly uri="activemq:queue:CustomerUpdates?jmsMessageType=Text"/>
    <transform>
```

```xml
```
Sending to the JMS endpoint in inOnly mode

Note how the message payload is sent to the JMS queue using the `inOnly` DSL command instead of the `to` DSL command. When you send a message using the `to` DSL command, the default behavior is to use the same invocation mode as the current exchange. But the current exchange has an `InOut` MEP, which means that the `to` DSL command would wait forever for a response message from JMS.

The invocation mode we want to use when sending the payload to the JMS queue is `InOnly` (asynchronous), and we can force this mode by inserting the `inOnly` DSL command into the route.

NOTE

By specifying the option, `jmsMessageType=Text`, Camel CXF implicitly converts the message payload to an XML string before pushing it onto the JMS queue.

Returning a literal response value

The `transform` DSL command uses an expression to set the body of the exchange's `Out` message and this message is then used as the response to the client. Your first impulse when defining a response in XML format might be to use a DOM API, but in this example, the response is specified as a string literal. This approach has the advantage of being both efficient and very easy to program.

Type conversion of the response message

In this example, the reply message (like the request message) is required to be of type, `javax.xml.transform.sax.SAXSource`. In the last step of the route, therefore, you must convert the message body from `String` type to `javax.xml.transform.sax.SAXSource` type, by invoking the `convertBodyTo` DSL command.

The implementation of the String to `SAXSource` conversion is provided by a custom type converter, as described in Section 37.7, “TypeConverter for SAXSource”.

37.6. GENERATING RESPONSES USING TEMPLATES

Overview

One of the simples and quickest approaches to generating a response message is to use a velocity template. Figure 37.3, “Response Generated by Velocity” shows the outline of a general template-based route. At the start of the route is a Camel CXF endpoint in provider mode, which is the appropriate mode to use for processing the message as an XML document. After doing the work required to process the message and stashing some
intermediate results in message headers, the route generates the response message using a Velocity template.

**Figure 37.3. Response Generated by Velocity**

![Camel Route Diagram]

**Sample template-based route**

For example, you could define a template-based route specifically for the `getCustoemrStatus` operation, as follows:

```xml
...<when>
  <simple>${in.header.operationName} == 'getCustomerStatus'</simple>
  <setHeader headerName="customerId">
    <xpath resultType="java.lang.String">/cus:getCustomerStatus/customerId</xpath>
    </setHeader>
    <to uri="getCustomerStatus"/>
    <to uri="velocity:getCustomerStatusResponse.vm"/>
    <convertBodyTo type="javax.xml.transform.sax.SAXSource"/>
  </when>
</choice>
</route>
</camelContext>
...<bean id="getCustomerStatus" class="com.fusesource.customerwscamelcxfpayload.GetCustomerStatus"/>
```

**Route processing steps**

Given the preceding route definition, any message whose operation name matches `getCustomerStatus` would be processed as follows:

1. The route applies an XPath expression to the message in order to extract the customer ID value and then stashes it in the `customerId` header.

2. The next step sends the message to the `getCustomerStatus` bean, which does whatever processing is required to get the customer status for the specified customer ID. The results from this step are stashed in message headers.

3. A response is generated using a Velocity template.

4. Finally, the XML string generated by the Velocity template must be explicitly converted to the `javax.xml.transform.sax.SAXSource` type using `convertBodyTo` (which implicitly relies on a type converter).
NOTE

A common pattern when implementing Apache Camel routes is to use message headers as a temporary stash to hold intermediate results (you could also use exchange properties in the same way).

XPath expressions and SAXSource

XPath expressions can be applied directly to SAXSource objects. The XPath implementation has a pluggable architecture that supports a variety of XML parsers and when XPath encounters a SAXSource object, it automatically loads the plug-in required to support SAXSource parsing.

getCustomerStatus processor bean

The getCustomerStatus processor bean is an instance of the GetCustomerStatus processor class, which is defined as follows:

```java
// Java
package com.fusesource.customerwscamelcxfpayload;

import org.apache.camel.Exchange;
import org.apache.camel.Processor;

public class GetCustomerStatus implements Processor {
    public void process(Exchange exchng) throws Exception {
        String id = exchng.getIn().getHeader("customerId", String.class);

        // Maybe do some kind of lookup here!
        //
        exchng.getIn().setHeader("status", "Away");
        exchng.getIn().setHeader("statusMessage", "Going to sleep.");
    }
}
```

The implementation shown here is just a placeholder. In a realistic application you would perform some sort of checks or database lookup to obtain the customer status. In the demonstration code, however, the status and statusMessage are simply set to constant values and stashed in message headers.

getCustomerStatusResponse.vm Velocity template

You can generate a response message very simply using a Velocity template. The Velocity template consists of a message in plain text, where specific pieces of data can be inserted using expressions—for example, the expression \${header.HeaderName} substitutes the value of a named header.

The Velocity template for generating the getCustomerStatus reponse is located in the customer-ws-camel-cxf-provider/src/main/resources directory and it contains the following template script:

```xml
<ns2:getCustomerStatusResponse
```
37.7. TYPECONVERTER FOR SAXSOURCE

Overview

Apache Camel supports a type converter mechanism, which is used to perform implicit and explicit type conversions of message bodies and message headers. The type converter mechanism is extensible and it so happens that the provider demonstration requires a custom type converter that can convert String objects to SAXSource objects.

String to SAXSource type converter

The String to SAXSource type converter is implemented in the AdditionalConverters class, as follows:

```java
// Java
package com.fusesource.customerwscamelcxfprovider;
import java.io.ByteArrayInputStream;
import javax.xml.transform.sax.SAXSource;
import org.apache.camel.Converter;
import org.xml.sax.InputSource;
@Converter
public class AdditionalConverters {
    @Converter
    public static SAXSource toSAXSource(String xml) {
        return new SAXSource(new InputSource(new ByteArrayInputStream(xml.getBytes())));
    }
}
```

Reference

For full details of the type converter mechanism in Apache Camel, see Section 40.3, “Built-In Type Converters” and Chapter 42, Type Converters.

37.8. DEPLOY TO OSGI

Overview

One of the options for deploying the provider-based route is to package it as an OSGi bundle and deploy it into an OSGi container such as Red Hat JBoss Fuse. Some of the advantages of an OSGi deployment include:

- Bundles are a relatively lightweight deployment option (because dependencies can be shared between deployed bundles).
OSGi provides sophisticated dependency management, ensuring that only version-consistent dependencies are added to the bundle's classpath.

Using the Maven bundle plug-in

The Maven bundle plug-in is used to package your project as an OSGi bundle, in preparation for deployment into the OSGi container. There are two essential modifications to make to your project's **pom.xml** file:

1. Change the packaging type to **bundle** (by editing the value of the `project/packaging` element in the POM).

2. Add the Maven bundle plug-in to your POM file and configure it as appropriate.

Configuring the Maven bundle plug-in is quite a technical task (although the default settings are often adequate). For full details of how to customize the plug-in configuration, consult *Deploying into the OSGi Container* and *Managing OSGi Dependencies*.

Sample bundle plug-in configuration

The following POM fragment shows a sample configuration of the Maven bundle plug-in, which is appropriate for the current example.

```xml
<?xml version="1.0"?>
<project ...>
  ...
  <groupId>com.fusesource.byexample.cxf-webinars</groupId>
  <artifactId>customer-ws-camel-cxf-provider</artifactId>
  <name>customer-ws-camel-cxf-provider</name>
  <packaging>bundle</packaging>
  ...
  <build>
    <plugins>
      ...
      <plugin>
        <groupId>org.apache.felix</groupId>
        <artifactId>maven-bundle-plugin</artifactId>
        <extensions>true</extensions>
        <configuration>
          <instructions>
            ...
            <Import-Package>
              org.apache.camel.component.velocity,
              META-INF.cxf,
              META-INF.cxf.osgi,
              javax.jws,
              javax.wSDL,
              javax.xml.bind,
              javax.xml.bind.annotation,
              javax.xml.namespace,
              javax.xml.ws,
              org.w3C.dom,
              <!-- Workaround to access DOM XPathFactory -->
              org.apache.xpath.jaxp,
            *
          </Import-Package>
          <DynamicImport-Package>
          </DynamicImport-Package>
        </configuration>
        ...
      </plugin>
    </plugins>
  </build>
</project>
```
Dynamic imports

The Java packages from Apache CXF and the Spring API are imported using dynamic imports (specified using the `DynamicImport-Package` element). This is a pragmatic way of dealing with the fact that Spring XML files are not terribly well integrated with the Maven bundle plug-in. At build time, the Maven bundle plug-in is not able to figure out which Java classes are required by the Spring XML code. By listing wildcarded package names in the `DynamicImport-Package` element, however, you allow the OSGi container to figure out which Java classes are needed by the Spring XML code at run time.

**NOTE**

In general, using `DynamicImport-Package` headers is not recommended in OSGi, because it short-circuits OSGi version checking. Normally, what should happen is that the Maven bundle plug-in lists the Java packages used at build time, along with their versions, in the `Import-Package` header. At deploy time, the OSGi container then checks that the available Java packages are compatible with the build time versions listed in the `Import-Package` header. With dynamic imports, this version checking cannot be performed.

Build and deploy the client bundle

After you have configured the POM file, you can build the Maven project and install it in your local repository by entering the following command:

```
mvn install
```

To deploy the route bundle, enter the following command at the container console:

```
karaf@root> install -s mvn:com.fusesource.byexample.cxf-webinars/customer-ws-camel-cxf-provider
```

**NOTE**

If your local Maven repository is stored in a non-standard location, you might need to customize the value of the `org.ops4j.pax.url.mvn.localRepository` property in the `EsbInstallDir/etc/org.ops4j.pax.url.mvn.cfg` file, before you can use the `mvn:` scheme to access Maven artifacts.
CHAPTER 38. PROXYING A WEB SERVICE

Abstract

A common use case for the Camel CXF component is to use a route as a proxy for a Web service. That is, in order to perform additional processing of WS request and response messages, you interpose a route between the WS client and the original Web service.

38.1. PROXYING WITH HTTP

Overview

The simplest way to proxy a SOAP/HTTP Web service is to treat the request and reply messages as HTTP packets. This type of proxying can be used where there is no requirement to read or modify the messages passing through the route. For example, you could use this kind of proxying to apply various patterns of flow control on the WS messages.

Figure 38.1, “Proxy Route with Message in HTTP Format” shows an overview of how to proxy a Web service using an Apache Camel route, where the route treats the messages as HTTP packets. The key feature of this route is that both the consumer endpoint (at the start of the route) and the producer endpoint (at the end of the route) must be compatible with the HTTP packet format.

Alternatives for the consumer endpoint

The following Apache Camel endpoints can be used as consumer endpoints for HTTP format messages:

- **Jetty endpoint**—is a lightweight Web server. You can use Jetty to handle messages for any HTTP-based protocol, including the commonly-used Web service SOAP/HTTP protocol.

- **Camel CXF endpoint in MESSAGE mode**—when a Camel CXF endpoint is used in MESSAGE mode, the body of the exchange message is the raw message received from the transport layer (which is HTTP). In other words, the Camel CXF endpoint in MESSAGE mode is equivalent to a Jetty endpoint in the case of HTTP-based protocols.

Consumer endpoint for HTTP

A Jetty endpoint has the general form, `{jetty:HttpAddress}`. To configure the Jetty endpoint to be a proxy for a Web service, use a `HttpAddress` value that is almost identical to the HTTP address the client connects to, except that Jetty's version of `HttpAddress` uses the
special hostname, **0.0.0.0** (which matches all of the network interfaces on the current machine).

```xml
<route>
  <from uri="jetty:http://0.0.0.0:9093/Customers?matchOnUriPrefix=true"/>
  ...
</route>
```

**matchOnUriPrefix option**

Normally, a Jetty consumer endpoint accepts only an exact match on the context path. For example, a request that is sent to the address `http://localhost:9093/Customers` would be accepted, but a request sent to `http://localhost:9093/Customers/Foo` would be rejected. By setting `matchOnUriPrefix` to `true`, however, you enable a kind of wildcarding on the context path, so that any context path prefixed by `/Customers` is accepted.

**Alternatives for the producer endpoint**

The following Apache Camel endpoints can be used as producer endpoints for HTTP format messages:

- **Jetty HTTP client endpoint**—(recommended) the Jetty library implements a HTTP client. In particular, the Jetty HTTP client features support for HttpClient thread pools, which means that the Jetty implementation scales particularly well.

- **HTTP endpoint**—the HTTP endpoint implements a HTTP client based on the HttpClient 3.x API.

- **HTTP4 endpoint**—the HTTP endpoint implements a HTTP client based on the HttpClient 4.x API.

**Producer endpoint for HTTP**

To configure a Jetty HTTP endpoint to send HTTP requests to a remote SOAP/HTTP Web service, set the `uri` attribute of the `to` element at the end of the route to be the address of the remote Web service, as follows:

```xml
<route>
  ...
  <to uri="jetty:http://localhost:8083/Customers?bridgeEndpoint=true&amp;throwExceptionOnFailure=false"/>
</route>
```

**bridgeEndpoint option**

The HTTP component supports a `bridgeEndpoint` option, which you can enable on a HTTP producer endpoint to configure the endpoint appropriately for operating in a HTTP-to-HTTP bridge (as is the case in this demonstration). In particular, when `bridgeEndpoint=true`, the HTTP endpoint ignores the value of the `Exchange.HTTP_URI` header, using the HTTP address from the endpoint URI instead.

**throwExceptionOnFailure option**
Setting `throwExceptionOnFailure` to `false` ensures that any HTTP exceptions are relayed back to the original WS client, instead of being thrown within the route.

**Handling message headers**

When defining a HTTP bridge application, the `CamelHttp*` headers set by the consumer endpoint at the start of the route can affect the behavior of the producer endpoint. For this reason, in a bridge application it is advisable to remove the `CamelHttp*` headers before the message reaches the producer endpoint, as follows:

```xml
<route>
    <from uri="jetty:http:..."/>
    ...
    <removeHeaders pattern="CamelHttp*"/>
    <to uri="jetty:http:..."/>
</route>
```

**Outgoing HTTP headers**

By default, any headers in the exchange that are `not` prefixed by `Camel` will be converted into HTTP headers and sent out over the wire by the HTTP producer endpoint. This could have adverse consequences on the behavior of your application, so it is important to be aware of any headers that are set in the exchange object and to remove them, if necessary.

For more details about dealing with headers, see Section 38.4, “Handling HTTP Headers”.

### 38.2. PROXYING WITH POJO FORMAT

**Overview**

If you want to access the content of the Web services messages that pass through the route, you might prefer to process the messages in POJO format: that is, where the body of the exchange consists of a list of Java objects representing the WS operation parameters. The key advantage of using POJO format is that you can easily process the contents of a message, by accessing the operation parameters as Java objects.

Figure 38.2, “Proxy Route with Message in POJO Format” shows an overview of how to proxy a Web service using an Apache Camel route, where the route processes the messages in POJO format. The key feature of this route is that both the consumer endpoint (at the start of the route) and the producer endpoint (at the end of the route) must be compatible with the POJO data format.

**Figure 38.2. Proxy Route with Message in POJO Format**

To parse incoming messages into POJO data format, the consumer endpoint at the start of
the route must be a Camel CXF endpoint that is configured to use POJO mode. Use the `cxf:bean:BeanID` URI format to reference the Camel CXF endpoint as follows (where the `dataFormat` option defaults to POJO):

```xml
<route>
  <from uri="cxf:bean:customerServiceProxy"/>
  ...
</route>
```

The bean with the ID, `customerServiceProxy`, is a Camel CXF/POJO endpoint, which is defined as follows:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<beans ...>
  ...  
  <cxf:cxfEndpoint
    id="customerServiceProxy"
    xmlns:c="http://demo.fusesource.org/wsdl/camelcxf"
    address="/Customers"
    endpointName="c:SOAPOverHTTP"
    serviceName="c:CustomerService"
    wsdlURL="wsdl/CustomerService.wsdl"
    serviceClass="org.fusesource.demo.wsdl.camelcxf.CustomerService"
  />
  ...
</beans>
```

### Producer endpoint for CXF/POJO

To convert the exchange body from POJO data format to a SOAP/HTTP message, the producer endpoint at the end of the route must be a Camel CXF endpoint configured to use POJO mode. Use the `cxf:bean:BeanID` URI format to reference the Camel CXF endpoint as follows (where the `dataFormat` option defaults to POJO):

```xml
<route>
  ...
  <to uri="cxf:bean:customerServiceReal"/>
</route>
```

The bean with the ID, `customerServiceReal`, is a Camel CXF/POJO endpoint, which is defined as follows:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<beans ...>
  ...
  <cxf:cxfEndpoint
    id="customerServiceReal"
    xmlns:c="http://demo.fusesource.org/wsdl/camelcxf"
    address="http://localhost:8083/Customers"
    endpointName="c:SOAPOverHTTP"
    serviceName="c:CustomerService"
    wsdlURL="wsdl/CustomerService.wsdl"
    serviceClass="org.fusesource.demo.wsdl.camelcxf.CustomerService"
  />
  ...
</beans>
```
38.3. PROXYING WITH PAYLOAD FORMAT

Overview

If you want to access the content of the Web services messages that pass through the route, you might prefer to process the messages in the normal PAYLOAD format: that is, where the body of the exchange is accessible as an XML document (essentially, an org.w3c.dom.Node object). The key advantage of using PAYLOAD format is that you can easily process the contents of a message by accessing the message body as an XML document.

Figure 38.3, “Proxy Route with Message in PAYLOAD Format” shows an overview of how to proxy a Web service using an Apache Camel route, where the route processes the messages in PAYLOAD format. The key feature of this route is that both the consumer endpoint (at the start of the route) and the producer endpoint (at the end of the route) must be compatible with the PAYLOAD data format.

Consumer endpoint for CXF/PAYLOAD

To parse incoming messages into PAYLOAD data format, the consumer endpoint at the start of the route must be a Camel CXF endpoint that is configured to use PAYLOAD mode. Use the cxf:bean:BeanID URI format to reference the Camel CXF endpoint as follows, where you must set the dataFormat option to PAYLOAD:

```xml
<route>
  <from uri="cxf:bean:customerServiceProxy?dataFormat=PAYLOAD"/>
  ...
</route>
```

The bean with the ID, customerServiceProxy, is a Camel CXF/PAYLOAD endpoint, which is defined as follows:

```xml
<beans version="1.0" encoding="UTF-8">...<cxf:cxfEndpoint
        id="customerServiceProxy"
        xmlns:c="http://demo.fusesource.org/wsdls/camelcxf"
        address="/Customers"
        endpointName="c:SOAPOverHTTP"
        serviceName="c:CustomerService"
        wsdlURL="wsdl/CustomerService.wsdl"/>...>
```
Producer endpoint for CXF/PAYLOAD

To convert the exchange body from PAYLOAD data format to a SOAP/HTTP message, the producer endpoint at the end of the route must be a Camel CXF endpoint configured to use PAYLOAD mode. Use the `cxf:bean:BeanID` URI format to reference the Camel CXF endpoint as follows, where you must set the `dataFormat` option to PAYLOAD:

```xml
<route>
  ...
  <to uri="cxf:bean:customerServiceReal?dataFormat=PAYLOAD"/>
</route>
```

The bean with the ID, `customerServiceReal`, is a Camel CXF/PAYLOAD endpoint, which is defined as follows:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<beans ...
  ...
  <cxf:cxfEndpoint
    id="customerServiceReal"
    xmlns:c="http://demo.fusesource.org/wsdl/camelcxf"
    address="http://localhost:8083/Customers"
    endpointName="c:SOAPOverHTTP"
    serviceName="c:CustomerService"
    wsdlURL="wsdl/CustomerService.wsdl"
  />
</beans>
```

Outgoing HTTP headers

By default, any headers in the exchange that are not prefixed by Camel will be converted into HTTP headers and sent out over the wire by the Camel CXF producer endpoint. This could have adverse consequences on the behavior of your application, so it is important to be aware of any headers that are set in the exchange object and to remove them, if necessary.

For more details about dealing with headers, see Section 38.4, “Handling HTTP Headers”.

38.4. HANDLING HTTP HEADERS

Overview

When building bridge applications using HTTP or HTTP-based components, it is important to be aware of how the HTTP-based endpoints process headers. In many cases, internal headers (prefixed by Camel) or other headers can cause unwanted side-effects on your application. It is often necessary to remove or filter out certain headings or classes of headings in your route, in order to ensure that your application behaves as expected.
HTTP-based components

The behavior described in this section affects not just the Camel HTTP component (camel-http), but also a number of other HTTP-based components, including:

- camel-http
- camel-http4
- camel-jetty
- camel-restlet
- camel-cxf

HTTP consumer endpoint

When a HTTP consumer endpoint receives an incoming message, it creates an In message with the following headers:

**CamelHttp* headers**

Several headers with the CamelHttp prefix are created, which record the status of the incoming message. For details of these internal headers, see HTTP.

**HTTP headers**

All of the HTTP headers from the original incoming message are mapped to headers on the exchange's In message.

**URL options (Jetty only)**

The URL options from the original HTTP request URL are mapped to headers on the exchange's In message. For example, given the client request with the URL, http://myserver/myserver?orderid=123, a Jetty consumer endpoint creates the orderid header with value 123.

