Abstract

This document describes how to deploy the OpenStack Block Storage Backup Service to use Google Cloud Storage as a back end. The instructions herein are specific to an overcloud deployment. Backup integration with Google Cloud Storage is offered in this release as a Technology Preview, and should not be deployed in a production environment. For more information about Technology Previews, see:

| CHAPTER 5. RE-DEPLOY THE OVERCLOUD | 11 |

CHAPTER 1. INTRODUCTION

The Red Hat OpenStack Platform Director is a toolset for installing and managing a complete OpenStack environment. It is based primarily on the OpenStack project TripleO (*OpenStack-on-OpenStack*). The Director's primary objective is to fully orchestrate a functional, Enterprise-grade OpenStack deployment with minimal manual configuration. It helps address many of the issues inherent in manually configuring individual OpenStack components.

The end-result OpenStack deployment provided by the Director is called the *Overcloud*. The Overcloud houses all the components that provide services to end users, including Block Storage. This document provides guidance on how to deploy custom back ends to the Overcloud's Block Storage service.

Red Hat OpenStack Platform supports several third-party services, devices, and applications for functions ranging from block storage back ends to data processing. This release allows you to configure the Block Storage service to use Google Cloud as a backup storage service. This Google Cloud integration is available in this release as a *technology preview* feature.

IMPORTANT

Technology Preview features are not fully supported by Red Hat. The deployment scenario described in this document should only be used for testing, and should not be deployed in a production environment.

For more information about Technology Preview features, see [Scope of Coverage Details](#).

This document presents a test scenario where the Block Storage service on an overcloud deployment is configured to back up volumes to Google Cloud storage. This test scenario requires that:

- The overcloud has already been deployed through director, per instructions in the [Director Installation and Usage](#) guide.
- You have the username and password of an account with elevated privileges. You can use the same account that was created to deploy the overcloud; in the [Director Installation and Usage](#) guide, a user named **stack** is created for this purpose.
- The Block Storage service is installed on the Controller node; or, as is the case in an HA deployment, on every Controller node.
- You have a Google account with access to Google Cloud Platform. This account will be used by the Block Storage service to access and use Google Cloud for storing backups.

CHAPTER 2. PROCESS DESCRIPTION

Configuring the Block Storage service to use Google Cloud as a backup service involves the following steps:

1. Creating and downloading the service account credentials of your Google account ([Chapter 3, *Create and Download the GCS Credentials File*](#)).
2. Creating an environment file to map out the Block Storage settings required ([Chapter 4, *Create the Environment File*](#)). This environment file will also use the service account credentials created in the previous step.
3. Re-deploying the overcloud using the environment file you created ([Chapter 5, *Re-Deploy the Overcloud*](#)).

The following sections describe each step in greater detail.

CHAPTER 3. CREATE AND DOWNLOAD THE GCS CREDENTIALS FILE

The Block Storage service needs your Google credentials in order to access and use Google Cloud for backups. You can provide these credentials to Block Storage by creating a *service account key*:

1. Log in to the Google developer console (<http://console.developers.google.com>) using your Google account.
2. Click the **Credentials** tab. From there, select **Service account key** from the **Create credentials** dropdown.

3. In the next screen (**Create service account key**), select the service account that the Block Storage service should use from the **Service account** dropdown:

Credentials

Create service account key

Service account

Key type

Downloads a file that contains the private key. Store the file securely because this key can't be recovered if lost.

JSON

Recommended

P12

For backward compatibility with code using the P12 format

Create

Cancel

- In the same screen, select **JSON** from the **Key type** section and click **Create**. The browser will then download the key to its default download location:

New private key

Cloud Backup-0c642522b844.json has been saved on your computer. This is the only copy of the key, so store it securely.

Close

- Open the file, and note the value of the **project_id** parameter:

```
{
  "type": "service_account",
  "project_id": "cloud-backup-1370",
  ...
}
```

The `/etc/cinder/Cloud-Backup.json` key will be used later in [Chapter 4, Create the Environment File](#) (in particular, the value of **project_id** and the absolute path to the file).

6. Copy the key file to `/etc/cinder/` on any Controller node. From there, change the user, group, and permissions of the key file to match that of `/etc/cinder/cinder.conf`. This will ensure that the Block Storage service can use it:

```
# cp Cloud-Backup.json /etc/cinder/  
# chown cinder:cinder /etc/cinder/Cloud-Backup.json  
# chmod 0600 /etc/cinder/Cloud-Backup.json
```

7. Copy the key file to the same location on each Controller node (namely, to `/etc/cinder/Cloud-Backup.json`). Use `rsync -a` to ensure that the permissions and ownership settings are preserved:

```
# rsync -a /etc/cinder/Cloud-Backup.json  
root@CONTROLLERHOST:/etc/cinder/
```

Replace `CONTROLLERHOST` with the hostname of a target Controller.