HTTP producer endpoint

When a HTTP producer endpoint receives an exchange and converts it to the target message format, it handles the In message headers as follows:

**CamelHttp**

Headers prefixed by CamelHttp are used to control the behavior of the HTTP producer endpoint. Any headers of this kind are consumed by the HTTP producer endpoint and the endpoint behaves as directed.

**Camel**

All other headers prefixed by Camel are presumed to be meant for internal use and are not mapped to HTTP headers in the target message (in other words, these headers are ignored).

****

All other headers are converted to HTTP headers in the target message, with the exception of the following headers, which are blocked (based on a case-insensitive match):

- content-length
Implications for HTTP bridge applications

When defining a HTTP bridge application (that is, a route starting with a HTTP consumer endpoint and ending with a HTTP producer endpoint), the CamelHttp* headers set by the consumer endpoint at the start of the route can affect the behavior of the producer endpoint. For this reason, in a bridge application it is advisable to remove the CamelHttp* headers, as follows:

```
from("http://0.0.0.0/context/path")
    .removeHeaders("CamelHttp*")
    ...
    .to("http://remoteHost/context/path");
```

Setting a custom header filter

If you want to customize the way that a HTTP producer endpoint processes headers, you can define your own customer header filter by defining the headerFilterStrategy option on the endpoint URI. For example, to configure a producer endpoint with the myHeaderFilterStrategy filter, you could use a URI like the following:

```
http://remoteHost/context/path?
    headerFilterStrategy=#myHeaderFilterStrategy
```

Where myHeaderFilterStrategy is the bean ID of your custom filter instance.
CHAPTER 39. FILTERING SOAP MESSAGE HEADERS

Abstract

The Camel CXF component supports a flexible header filtering mechanism, which enables you to process SOAP headers, applying different filters according to the header's XML namespace.

39.1. BASIC CONFIGURATION

Overview

When more than one CXF endpoint appears in a route, you need to decide whether or not to allow headers to propagate between the endpoints. By default, the headers are relayed back and forth between the endpoints, but in many cases it might be necessary to filter the headers or to block them altogether. You can control header propagation by applying filters to producer endpoints.

CxfHeaderFilterStrategy

Header filtering is controlled by the CxfHeaderFilterStrategy class. Basic configuration of the CxfHeaderFilterStrategy class involves setting one or more of the following options:

- the section called “relayHeaders option”.
- the section called “relayAllMessageHeaders option”.

relayHeaders option

The semantics of the relayHeaders option can be summarized as follows:

<table>
<thead>
<tr>
<th>relayHeaders</th>

In-band headers

An in-band header is a header that is explicitly defined as part of the WSDL binding contract for an endpoint.

Out-of-band headers

An out-of-band header is a header that is serialized over the wire, but is not explicitly part of the WSDL binding contract. In particular, the SOAP binding permits out-of-band headers,
because the SOAP specification does not require headers to be defined in the WSDL contract.

**Payload format**

The CXF endpoint's payload format affects the filter behavior as follows:

**POJO**

*(Default)* Only out-of-band headers are available for filtering, because the in-band headers have already been processed and removed from the list by CXF. The in-band headers are incorporated into the **MessageContentList** in POJO mode. If you require access to headers in POJO mode, you have the option of implementing a custom CXF interceptor or JAX-WS handler.

**PAYLOAD**

In this mode, both in-band and out-of-band headers are available for filtering.

**MESSAGE**

Not applicable. (In this mode, the message remains in a raw format and the headers are not processed at all.)

**Default filter**

The default filter is of type, **SoapMessageHeaderFilter**, which removes only the SOAP headers that the SOAP specification expects an intermediate Web service to consume. For more details, see the section called “SoapMessageHeaderFilter”.

**Overriding the default filter**

You can override the default **CxfHeaderFilterStrategy** instance by defining a new **CxfHeaderFilterStrategy** bean and associating it with a CXF endpoint.

**Sample relayHeaders configuration**

The following example shows how you can use the **relayHeaders** option to create a **CxfHeaderFilterStrategy** bean that blocks all message headers. The CXF endpoints in the route use the **headerFilterStrategy** option to install the filter strategy in the endpoint, where the **headerFilterStrategy** setting has the syntax, **headerFilterStrategy=#BeanID**.

```xml
<beans ...>
  ...
  <bean id="dropAllMessageHeadersStrategy" class="org.apache.camel.component.cxf.common.header.CxfHeaderFilterStrategy">
    <!-- Set relayHeaders to false to drop all SOAP headers -->
    <property name="relayHeaders" value="false"/>
  </bean>
  ...
</beans>

<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="cxf:bean:routerNoRelayEndpoint?"/>
  </route>
</camelContext>
```
relayAllMessageHeaders option

The relayAllMessageHeaders option is used to propagate all SOAP headers, without applying any filtering (any installed filters would be bypassed). In order to enable this feature, you must set both relayHeaders and relayAllMessageHeaders to true.

Sample relayAllMessageHeaders configuration

The following example shows how to configure CXF endpoints to propagate all SOAP message headers. The propagateAllMessages filter strategy sets both relayHeaders and relayAllMessageHeaders to true.

```xml
<beans ...>
  ...
  <bean id="propagateAllMessages"
      class="org.apache.camel.component.cxf.common.header.CxfHeaderFilterStrategy">
    <!-- Set both properties to true to propagate *all* SOAP headers -->
    <property name="relayHeaders" value="true"/>
    <property name="relayAllMessageHeaders" value="true"/>
  </bean>
  ...
  <camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
    <route>
      <from uri="cxf:bean:routerNoRelayEndpoint?headerFilterStrategy=#propagateAllMessages"/>
      <to uri="cxf:bean:serviceNoRelayEndpoint?headerFilterStrategy=#propagateAllMessages"/>
      <route>
    </route>
  </camelContext>
  ...
</beans>
```

39.2. HEADER FILTERING

Overview

You can optionally install multiple headers in a CxfHeaderFilterStrategy instance. The filtering mechanism then uses the header's XML namespace to lookup a particular filter, which it then applies to the header.

Filter map

Figure 39.1, “Filter Map” shows an overview of the filter map that is contained within a
CxfHeaderFilterStrategy instance. For each filter that you install in CxfHeaderFilterStrategy, corresponding entries are made in the filter map, where one or more XML schema namespaces are associated with each filter.

Figure 39.1. Filter Map

Filter Map

<table>
<thead>
<tr>
<th>XML Namespaces</th>
<th>Header Filters</th>
</tr>
</thead>
<tbody>
<tr>
<td><a href="http://foo/a/b/c/d">http://foo/a/b/c/d</a></td>
<td>Foo Filter</td>
</tr>
<tr>
<td><a href="http://foo/a/b/c/e">http://foo/a/b/c/e</a></td>
<td></td>
</tr>
<tr>
<td><a href="http://foo/a/b/c/f">http://foo/a/b/c/f</a></td>
<td></td>
</tr>
<tr>
<td><a href="http://bar/a/b/c/d">http://bar/a/b/c/d</a></td>
<td>Bar Filter</td>
</tr>
<tr>
<td><a href="http://bar/a/b/c/e">http://bar/a/b/c/e</a></td>
<td></td>
</tr>
<tr>
<td><a href="http://soap/a/b/c/d">http://soap/a/b/c/d</a></td>
<td>SOAP Filter</td>
</tr>
<tr>
<td><a href="http://soap/a/b/c/e">http://soap/a/b/c/e</a></td>
<td></td>
</tr>
</tbody>
</table>

Filter behavior

When a header is filtered, the filter mechanism peeks at the header to discover the header’s XML namespace. The filter then looks up the XML namespace in the filter map to find the corresponding filter implementation. This filter is then applied to the header.

PAYLOAD mode

In PAYLOAD mode, both in-band and out-of-band messages pass through the installed filters.

POJO mode

In POJO mode, only out-of-band messages pass through the installed filters. In-band messages bypass the filters and are propagated by default.

39.3. IMPLEMENTING A CUSTOM FILTER

Overview

You can implement your own customer message header filters by implementing the MessageHeaderFilter Java interface. You must associate a filter with one or more XML schema namespaces (representing the header’s namespace) and it is possible to differentiate between request message headers and response message headers.

MessageHeaderFilter interface
The **MessageHeaderFilter** interface is defined in the
org.apache.camel.component.cxf.common.header package, as follows:

```java
// Java
package org.apache.camel.component.cxf.common.header;

import java.util.List;
import org.apache.camel.spi.HeaderFilterStrategy.Direction;
import org.apache.cxf.headers.Header;

public interface MessageHeaderFilter {
    List<String> getActivationNamespaces();
    void filter(Direction direction, List<Header> headers);
}
```

### Implementing the filter() method

The **MessageHeaderFilter.filter()** method is responsible for applying header filtering. Filtering is applied both before and after an operation is invoked on an endpoint. Hence, there are two directions to which filtering is applied, as follows:

**Direction.OUT**

When the `direction` parameter equals `Direction.OUT`, the filter is being applied to a request either leaving a consumer endpoint or entering a producer endpoint (that is, it applies to a WS request message propagating through a route).

**Direction.IN**

When the `direction` parameter equals `Direction.IN`, the filter is being applied to a response either leaving a producer endpoint or entering a consumer endpoint (that is, it applies to a WS response message being sent back).

Filtering can be applied by removing elements from the list of headers, **headers**. Any headers left in the list are propagated.

### Binding filters to XML namespaces

It is possible to register multiple header filters against a given CXF endpoint. The CXF endpoint selects the appropriate filter to use based on the XML namespace of the WSDL binding protocol (for example, the namespace for the SOAP 1.1 binding or for the SOAP 1.2 binding). If a header's namespace is unknown, the header is propagated by default.

To bind a filter to one or more namespaces, implement the **getActivationNamespaces()** method, which returns the list of bound XML namespaces.

### Identifying the namespace to bind to

**Example 39.1. “Sample Binding Namespaces”** illustrates how to identify the namespaces to which you can bind a filter. This example shows the WSDL file for a Bank server that exposes SOAP endpoints.

**Example 39.1. Sample Binding Namespaces**
From the `soap:binding` tag, you can infer that namespace associated with the SOAP binding is `http://schemas.xmlsoap.org/wsdl/soap/`.

**Implementing a custom filter**

If you want to implement your own custom filter, define a class that inherits from the `MessageHeaderFilter` interface and implement its methods as described in this section. For example, Example 39.2, “Sample Header Filter Implementation” shows an example of a custom filter, `CustomHeaderFilter`, that binds to the namespace, `http://cxf.apache.org/bindings/custom`, and relays all of the headers that pass through it.

**Example 39.2. Sample Header Filter Implementation**

```java
// Java
package org.apache.camel.component.cxf.soap.headers;

import java.util.Arrays;
import java.util.List;
import org.apache.camel.component.cxf.common.header.MessageHeaderFilter;
import org.apache.camel.spi.HeaderFilterStrategy.Direction;
import org.apache.cxf.headers.Header;

public class CustomHeaderFilter implements MessageHeaderFilter {
    public static final String ACTIVATION_NAMESPACE =
            "http://cxf.apache.org/bindings/custom";
    public static final List<String> ACTIVATION_NAMESPACES =
            Arrays.asList(ACTIVATION_NAMESPACE);

    public List<String> getActivationNamespaces() {
        return ACTIVATION_NAMESPACES;
    }
```
39.4. INSTALLING FILTERS

Overview

To install message header filters, set the `messageHeaderFilters` property of the `CxfHeaderFilterStrategy` object. When you initialize this property with a list of message header filters, the header filter strategy combines the specified filters to make a filter map.

The `messageHeaderFilters` property is of type, `List<MessageHeaderFilter>`. 

Installing filters in XML

The following example shows how to create a `CxfHeaderFilterStrategy` instance, specifying a customized list of header filters in the `messageHeaderFilters` property. There are two header filters in this example: `SoapMessageHeaderFilter` and `CustomHeaderFilter`.

```xml
<bean id="customMessageFilterStrategy" class="org.apache.camel.component.cxf.common.header.CxfHeaderFilterStrategy">
    <property name="messageHeaderFilters">
        <list>
            <!-- SoapMessageHeaderFilter is the built in filter. It can be removed by omitting it. -->
            <bean class="org.apache.camel.component.cxf.common.header.SoapMessageHeaderFilter"/>
            <!-- Add custom filter here -->
            <bean class="org.apache.camel.component.cxf.soap.headers.CustomHeaderFilter"/>  
            </list>
            </property>
        </bean>
</bean>
```

SoapMessageHeaderFilter

The first header filter in the preceding example is the `SoapMessageHeaderFilter` filter, which is the default header filter. This filter is designed to filter standard SOAP headers and is bound to the following XML namespaces:

- `http://schemas.xmlsoap.org/soap/`
- `http://schemas.xmlsoap.org/wsdls/soap/`
- `http://schemas.xmlsoap.org/wsdls/soap12/`

This filter peeks at the header element, in order to decide whether or not to block a particular header. If the `soap:actor` attribute (SOAP 1.1) or the `soap:role` attribute (SOAP
1.2) is present and has the value next, the header is removed from the message. Otherwise, the header is propagated.

**Namespace clashes**

Normally, each namespace should be bound to just a single header filter. If a namespace is bound to more than one header filter, this normally causes an error. It is possible, however, to override this policy by setting the `allowFilterNamespaceClash` property to `true` in the `CxfHeaderFilterStrategy` instance. When this policy is set to `true`, the nearest to last filter is selected, in the event of a namespace clash.
PART IV. PROGRAMMING EIP COMPONENTS

Abstract

This guide describes how to use the Apache Camel API.
CHAPTER 40. UNDERSTANDING MESSAGE FORMATS

Abstract

Before you can begin programming with Apache Camel, you should have a clear understanding of how messages and message exchanges are modelled. Because Apache Camel can process many message formats, the basic message type is designed to have an abstract format. Apache Camel provides the APIs needed to access and transform the data formats that underly message bodies and message headers.

40.1. EXCHANGES

Overview

An exchange object is a wrapper that encapsulates a received message and stores its associated metadata (including the exchange properties). In addition, if the current message is dispatched to a producer endpoint, the exchange provides a temporary slot to hold the reply (the Out message).

An important feature of exchanges in Apache Camel is that they support lazy creation of messages. This can provide a significant optimization in the case of routes that do not require explicit access to messages.

Figure 40.1. Exchange Object Passing through a Route

Figure 40.1, “Exchange Object Passing through a Route” shows an exchange object passing through a route. In the context of a route, an exchange object gets passed as the argument of the Processor.process() method. This means that the exchange object is directly accessible to the source endpoint, the target endpoint, and all of the processors in between.

The Exchange interface

The org.apache.camel.Exchange interface defines methods to access In and Out messages, as shown in Example 40.1, “Exchange Methods”.

Example 40.1. Exchange Methods

```java
// Access the In message
Message getIn();
void setIn(Message in);
```
Lazy creation of messages

Apache Camel supports lazy creation of In, Out, and Fault messages. This means that message instances are not created until you try to access them (for example, by calling `getIn()` or `getOut()`). The lazy message creation semantics are implemented by the `org.apache.camel.impl.DefaultExchange` class.

If you call one of the no-argument accessors (`getIn()` or `getOut()`), or if you call an accessor with the boolean argument equal to `true` (that is, `getIn(true)` or `getOut(true)`), the default method implementation creates a new message instance, if one does not already exist.

If you call an accessor with the boolean argument equal to `false` (that is, `getIn(false)` or `getOut(false)`), the default method implementation returns the current message value.

Lazy creation of exchange IDs

Apache Camel supports lazy creation of exchange IDs. You can call `getExchangeId()` on any exchange to obtain a unique ID for that exchange instance, but the ID is generated only when you actually call the method. The `DefaultExchange.getExchangeId()` implementation of this method delegates ID generation to the UUID generator that is registered with the `CamelContext`.

For details of how to register UUID generators with the `CamelContext`, see Section 40.4, “Built-In UUID Generators”.

40.2. MESSAGES

Overview

Message objects represent messages using the following abstract model:

- **Message body**
- **Message headers**
- **Message attachments**

The message body and the message headers can be of arbitrary type (they are declared as type `Object`) and the message attachments are declared to be of type `javax.activation.DataHandler`, which can contain arbitrary MIME types. If you need to
obtain a concrete representation of the message contents, you can convert the body and headers to another type using the type converter mechanism and, possibly, using the marshalling and unmarshalling mechanism.

One important feature of Apache Camel messages is that they support lazy creation of message bodies and headers. In some cases, this means that a message can pass through a route without needing to be parsed at all.

## The Message interface

The `org.apache.camel.Message` interface defines methods to access the message body, message headers and message attachments, as shown in Example 40.2, "Message Interface".

### Example 40.2. Message Interface

```java
// Access the message body
Object getBody();
<T> T getBody(Class<T> type);
void setBody(Object body);
<T> void setBody(Object body, Class<T> type);

// Access message headers
Object getHeader(String name);
<T> T getHeader(String name, Class<T> type);
void setHeader(String name, Object value);
Object removeHeader(String name);
Map<String, Object> getHeaders();
void setHeaders(Map<String, Object> headers);

// Access message attachments
javax.activation.DataHandler getAttachment(String id);
java.util.Map<String, javax.activation.DataHandler> getAttachments();
java.util.Set<String> getAttachmentNames();
void addAttachment(String id, javax.activation.DataHandler content)

// Access the message ID
String getMessageId();
void setMessageId(String messageId);
```

For a complete description of the methods in the `Message` interface, see Section 50.1, “The Message Interface”.

### Lazy creation of bodies, headers, and attachments

Apache Camel supports lazy creation of bodies, headers, and attachments. This means that the objects that represent a message body, a message header, or a message attachment are not created until they are needed.

For example, consider the following route that accesses the `foo` message header from the `In` message:

```java
from("SourceURL")
```
In this route, if we assume that the component referenced by SourceURL supports lazy creation, the In message headers are not actually parsed until the header("foo") call is executed. At that point, the underlying message implementation parses the headers and populates the header map. The message body is not parsed until you reach the end of the route, at the to("TargetURL") call. At that point, the body is converted into the format required for writing it to the target endpoint, TargetURL.

By waiting until the last possible moment before populating the bodies, headers, and attachments, you can ensure that unnecessary type conversions are avoided. In some cases, you can completely avoid parsing. For example, if a route contains no explicit references to message headers, a message could traverse the route without ever parsing the headers.

Whether or not lazy creation is implemented in practice depends on the underlying component implementation. In general, lazy creation is valuable for those cases where creating a message body, a message header, or a message attachment is expensive. For details about implementing a message type that supports lazy creation, see Section 50.2, “Implementing the Message Interface”.

Lazy creation of message IDs

Apache Camel supports lazy creation of message IDs. That is, a message ID is generated only when you actually call the getMessageId() method. The DefaultExchange.getExchangeId() implementation of this method delegates ID generation to the UUID generator that is registered with the CamelContext.

Some endpoint implementations would call the getMessageId() method implicitly, if the endpoint implements a protocol that requires a unique message ID. In particular, JMS messages normally include a header containing unique message ID, so the JMS component automatically calls getMessageId() to obtain the message ID (this is controlled by the messageIdEnabled option on the JMS endpoint).

For details of how to register UUID generators with the CamelContext, see Section 40.4, “Built-In UUID Generators”.

Initial message format

The initial format of an In message is determined by the source endpoint, and the initial format of an Out message is determined by the target endpoint. If lazy creation is supported by the underlying component, the message remains unparsed until it is accessed explicitly by the application. Most Apache Camel components create the message body in a relatively raw form—for example, representing it using types such as byte[], ByteBuffer, InputStream, or OutputStream. This ensures that the overhead required for creating the initial message is minimal. Where more elaborate message formats are required components usually rely on type converters or marshalling processors.

Type converters

It does not matter what the initial format of the message is, because you can easily convert a message from one format to another using the built-in type converters (see Section 40.3, “Built-In Type Converters”). There are various methods in the Apache Camel API that
expose type conversion functionality. For example, the `convertBodyTo(Class type)` method can be inserted into a route to convert the body of an `In` message, as follows:

```java
from("SourceURL").convertBodyTo(String.class).to("TargetURL");
```

Where the body of the `In` message is converted to a `java.lang.String`. The following example shows how to append a string to the end of the `In` message body:

```java
from("SourceURL").setBody(bodyAs(String.class).append("My Special Signature")).to("TargetURL");
```

Where the message body is converted to a string format before appending a string to the end. It is not necessary to convert the message body explicitly in this example. You can also use:

```java
from("SourceURL").setBody(body().append("My Special Signature")).to("TargetURL");
```

Where the `append()` method automatically converts the message body to a string before appending its argument.

## Type conversion methods in Message

The `org.apache.camel.Message` interface exposes some methods that perform type conversion explicitly:

- `getBody(Class<T> type)`—Returns the message body as type, `T`.
- `getHeader(String name, Class<T> type)`—Returns the named header value as type, `T`.

For the complete list of supported conversion types, see Section 40.3, “Built-In Type Converters”.

## Converting to XML

In addition to supporting conversion between simple types (such as `byte[]`, `ByteBuffer`, `String`, and so on), the built-in type converter also supports conversion to XML formats. For example, you can convert a message body to the `org.w3c.dom.Document` type. This conversion is more expensive than the simple conversions, because it involves parsing the entire message and then creating a tree of nodes to represent the XML document structure. You can convert to the following XML document types:

- `org.w3c.dom.Document`
- `javax.xml.transform.sax.SAXSource`

XML type conversions have narrower applicability than the simpler conversions. Because not every message body conforms to an XML structure, you have to remember that this type conversion might fail. On the other hand, there are many scenarios where a router deals exclusively with XML message types.

## Marshalling and unmarshalling
**Marshalling** involves converting a high-level format to a low-level format, and **unmarshalling** involves converting a low-level format to a high-level format. The following two processors are used to perform marshalling or unmarshalling in a route:

- `marshal()`
- `unmarshal()`

For example, to read a serialized Java object from a file and unmarshal it into a Java object, you could use the route definition shown in Example 40.3, “Unmarshalling a Java Object”.

**Example 40.3. Unmarshalling a Java Object**

```java
from("file://tmp/appfiles/serialized")
  .unmarshal()
  .serialization()
  .<FurtherProcessing>
  .to("TargetURL");
```

**Final message format**

When an *In* message reaches the end of a route, the target endpoint must be able to convert the message body into a format that can be written to the physical endpoint. The same rule applies to *Out* messages that arrive back at the source endpoint. This conversion is usually performed implicitly, using the Apache Camel type converter. Typically, this involves converting from a low-level format to another low-level format, such as converting from a `byte[]` array to an `InputStream` type.

### 40.3. BUILT-IN TYPE CONVERTERS

**Overview**

This section describes the conversions supported by the master type converter. These conversions are built into the Apache Camel core.

Usually, the type converter is called through convenience functions, such as `Message.getBody(Class<T> type)` or `Message.getHeader(String name, Class<T> type)`. It is also possible to invoke the master type converter directly. For example, if you have an exchange object, `exchange`, you could convert a given value to a `String` as shown in Example 40.4, “Converting a Value to a String”.

**Example 40.4. Converting a Value to a String**

```java
org.apache.camel.TypeConverter tc = exchange.getContext().getTypeConverter();
String str_value = tc.convertTo(String.class, value);
```

**Basic type converters**

Apache Camel provides built-in type converters that perform conversions to and from the following basic types:
• java.io.File
• String
• byte[] and java.nio.ByteBuffer
• java.io.InputStream and java.io.OutputStream
• java.io.Reader and java.io.Writer
• java.io.BufferedReader and java.io.BufferedWriter
• java.io.StringReader

However, not all of these types are inter-convertible. The built-in converter is mainly focused on providing conversions from the File and String types. The File type can be converted to any of the preceding types, except Reader, Writer, and StringReader. The String type can be converted to File, byte[], ByteBuffer, InputStream, or StringReader. The conversion from String to File works by interpreting the string as a file name. The trio of String, byte[], and ByteBuffer are completely inter-convertible.

**NOTE**

You can explicitly specify which character encoding to use for conversion from byte[] to String and from String to byte[] by setting the Exchange.CHARSET_NAME exchange property in the current exchange. For example, to perform conversions using the UTF-8 character encoding, call exchange.setProperty("Exchange.CHARSET_NAME", "UTF-8"). The supported character sets are described in the java.nio.charset.Charset class.

**Collection type converters**

Apache Camel provides built-in type converters that perform conversions to and from the following collection types:

• Object[]
• java.util.Set
• java.util.List

All permutations of conversions between the preceding collection types are supported.

**Map type converters**

Apache Camel provides built-in type converters that perform conversions to and from the following map types:

• java.util.Map
• java.util.HashMap
• java.util.Hashtable
• java.util.Properties
The preceding map types can also be converted into a set, of `java.util.Set` type, where
the set elements are of the `MapEntry<K,V>` type.

**DOM type converters**

You can perform type conversions to the following Document Object Model (DOM) types:

- `org.w3c.dom.Node`
- `javax.xml.transform.dom.DOMSource`—convertible from `String`.
- `javax.xml.transform.Source`—convertible from `byte[]` and `String`.

All permutations of conversions between the preceding DOM types are supported.

**SAX type converters**

You can also perform conversions to the `javax.xml.transform.sax.SAXSource` type, which supports the SAX event-driven XML parser (see the [SAX Web site](http://sax.apache.org) for details). You can convert to `SAXSource` from the following types:

- `String`
- `InputStream`
- `Source`
- `StreamSource`
- `DOMSource`

**Custom type converters**

Apache Camel also enables you to implement your own custom type converters. For details on how to implement a custom type converter, see Chapter 42, *Type Converters*.

**40.4. BUILT-IN UUID GENERATORS**

**Overview**

Apache Camel enables you to register a UUID generator in the `CamelContext`. This UUID
generator is then used whenever Apache Camel needs to generate a unique ID—in
particular, the registered UUID generator is called to generate the IDs returned by the
`Exchange.getExchangeId()` and the `Message.getMessageId()` methods.

For example, you might prefer to replace the default UUID generator, if part of your
application does not support IDs with a length of 36 characters (like Websphere MQ). Also,
it can be convenient to generate IDs using a simple counter (see the `SimpleUuidGenerator`) for testing purposes.

**Provided UUID generators**
You can configure Apache Camel to use one of the following UUID generators, which are provided in the core:

- `org.apache.camel.impl.ActiveMQUuidGenerator`—*(Default)* generates the same style of ID as is used by Apache ActiveMQ. This implementation might not be suitable for all applications, because it uses some JDK APIs that are forbidden in the context of cloud computing (such as the Google App Engine).

- `org.apache.camel.impl.SimpleUuidGenerator`—implements a simple counter ID, starting at 1. The underlying implementation uses the `java.util.concurrent.atomic.AtomicLong` type, so that it is thread-safe.

- `org.apache.camel.impl.JavaUuidGenerator`—implements an ID based on the `java.util.UUID` type. Because `java.util.UUID` is synchronized, this might affect performance on some highly concurrent systems.

### Custom UUID generator

To implement a custom UUID generator, implement the `org.apache.camel.spi.UuidGenerator` interface, which is shown in Example 40.5, “UuidGenerator Interface”. The `generateUuid()` must be implemented to return a unique ID string.

#### Example 40.5. UuidGenerator Interface

```java
// Java
package org.apache.camel.spi;

/**
 * Generator to generate UUID strings.
 */
public interface UuidGenerator {
    String generateUuid();
}
```

### Specifying the UUID generator using Java

To replace the default UUID generator using Java, call the `setUuidGenerator()` method on the current `CamelContext` object. For example, you can register a `SimpleUuidGenerator` instance with the current `CamelContext`, as follows:

```java
// Java
getContext().setUuidGenerator(new org.apache.camel.impl.SimpleUuidGenerator());
```

**NOTE**

The `setUuidGenerator()` method should be called during startup, before any routes are activated.

### Specifying the UUID generator using Spring
To replace the default UUID generator using Spring, all you need to do is to create an instance of a UUID generator using the Spring bean element. When a camelContext instance is created, it automatically looks up the Spring registry, searching for a bean that implements org.apache.camel.spi.UuidGenerator. For example, you can register a SimpleUuidGenerator instance with the CamelContext as follows:

```xml
<beans ...>
  <bean id="simpleUuidGenerator"
       class="org.apache.camel.impl.SimpleUuidGenerator" />

  <camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
    ...
  </camelContext>
  ...
</beans>
```

[2] If there is no active method the returned value will be null.
CHAPTER 41. IMPLEMENTING A PROCESSOR

Abstract

Apache Camel allows you to implement a custom processor. You can then insert the custom processor into a route to perform operations on exchange objects as they pass through the route.

41.1. PROCESSING MODEL

Pipelining model

The pipelining model describes the way in which processors are arranged in Section 4.4, "Pipes and Filters". Pipelining is the most common way to process a sequence of endpoints (a producer endpoint is just a special type of processor). When the processors are arranged in this way, the exchange's In and Out messages are processed as shown in Figure 41.1, "Pipelining Model".

Figure 41.1. Pipelining Model

The processors in the pipeline look like services, where the In message is analogous to a request, and the Out message is analogous to a reply. In fact, in a realistic pipeline, the nodes in the pipeline are often implemented by Web service endpoints, such as the CXF component.

For example, Example 41.1, "Java DSL Pipeline" shows a Java DSL pipeline constructed from a sequence of two processors, ProcessorA, ProcessorB, and a producer endpoint, TargetURI.

Example 41.1. Java DSL Pipeline

from(SourceURI).pipeline(ProcessorA, ProcessorB, TargetURI);

41.2. IMPLEMENTING A SIMPLE PROCESSOR

Overview

This section describes how to implement a simple processor that executes message processing logic before delegating the exchange to the next processor in the route.

Processor interface
Simple processors are created by implementing the `org.apache.camel.Processor` interface. As shown in Example 41.2, “Processor Interface”, the interface defines a single method, `process()`, which processes an exchange object.

**Example 41.2. Processor Interface**

```java
package org.apache.camel;

public interface Processor {
    void process(Exchange exchange) throws Exception;
}
```

**Implementing the Processor interface**

To create a simple processor you must implement the `Processor` interface and provide the logic for the `process()` method. Example 41.3, “Simple Processor Implementation” shows the outline of a simple processor implementation.

**Example 41.3. Simple Processor Implementation**

```java
import org.apache.camel.Processor;

public class MyProcessor implements Processor {
    public MyProcessor() { }

    public void process(Exchange exchange) throws Exception {
        // Insert code that gets executed *before* delegating
        // to the next processor in the chain.
        ...
    }
}
```

All of the code in the `process()` method gets executed before the exchange object is delegated to the next processor in the chain.

For examples of how to access the message body and header values inside a simple processor, see Section 41.3, “Accessing Message Content”.

**Inserting the simple processor into a route**

Use the `process()` DSL command to insert a simple processor into a route. Create an instance of your custom processor and then pass this instance as an argument to the `process()` method, as follows:

```java
org.apache.camel.Processor myProc = new MyProcessor();
from("SourceURL").process(myProc).to("TargetURL");
```

41.3. ACCESSING MESSAGE CONTENT
Accessing message headers

Message headers typically contain the most useful message content from the perspective of a router, because headers are often intended to be processed in a router service. To access header data, you must first get the message from the exchange object (for example, using `Exchange.getIn()`), and then use the `Message` interface to retrieve the individual headers (for example, using `Message.getHeader()`).

Example 41.4, “Accessing an Authorization Header” shows an example of a custom processor that accesses the value of a header named Authorization. This example uses the `ExchangeHelper.getMandatoryHeader()` method, which eliminates the need to test for a null header value.

```java
import org.apache.camel.*;
import org.apache.camel.util.ExchangeHelper;

public class MyProcessor implements Processor {
    public void process(Exchange exchange) {
        String auth = ExchangeHelper.getMandatoryHeader(
            exchange, 
            "Authorization", 
            String.class
        );
        // process the authorization string...
        // ...
    }
}
```

For full details of the `Message` interface, see Section 40.2, “Messages”.

Accessing the message body

You can also access the message body. For example, to append a string to the end of the In message, you can use the processor shown in Example 41.5, “Accessing the Message Body”.

```java
import org.apache.camel.*;
import org.apache.camel.util.ExchangeHelper;

public class MyProcessor implements Processor {
    public void process(Exchange exchange) {
        Message in = exchange.getIn();
        in.setBody(in.getBody(String.class) + " World!");
    }
}
```

Accessing message attachments
You can access a message's attachments using either the `Message.getAttachment()` method or the `Message.getAttachments()` method. See Example 40.2, “Message Interface” for more details.

### 41.4. THE EXCHANGEHELPER CLASS

#### Overview

The `org.apache.camel.util.ExchangeHelper` class is a Apache Camel utility class that provides methods that are useful when implementing a processor.

#### Resolve an endpoint

The static `resolveEndpoint()` method is one of the most useful methods in the `ExchangeHelper` class. You use it inside a processor to create new `Endpoint` instances on the fly.

#### Example 41.6. The `resolveEndpoint()` Method

```java
public final class ExchangeHelper {
    ...
    @SuppressWarnings(value="unchecked")
    public static Endpoint resolveEndpoint(Exchange exchange, Object value)
    throws NoSuchEndpointException {
        ...
    }
    ...
}
```

The first argument to `resolveEndpoint()` is an exchange instance, and the second argument is usually an endpoint URI string. Example 41.7, “Creating a File Endpoint” shows how to create a new file endpoint from an exchange instance `exchange`.

#### Example 41.7. Creating a File Endpoint

```java
Endpoint file_endp = ExchangeHelper.resolveEndpoint(exchange, "file://tmp/messages/in.xml");
```

#### Wrapping the exchange accessors

The `ExchangeHelper` class provides several static methods of the form `getMandatoryBeanProperty()`, which wrap the corresponding `getBeanProperty()` methods on the `Exchange` class. The difference between them is that the original `getBeanProperty()` accessors return `null` if the corresponding property is unavailable, and the `getMandatoryBeanProperty()` wrapper methods throw a Java exception. The following wrapper methods are implemented in the `ExchangeHelper` class:

```java
public final class ExchangeHelper {
    ...
    public static <T> T getMandatoryProperty(Exchange exchange, String propertyName, Class<T> type)
    }
```
Testing the exchange pattern

Several different exchange patterns are compatible with holding an *In* message. Several different exchange patterns are also compatible with holding an *Out* message. To provide a quick way of checking whether or not an exchange object is capable of holding an *In* message or an *Out* message, the `ExchangeHelper` class provides the following methods:

```java
public final class ExchangeHelper {
    ...
    public static boolean isInCapable(Exchange exchange) { ... }
    public static boolean isOutCapable(Exchange exchange) { ... }
}
```

Get the *In* message's MIME content type

If you want to find out the MIME content type of the exchange's *In* message, you can access it by calling the `ExchangeHelper.getContentType(exchange)` method. To implement this, the `ExchangeHelper` object looks up the value of the *In* message's `Content-Type` header—this method relies on the underlying component to populate the header value).
CHAPTER 42. TYPE CONVERTERS

Abstract

Apache Camel has a built-in type conversion mechanism, which is used to convert message bodies and message headers to different types. This chapter explains how to extend the type conversion mechanism by adding your own custom converter methods.

42.1. TYPE CONVERTER ARCHITECTURE

Overview

This section describes the overall architecture of the type converter mechanism, which you must understand, if you want to write custom type converters. If you only need to use the built-in type converters, see Chapter 40, Understanding Message Formats.

Type converter interface

Example 42.1, “TypeConverter Interface” shows the definition of the org.apache.camel.TypeConverter interface, which all type converters must implement.

Example 42.1. TypeConverter Interface

```
package org.apache.camel;

public interface TypeConverter {
    <T> T convertTo(Class<T> type, Object value);
}
```

Master type converter

The Apache Camel type converter mechanism follows a master/slave pattern. There are many slave type converters, which are each capable of performing a limited number of type conversions, and a single master type converter, which aggregates the type conversions performed by the slaves. The master type converter acts as a front-end for the slave type converters. When you request the master to perform a type conversion, it selects the appropriate slave and delegates the conversion task to that slave.

For users of the type conversion mechanism, the master type converter is the most important because it provides the entry point for accessing the conversion mechanism. During start up, Apache Camel automatically associates a master type converter instance with the CamelContext object. To obtain a reference to the master type converter, you call the CamelContext.getTypeConverter() method. For example, if you have an exchange object, exchange, you can obtain a reference to the master type converter as shown in Example 42.2, “Getting a Master Type Converter”.

Example 42.2. Getting a Master Type Converter

```
org.apache.camel.TypeConverter tc = exchange.getContext().getTypeConverter();
```
Type converter loader

The master type converter uses a type converter loader to populate the registry of slave type converters. A type converter loader is any class that implements the `TypeConverterLoader` interface. Apache Camel currently uses only one kind of type converter loader—the annotation type converter loader (of `AnnotationTypeConverterLoader` type).

Type conversion process

Figure 42.1, “Type Conversion Process” gives an overview of the type conversion process, showing the steps involved in converting a given data value, `value`, to a specified type, `toType`.

Figure 42.1. Type Conversion Process

1. The `CamelContext` object holds a reference to the master `TypeConverter` instance. The first step in the conversion process is to retrieve the master type converter by calling `CamelContext.getTypeConverter()`.

The type conversion mechanism proceeds as follows:

1. The `CamelContext` object holds a reference to the master `TypeConverter` instance. The first step in the conversion process is to retrieve the master type converter by calling `CamelContext.getTypeConverter()`.
2. Type conversion is initiated by calling the `convertTo()` method on the master type converter. This method instructs the type converter to convert the data object, `value`, from its original type to the type specified by the `toType` argument.

3. Because the master type converter is a front end for many different slave type converters, it looks up the appropriate slave type converter by checking a registry of type mappings. The registry of type converters is keyed by a type mapping pair `(toType, fromType)`. If a suitable type converter is found in the registry, the master type converter calls the slave's `convertTo()` method and returns the result.

4. If a suitable type converter cannot be found in the registry, the master type converter loads a new type converter, using the type converter loader.

5. The type converter loader searches the available JAR libraries on the classpath to find a suitable type converter. Currently, the loader strategy that is used is implemented by the annotation type converter loader, which attempts to load a class annotated by the `org.apache.camel.Converter` annotation. See the section called “Create a TypeConverter file”.

6. If the type converter loader is successful, a new slave type converter is loaded and entered into the type converter registry. This type converter is then used to convert the `value` argument to the `toType` type.

7. If the data is successfully converted, the converted data value is returned. If the conversion does not succeed, `null` is returned.

### 42.2. IMPLEMENTING TYPE CONVERTER USING ANNOTATIONS

**Overview**

The type conversion mechanism can easily be customized by adding a new slave type converter. This section describes how to implement a slave type converter and how to integrate it with Apache Camel, so that it is automatically loaded by the annotation type converter loader.

**How to implement a type converter**

To implement a custom type converter, perform the following steps:

1. Implement an annotated converter class
2. Create a TypeConverter file.
3. Package the type converter.

**Implement an annotated converter class**

You can implement a custom type converter class using the `@Converter` annotation. You must annotate the class itself and each of the `static` methods intended to perform type conversion. Each converter method takes an argument that defines the `from` type, optionally takes a second `Exchange` argument, and has a non-void return value that defines the `to` type. The type converter loader uses Java reflection to find the annotated methods and integrate them into the type converter mechanism. Example 42.3, “Example of an Annotated Converter Class” shows an example of an annotated converter class that defines
a converter method for converting from `java.io.File` to `java.io.InputStream` and another converter method (with an `Exchange` argument) for converting from `byte[]` to `String`.

Example 42.3. Example of an Annotated Converter Class

```java
package com.YourDomain.YourPackageName;

import org.apache.camel.Converter;
import java.io.*;

@Converter
public class IOConverter {
    private IOConverter() {
    }

    @Converter
    public static InputStream toInputStream(File file) throws FileNotFoundException {
        return new BufferedInputStream(new FileInputStream(file));
    }

    @Converter
    public static String toString(byte[] data, Exchange exchange) {
        if (exchange != null) {
            String charsetName = exchange.getProperty(Exchange.CHARSET_NAME, String.class);
            if (charsetName != null) {
                try {
                    return new String(data, charsetName);
                } catch (UnsupportedEncodingException e) {
                    LOG.warn("Can't convert the byte to String with the charset " + charsetName, e);
                }
            }
        }
        return new String(data);
    }
}
```

The `toInputStream()` method is responsible for performing the conversion from the `File` type to the `InputStream` type and the `toString()` method is responsible for performing the conversion from the `byte[]` type to the `String` type.

NOTE

The method name is unimportant, and can be anything you choose. What is important are the argument type, the return type, and the presence of the `@Converter` annotation.

Create a `TypeConverter` file

To enable the discovery mechanism (which is implemented by the `annotation` type
converter loader) for your custom converter, create a `TypeConverter` file at the following location:

```
META-INF/services/org/apache/camel/TypeConverter
```

The `TypeConverter` file must contain a comma-separated list of package names identifying the packages that contain type converter classes. For example, if you want the type converter loader to search the `com.YourDomain.YourPackageName` package for annotated converter classes, the `TypeConverter` file would have the following contents:

```
com.YourDomain.YourPackageName
```

**Package the type converter**

The type converter is packaged as a JAR file containing the compiled classes of your custom type converters and the `META-INF` directory. Put this JAR file on your classpath to make it available to your Apache Camel application.

**Fallback converter method**

In addition to defining regular converter methods using the `@Converter` annotation, you can optionally define a fallback converter method using the `@FallbackConverter` annotation. The fallback converter method will only be tried, if the master type converter fails to find a regular converter method in the type registry.

The essential difference between a regular converter method and a fallback converter method is that whereas a regular converter is defined to perform conversion between a specific pair of types (for example, from `byte[]` to `String`), a fallback converter can potentially perform conversion between any pair of types. It is up to the code in the body of the fallback converter method to figure out which conversions it is able to perform. At runtime, if a conversion cannot be performed by a regular converter, the master type converter iterates through every available fallback converter until it finds one that can perform the conversion.

The method signature of a fallback converter can have either of the following forms:

```
// 1. Non-generic form of signature
@FallbackConverter
public static Object MethodName(
    Class type,
    Exchange exchange,
    Object value,
    TypeConverterRegistry registry
)

// 2. Templating form of signature
@FallbackConverter
public static <T> T MethodName(
    Class<T> type,
    Exchange exchange,
    Object value,
    TypeConverterRegistry registry
)
```
Where *MethodName* is an arbitrary method name for the fallback converter.

For example, the following code extract (taken from the implementation of the File component) shows a fallback converter that can convert the body of a *GenericFile* object, exploiting the type converters already available in the type converter registry:

```java
package org.apache.camel.component.file;

import org.apache.camel.Converter;
import org.apache.camel.FallbackConverter;
import org.apache.camel.Exchange;
import org.apache.camel.TypeConverter;
import org.apache.camel.spi.TypeConverterRegistry;

@Converter
public final class GenericFileConverter {

    private GenericFileConverter() {
        // Helper Class
    }

    @FallbackConverter
    public static <T> T convertTo(Class<T> type, Exchange exchange, Object value, TypeConverterRegistry registry) {
        // use a fallback type converter so we can convert the embedded body if the value is GenericFile
        if (GenericFile.class.isAssignableFrom(value.getClass())) {
            GenericFile file = (GenericFile) value;
            Class from = file.getBody().getClass();
            TypeConverter tc = registry.lookup(type, from);
            if (tc != null) {
                Object body = file.getBody();
                return tc.convertTo(type, exchange, body);
            }
        }
        return null;
    }
}
```

### 42.3. IMPLEMENTING A TYPE CONVERTER DIRECTLY

#### Overview

Generally, the recommended way to implement a type converter is to use an annotated class, as described in the previous section, Section 42.2, “Implementing Type Converter Using Annotations”. But if you want to have complete control over the registration of your type converter, you can implement a custom slave type converter and add it directly to the type converter registry, as described here.

#### Implement the TypeConverter interface

To implement your own type converter class, define a class that implements the...
TypeConverter interface. For example, the following MyOrderTypeConverter class converts an integer value to a MyOrder object, where the integer value is used to initialize the order ID in the MyOrder object.

```java
import org.apache.camel.TypeConverter

private class MyOrderTypeConverter implements TypeConverter {

    public <T> T convertTo(Class<T> type, Object value) {
        // converter from value to the MyOrder bean
        MyOrder order = new MyOrder();
        order.setId(Integer.parseInt(value.toString()));
        return (T) order;
    }

    public <T> T convertTo(Class<T> type, Exchange exchange, Object value) {
        // this method with the Exchange parameter will be prefered by Camel to invoke
        // this allows you to fetch information from the exchange during conversions
        // such as an encoding parameter or the likes
        return convertTo(type, value);
    }

    public <T> T mandatoryConvertTo(Class<T> type, Object value) {
        return convertTo(type, value);
    }

    public <T> T mandatoryConvertTo(Class<T> type, Exchange exchange, Object value) {
        return convertTo(type, value);
    }
}
```

Add the type converter to the registry

You can add the custom type converter directly to the type converter registry using code like the following:

```java
// Add the custom type converter to the type converter registry
context.getTypeConverterRegistry().addTypeConverter(MyOrder.class, String.class, new MyOrderTypeConverter());
```

Where `context` is the current `org.apache.camel.CamelContext` instance. The `addTypeConverter()` method registers the `MyOrderTypeConverter` class against the specific type conversion, from `String.class` to `MyOrder.class`.

Red Hat JBoss Fuse 6.1 Apache Camel Development Guide

474
CHAPTER 43. PRODUCER AND CONSUMER TEMPLATES

Abstract
The producer and consumer templates in Apache Camel are modelled after a feature of the Spring container API, whereby access to a resource is provided through a simplified, easy-to-use API known as a template. In the case of Apache Camel, the producer template and consumer template provide simplified interfaces for sending messages to and receiving messages from producer endpoints and consumer endpoints.

43.1. USING THE PRODUCER TEMPLATE

43.1.1. Introduction to the Producer Template

Overview
The producer template supports a variety of different approaches to invoking producer endpoints. There are methods that support different formats for the request message (as an Exchange object, as a message body, as a message body with a single header setting, and so on) and there are methods to support both the synchronous and the asynchronous style of invocation. Overall, producer template methods can be grouped into the following categories:

- the section called “Synchronous invocation”.
- the section called “Synchronous invocation with a processor”.
- the section called “Asynchronous invocation”.
- the section called “Asynchronous invocation with a callback”.

Synchronous invocation

The methods for invoking endpoints synchronously have names of the form sendSuffix() and requestSuffix(). For example, the methods for invoking an endpoint using either the default message exchange pattern (MEP) or an explicitly specified MEP are named send(), sendBody(), and sendBodyAndHeader() (where these methods respectively send an Exchange object, a message body, or a message body and header value). If you want to force the MEP to be InOut (request/reply semantics), you can call the request(), requestBody(), and requestBodyAndHeader() methods instead.

The following example shows how to create a ProducerTemplate instance and use it to send a message body to the activemq:MyQueue endpoint. The example also shows how to send a message body and header value using sendBodyAndHeader().

```java
import org.apache.camel.ProducerTemplate
import org.apache.camel.impl.DefaultProducerTemplate
...
ProducerTemplate template = context.createProducerTemplate();

// Send to a specific queue
```
Synchronous invocation with a processor

A special case of synchronous invocation is where you provide the send() method with a Processor argument instead of an Exchange argument. In this case, the producer template implicitly asks the specified endpoint to create an Exchange instance (typically, but not always having the InOnly MEP by default). This default exchange is then passed to the processor, which initializes the contents of the exchange object.

The following example shows how to send an exchange initialized by the MyProcessor processor to the activemq:MyQueue endpoint.

```java
import org.apache.camel.ProducerTemplate
import org.apache.camel.impl.DefaultProducerTemplate
...
ProducerTemplate template = context.createProducerTemplate();

// Send to a specific queue, using a processor to initialize
template.send("activemq:MyQueue", new MyProcessor());
```

The MyProcessor class is implemented as shown in the following example. In addition to setting the in message body (as shown here), you could also initialize message heads and exchange properties.

```java
public class MyProcessor implements Processor {
    public MyProcessor() { }

    public void process(Exchange ex) {
        ex.getIn().setBody("<hello>world!</hello>");
    }
}
```

Asynchronous invocation

The methods for invoking endpoints asynchronously have names of the form `asyncSendSuffix()` and `asyncRequestSuffix()`. For example, the methods for invoking an endpoint using either the default message exchange pattern (MEP) or an explicitly specified MEP are named `asyncSend()` and `asyncSendBody()` (where these methods respectively send an Exchange object or a message body). If you want to force the MEP to be InOut (request/reply semantics), you can call the `asyncRequestBody()`, `asyncRequestBodyAndHeader()`, and `asyncRequestBodyAndHeaders()` methods instead.

The following example shows how to send an exchange asynchronously to the direct:start endpoint. The `asyncSend()` method returns a
java.util.concurrent.Future object, which is used to retrieve the invocation result at a later time.

```java
import java.util.concurrent.Future;
import org.apache.camel.Exchange;
import org.apache.camel.impl.DefaultExchange;
...
Exchange exchange = new DefaultExchange(context);
exchange.getIn().setBody("Hello");

Future<Exchange> future = template.asyncSend("direct:start", exchange);

// You can do other things, whilst waiting for the invocation to complete
...
// Now, retrieve the resulting exchange from the Future
Exchange result = future.get();
```

The producer template also provides methods to send a message body asynchronously (for example, using `asyncSendBody()` or `asyncRequestBody()`). In this case, you can use one of the following helper methods to extract the returned message body from the `Future` object:

```java
<T> T extractFutureBody(Future future, Class<T> type);
<T> T extractFutureBody(Future future, long timeout, TimeUnit unit,
Class<T> type) throws TimeoutException;
```

The first version of the `extractFutureBody()` method blocks until the invocation completes and the reply message is available. The second version of the `extractFutureBody()` method allows you to specify a timeout. Both methods have a type argument, `type`, which casts the returned message body to the specified type using a built-in type converter.

The following example shows how to use the `asyncRequestBody()` method to send a message body to the `direct:start` endpoint. The blocking `extractFutureBody()` method is then used to retrieve the reply message body from the `Future` object.

```java
Future<Object> future = template.asyncRequestBody("direct:start", "Hello");

// You can do other things, whilst waiting for the invocation to complete
...
// Now, retrieve the reply message body as a String type
String result = template.extractFutureBody(future, String.class);
```

**Asynchronous invocation with a callback**

In the preceding asynchronous examples, the request message is dispatched in a sub-thread, while the reply is retrieved and processed by the main thread. The producer template also gives you the option, however, of processing replies in the sub-thread, using one of the `asyncCallback()`, `asyncCallbackSendBody()`, or `asyncCallbackRequestBody()` methods. In this case, you supply a callback object (of `org.apache.camel.impl.SynchronizationAdapter` type), which automatically gets invoked in the sub-thread as soon as a reply message arrives.
The **Synchronization** callback interface is defined as follows:

```java
package org.apache.camel.spi;
import org.apache.camel.Exchange;

public interface Synchronization {
    void onComplete(Exchange exchange);
    void onFailure(Exchange exchange);
}
```

Where the `onComplete()` method is called on receipt of a normal reply and the `onFailure()` method is called on receipt of a fault message reply. Only one of these methods gets called back, so you must override both of them to ensure that all types of reply are processed.

The following example shows how to send an exchange to the `direct:start` endpoint, where the reply message is processed in the sub-thread by the `SynchronizationAdapter` callback object.

```java
import java.util.concurrent.Future;
import java.util.concurrent.TimeUnit;
import org.apache.camel.Exchange;
import org.apache.camel.impl.DefaultExchange;
import org.apache.camel.impl.SynchronizationAdapter;
...
Exchange exchange = context.getEndpoint("direct:start").createExchange();
exchange.getIn().setBody("Hello");

Future<Exchange> future = template.asyncCallback("direct:start", exchange,
new SynchronizationAdapter() {
    @Override
    public void onComplete(Exchange exchange) {
        assertEquals("Hello World", exchange.getIn().getBody());
    }
});

// Retrieve the reply from the main thread, specifying a timeout
Exchange reply = future.get(10, TimeUnit.SECONDS);
```

Where the `SynchronizationAdapter` class is a default implementation of the `Synchronization` interface, which you can override to provide your own definitions of the `onComplete()` and `onFailure()` callback methods.

You still have the option of accessing the reply from the main thread, because the `asyncCallback()` method also returns a `Future` object—for example:

```java
// Retrieve the reply from the main thread, specifying a timeout
Exchange reply = future.get(10, TimeUnit.SECONDS);
```

### 43.1.2. Synchronous Send

**Overview**

The *synchronous send* methods are a collection of methods that you can use to invoke a producer endpoint, where the current thread blocks until the method invocation is
complete and the reply (if any) has been received. These methods are compatible with any kind of message exchange protocol.

**Send an exchange**

The basic `send()` method is a general-purpose method that sends the contents of an `Exchange` object to an endpoint, using the message exchange pattern (MEP) of the exchange. The return value is the exchange that you get after it has been processed by the producer endpoint (possibly containing an `Out` message, depending on the MEP).

There are three varieties of `send()` method for sending an exchange that let you specify the target endpoint in one of the following ways: as the default endpoint, as an endpoint URI, or as an `Endpoint` object.

```java
Exchange send(Exchange exchange);
Exchange send(String endpointUri, Exchange exchange);
Exchange send(Endpoint endpoint, Exchange exchange);
```

**Send an exchange populated by a processor**

A simple variation of the general `send()` method is to use a processor to populate a default exchange, instead of supplying the exchange object explicitly (see the section called “Synchronous invocation with a processor” for details).

The `send()` methods for sending an exchange populated by a processor let you specify the target endpoint in one of the following ways: as the default endpoint, as an endpoint URI, or as an `Endpoint` object. In addition, you can optionally specify the exchange’s MEP by supplying the `pattern` argument, instead of accepting the default.

```java
Exchange send(Processor processor);
Exchange send(String endpointUri, Processor processor);
Exchange send(Endpoint endpoint, Processor processor);
Exchange send(
    String endpointUri,
    ExchangePattern pattern,
    Processor processor
);
Exchange send(
    Endpoint endpoint,
    ExchangePattern pattern,
    Processor processor
);
```

**Send a message body**

If you are only concerned with the contents of the message body that you want to send, you can use the `sendBody()` methods to provide the message body as an argument and let the producer template take care of inserting the body into a default exchange object.

The `sendBody()` methods let you specify the target endpoint in one of the following ways: as the default endpoint, as an endpoint URI, or as an `Endpoint` object. In addition, you can optionally specify the exchange’s MEP by supplying the `pattern` argument, instead of accepting the default. The methods without a `pattern` argument return `void` (even though
the invocation might give rise to a reply in some cases); and the methods with a pattern argument return either the body of the Out message (if there is one) or the body of the In message (otherwise).

```java
void sendBody(Object body);
void sendBody(String endpointUri, Object body);
void sendBody(Endpoint endpoint, Object body);
Object sendBody(
    String endpointUri,
    ExchangePattern pattern,
    Object body
);
Object sendBody(
    Endpoint endpoint,
    ExchangePattern pattern,
    Object body
);
```

**Send a message body and header(s)**

For testing purposes, it is often interesting to try out the effect of a single header setting and the `sendBodyAndHeader()` methods are useful for this kind of header testing. You supply the message body and header setting as arguments to `sendBodyAndHeader()` and let the producer template take care of inserting the body and header setting into a default exchange object.

The `sendBodyAndHeader()` methods let you specify the target endpoint in one of the following ways: as the default endpoint, as an endpoint URI, or as an Endpoint object. In addition, you can optionally specify the exchange's MEP by supplying the pattern argument, instead of accepting the default. The methods without a pattern argument return `void` (even though the invocation might give rise to a reply in some cases); and the methods with a pattern argument return either the body of the Out message (if there is one) or the body of the In message (otherwise).

```java
void sendBodyAndHeader(
    Object body,
    String header,
    Object headerValue
);
void sendBodyAndHeader(
    String endpointUri,
    Object body,
    String header,
    Object headerValue
);
void sendBodyAndHeader(
    Endpoint endpoint,
    Object body,
    String header,
    Object headerValue
);
Object sendBodyAndHeader(
    String endpointUri,
    ExchangePattern pattern,
    Object body,
```
The `sendBodyAndHeaders()` methods are similar to the `sendBodyAndHeader()` methods, except that instead of supplying just a single header setting, these methods allow you to specify a complete hash map of header settings.

```java
void sendBodyAndHeaders(
    Object body,
    Map<String, Object> headers
);  
void sendBodyAndHeaders(
    String endpointUri,
    Object body,
    Map<String, Object> headers
);  
void sendBodyAndHeaders(
    Endpoint endpoint,
    Object body,
    Map<String, Object> headers
);  
Object sendBodyAndHeaders(
    String endpointUri,
    ExchangePattern pattern,
    Object body,
    Map<String, Object> headers
);  
Object sendBodyAndHeaders(
    Endpoint endpoint,
    ExchangePattern pattern,
    Object body,
    Map<String, Object> headers
);  
```

**Send a message body and exchange property**

You can try out the effect of setting a single exchange property using the `sendBodyAndProperty()` methods. You supply the message body and property setting as arguments to `sendBodyAndProperty()` and let the producer template take care of inserting the body and exchange property into a default exchange object.

The `sendBodyAndProperty()` methods let you specify the target endpoint in one of the following ways: as the default endpoint, as an endpoint URI, or as an `Endpoint` object. In addition, you can optionally specify the exchange's MEP by supplying the `pattern` argument, instead of accepting the default. The methods *without a `pattern` argument*
return `void` (even though the invocation might give rise to a reply in some cases); and the methods with a `pattern` argument return either the body of the `Out` message (if there is one) or the body of the `In` message (otherwise).

```
void sendBodyAndProperty(
    Object body,
    String property,
    Object propertyValue
);
void sendBodyAndProperty(
    String endpointUri,
    Object body,
    String property,
    Object propertyValue
);
void sendBodyAndProperty(
    Endpoint endpoint,
    Object body,
    String property,
    Object propertyValue
);
Object sendBodyAndProperty(
    String endpoint,
    ExchangePattern pattern,
    Object body,
    String property,
    Object propertyValue
);
Object sendBodyAndProperty(
    Endpoint endpoint,
    ExchangePattern pattern,
    Object body,
    String property,
    Object propertyValue
);
```

### 43.1.3. Synchronous Request with InOut Pattern

**Overview**

The *synchronous request* methods are similar to the synchronous send methods, except that the request methods force the message exchange pattern to be `InOut` (conforming to request/reply semantics). Hence, it is generally convenient to use a synchronous request method, if you expect to receive a reply from the producer endpoint.

**Request an exchange populated by a processor**

The basic `request()` method is a general-purpose method that uses a processor to populate a default exchange and forces the message exchange pattern to be `InOut` (so that the invocation obeys request/reply semantics). The return value is the exchange that you get after it has been processed by the producer endpoint, where the `Out` message contains the reply message.

The `request()` methods for sending an exchange populated by a processor let you specify the target endpoint in one of the following ways: as an endpoint URI, or as an `Endpoint`...
Request a message body

If you are only concerned with the contents of the message body in the request and in the reply, you can use the `requestBody()` methods to provide the request message body as an argument and let the producer template take care of inserting the body into a default exchange object.

The `requestBody()` methods let you specify the target endpoint in one of the following ways: as the default endpoint, as an endpoint URI, or as an `Endpoint` object. The return value is the body of the reply message (Out message body), which can either be returned as plain `Object` or converted to a specific type, `T`, using the built-in type converters (see Section 40.3, “Built-In Type Converters”).

```java
Object requestBody(Object body);
<T> T requestBody(Object body, Class<T> type);
Object requestBody(
    String endpointUri,
    Object body
);
<T> T requestBody(
    String endpointUri,
    Object body,
    Class<T> type
);
Object requestBody(
    Endpoint endpoint,
    Object body
);
<T> T requestBody(
    Endpoint endpoint,
    Object body,
    Class<T> type
);
```

Request a message body and header(s)

You can try out the effect of setting a single header value using the `requestBodyAndHeader()` methods. You supply the message body and header setting as arguments to `requestBodyAndHeader()` and let the producer template take care of inserting the body and exchange property into a default exchange object.

The `requestBodyAndHeader()` methods let you specify the target endpoint in one of the following ways: as an endpoint URI, or as an `Endpoint` object. The return value is the body of the reply message (Out message body), which can either be returned as plain `Object` or converted to a specific type, `T`, using the built-in type converters (see Section 40.3, “Built-In Type Converters”).

```java
Object requestBodyAndHeader(
    String endpointUri,
    
```
Object body,
String header,
Object headerValue
);
<T> T requestBodyAndHeader(
    String endpointUri,
    Object body,
    String header,
    Object headerValue,
    Class<T> type
);
Object requestBodyAndHeader(
    Endpoint endpoint,
    Object body,
    String header,
    Object headerValue
);
<T> T requestBodyAndHeader(
    Endpoint endpoint,
    Object body,
    String header,
    Object headerValue,
    Class<T> type
);

The `requestBodyAndHeaders()` methods are similar to the `requestBodyAndHeader()` methods, except that instead of supplying just a single header setting, these methods allow you to specify a complete hash map of header settings.

Object requestBodyAndHeaders(
    String endpointUri,
    Object body,
    Map<String, Object> headers
);
<T> T requestBodyAndHeaders(
    String endpointUri,
    Object body,
    Map<String, Object> headers,
    Class<T> type
);
Object requestBodyAndHeaders(
    Endpoint endpoint,
    Object body,
    Map<String, Object> headers
);
<T> T requestBodyAndHeaders(
    Endpoint endpoint,
    Object body,
    Map<String, Object> headers,
    Class<T> type
);

43.1.4. Asynchronous Send
Overview

The producer template provides a variety of methods for invoking a producer endpoint asynchronously, so that the main thread does not block while waiting for the invocation to complete and the reply message can be retrieved at a later time. The asynchronous send methods described in this section are compatible with any kind of message exchange protocol.

Send an exchange

The basic `asyncSend()` method takes an `Exchange` argument and invokes an endpoint asynchronously, using the message exchange pattern (MEP) of the specified exchange. The return value is a `java.util.concurrent.Future` object, which is a ticket you can use to collect the reply message at a later time—for details of how to obtain the return value from the `Future` object, see the section called “Asynchronous invocation”.

The following `asyncSend()` methods let you specify the target endpoint in one of the following ways: as an endpoint URI, or as an `Endpoint` object.

```java
Future<Exchange> asyncSend(String endpointUri, Exchange exchange);
Future<Exchange> asyncSend(Endpoint endpoint, Exchange exchange);
```

Send an exchange populated by a processor

A simple variation of the general `asyncSend()` method is to use a processor to populate a default exchange, instead of supplying the exchange object explicitly.

The following `asyncSend()` methods let you specify the target endpoint in one of the following ways: as an endpoint URI, or as an `Endpoint` object.

```java
Future<Exchange> asyncSend(String endpointUri, Processor processor);
Future<Exchange> asyncSend(Endpoint endpoint, Processor processor);
```

Send a message body

If you are only concerned with the contents of the message body that you want to send, you can use the `asyncSendBody()` methods to send a message body asynchronously and let the producer template take care of inserting the body into a default exchange object.

The `asyncSendBody()` methods let you specify the target endpoint in one of the following ways: as an endpoint URI, or as an `Endpoint` object.

```java
Future<Object> asyncSendBody(String endpointUri, Object body);
Future<Object> asyncSendBody(Endpoint endpoint, Object body);
```

43.1.5. Asynchronous Request with InOut Pattern

Overview

The `asynchronous request` methods are similar to the asynchronous send methods, except that the request methods force the message exchange pattern to be `InOut` (conforming to request/reply semantics). Hence, it is generally convenient to use an asynchronous request method, if you expect to receive a reply from the producer endpoint.
### Request a message body

If you are only concerned with the contents of the message body in the request and in the reply, you can use the `requestBody()` methods to provide the request message body as an argument and let the producer template take care of inserting the body into a default exchange object.

The `asyncRequestBody()` methods let you specify the target endpoint in one of the following ways: as an endpoint URI, or as an `Endpoint` object. The return value that is retrievable from the `Future` object is the body of the reply message (Out message body), which can be returned either as a plain `Object` or converted to a specific type, `T`, using a built-in type converter (see the section called “Asynchronous invocation”).

```java
Future<Object> asyncRequestBody(
    String endpointUri,
    Object body
);
<T> Future<T> asyncRequestBody(
    String endpointUri,
    Object body,
    Class<T> type
);
Future<Object> asyncRequestBody(
    Endpoint endpoint,
    Object body
);
<T> Future<T> asyncRequestBody(
    Endpoint endpoint,
    Object body,
    Class<T> type
);
```

### Request a message body and header(s)

You can try out the effect of setting a single header value using the `asyncRequestBodyAndHeader()` methods. You supply the message body and header setting as arguments to `asyncRequestBodyAndHeader()` and let the producer template take care of inserting the body and exchange property into a default exchange object.

The `asyncRequestBodyAndHeader()` methods let you specify the target endpoint in one of the following ways: as an endpoint URI, or as an `Endpoint` object. The return value that is retrievable from the `Future` object is the body of the reply message (Out message body), which can be returned either as a plain `Object` or converted to a specific type, `T`, using a built-in type converter (see the section called “Asynchronous invocation”).

```java
Future<Object> asyncRequestBodyAndHeader(
    String endpointUri,
    Object body,
    String header,
    Object headerValue
);
<T> Future<T> asyncRequestBodyAndHeader(
    String endpointUri,
    Object body,
    String header,
    String headerValue
);
```
Object headerValue,
Class<T> type
);
Future<Object> asyncRequestBodyAndHeader(
    Endpoint endpoint,
    Object body,
    String header,
    Object headerValue
);
<T> Future<T> asyncRequestBodyAndHeader(
    Endpoint endpoint,
    Object body,
    String header,
    Object headerValue,
    Class<T> type
);

The `asyncRequestBodyAndHeaders()` methods are similar to the
`asyncRequestBodyAndHeader()` methods, except that instead of supplying just a single
header setting, these methods allow you to specify a complete hash map of header
settings.

Future<Object> asyncRequestBodyAndHeaders(
    String endpointUri,
    Object body,
    Map<String, Object> headers
);
<T> Future<T> asyncRequestBodyAndHeaders(
    String endpointUri,
    Object body,
    Map<String, Object> headers,
    Class<T> type
);

Future<Object> asyncRequestBodyAndHeaders(
    Endpoint endpoint,
    Object body,
    Map<String, Object> headers
);
<T> Future<T> asyncRequestBodyAndHeaders(
    Endpoint endpoint,
    Object body,
    Map<String, Object> headers,
    Class<T> type
);

43.1.6. Asynchronous Send with Callback

Overview

The producer template also provides the option of processing the reply message in the
same sub-thread that is used to invoke the producer endpoint. In this case, you provide a
callback object, which automatically gets invoked in the sub-thread as soon as the reply
message is received. In other words, the `asynchronous send with callback` methods enable
you to initiate an invocation in your main thread and then have all of the associated processing—invocation of the producer endpoint, waiting for a reply and processing the reply—occur asynchronously in a sub-thread.

**Send an exchange**

The basic `asyncCallback()` method takes an `Exchange` argument and invokes an endpoint asynchronously, using the message exchange pattern (MEP) of the specified exchange. This method is similar to the `asyncSend()` method for exchanges, except that it takes an additional `org.apache.camel.spi.Synchronization` argument, which is a callback interface with two methods: `onComplete()` and `onFailure()`. For details of how to use the `Synchronization` callback, see the section called “Asynchronous invocation with a callback”.

The following `asyncCallback()` methods let you specify the target endpoint in one of the following ways: as an endpoint URI, or as an `Endpoint` object.

```
Future<Exchange> asyncCallback(
    String endpointUri,
    Exchange exchange,
    Synchronization onCompletion
);
Future<Exchange> asyncCallback(
    Endpoint endpoint,
    Exchange exchange,
    Synchronization onCompletion
);
```

**Send an exchange populated by a processor**

The `asyncCallback()` method for processors calls a processor to populate a default exchange and forces the message exchange pattern to be `InOut` (so that the invocation obeys request/reply semantics).

The following `asyncCallback()` methods let you specify the target endpoint in one of the following ways: as an endpoint URI, or as an `Endpoint` object.

```
Future<Exchange> asyncCallback(
    String endpointUri,
    Processor processor,
    Synchronization onCompletion
);
Future<Exchange> asyncCallback(
    Endpoint endpoint,
    Processor processor,
    Synchronization onCompletion
);
```

**Send a message body**

If you are only concerned with the contents of the message body that you want to send, you can use the `asyncCallbackSendBody()` methods to send a message body asynchronously and let the producer template take care of inserting the body into a default exchange object.
The `asyncCallbackSendBody()` methods let you specify the target endpoint in one of the following ways: as an endpoint URI, or as an `Endpoint` object.

```java
Future<Object> asyncCallbackSendBody(
    String endpointUri,
    Object body,
    Synchronization onCompletion
);
Future<Object> asyncCallbackSendBody(
    Endpoint endpoint,
    Object body,
    Synchronization onCompletion
);
```

**Request a message body**

If you are only concerned with the contents of the message body in the request and in the reply, you can use the `asyncCallbackRequestBody()` methods to provide the request message body as an argument and let the producer template take care of inserting the body into a default exchange object.

```java
Future<Object> asyncCallbackRequestBody(
    String endpointUri,
    Object body,
    Synchronization onCompletion
);
Future<Object> asyncCallbackRequestBody(
    Endpoint endpoint,
    Object body,
    Synchronization onCompletion
);
```

### 43.2. USING THE CONSUMER TEMPLATE

**Overview**

The consumer template provides methods for polling a consumer endpoint in order to receive incoming messages. You can choose to receive the incoming message either in the form of an exchange object or in the form of a message body (where the message body can be cast to a particular type using a built-in type converter).

**Example of polling exchanges**

You can use a consumer template to poll a consumer endpoint for exchanges using one of the following polling methods: blocking `receive(); receive()` with a timeout; or `receiveNowait()`, which returns immediately. Because a consumer endpoint represents a service, it is also essential to start the service thread by calling `start()` before you attempt to poll for exchanges.
The following example shows how to poll an exchange from the `seda:foo` consumer endpoint using the blocking `receive()` method:

```java
import org.apache.camel.ProducerTemplate;
import org.apache.camel.ConsumerTemplate;
import org.apache.camel.Exchange;
...
ProducerTemplate template = context.createProducerTemplate();
ConsumerTemplate consumer = context.createConsumerTemplate();

// Start the consumer service
consumer.start();
...
template.sendBody("seda:foo", "Hello");
Exchange out = consumer.receive("seda:foo");
...
// Stop the consumer service
consumer.stop();
```

Where the consumer template instance, `consumer`, is instantiated using the `CamelContext.createConsumerTemplate()` method and the consumer service thread is started by calling `ConsumerTemplate.start()`.

**Example of polling message bodies**

You can also poll a consumer endpoint for incoming message bodies using one of the following methods: blocking `receiveBody()`; `receiveBody()` with a timeout; or `receiveBodyNoWait()`, which returns immediately. As in the previous example, it is also essential to start the service thread by calling `start()` before you attempt to poll for exchanges.

The following example shows how to poll an incoming message body from the `seda:foo` consumer endpoint using the blocking `receiveBody()` method:

```java
import org.apache.camel.ProducerTemplate;
import org.apache.camel.ConsumerTemplate;
...
ProducerTemplate template = context.createProducerTemplate();
ConsumerTemplate consumer = context.createConsumerTemplate();

// Start the consumer service
consumer.start();
...
template.sendBody("seda:foo", "Hello");
Object body = consumer.receiveBody("seda:foo");
...
// Stop the consumer service
consumer.stop();
```

**Methods for polling exchanges**

There are three basic methods for polling `exchanges` from a consumer endpoint: `receive()` without a timeout blocks indefinitely; `receive()` with a timeout blocks for the specified period of milliseconds; and `receiveNoWait()` is non-blocking. You can specify the consumer endpoint either as an endpoint URI or as an `Endpoint` instance.
Methods for polling message bodies

There are three basic methods for polling message bodies from a consumer endpoint: `receiveBody()` without a timeout blocks indefinitely; `receiveBody()` with a timeout blocks for the specified period of milliseconds; and `receiveBodyNoWait()` is non-blocking. You can specify the consumer endpoint either as an endpoint URI or as an `Endpoint` instance. Moreover, by calling the templating forms of these methods, you can convert the returned body to a particular type, `T`, using a built-in type converter.

```java
Exchange receive(String endpointUri);
Exchange receive(String endpointUri, long timeout);
Exchange receiveNoWait(String endpointUri);

Exchange receive(Endpoint endpoint);
Exchange receive(Endpoint endpoint, long timeout);
Exchange receiveNoWait(Endpoint endpoint);

Object receiveBody(String endpointUri);
Object receiveBody(String endpointUri, long timeout);
Object receiveBodyNoWait(String endpointUri);

Object receiveBody(Endpoint endpoint);
Object receiveBody(Endpoint endpoint, long timeout);
Object receiveBodyNoWait(Endpoint endpoint);

<T> T receiveBody(String endpointUri, Class<T> type);
<T> T receiveBody(String endpointUri, long timeout, Class<T> type);
<T> T receiveBodyNoWait(String endpointUri, Class<T> type);

<T> T receiveBody(Endpoint endpoint, Class<T> type);
<T> T receiveBody(Endpoint endpoint, long timeout, Class<T> type);
<T> T receiveBodyNoWait(Endpoint endpoint, Class<T> type);
```
CHAPTER 44. IMPLEMENTING A COMPONENT

Abstract

This chapter provides a general overview of the approaches can be used to implement a Apache Camel component.

44.1. COMPONENT ARCHITECTURE

44.1.1. Factory Patterns for a Component

Overview

A Apache Camel component consists of a set of classes that are related to each other through a factory pattern. The primary entry point to a component is the Component object itself (an instance of org.apache.camel.Component type). You can use the Component object as a factory to create Endpoint objects, which in turn act as factories for creating Consumer, Producer, and Exchange objects. These relationships are summarized in Figure 44.1, “Component Factory Patterns”

![Figure 44.1. Component Factory Patterns](image)

Component

A component implementation is an endpoint factory. The main task of a component implementor is to implement the Component.createEndpoint() method, which is responsible for creating new endpoints on demand.

Each kind of component must be associated with a component prefix that appears in an endpoint URI. For example, the file component is usually associated with the file prefix, which can be used in an endpoint URI like file://tmp/messages/input. When you install a new component in Apache Camel, you must define the association between a particular component prefix and the name of the class that implements the component.

Endpoint
Each endpoint instance encapsulates a particular endpoint URI. Every time Apache Camel encounters a new endpoint URI, it creates a new endpoint instance. An endpoint object is also a factory for creating consumer endpoints and producer endpoints.

Endpoints must implement the `org.apache.camel.Endpoint` interface. The `Endpoint` interface defines the following factory methods:

- `createConsumer()` and `createPollingConsumer()`—Creates a consumer endpoint, which represents the source endpoint at the beginning of a route.
- `createProducer()`—Creates a producer endpoint, which represents the target endpoint at the end of a route.
- `createExchange()`—Creates an exchange object, which encapsulates the messages passed up and down the route.

**Consumer**

Consumer endpoints consume requests. They always appear at the start of a route and they encapsulate the code responsible for receiving incoming requests and dispatching outgoing replies. From a service-oriented prospective a consumer represents a service.

Consumers must implement the `org.apache.camel.Consumer` interface. There are a number of different patterns you can follow when implementing a consumer. These patterns are described in *Section 44.1.3, “Consumer Patterns and Threading”*.

**Producer**

Producer endpoints produce requests. They always appears at the end of a route and they encapsulate the code responsible for dispatching outgoing requests and receiving incoming replies. From a service-oriented prospective a producer represents a service consumer.

Producers must implement the `org.apache.camel.Producer` interface. You can optionally implement the producer to support an asynchronous style of processing. See *Section 44.1.4, “Asynchronous Processing”* for details.

**Exchange**

Exchange objects encapsulate a related set of messages. For example, one kind of message exchange is a synchronous invocation, which consists of a request message and its related reply.

Exchanges must implement the `org.apache.camel.Exchange` interface. The default implementation, `DefaultExchange`, is sufficient for many component implementations. However, if you want to associated extra data with the exchanges or have the exchanges preform additional processing, it can be useful to customize the exchange implementation.

**Message**

There are two different message slots in an `Exchange` object:

- *In* message—holds the current message.
- *Out* message—temporarily holds a reply message.
All of the message types are represented by the same Java object, `org.apache.camel.Message`. It is not always necessary to customize the message implementation—the default implementation, `DefaultMessage`, is usually adequate.

### 44.1.2. Using a Component in a Route

**Overview**

A Apache Camel route is essentially a pipeline of processors, of `org.apache.camel.Processor` type. Messages are encapsulated in an exchange object, `E`, which gets passed from node to node by invoking the `process()` method. The architecture of the processor pipeline is illustrated in Figure 44.2, “Consumer and Producer Instances in a Route”.

#### Figure 44.2. Consumer and Producer Instances in a Route

![Diagram of Consumer and Producer Instances in a Route](image)

**Source endpoint**

At the start of the route, you have the source endpoint, which is represented by an `org.apache.camel.Consumer` object. The source endpoint is responsible for accepting incoming request messages and dispatching replies. When constructing the route, Apache Camel creates the appropriate `Consumer` type based on the component prefix from the endpoint URI, as described in Section 44.1.1, “Factory Patterns for a Component”.

**Processors**

Each intermediate node in the pipeline is represented by a processor object (implementing the `org.apache.camel.Processor` interface). You can insert either standard processors (for example, `filter`, `throttler`, or `delay`) or insert your own custom processor implementations.

**Target endpoint**

At the end of the route is the target endpoint, which is represented by an `org.apache.camel.Producer` object. Because it comes at the end of a processor pipeline, the producer is also a processor object (implementing the `org.apache.camel.Processor` interface). The target endpoint is responsible for sending outgoing request messages and receiving incoming replies. When constructing the route, Apache Camel creates the appropriate `Producer` type based on the component prefix from the endpoint URI.

### 44.1.3. Consumer Patterns and Threading

**Overview**

The pattern used to implement the consumer determines the threading model used in processing the incoming exchanges. Consumers can be implemented using one of the following patterns:
- **Event-driven pattern**—The consumer is driven by an external thread.
- **Scheduled poll pattern**—The consumer is driven by a dedicated thread pool.
- **Polling pattern**—The threading model is left undefined.

### Event-driven pattern

In the event-driven pattern, the processing of an incoming request is initiated when another part of the application (typically a third-party library) calls a method implemented by the consumer. A good example of an event-driven consumer is the Apache Camel JMX component, where events are initiated by the JMX library. The JMX library calls the `handleNotification()` method to initiate request processing—see Example 47.4, “JMXConsumer Implementation” for details.

Figure 44.3, “Event-Driven Consumer” shows an outline of the event-driven consumer pattern. In this example, it is assumed that processing is triggered by a call to the `notify()` method.

**Figure 44.3. Event-Driven Consumer**

The event-driven consumer processes incoming requests as follows:

1. The consumer must implement a method to receive the incoming event (in Figure 44.3, “Event-Driven Consumer” this is represented by the `notify()` method). The thread that calls `notify()` is normally a separate part of the application, so the consumer's threading policy is externally driven.

   For example, in the case of the JMX consumer implementation, the consumer implements the `NotificationListener.handleNotification()` method to receive notifications from JMX. The threads that drive the consumer processing are created within the JMX layer.

2. In the body of the `notify()` method, the consumer first converts the incoming event into an exchange object, `E`, and then calls `process()` on the next processor in the route, passing the exchange object as its argument.

### Scheduled poll pattern

In the scheduled poll pattern, the consumer retrieves incoming requests by checking at regular time intervals whether or not a request has arrived. Checking for requests is scheduled automatically by a built-in timer class, the `scheduled executor service`, which is a standard pattern provided by the java.util.concurrent library. The scheduled executor service executes a particular task at timed intervals and it also manages a pool of threads, which are used to run the task instances.

Figure 44.4, “Scheduled Poll Consumer” shows an outline of the scheduled poll consumer pattern.
The scheduled poll consumer processes incoming requests as follows:

1. The scheduled executor service has a pool of threads at its disposal, that can be used to initiate consumer processing. After each scheduled time interval has elapsed, the scheduled executor service attempts to grab a free thread from its pool (there are five threads in the pool by default). If a free thread is available, it uses that thread to call the `poll()` method on the consumer.

2. The consumer's `poll()` method is intended to trigger processing of an incoming request. In the body of the `poll()` method, the consumer attempts to retrieve an incoming message. If no request is available, the `poll()` method returns immediately.

3. If a request message is available, the consumer inserts it into an exchange object and then calls `process()` on the next processor in the route, passing the exchange object as its argument.

**Polling pattern**

In the polling pattern, processing of an incoming request is initiated when a third-party calls one of the consumer's polling methods:

- `receive()`
- `receiveNoWait()`
- `receive(long timeout)`

It is up to the component implementation to define the precise mechanism for initiating calls on the polling methods. This mechanism is not specified by the polling pattern.

*Figure 44.5, “Polling Consumer”* shows an outline of the polling consumer pattern.
Polling Consumer

The polling consumer processes incoming requests as follows:

1. Processing of an incoming request is initiated whenever one of the consumer’s polling methods is called. The mechanism for calling these polling methods is implementation defined.

2. In the body of the `receive()` method, the consumer attempts to retrieve an incoming request message. If no message is currently available, the behavior depends on which receive method was called.
   - `receiveNoWait()` returns immediately
   - `receive(long timeout)` waits for the specified timeout interval before returning
   - `receive()` waits until a message is received

3. If a request message is available, the consumer inserts it into an exchange object and then calls `process()` on the next processor in the route, passing the exchange object as its argument.

44.1.4. Asynchronous Processing

Overview

Producer endpoints normally follow a *synchronous* pattern when processing an exchange. When the preceding processor in a pipeline calls `process()` on a producer, the `process()` method blocks until a reply is received. In this case, the processor’s thread remains blocked until the producer has completed the cycle of sending the request and receiving the reply.

Sometimes, however, you might prefer to decouple the preceding processor from the producer, so that the processor’s thread is released immediately and the `process()` call does not block. In this case, you should implement the producer using an *asynchronous* pattern, which gives the preceding processor the option of invoking a non-blocking version of the `process()` method.

To give you an overview of the different implementation options, this section describes both the synchronous and the asynchronous patterns for implementing a producer endpoint.
**Synchronous producer**

Figure 44.6, “Synchronous Producer” shows an outline of a synchronous producer, where the preceding processor blocks until the producer has finished processing the exchange.

**Figure 44.6. Synchronous Producer**

The synchronous producer processes an exchange as follows:

1. The preceding processor in the pipeline calls the synchronous `process()` method on the producer to initiate synchronous processing. The synchronous `process()` method takes a single exchange argument.

2. In the body of the `process()` method, the producer sends the request `In message` to the endpoint.

3. If required by the exchange pattern, the producer waits for the reply `Out message` to arrive from the endpoint. This step can cause the `process()` method to block indefinitely. However, if the exchange pattern does not mandate a reply, the `process()` method can return immediately after sending the request.

4. When the `process()` method returns, the exchange object contains the reply from the synchronous call (an `Out message` message).

**Asynchronous producer**

Figure 44.7, “Asynchronous Producer” shows an outline of an asynchronous producer, where the producer processes the exchange in a sub-thread, and the preceding processor is not blocked for any significant length of time.
The asynchronous producer processes an exchange as follows:

1. Before the processor can call the asynchronous `process()` method, it must create an asynchronous `Callback` object, which is responsible for processing the exchange on the return portion of the route. For the asynchronous callback, the processor must implement a class that inherits from the `AsyncCallback` interface.

2. The processor calls the asynchronous `process()` method on the producer to initiate asynchronous processing. The asynchronous `process()` method takes two arguments:
   - an exchange object
   - a synchronous callback object

3. In the body of the `process()` method, the producer creates a `Runnable` object that encapsulates the processing code. The producer then delegates the execution of this `Runnable` object to a sub-thread.

4. The asynchronous `process()` method returns, thereby freeing up the processor's thread. The exchange processing continues in a separate sub-thread.

5. The `Runnable` object sends the `In` message to the endpoint.

6. If required by the exchange pattern, the `Runnable` object waits for the reply `Out` or `Fault` message to arrive from the endpoint. The `Runnable` object remains blocked until the reply is received.

7. After the reply arrives, the `Runnable` object inserts the reply `Out` message into the exchange object and then calls `done()` on the asynchronous callback object. The asynchronous callback is then responsible for processing the reply message (executed in the sub-thread).
44.2. HOW TO IMPLEMENT A COMPONENT

Overview

This section gives a brief overview of the steps required to implement a custom Apache Camel component.

Which interfaces do you need to implement?

When implementing a component, it is usually necessary to implement the following Java interfaces:

- `org.apache.camel.Component`
- `org.apache.camel.Endpoint`
- `org.apache.camel.Consumer`
- `org.apache.camel.Producer`

In addition, it can also be necessary to implement the following Java interfaces:

- `org.apache.camel.Exchange`
- `org.apache.camel.Message`

Implementation steps

You typically implement a custom component as follows:

1. **Implement the Component interface**—A component object acts as an endpoint factory. You extend the `DefaultComponent` class and implement the `createEndpoint()` method.

   See Chapter 45, Component Interface.

2. **Implement the Endpoint interface**—An endpoint represents a resource identified by a specific URI. The approach taken when implementing an endpoint depends on whether the consumers follow an event-driven pattern, a scheduled poll pattern, or a polling pattern.

   For an event-driven pattern, implement the endpoint by extending the `DefaultEndpoint` class and implementing the following methods:

   - `createProducer()`
   - `createConsumer()`

   For a scheduled poll pattern, implement the endpoint by extending the `ScheduledPollEndpoint` class and implementing the following methods:

   - `createProducer()`
   - `createConsumer()`
For a polling pattern, implement the endpoint by extending the `DefaultPollingEndpoint` class and implementing the following methods:

- `createProducer()`
- `createPollConsumer()`

See Chapter 46, *Endpoint Interface*.

3. **Implement the Consumer interface**—There are several different approaches you can take to implementing a consumer, depending on which pattern you need to implement (event-driven, scheduled poll, or polling). The consumer implementation is also crucially important for determining the threading model used for processing a message exchange.

See Section 47.2, “Implementing the Consumer Interface”.

4. **Implement the Producer interface**—To implement a producer, you extend the `DefaultProducer` class and implement the `process()` method.

See Chapter 48, *Producer Interface*.

5. **Optionally implement the Exchange or the Message interface**—The default implementations of `Exchange` and `Message` can be used directly, but occasionally, you might find it necessary to customize these types.

### Installing and configuring the component

You can install a custom component in one of the following ways:

- **Add the component directly to the CamelContext**—The `CamelContext.addComponent()` method adds a component programatically.

- **Add the component using Spring configuration**—The standard Spring `bean` element creates a component instance. The bean’s `id` attribute implicitly defines the component prefix. For details, see Section 44.3.2, “Configuring a Component”.

- **Configure Apache Camel to auto-discover the component**—Auto-discovery, ensures that Apache Camel automatically loads the component on demand. For details, see Section 44.3.1, “Setting Up Auto-Discovery”.

### 44.3. AUTO-DISCOVERY AND CONFIGURATION

#### 44.3.1. Setting Up Auto-Discovery

**Overview**

Auto-discovery is a mechanism that enables you to dynamically add components to your Apache Camel application. The component URI prefix is used as a key to load components on demand. For example, if Apache Camel encounters the endpoint URI, `activemq://MyQName`, and the ActiveMQ endpoint is not yet loaded, Apache Camel searches for the component identified by the `activemq` prefix and dynamically loads the component.
Availability of component classes

Before configuring auto-discovery, you must ensure that your custom component classes are accessible from your current classpath. Typically, you bundle the custom component classes into a JAR file, and add the JAR file to your classpath.

Configuring auto-discovery

To enable auto-discovery of your component, create a Java properties file named after the component prefix, `component-prefix`, and store that file in the following location:

```
/META-INF/services/org/apache/camel/component/component-prefix
```

The `component-prefix` properties file must contain the following property setting:

```
class=component-class-name
```

Where `component-class-name` is the fully-qualified name of your custom component class. You can also define additional system property settings in this file.

Example

For example, you can enable auto-discovery for the Apache Camel FTP component by creating the following Java properties file:

```
/META-INF/services/org/apache/camel/component/ftp
```

Which contains the following Java property setting:

```
class=org.apache.camel.component.file.remote.RemoteFileComponent
```

NOTE

The Java properties file for the FTP component is already defined in the JAR file, `camel-ftp-Version.jar`.

44.3.2. Configuring a Component

Overview

You can add a component by configuring it in the Apache Camel Spring configuration file, `META-INF/spring/camel-context.xml`. To find the component, the component's URI prefix is matched against the ID attribute of a `bean` element in the Spring configuration. If the component prefix matches a bean element ID, Apache Camel instantiates the referenced class and injects the properties specified in the Spring configuration.

NOTE

This mechanism has priority over auto-discovery. If the CamelContext finds a Spring bean with the requisite ID, it will not attempt to find the component using auto-discovery.
Define bean properties on your component class

If there are any properties that you want to inject into your component class, define them as bean properties. For example:

```java
public class CustomComponent extends DefaultComponent<CustomExchange> {
    PropType getProperty() { ... }
    void setProperty(PropType v) { ... }
}
```

The `getProperty()` method and the `setProperty()` method access the value of `property`.

Configure the component in Spring

To configure a component in Spring, edit the configuration file, `META-INF/spring/camel-context.xml`, as shown in Example 44.1, “Configuring a Component in Spring”:

```xml
<?xml version="1.0" encoding="UTF-8"?>
<beans xmlns="http://www.springframework.org/schema/beans"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="http://www.springframework.org/schema/beans
    http://www.springframework.org/schema/beans/spring-beans-2.0.xsd
    http://camel.apache.org/schema/spring
    http://camel.apache.org/schema/spring/camel-spring.xsd">

    <camelContext id="camel"
        xmlns="http://camel.apache.org/schema/spring">
        <package>RouteBuilderPackage</package>
    </camelContext>

    <bean id="component-prefix" class="component-class-name">
        <property name="property" value="propertyValue"/>
    </bean>
</beans>
```

The `bean` element with ID `component-prefix` configures the `component-class-name` component. You can inject properties into the component instance using `property` elements. For example, the `property` element in the preceding example would inject the value, `propertyValue`, into the `property` property by calling `setProperty()` on the component.

Examples

Example 44.2, “JMS Component Spring Configuration” shows an example of how to configure the Apache Camel’s JMS component by defining a bean element with ID equal to `jms`. These settings are added to the Spring configuration file `camel-context.xml`.

```java
public class CustomComponent extends DefaultComponent<CustomExchange> {
    PropType getProperty() { ... }
    void setProperty(PropType v) { ... }
}
```
The CamelContext automatically instantiates any RouteBuilder classes that it finds in the specified Java package, org.apache.camel.example.spring.

The bean element with ID, jms, configures the JMS component. The bean ID corresponds to the component's URI prefix. For example, if a route specifies an endpoint with the URI, jms://MyQName, Apache Camel automatically loads the JMS component using the settings from the jms bean element.

JMS is just a wrapper for a messaging service. You must specify the concrete implementation of the messaging system by setting the connectionFactory property on the JmsComponent class.

In this example, the concrete implementation of the JMS messaging service is Apache ActiveMQ. The brokerURL property initializes a connection to an ActiveMQ broker instance, where the message broker is embedded in the local Java virtual machine (JVM). If a broker is not already present in the JVM, ActiveMQ will instantiate it with the options broker.persistent=false (the broker does not persist messages) and broker.useJmx=false (the broker does not open a JMX port).

CHAPTER 45. COMPONENT INTERFACE

Abstract

This chapter describes how to implement the `Component` interface.

45.1. THE COMPONENT INTERFACE

Overview

To implement a Apache Camel component, you must implement the `org.apache.camel.Component` interface. An instance of `Component` type provides the entry point into a custom component. That is, all of the other objects in a component are ultimately accessible through the `Component` instance. Figure 45.1, “Component Inheritance Hierarchy” shows the relevant Java interfaces and classes that make up the `Component` inheritance hierarchy.

Figure 45.1. Component Inheritance Hierarchy

```
Component
```

```
DefaultComponent
```

The Component interface

Example 45.1, “Component Interface” shows the definition of the `org.apache.camel.Component` interface.

Example 45.1. Component Interface

```java
package org.apache.camel;

public interface Component {
    CamelContext getCamelContext();
    void setCamelContext(CamelContext context);

    Endpoint createEndpoint(String uri) throws Exception;
}
```

Component methods

The `Component` interface defines the following methods:
- `getCamelContext()` and `setCamelContext()`—References the `CamelContext` to which this `Component` belongs. The `setCamelContext()` method is automatically called when you add the component to a `CamelContext`.

- `createEndpoint()`—The factory method that gets called to create `Endpoint` instances for this component. The `uri` parameter is the endpoint URI, which contains the details required to create the endpoint.

## 45.2. IMPLEMENTING THE COMPONENT INTERFACE

### The DefaultComponent class

You implement a new component by extending the `org.apache.camel.impl.DefaultComponent` class, which provides some standard functionality and default implementations for some of the methods. In particular, the `DefaultComponent` class provides support for URI parsing and for creating scheduled executor (which is used for the scheduled poll pattern).

### URI parsing

The `createEndpoint(String uri)` method defined in the base `Component` interface takes a complete, unparsed endpoint URI as its sole argument. The `DefaultComponent` class, on the other hand, defines a three-argument version of the `createEndpoint()` method with the following signature:

```java
protected abstract Endpoint createEndpoint(
    String uri,
    String remaining,
    Map parameters
) throws Exception;
```

- `uri` is the original, unparsed URI; `remaining` is the part of the URI that remains after stripping off the component prefix at the start and cutting off the query options at the end; and `parameters` contains the parsed query options. It is this version of the `createEndpoint()` method that you must override when inheriting from `DefaultComponent`. This has the advantage that the endpoint URI is already parsed for you.

The following sample endpoint URI for the `file` component shows how URI parsing works in practice:

```text
file:///tmp/messages/foo?delete=true&moveNamePostfix=.old
```

For this URI, the following arguments are passed to the three-argument version of `createEndpoint()`:

<table>
<thead>
<tr>
<th>Argument</th>
<th>Sample Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>uri</code></td>
<td><code>file:///tmp/messages/foo?delete=true&amp;moveNamePostfix=.old</code></td>
</tr>
<tr>
<td><code>remaining</code></td>
<td><code>/tmp/messages/foo</code></td>
</tr>
</tbody>
</table>
parameters

Two entries are set in java.util.Map:

- parameter delete is boolean true
- parameter moveNamePostfix has the string value, .old.

Parameter injection

By default, the parameters extracted from the URI query options are injected on the endpoint's bean properties. The DefaultComponent class automatically injects the parameters for you.

For example, if you want to define a custom endpoint that supports two URI query options: delete and moveNamePostfix. All you must do is define the corresponding bean methods (getters and setters) in the endpoint class:

```java
public class FileEndpoint extends ScheduledPollEndpoint {
    ...
    public boolean isDelete() {
        return delete;
    }
    public void setDelete(boolean delete) {
        this.delete = delete;
    }
    ...
    public String getMoveNamePostfix() {
        return moveNamePostfix;
    }
    public void setMoveNamePostfix(String moveNamePostfix) {
        this.moveNamePostfix = moveNamePostfix;
    }
}
```

It is also possible to inject URI query options into consumer parameters. For details, see the section called “Consumer parameter injection”.

Disabling endpoint parameter injection

If there are no parameters defined on your Endpoint class, you can optimize the process of endpoint creation by disabling endpoint parameter injection. To disable parameter injection on endpoints, override the useIntrospectionOnEndpoint() method and implement it to return false, as follows:

```java
protected boolean useIntrospectionOnEndpoint() {
    return false;
}
```
NOTE

The `useIntrospectionOnEndpoint()` method does not affect the parameter injection that might be performed on a `Consumer` class. Parameter injection at that level is controlled by the `Endpoint.configureProperties()` method (see Section 46.2, “Implementing the Endpoint Interface”).

Scheduled executor service

The scheduled executor is used in the scheduled poll pattern, where it is responsible for driving the periodic polling of a consumer endpoint (a scheduled executor is effectively a thread pool implementation).

To instantiate a scheduled executor service, use the `ExecutorServiceStrategy` object that is returned by the `CamelContext.getExecutorServiceStrategy()` method. For details of the Apache Camel threading model, see Section 2.9, “Threading Model”.

NOTE

Prior to Apache Camel 2.3, the `DefaultComponent` class provided a `getExecutorService()` method for creating thread pool instances. Since 2.3, however, the creation of thread pools is now managed centrally by the `ExecutorServiceStrategy` object.

Validating the URI

If you want to validate the URI before creating an endpoint instance, you can override the `validateURI()` method from the `DefaultComponent` class, which has the following signature:

```java
protected void validateURI(String uri, String path, Map parameters) throws ResolveEndpointFailedException;
```

If the supplied URI does not have the required format, the implementation of `validateURI()` should throw the `org.apache.camel.ResolveEndpointFailedException` exception.

Creating an endpoint

Example 45.2, “Implementation of `createEndpoint()`” outlines how to implement the `DefaultComponent.createEndpoint()` method, which is responsible for creating endpoint instances on demand.

```java
public class CustomComponent extends DefaultComponent {
  ...
  protected Endpoint createEndpoint(String uri, String remaining, Map parameters) throws Exception {
    CustomEndpoint result = new CustomEndpoint(uri, this);
    // ...
    return result;
  }
}
```
The `CustomComponent` is the name of your custom component class, which is defined by extending the `DefaultComponent` class.

When extending `DefaultComponent`, you must implement the `createEndpoint()` method with three arguments (see the section called “URI parsing”).

Create an instance of your custom endpoint type, `CustomEndpoint`, by calling its constructor. At a minimum, this constructor takes a copy of the original URI string, `uri`, and a reference to this component instance, `this`.

Example

Example 45.3, “FileComponent Implementation” shows a sample implementation of a `FileComponent` class.

```java
package org.apache.camel.component.file;

import org.apache.camel.CamelContext;
import org.apache.camel.Endpoint;
import org.apache.camel.impl.DefaultComponent;
import java.io.File;
import java.util.Map;

public class FileComponent extends DefaultComponent {
    public static final String HEADER_FILE_NAME = "org.apache.camel.file.name";

    public FileComponent() {
    }

    public FileComponent(CamelContext context) {
        super(context);
    }

    protected Endpoint createEndpoint(String uri, String remaining, Map parameters) throws Exception {
        File file = new File(remaining);
        FileEndpoint result = new FileEndpoint(file, uri, this);
        return result;
    }
}
```

Always define a no-argument constructor for the component class in order to facilitate automatic instantiation of the class.

A constructor that takes the parent `CamelContext` instance as an argument is convenient when creating a component instance by programming.
The implementation of the `FileComponent.createEndpoint()` method follows the pattern described in Example 45.2, “Implementation of `createEndpoint()`”. The implementation creates a `FileEndpoint` object.
CHAPTER 46. ENDPOINT INTERFACE

Abstract
This chapter describes how to implement the Endpoint interface, which is an essential step in the implementation of a Apache Camel component.

46.1. THE ENDPOINT INTERFACE

Overview
An instance of org.apache.camel.Endpoint type encapsulates an endpoint URI, and it also serves as a factory for Consumer, Producer, and Exchange objects. There are three different approaches to implementing an endpoint:

- Event-driven
- scheduled poll
- polling

These endpoint implementation patterns complement the corresponding patterns for implementing a consumer—see Section 47.2, “Implementing the Consumer Interface”.

Figure 46.1, “Endpoint Inheritance Hierarchy” shows the relevant Java interfaces and classes that make up the Endpoint inheritance hierarchy.
Figure 46.1. Endpoint Inheritance Hierarchy

The Endpoint interface

Example 46.1, “Endpoint Interface” shows the definition of the org.apache.camel.Endpoint interface.

Example 46.1. Endpoint Interface

```java
package org.apache.camel;

public interface Endpoint {
    boolean isSingleton();

    String getEndpointUri();

    String getEndpointKey();

    CamelContext getCamelContext();

    void setCamelContext(CamelContext context);

    void configureProperties(Map options);

    boolean isLenientProperties();
}"
```
Endpoint methods

The Endpoint interface defines the following methods:

- `isSingleton()`—Returns `true`, if you want to ensure that each URI maps to a single endpoint within a CamelContext. When this property is `true`, multiple references to the identical URI within your routes always refer to a single endpoint instance. When this property is `false`, on the other hand, multiple references to the same URI within your routes refer to distinct endpoint instances. Each time you refer to the URI in a route, a new endpoint instance is created.

- `getEndpointUri()`—Returns the endpoint URI of this endpoint.

- `getEndpointKey()`—Used by `org.apache.camel.spi.LifecycleStrategy` when registering the endpoint.

- `getCamelContext()`—return a reference to the `CamelContext` instance to which this endpoint belongs.

- `setCamelContext()`—Sets the `CamelContext` instance to which this endpoint belongs.

- `configureProperties()`—Stores a copy of the parameter map that is used to inject parameters when creating a new `Consumer` instance.

- `isLenientProperties()`—Returns `true` to indicate that the URI is allowed to contain unknown parameters (that is, parameters that cannot be injected on the Endpoint or the Consumer class). Normally, this method should be implemented to return `false`.

- `createExchange()`—An overloaded method with the following variants:
  - `Exchange createExchange()`—Creates a new exchange instance with a default exchange pattern setting.
  - `Exchange createExchange(ExchangePattern pattern)`—Creates a new exchange instance with the specified exchange pattern.
  - `Exchange createExchange(Exchange exchange)`—Converts the given exchange argument to the type of exchange needed for this endpoint. If the given exchange is not already of the correct type, this method copies it into a new instance of the correct type. A default implementation of this method is provided in the `DefaultEndpoint` class.

- `createProducer()`—Factory method used to create new `Producer` instances.
- `createConsumer()`—Factory method to create new event-driven consumer instances. The `processor` argument is a reference to the first processor in the route.
- `createPollingConsumer()`—Factory method to create new polling consumer instances.

**Endpoint singletons**

In order to avoid unnecessary overhead, it is a good idea to create a single endpoint instance for all endpoints that have the same URI (within a CamelContext). You can enforce this condition by implementing `isSingleton()` to return `true`.

**NOTE**

In this context, *same URI* means that two URIs are the same when compared using string equality. In principle, it is possible to have two URIs that are equivalent, though represented by different strings. In that case, the URIs would not be treated as the same.

### 46.2. IMPLEMENTING THE ENDPOINT INTERFACE

**Alternative ways of implementing an endpoint**

The following alternative endpoint implementation patterns are supported:

- Event-driven endpoint implementation
- Scheduled poll endpoint implementation
- Polling endpoint implementation

**Event-driven endpoint implementation**

If your custom endpoint conforms to the event-driven pattern (see Section 44.1.3, “Consumer Patterns and Threading”), it is implemented by extending the abstract class, `org.apache.camel.impl.DefaultEndpoint`, as shown in Example 46.2, “Implementing DefaultEndpoint”.

**Example 46.2. Implementing DefaultEndpoint**

```java
import java.util.Map;
import java.util.concurrent.BlockingQueue;

import org.apache.camel.Component;
import org.apache.camel.Consumer;
import org.apache.camel.Exchange;
import org.apache.camel.Processor;
import org.apache.camel.Producer;
import org.apache.camel.impl.DefaultEndpoint;
import org.apache.camel.impl.DefaultExchange;

public class CustomEndpoint extends DefaultEndpoint {
    public CustomEndpoint(String endpointUri, Component component) {
```
Implement an event-driven custom endpoint, `CustomEndpoint`, by extending the `DefaultEndpoint` class.

You must have at least one constructor that takes the endpoint URI, `endpointUri`, and the parent component reference, `component`, as arguments.

Implement the `createProducer()` factory method to create producer endpoints.

Implement the `createConsumer()` factory method to create event-driven consumer instances.

**IMPORTANT**

Do not override the `createPollingConsumer()` method.

In general, it is not necessary to override the `createExchange()` methods. The implementations inherited from `DefaultEndpoint` create a `DefaultExchange` object by default, which can be used in any Apache Camel component. If you need to initialize some exchange properties in the `DefaultExchange` object, however, it is appropriate to override the `createExchange()` methods here in order to add the exchange property settings.
The **DefaultEndpoint** class provides default implementations of the following methods, which you might find useful when writing your custom endpoint code:

- `getEndpointUri()`—Returns the endpoint URI.
- `getCamelContext()`—Returns a reference to the `CamelContext`.
- `getComponent()`—Returns a reference to the parent component.
- `createPollingConsumer()`—Creates a polling consumer. The created polling consumer's functionality is based on the event-driven consumer. If you override the event-driven consumer method, `createConsumer()`, you get a polling consumer implementation for free.
- `createExchange(Exchange e)`—Converts the given exchange object, `e`, to the type required for this endpoint. This method creates a new endpoint using the overridden `createExchange()` endpoints. This ensures that the method also works for custom exchange types.

**Scheduled poll endpoint implementation**

If your custom endpoint conforms to the scheduled poll pattern (see Section 44.1.3, “Consumer Patterns and Threading”) it is implemented by inheriting from the abstract class, `org.apache.camel.impl.ScheduledPollEndpoint`, as shown in Example 46.3, “ScheduledPollEndpoint Implementation”.

**Example 46.3. ScheduledPollEndpoint Implementation**

```java
import org.apache.camel.Consumer;
import org.apache.camel.Processor;
import org.apache.camel.Producer;
import org.apache.camel.ExchangePattern;
import org.apache.camel.Message;
import org.apache.camel.impl.ScheduledPollEndpoint;

public class CustomEndpoint extends ScheduledPollEndpoint {

    protected CustomEndpoint(String endpointUri, CustomComponent component) {
        super(endpointUri, component);
        // Do any other initialization...
    }

    public Producer createProducer() throws Exception {
        Producer result = new CustomProducer(this);
        return result;
    }

    public Consumer createConsumer(Processor processor) throws Exception {
        Consumer result = new CustomConsumer(this, processor);
        configureConsumer(result);
        return result;
    }

    public boolean isSingleton() {
```
Implement a scheduled poll custom endpoint, *CustomEndpoint*, by extending the `ScheduledPollEndpoint` class.

You must have at least one constructor that takes the endpoint URI, `endpointUri`, and the parent component reference, `component`, as arguments.

Implement the `createProducer()` factory method to create a producer endpoint.

Implement the `createConsumer()` factory method to create a scheduled poll consumer instance.

**IMPORTANT**

Do not override the `createPollingConsumer()` method.

The `configureConsumer()` method, defined in the `ScheduledPollEndpoint` base class, is responsible for injecting consumer query options into the consumer. See the section called “Consumer parameter injection”.

In general, it is not necessary to override the `createExchange()` methods. The implementations inherited from `DefaultEndpoint` create a `DefaultExchange` object by default, which can be used in any Apache Camel component. If you need to initialize some exchange properties in the `DefaultExchange` object, however, it is appropriate to override the `createExchange()` methods here in order to add the exchange property settings.

### Polling endpoint implementation

If your custom endpoint conforms to the polling consumer pattern (see Section 44.1.3, “Consumer Patterns and Threading”), it is implemented by inheriting from the abstract class, `org.apache.camel.impl.DefaultPollingEndpoint`, as shown in Example 46.4, “DefaultPollingEndpoint Implementation”.

```java
return true;
}
// Implement the following methods, only if you need to set exchange properties.
//
// public Exchange createExchange() {
//   return this.createExchange(getExchangePattern());
//
// public Exchange createExchange(ExchangePattern pattern) {
//   Exchange result = new DefaultExchange(getCamelContext(), pattern);
//   // Set exchange properties
//   ...  
//   return result;
// }
}
```

**Example 46.4. DefaultPollingEndpoint Implementation**
Because this `CustomEndpoint` class is a polling endpoint, you must implement the `createPollingConsumer()` method instead of the `createConsumer()` method. The consumer instance returned from `createPollingConsumer()` must inherit from the `PollingConsumer` interface. For details of how to implement a polling consumer, see the section called “Polling consumer implementation”.

Apart from the implementation of the `createPollingConsumer()` method, the steps for implementing a `DefaultPollingEndpoint` are similar to the steps for implementing a `ScheduledPollEndpoint`. See Example 46.3, “ScheduledPollEndpoint Implementation” for details.

### Implementing the BrowsableEndpoint interface

If you want to expose the list of exchange instances that are pending in the current endpoint, you can implement the `org.apache.camel.spi.BrowsableEndpoint` interface, as shown in Example 46.5, “BrowsableEndpoint Interface”. It makes sense to implement this interface if the endpoint performs some sort of buffering of incoming events. For example, the Apache Camel SEDA endpoint implements the `BrowsableEndpoint` interface—see Example 46.6, “SedaEndpoint Implementation”.

#### Example 46.5. BrowsableEndpoint Interface

```java
package org.apache.camel.spi;

import java.util.List;

import org.apache.camel.Endpoint;
import org.apache.camel.Exchange;

public interface BrowsableEndpoint extends Endpoint {
    List<Exchange> getExchanges();
}
```
Example

Example 46.6, “SedaEndpoint Implementation” shows a sample implementation of SedaEndpoint. The SEDA endpoint is an example of an event-driven endpoint. Incoming events are stored in a FIFO queue (an instance of java.util.concurrent.BlockingQueue) and a SEDA consumer starts up a thread to read and process the events. The events themselves are represented by org.apache.camel.Exchange objects.

Example 46.6. SedaEndpoint Implementation

```java
package org.apache.camel.component.seda;

import java.util.ArrayList;
import java.util.List;
import java.util.Map;
import java.util.concurrent.BlockingQueue;
import org.apache.camel.Component;
import org.apache.camel.Consumer;
import org.apache.camel.Exchange;
import org.apache.camel.Processor;
import org.apache.camel.Producer;
import org.apache.camel.impl.DefaultEndpoint;
import org.apache.camel.spi.BrowsableEndpoint;

public class SedaEndpoint extends DefaultEndpoint implements BrowsableEndpoint {
    private BlockingQueue<Exchange> queue;

    public SedaEndpoint(String endpointUri, Component component,
            BlockingQueue<Exchange> queue) {
        super(endpointUri, component);
        this.queue = queue;
    }

    public SedaEndpoint(String uri, SedaComponent component, Map parameters) {
        this(uri, component, component.createQueue(uri, parameters));
    }

    public Producer createProducer() throws Exception {
        return new CollectionProducer(this, getQueue());
    }

    public Consumer createConsumer(Processor processor) throws Exception {
        return new SedaConsumer(this, processor);
    }

    public BlockingQueue<Exchange> getQueue() {
        return queue;
    }

    public boolean isSingleton() {
        return true;
    }
}
```
The `SedaEndpoint` class follows the pattern for implementing an event-driven endpoint by extending the `DefaultEndpoint` class. The `SedaEndpoint` class also implements the `BrowsableEndpoint` interface, which provides access to the list of exchange objects in the queue.

Following the usual pattern for an event-driven consumer, `SedaEndpoint` defines a constructor that takes an endpoint argument, `endpointUri`, and a component reference argument, `component`.

Another constructor is provided, which delegates queue creation to the parent component instance.

The `createProducer()` factory method creates an instance of `CollectionProducer`, which is a producer implementation that adds events to the queue.

The `createConsumer()` factory method creates an instance of `SedaConsumer`, which is responsible for pulling events off the queue and processing them.

The `getQueue()` method returns a reference to the queue.

The `isSingleton()` method returns `true`, indicating that a single endpoint instance should be created for each unique URI string.

The `getExchanges()` method implements the corresponding abstract method from `BrowsableEndpoint`.

```java
8 public List<Exchange> getExchanges() {
    return new ArrayList<Exchange>(getQueue());
}
```
CHAPTER 47. CONSUMER INTERFACE

Abstract

This chapter describes how to implement the Consumer interface, which is an essential step in the implementation of a Apache Camel component.

47.1. THE CONSUMER INTERFACE

Overview

An instance of org.apache.camel.Consumer type represents a source endpoint in a route. There are several different ways of implementing a consumer (see Section 44.1.3, “Consumer Patterns and Threading”), and this degree of flexibility is reflected in the inheritance hierarchy (see Figure 47.1, “Consumer Inheritance Hierarchy”), which includes several different base classes for implementing a consumer.

Figure 47.1. Consumer Inheritance Hierarchy

Consumer parameter injection

For consumers that follow the scheduled poll pattern (see the section called “Scheduled poll pattern”), Apache Camel provides support for injecting parameters into consumer instances. For example, consider the following endpoint URI for a component identified by the custom prefix:

custom:destination?consumer.myConsumerParam
Apache Camel provides support for automatically injecting query options of the form `consumer.*`. For the `consumer.myConsumerParam` parameter, you need to define corresponding setter and getter methods on the `Consumer` implementation class as follows:

```java
public class CustomConsumer extends ScheduledPollConsumer {
    String getMyConsumerParam() { ... }
    void setMyConsumerParam(String s) { ... }
    ...
}
```

Where the getter and setter methods follow the usual Java bean conventions (including capitalizing the first letter of the property name).

In addition to defining the bean methods in your Consumer implementation, you must also remember to call the `configureConsumer()` method in the implementation of `Endpoint.createConsumer()`. See the section called “Scheduled poll endpoint implementation”). Example 47.1, “FileEndpoint createConsumer() Implementation” shows an example of a `createConsumer()` method implementation, taken from the `FileEndpoint` class in the file component:

```
Example 47.1. FileEndpoint createConsumer() Implementation

public class FileEndpoint extends ScheduledPollEndpoint {
    ...
    public Consumer createConsumer(Processor processor) throws Exception {
        Consumer result = new FileConsumer(this, processor);
        configureConsumer(result);
        return result;
    }
    ...
}
```

At run time, consumer parameter injection works as follows:

1. When the endpoint is created, the default implementation of `DefaultComponent.createEndpoint(String uri)` parses the URI to extract the consumer parameters, and stores them in the endpoint instance by calling `ScheduledPollEndpoint.configureProperties()`.

2. When `createConsumer()` is called, the method implementation calls `configureConsumer()` to inject the consumer parameters (see Example 47.1, “FileEndpoint createConsumer() Implementation”).

3. The `configureConsumer()` method uses Java reflection to call the setter methods whose names match the relevant options after the `consumer.` prefix has been stripped off.

**Scheduled poll parameters**
A consumer that follows the scheduled poll pattern automatically supports the consumer parameters shown in Table 47.1, “Scheduled Poll Parameters” (which can appear as query options in the endpoint URI).

Table 47.1. Scheduled Poll Parameters

<table>
<thead>
<tr>
<th>Name</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>initialDelay</td>
<td>1000</td>
<td>Delay, in milliseconds, before the first poll.</td>
</tr>
<tr>
<td>delay</td>
<td>500</td>
<td>Depends on the value of the useFixedDelay flag (time unit is milliseconds).</td>
</tr>
<tr>
<td>useFixedDelay</td>
<td>false</td>
<td>If false, the delay parameter is interpreted as the polling period. Polls will occur at initialDelay, initialDelay+delay, initialDelay+2*delay, and so on. If true, the delay parameter is interpreted as the time elapsed between the previous execution and the next execution. Polls will occur at initialDelay, initialDelay+[ProcessingTime]+delay, and so on. Where ProcessingTime is the time taken to process an exchange object in the current thread.</td>
</tr>
</tbody>
</table>

Converting between event-driven and polling consumers

Apache Camel provides two special consumer implementations which can be used to convert back and forth between an event-driven consumer and a polling consumer. The following conversion classes are provided:

- org.apache.camel.impl.EventDrivenPollingConsumer—Converts an event-driven consumer into a polling consumer instance.
- org.apache.camel.impl.DefaultScheduledPollConsumer—Converts a polling consumer into an event-driven consumer instance.

In practice, these classes are used to simplify the task of implementing an Endpoint type. The Endpoint interface defines the following two methods for creating a consumer instance:

```java
package org.apache.camel;

public interface Endpoint {
   ...
   Consumer createConsumer(Processor processor) throws Exception;
   PollingConsumer createPollingConsumer() throws Exception;
}
```

createConsumer() returns an event-driven consumer and createPollingConsumer() returns a polling consumer. You would only implement one of these methods. For example, if you are following the event-driven pattern for your consumer, you would implement the createConsumer() method provide a method implementation for createPollingConsumer() that simply raises an exception. With the help of the conversion classes, however, Apache Camel is able to provide a more useful default implementation.
For example, if you want to implement your consumer according to the event-driven pattern, you implement the endpoint by extending `DefaultEndpoint` and implementing the `createConsumer()` method. The implementation of `createPollingConsumer()` is inherited from `DefaultEndpoint`, where it is defined as follows:

```java
public PollingConsumer<E> createPollingConsumer() throws Exception {
    return new EventDrivenPollingConsumer<E>(this);
}
```

The `EventDrivenPollingConsumer` constructor takes a reference to the event-driven consumer, `this`, effectively wrapping it and converting it into a polling consumer. To implement the conversion, the `EventDrivenPollingConsumer` instance buffers incoming events and makes them available on demand through the `receive()`, the `receive(long timeout)`, and the `receiveNoWait()` methods.

Analogously, if you are implementing your consumer according to the polling pattern, you implement the endpoint by extending `DefaultPollingEndpoint` and implementing the `createPollingConsumer()` method. In this case, the implementation of the `createConsumer()` method is inherited from `DefaultPollingEndpoint`, and the default implementation returns a `DefaultScheduledPollConsumer` instance (which converts the polling consumer into an event-driven consumer).

**ShutdownPrepared interface**

Consumer classes can optionally implement the `org.apache.camel.spi.ShutdownPrepared` interface, which enables your custom consumer endpoint to receive shutdown notifications.

Example 47.2, “ShutdownPrepared Interface” shows the definition of the `ShutdownPrepared` interface.

```java
package org.apache.camel.spi;

public interface ShutdownPrepared {
    void prepareShutdown(boolean forced);
}
```

The `ShutdownPrepared` interface defines the following methods:

**prepareShutdown**

Receives notifications to shut down the consumer endpoint in one or two phases, as follows:

1. *Graceful shutdown*—where the `forced` argument has the value `false`. Attempt to clean up resources gracefully. For example, by stopping threads gracefully.

2. *Forced shutdown*—where the `forced` argument has the value `true`. This means that the shutdown has timed out, so you must clean up resources more aggressively. This is the last chance to clean up resources before the process
ShutdownAware interface

Consumer classes can optionally implement the org.apache.camel.spi.ShutdownAware interface, which interacts with the graceful shutdown mechanism, enabling a consumer to ask for extra time to shut down. This is typically needed for components such as SEDA, which can have pending exchanges stored in an internal queue. Normally, you would want to process all of the exchanges in the queue before shutting down the SEDA consumer.

Example 47.3, “ShutdownAware Interface” shows the definition of the ShutdownAware interface.

```java
// Java
package org.apache.camel.spi;
import org.apache.camel.ShutdownRunningTask;
public interface ShutdownAware extends ShutdownPrepared {
    boolean deferShutdown(ShutdownRunningTask shutdownRunningTask);
    int getPendingExchangesSize();
}
```

The ShutdownAware interface defines the following methods:

**deferShutdown**

Return true from this method, if you want to delay shutdown of the consumer. The shutdownRunningTask argument is an enum which can take either of the following values:

- **ShutdownRunningTask.CompleteCurrentTaskOnly**—finish processing the exchanges that are currently being processed by the consumer’s thread pool, but do not attempt to process any more exchanges than that.

- **ShutdownRunningTask.CompleteAllTasks**—process all of the pending exchanges. For example, in the case of the SEDA component, the consumer would process all of the exchanges from its incoming queue.

**getPendingExchangesSize**

Indicates how many exchanges remain to be processed by the consumer. A zero value indicates that processing is finished and the consumer can be shut down.

For an example of how to define the ShutdownAware methods, see Example 47.7, “Custom Threading Implementation”.

47.2. IMPLEMENTING THE CONSUMER INTERFACE
**Alternative ways of implementing a consumer**

You can implement a consumer in one of the following ways:

- Event-driven consumer implementation
- Scheduled poll consumer implementation
- Polling consumer implementation
- Custom threading implementation

**Event-driven consumer implementation**

In an event-driven consumer, processing is driven explicitly by external events. The events are received through an event-listener interface, where the listener interface is specific to the particular event source.

Example 47.4, “JMXConsumer Implementation” shows the implementation of the JMXConsumer class, which is taken from the Apache Camel JMX component implementation. The JMXConsumer class is an example of an event-driven consumer, which is implemented by inheriting from the org.apache.camel.impl.DefaultConsumer class. In the case of the JMXConsumer example, events are represented by calls on the NotificationListener.handleNotification() method, which is a standard way of receiving JMX events. In order to receive these JMX events, it is necessary to implement the NotificationListener interface and override the handleNotification() method, as shown in Example 47.4, “JMXConsumer Implementation”.

**Example 47.4. JMXConsumer Implementation**

```java
package org.apache.camel.component.jmx;

import javax.management.Notification;
import javax.management.NotificationListener;
import org.apache.camel.Processor;
import org.apache.camel.impl.DefaultConsumer;

public class JMXConsumer extends DefaultConsumer implements NotificationListener {
  JMXEndpoint jmxEndpoint;

  public JMXConsumer(JMXEndpoint endpoint, Processor processor) {
    super(endpoint, processor);
    this.jmxEndpoint = endpoint;
  }

  public void handleNotification(Notification notification, Object handback) {
    try {
      getProcessor().process(jmxEndpoint.createExchange(notification));
    } catch (Throwable e) {
      handleException(e);
    }
  }
}
```
The JMXConsumer pattern follows the usual pattern for event-driven consumers by extending the DefaultConsumer class. Additionally, because this consumer is designed to receive events from JMX (which are represented by JMX notifications), it is necessary to implement the NotificationListener interface.

You must implement at least one constructor that takes a reference to the parent endpoint, `endpoint`, and a reference to the next processor in the chain, `processor`, as arguments.

The `handleNotification()` method (which is defined in `NotificationListener`) is automatically invoked by JMX whenever a JMX notification arrives. The body of this method should contain the code that performs the consumer's event processing. Because the `handleNotification()` call originates from the JMX layer, the consumer's threading model is implicitly controlled by the JMX layer, not by the JMXConsumer class.

NOTE

The `handleNotification()` method is specific to the JMX example. When implementing your own event-driven consumer, you must identify an analogous event listener method to implement in your custom consumer.

This line of code combines two steps. First, the JMX notification object is converted into an exchange object, which is the generic representation of an event in Apache Camel. Then the newly created exchange object is passed to the next processor in the route (invoked synchronously).

The `handleException()` method is implemented by the DefaultConsumer base class. By default, it handles exceptions using the `org.apache.camel.impl.LoggingExceptionHandler` class.

Scheduled poll consumer implementation

In a scheduled poll consumer, polling events are automatically generated by a timer class, `java.util.concurrent.ScheduledExecutorService`. To receive the generated polling events, you must implement the `ScheduledPollConsumer.poll()` method (see Section 44.1.3, “Consumer Patterns and Threading”).

Example 47.5, “ScheduledPollConsumer Implementation” shows how to implement a consumer that follows the scheduled poll pattern, which is implemented by extending the ScheduledPollConsumer class.

Example 47.5. ScheduledPollConsumer Implementation

```java
import java.util.concurrent.ScheduledExecutorService;
import org.apache.camel.Consumer;
import org.apache.camel.Endpoint;
import org.apache.camel.Exchange;
import org.apache.camel.Message;
import org.apache.camel.PollingConsumer;
import org.apache.camel.Processor;
```
Implement a scheduled poll consumer class, `CustomConsumer`, by extending the `org.apache.camel.impl.ScheduledPollConsumer` class.

You must implement at least one constructor that takes a reference to the parent endpoint, `endpoint`, and a reference to the next processor in the chain, `processor`, as arguments.

Override the `poll()` method to receive the scheduled polling events. This is where you should put the code that retrieves and processes incoming events (represented by exchange objects).

In this example, the event is processed synchronously. If you want to process events asynchronously, you should use a reference to an asynchronous processor instead, by calling `getAsyncProcessor()`. For details of how to process events asynchronously, see Section 44.1.4, “Asynchronous Processing”.

```java
import org.apache.camel.impl.ScheduledPollConsumer;

public class CustomConsumer extends ScheduledPollConsumer {
    private final CustomEndpoint endpoint;

    public CustomConsumer(CustomEndpoint endpoint, Processor processor) {
        super(endpoint, processor);
        this.endpoint = endpoint;
    }

    protected void poll() throws Exception {
        Exchange exchange = /* Receive exchange object ... */;

        // Example of a synchronous processor.
        getProcessor().process(exchange);
    }

    @Override
    protected void doStart() throws Exception {
        // Pre-Start:
        // Place code here to execute just before start of processing.
        super.doStart();
        // Post-Start:
        // Place code here to execute just after start of processing.
    }

    @Override
    protected void doStop() throws Exception {
        // Pre-Stop:
        // Place code here to execute just before processing stops.
        super.doStop();
        // Post-Stop:
        // Place code here to execute just after processing stops.
    }
}
```
If you want some lines of code to execute as the consumer is starting up, override the `doStart()` method as shown.

If you want some lines of code to execute as the consumer is stopping, override the `doStop()` method as shown.

### Polling consumer implementation

Example 47.6, “PollingConsumerSupport Implementation” outlines how to implement a consumer that follows the polling pattern, which is implemented by extending the `PollingConsumerSupport` class.

#### Example 47.6. PollingConsumerSupport Implementation

```java
import org.apache.camel.Exchange;
import org.apache.camel.RuntimeCamelException;
import org.apache.camel.impl.PollingConsumerSupport;

public class CustomConsumer extends PollingConsumerSupport {
    private final CustomEndpoint endpoint;

    public CustomConsumer(CustomEndpoint endpoint) {
        super(endpoint);
        this.endpoint = endpoint;
    }

    public Exchange receiveNoWait() {
        Exchange exchange = /* Obtain an exchange object. */;
        // Further processing ...
        return exchange;
    }

    public Exchange receive() {
        // Blocking poll ...
    }

    public Exchange receive(long timeout) {
        // Poll with timeout ...
    }

    protected void doStart() throws Exception {
        // Code to execute whilst starting up.
    }

    protected void doStop() throws Exception {
        // Code to execute whilst shutting down.
    }
}
```

Implement your polling consumer class, `CustomConsumer`, by extending the `org.apache.camel.impl.PollingConsumerSupport` class.
You must implement at least one constructor that takes a reference to the parent endpoint, `endpoint`, as an argument. A polling consumer does not need a reference to it.

3. The `receiveNoWait()` method should implement a non-blocking algorithm for retrieving an event (exchange object). If no event is available, it should return `null`.

4. The `receive()` method should implement a blocking algorithm for retrieving an event. This method can block indefinitely, if events remain unavailable.

5. The `receive(long timeout)` method implements an algorithm that can block for as long as the specified timeout (typically specified in units of milliseconds).

6. If you want to insert code that executes while a consumer is starting up or shutting down, implement the `doStart()` method and the `doStop()` method, respectively.

Custom threading implementation

If the standard consumer patterns are not suitable for your consumer implementation, you can implement the `Consumer` interface directly and write the threading code yourself. When writing the threading code, however, it is important that you comply with the standard Apache Camel threading model, as described in Section 2.9, “Threading Model”.

For example, the SEDA component from `camel-core` implements its own consumer threading, which is consistent with the Apache Camel threading model. Example 47.7, “Custom Threading Implementation” shows an outline of how the `SedaConsumer` class implements its threading.

Example 47.7. Custom Threading Implementation

```java
package org.apache.camel.component.seda;

import java.util.ArrayList;
import java.util.List;
import java.util.concurrent.BlockingQueue;
import java.util.concurrent.ExecutorService;
import java.util.concurrent.TimeUnit;
import org.apache.camel.Consumer;
import org.apache.camel.Endpoint;
import org.apache.camel.Exchange;
import org.apache.camel.Processor;
import org.apache.camel.ShutdownRunningTask;
import org.apache.camel.impl.LoggingExceptionHandler;
import org.apache.camel.impl.ServiceSupport;
import org.apache.camel.util.ServiceHelper;
...
import org.apache.commons.logging.Log;
import org.apache.commons.logging.LogFactory;

/**
 * A Consumer for the SEDA component.
 *
 * @version $Revision: 922485 $
 */
public class SedaConsumer extends ServiceSupport implements Consumer,
```
Runnable, ShutdownAware {
    private static final transient Log LOG =
        LogFactory.getLog(SedaConsumer.class);

    private SedaEndpoint endpoint;
    private Processor processor;
    private ExecutorService executor;
    ...
    public SedaConsumer(SedaEndpoint endpoint, Processor processor) {
        this.endpoint = endpoint;
        this.processor = processor;
    }
    ...

    public void run() {
        BlockingQueue<Exchange> queue = endpoint.getQueue();
        // Poll the queue and process exchanges
        ...
    }
    ...
    protected void doStart() throws Exception {
        int poolSize = endpoint.getConcurrentConsumers();
        executor =
            endpoint.getCamelContext().getExecutorServiceStrategy() .newFixedThreadPool(this, endpoint.getEndpointUri(),

            poolSize);
        for (int i = 0; i < poolSize; i++) {
            executor.execute(this);
        }
        endpoint.onStarted(this);
    }
    protected void doStop() throws Exception {
        endpoint.onStopped(this);
        // must shutdown executor on stop to avoid overhead of having
        them running
        endpoint.getCamelContext().getExecutorServiceStrategy().shutdownNow(executor);
        executor = null;
        if (multicast != null) {
            ServiceHelper.stopServices(multicast);
        }
    }
    ...
    //----------
    // Implementation of ShutdownAware interface
    public boolean deferShutdown(ShutdownRunningTask shutdownRunningTask) {
        // deny stopping on shutdown as we want seda consumers to run
        in case some other queues
        // depend on this consumer to run, so it can complete its
exchanges
The `SedaConsumer` class is implemented by extending the `org.apache.camel.impl.ServiceSupport` class and implementing the `Consumer`, `Runnable`, and `ShutdownAware` interfaces.

Implement the `Runnable.run()` method to define what the consumer does while it is running in a thread. In this case, the consumer runs in a loop, polling the queue for new exchanges and then processing the exchanges in the latter part of the queue.

The `doStart()` method is inherited from `ServiceSupport`. You override this method in order to define what the consumer does when it starts up.

Instead of creating threads directly, you should create a thread pool using the `ExecutorServiceStrategy` object that is registered with the `CamelContext`. This is important, because it enables Apache Camel to implement centralized management of threads and support such features as graceful shutdown.

For details, see Section 2.9, “Threading Model”.

Kick off the threads by calling the `ExecutorService.execute()` method `poolSize` times.

The `doStop()` method is inherited from `ServiceSupport`. You override this method in order to define what the consumer does when it shuts down.

Shut down the thread pool, which is represented by the `executor` instance.
CHAPTER 48. PRODUCER INTERFACE

Abstract
This chapter describes how to implement the Producer interface, which is an essential step in the implementation of a Apache Camel component.

48.1. THE PRODUCER INTERFACE

Overview
An instance of org.apache.camel.Producer type represents a target endpoint in a route. The role of the producer is to send requests (In messages) to a specific physical endpoint and to receive the corresponding response (Out or Fault message). A Producer object is essentially a special kind of Processor that appears at the end of a processor chain (equivalent to a route). Figure 48.1, “Producer Inheritance Hierarchy” shows the inheritance hierarchy for producers.

Figure 48.1. Producer Inheritance Hierarchy

The Producer interface
Example 48.1, “Producer Interface” shows the definition of the org.apache.camel.Producer interface.

Example 48.1. Producer Interface

```java
package org.apache.camel;

public interface Producer extends Processor, Service, IsSingleton {
    Endpoint<E> getEndpoint();
    Exchange createExchange();
    Exchange createExchange(ExchangePattern pattern);
    Exchange createExchange(E exchange);
}
```
Producer methods

The Producer interface defines the following methods:

- **process()** *(inherited from Processor)* — The most important method. A producer is essentially a special type of processor that sends a request to an endpoint, instead of forwarding the exchange object to another processor. By overriding the `process()` method, you define how the producer sends and receives messages to and from the relevant endpoint.

- **getEndpoint()** — Returns a reference to the parent endpoint instance.

- **createExchange()** — These overloaded methods are analogous to the corresponding methods defined in the Endpoint interface. Normally, these methods delegate to the corresponding methods defined on the parent Endpoint instance (this is what the DefaultEndpoint class does by default). Occasionally, you might need to override these methods.

Asynchronous processing

Processing an exchange object in a producer—which usually involves sending a message to a remote destination and waiting for a reply—can potentially block for a significant length of time. If you want to avoid blocking the current thread, you can opt to implement the producer as an asynchronous processor. The asynchronous processing pattern decouples the preceding processor from the producer, so that the `process()` method returns without delay. See Section 44.1.4, “Asynchronous Processing”.

When implementing a producer, you can support the asynchronous processing model by implementing the org.apache.camel.AsyncProcessor interface. On its own, this is not enough to ensure that the asynchronous processing model will be used: it is also necessary for the preceding processor in the chain to call the asynchronous version of the `process()` method. The definition of the AsyncProcessor interface is shown in Example 48.2, “AsyncProcessor Interface”.

**Example 48.2. AsyncProcessor Interface**

```java
package org.apache.camel;

public interface AsyncProcessor extends Processor {
    boolean process(Exchange exchange, AsyncCallback callback);
}
```

The asynchronous version of the `process()` method takes an extra argument, `callback`, of org.apache.camel.AsyncCallback type. The corresponding AsyncCallback interface is defined as shown in Example 48.3, “AsyncCallback Interface”.

**Example 48.3. AsyncCallback Interface**

```java
package org.apache.camel;

public interface AsyncCallback {
    void done(Exception exception);
    void failed(Exception exception);
}
```
The caller of `AsyncProcessor.process()` must provide an implementation of `AsyncCallback` to receive the notification that processing has finished. The `AsyncCallback.done()` method takes a boolean argument that indicates whether the processing was performed synchronously or not. Normally, the flag would be `false`, to indicate asynchronous processing. In some cases, however, it can make sense for the producer not to process asynchronously (in spite of being asked to do so). For example, if the producer knows that the processing of the exchange will complete rapidly, it could optimise the processing by doing it synchronously. In this case, the `doneSynchronously` flag should be set to `true`.

### ExchangeHelper class

When implementing a producer, you might find it helpful to call some of the methods in the `org.apache.camel.util.ExchangeHelper` utility class. For full details of the `ExchangeHelper` class, see Section 41.4, “The ExchangeHelper Class”.

### 48.2. IMPLEMENTING THE PRODUCER INTERFACE

#### Alternative ways of implementing a producer

You can implement a producer in one of the following ways:

- How to implement a synchronous producer
- How to implement an asynchronous producer

#### How to implement a synchronous producer

Example 48.4, “DefaultProducer Implementation” outlines how to implement a synchronous producer. In this case, call to `Producer.process()` blocks until a reply is received.

```java
import org.apache.camel.Endpoint;
import org.apache.camel.Exchange;
import org.apache.camel.Producer;
import org.apache.camel.impl.DefaultProducer;

public class CustomProducer extends DefaultProducer {

    public CustomProducer(Endpoint endpoint) {
        super(endpoint);
        // Perform other initialization tasks...
    }

    public void process(Exchange exchange) throws Exception {
        // Process exchange synchronously.
        // ...
    }
}
```

Example 48.4. DefaultProducer Implementation
1. Implement a custom synchronous producer class, `CustomProducer`, by extending the `org.apache.camel.impl.DefaultProducer` class.

2. Implement a constructor that takes a reference to the parent endpoint.

3. The `process()` method implementation represents the core of the producer code. The implementation of the `process()` method is entirely dependent on the type of component that you are implementing. In outline, the `process()` method is normally implemented as follows:

   - If the exchange contains an `In` message, and if this is consistent with the specified exchange pattern, then send the `In` message to the designated endpoint.

   - If the exchange pattern anticipates the receipt of an `Out` message, then wait until the `Out` message has been received. This typically causes the `process()` method to block for a significant length of time.

   - When a reply is received, call `exchange.setOut()` to attach the reply to the exchange object. If the reply contains a fault message, set the fault flag on the `Out` message using `Message.setFault(true)`.

---

**How to implement an asynchronous producer**

Example 48.5, “CollectionProducer Implementation” outlines how to implement an asynchronous producer. In this case, you must implement both a synchronous `process()` method and an asynchronous `process()` method (which takes an additional `AsyncCallback` argument).

**Example 48.5. CollectionProducer Implementation**

```java
import org.apache.camel.AsyncCallback;
import org.apache.camel.AsyncProcessor;
import org.apache.camel.Endpoint;
import org.apache.camel.Exchange;
import org.apache.camel.Producer;
import org.apache.camel.impl.DefaultProducer;

public class CustomProducer extends DefaultProducer implements AsyncProcessor {
    public CustomProducer(Endpoint endpoint) {
        super(endpoint);
        // ...
    }

    public void process(Exchange exchange) throws Exception {
        // Process exchange synchronously.
        // ...
    }

    public boolean process(Exchange exchange, AsyncCallback callback) {
        // Process exchange asynchronously.
        // ...
    }
}
```
Implement a custom asynchronous producer class, `CustomProducer`, by extending the `org.apache.camel.impl.DefaultProducer` class, and implementing the `AsyncProcessor` interface.

Implement a constructor that takes a reference to the parent endpoint.

Implement the synchronous `process()` method.

Implement the asynchronous `process()` method. You can implement the asynchronous method in several ways. The approach shown here is to create a `java.lang.Runnable` instance, `task`, that represents the code that runs in a sub-thread. You then use the Java threading API to run the task in a sub-thread (for example, by creating a new thread or by allocating the task to an existing thread pool).

Normally, you return `false` from the asynchronous `process()` method, to indicate that the exchange was processed asynchronously.

The `CustomProducerTask` class encapsulates the processing code that runs in a sub-thread. This class must store a copy of the `Exchange` object, `exchange`, and the `AsyncCallback` object, `callback`, as private member variables.

The `run()` method contains the code that sends the `In` message to the producer endpoint and waits to receive the reply, if any. After receiving the reply ( `Out` message or `Fault` message) and inserting it into the exchange object, you must call `callback.done()` to notify the caller that processing is complete.
CHAPTER 49. EXCHANGE INTERFACE

Abstract

This chapter describes the Exchange interface. Since the refactoring of the camel-core module performed in Apache Camel 2.0, there is no longer any necessity to define custom exchange types. The DefaultExchange implementation can now be used in all cases.

49.1. THE EXCHANGE INTERFACE

Overview

An instance of org.apache.camel.Exchange type encapsulates the current message passing through a route, with additional metadata encoded as exchange properties.

Figure 49.1, “Exchange Inheritance Hierarchy” shows the inheritance hierarchy for the exchange type. The default implementation, DefaultExchange, is always used.

Figure 49.1. Exchange Inheritance Hierarchy

The Exchange interface

Example 49.1, “Exchange Interface” shows the definition of the org.apache.camel.Exchange interface.

Example 49.1. Exchange Interface

```java
package org.apache.camel;
import java.util.Map;
import org.apache.camel.spi.Synchronization;
import org.apache.camel.spi.UnitOfWork;

public interface Exchange {
    // Exchange property names (string constants)
    // (Not shown here)
    
    ExchangePattern getPattern();
    void setPattern(ExchangePattern pattern);
```
Exchange methods

The Exchange interface defines the following methods:

```java
Object getProperty(String name);
Object getProperty(String name, Object defaultValue);
<T> T getProperty(String name, Class<T> type);
<T> T getProperty(String name, Object defaultValue, Class<T> type);
void setProperty(String name, Object value);
Object removeProperty(String name);
Map<String, Object> getProperties();
boolean hasProperties();

Message getIn();
<T> T getIn(Class<T> type);
void setIn(Message in);

Message getOut();
<T> T getOut(Class<T> type);
void setOut(Message out);
boolean hasOut();

Throwable getException();
<T> T getException(Class<T> type);
void setException(Throwable e);

boolean isFailed();

boolean isTransacted();

boolean isRollbackOnly();

CamelContext getContext();

Exchange copy();

Endpoint getFromEndpoint();
void setFromEndpoint(Endpoint fromEndpoint);

String getFromRouteId();
void setFromRouteId(String fromRouteId);

UnitOfWork getUnitOfWork();
void setUnitOfWork(UnitOfWork unitOfWork);

String getExchangeId();
void setExchangeId(String id);

void addOnCompletion(Synchronization onCompletion);
void handoverCompletions(Exchange target);
```
getPattern(), setPattern()—The exchange pattern can be one of the values enumerated in org.apache.camel.ExchangePattern. The following exchange pattern values are supported:

- InOnly
- RobustInOnly
- InOut
- InOptionalOut
- OutOnly
- RobustOutOnly
- OutIn
- OutOptionalIn

setProperty(), getProperty(), getProperties(), removeProperty(), hasProperties()—Use the property setter and getter methods to associate named properties with the exchange instance. The properties consist of miscellaneous metadata that you might need for your component implementation.

setIn(), getIn()—Setter and getter methods for the In message.

The getIn() implementation provided by the DefaultExchange class implements lazy creation semantics: if the In message is null when getIn() is called, the DefaultExchange class creates a default In message.

setOut(), getOut(), hasOut()—Setter and getter methods for the Out message.

The getOut() method implicitly supports lazy creation of an Out message. That is, if the current Out message is null, a new message instance is automatically created.

setException(), getException()—Getter and setter methods for an exception object (of Throwable type).

isFailed()—Returns true, if the exchange failed either due to an exception or due to a fault.

isTransacted()—Returns true, if the exchange is transacted.

isRollback()—Returns true, if the exchange is marked for rollback.

getContext()—Returns a reference to the associated CamelContext instance.

copy()—Creates a new, identical (apart from the exchange ID) copy of the current custom exchange object. The body and headers of the In message, the Out message (if any), and the Fault message (if any) are also copied by this operation.

setFromEndpoint(), getFromEndpoint()—Getter and setter methods for the consumer endpoint that originated this message (which is typically the endpoint appearing in the from() DSL command at the start of a route).
- `setFromRouteId()`, `getFromRouteId()`—Getters and setters for the route ID that originated this exchange. The `getFromRouteId()` method should only be called internally.

- `setUnitOfWork()`, `getUnitOfWork()`—Getter and setter methods for the `org.apache.camel.spi.UnitOfWork` bean property. This property is only required for exchanges that can participate in a transaction.

- `setExchangeId()`, `getExchangeId()`—Getter and setter methods for the exchange ID. Whether or not a custom component uses and exchange ID is an implementation detail.

- `addOnCompletion()`—Adds an `org.apache.camel.spi.Synchronization` callback object, which gets called when processing of the exchange has completed.

- `handoverCompletions()`—Hands over all of the `OnCompletion` callback objects to the specified exchange object.
CHAPTER 50. MESSAGE INTERFACE

Abstract

This chapter describes how to implement the Message interface, which is an optional step in the implementation of an Apache Camel component.

50.1. THE MESSAGE INTERFACE

Overview

An instance of `org.apache.camel.Message` type can represent any kind of message (In or Out). Figure 50.1, “Message Inheritance Hierarchy” shows the inheritance hierarchy for the message type. You do not always need to implement a custom message type for a component. In many cases, the default implementation, `DefaultMessage`, is adequate.

Figure 50.1. Message Inheritance Hierarchy

```
Message                  
  \                      
   \                   
   DefaultMessage
```

The Message interface

Example 50.1, “Message Interface” shows the definition of the `org.apache.camel.Message` interface.

Example 50.1. Message Interface

```java
package org.apache.camel;

import java.util.Map;
import java.util.Set;
import javax.activation.DataHandler;

public interface Message {
    String getMessageId();
    void setMessageId(String messageId);
    Exchange getExchange();
    boolean isFault();
}
```
void setFault(boolean fault);

Object getHeader(String name);
Object getHeader(String name, Object defaultValue);
<T> T getHeader(String name, Class<T> type);
<T> T getHeader(String name, Object defaultValue, Class<T> type);
Map<String, Object> getHeaders();
void setHeader(String name, Object value);
void setHeaders(Map<String, Object> headers);
Object removeHeader(String name);
boolean removeHeaders(String pattern);
boolean hasHeaders();

Object getBody();
Object getMandatoryBody() throws InvalidPayloadException;
<T> T getBody(Class<T> type);
<T> T getMandatoryBody(Class<T> type) throws InvalidPayloadException;
void setBody(Object body);
<T> void setBody(Object body, Class<T> type);

DataHandler getAttachment(String id);
Map<String, DataHandler> getAttachments();
Set<String> getAttachmentNames();
void removeAttachment(String id);
void addAttachment(String id, DataHandler content);
void setAttachments(Map<String, DataHandler> attachments);
boolean hasAttachments();

Message copy();

void copyFrom(Message message);

String createExchangeId();

Message methods

The Message interface defines the following methods:

- **setMessageId(), getMessageId()**—Getter and setter methods for the message ID. Whether or not you need to use a message ID in your custom component is an implementation detail.

- **getExchange()**—Returns a reference to the parent exchange object.

- **isFault(), setFault()**—Getter and setter methods for the fault flag, which indicates whether or not this message is a fault message.

- **getHeader(), getHeaders(), setHeader(), setHeaders(), removeHeader(), hasHeaders()**—Getter and setter methods for the message headers. In general, these message headers can be used either to store actual header data, or to store miscellaneous metadata.
getBody(), getMandatoryBody(), setBody()—Getter and setter methods for the message body. The getMandatoryBody() accessor guarantees that the returned body is non-null, otherwise the InvalidPayloadException exception is thrown.

getAttachment(), getAttachments(), getAttachmentNames(), removeAttachment(), addAttachment(), setAttachments(), hasAttachments()—Methods to get, set, add, and remove attachments.

copy()—Creates a new, identical (including the message ID) copy of the current custom message object.

copyFrom()—Copies the complete contents (including the message ID) of the specified generic message object, message, into the current message instance. Because this method must be able to copy from any message type, it copies the generic message properties, but not the custom properties.

createExchangeId()—Returns the unique ID for this exchange, if the message implementation is capable of providing an ID; otherwise, return null.

50.2. IMPLEMENTING THE MESSAGE INTERFACE

How to implement a custom message

Example 50.2, “Custom Message Implementation” outlines how to implement a message by extending the DefaultMessage class.

Example 50.2. Custom Message Implementation

```java
import org.apache.camel.Exchange;
import org.apache.camel.impl.DefaultMessage;

public class CustomMessage extends DefaultMessage {

    public CustomMessage() {
        // Create message with default properties...
    }

    @Override
    public String toString() {
        // Return a stringified message...
    }

    @Override
    public CustomMessage newInstance() {
        return new CustomMessage( ... );
    }

    @Override
    protected Object createBody() {
        // Return message body (lazy creation).
    }

    @Override
    protected void populateInitialHeaders(Map<String, Object> map) {
        // Initialize headers from underlying message (lazy
```
Implements a custom message class, `CustomMessage`, by extending the `org.apache.camel.impl.DefaultMessage` class.

Typically, you need a default constructor that creates a message with default properties.

Override the `toString()` method to customize message stringification.

The `newInstance()` method is called from inside the `MessageSupport.copy()` method. Customization of the `newInstance()` method should focus on copying all of the custom properties of the current message instance into the new message instance. The `MessageSupport.copy()` method copies the generic message properties by calling `copyFrom()`.

The `createBody()` method works in conjunction with the `MessageSupport.getBody()` method to implement lazy access to the message body. By default, the message body is `null`. It is only when the application code tries to access the body (by calling `getBody()`), that the body should be created. The `MessageSupport.getBody()` automatically calls `createBody()`, when the message body is accessed for the first time.

The `populateInitialHeaders()` method works in conjunction with the header getter and setter methods to implement lazy access to the message headers. This method parses the message to extract any message headers and inserts them into the hash map, `map`. The `populateInitialHeaders()` method is automatically called when a user attempts to access a header (or headers) for the first time (by calling `getHeader()`, `getHeaders()`, `setHeader()`, or `setHeaders()`).

The `populateInitialAttachments()` method works in conjunction with the attachment getter and setter methods to implement lazy access to the attachments. This method extracts the message attachments and inserts them into the hash map, `map`. The `populateInitialAttachments()` method is automatically called when a user attempts to access an attachment (or attachments) for the first time by calling `getAttachment()`, `getAttachments()`, `getAttachmentNames()`, or `addAttachment()`.