CHAPTER 4. CREATE THE ENVIRONMENT FILE

The environment file contains the settings you want to apply to the Block Storage service. In this case, the Block Storage service will be configured to store volume backups to Google Cloud. For more information about environment files, see the [Director Installation and Usage](#) guide.

Each setting is defined in the environment file as follows:

Entry format

```
SECT/PARAM: # 1
            value: CONFIG # 2
```

- 1 All Block Storage settings are configured in the `/etc/cinder/cinder.conf` file of the node hosting the Block Storage service. This file is divided into different sections, making it easier to manage different settings. *PARAM* is the setting you want to apply, and *SECT* is the section to which it belongs.
- 2 *CONFIG* is the value you want to set to *PARAM*.

In this document, all parameters are declared in the **DEFAULT** section. The following table describes each setting required to configure Google Cloud Storage (GCS) as your backup service:

1. Google Cloud backup settings

| <i>PARAM</i> | Default | <i>CONFIG</i> Description |
|----------------------------|-----------------------------|--|
| backup_driver | cinder.backup.drivers.swift | The backup driver that the Block Storage server should use. For Google Cloud Storage, use cinder.backup.drivers.google . |
| backup_gcs_credential_file | | The absolute path to the service account key file you created earlier in Chapter 3, Create and Download the GCS Credentials File . |
| backup_gcs_bucket | | The GCS bucket (or object storage repository) to use, which may or may not exist. If you specify a non-existent bucket, the Google Cloud Storage backup driver creates one using the name you specify here. See Buckets and Bucket name requirements for more information. |

| | | |
|------------------------------|-----------|--|
| backup_gcs_bucket_location | US | The location of the GCS bucket. This value is only used if you specify a non-existent bucket in backup_gcs_bucket ; in which case, the Google Cloud Storage backup driver will specify this as the GCS bucket location. See Bucket Locations for more information. |
| backup_gcs_project_id | | The project ID of the service account you are using, as noted in the project_id of the service account key from Chapter 3, Create and Download the GCS Credentials File . |
| backup_gcs_object_size | 52428800 | The size (in bytes) of GCS backup objects. |
| backup_gcs_block_size | 32768 | The size (in bytes) that changes are tracked for incremental backups. This value must be a multiple of the backup_gcs_object_size value. |
| backup_gcs_user_agent | gcscinder | The HTTP user-agent string for the GCS API. |
| backup_gcs_reader_chunk_size | 2097152 | GCS objects will be downloaded in chunks of this size (in bytes). |
| backup_gcs_writer_chunk_size | 2097152 | GCS objects will be uploaded in chunks of this size (in bytes). To upload files as a single chunk instead, use the value -1 . |
| backup_gcs_num_retries | 3 | Number of retries to attempt. |
| backup_gcs_storage_class | NEARLINE | Storage class of the GCS bucket. This value is only used if you specify a non-existent bucket in backup_gcs_bucket ; in which case, the Google Cloud Storage backup driver will specify this as the GCS bucket storage class. See Storage Classes for more information. |

| | | |
|----------------------------------|------|---|
| backup_gcs_retry_error_codes | 429 | List of GCS error codes. |
| backup_gcs_enable_progress_timer | True | Boolean to enable or disable the timer for sending periodic progress notifications to the Telemetry service (ceilometer) during volume backups. This is enabled by default (True) |

WARNING

When creating new buckets, Google Cloud Storage charges based on your chosen storage class (**backup_gcs_storage_class**). The default **NEARLINE** class is appropriate for backup services.

In addition, you cannot edit the location or class of a bucket once it is created. For more information, see [Managing a bucket's storage class or location](#).

The following sample shows the typical contents of an environment file for configuring GCS as a backup service:

/home/stack/templates/gcs-backup.yaml

```
parameter_defaults:
  ControllerExtraConfig: # 1
    cinder::config::cinder_config:
      DEFAULT/backup_driver
      value: cinder.backup.drivers.google
      DEFAULT/backup_gcs_credential_file
      value: /etc/cinder/Cloud-Backup.json
      DEFAULT/backup_gcs_bucket
      value: mycinderbucket
      DEFAULT/backup_gcs_project_id
      value: cloud-backup-1370
      DEFAULT/backup_gcs_user_agent
      value: myuseragent
```

- 1** **ControllerExtraConfig** defines custom settings that will be applied to all Controller nodes. The **cinder::config::cinder_config** class means the settings should be applied to the Block Storage (**cinder**) service. This, in turn, means that the back end settings will ultimately end in the **/etc/cinder/cinder.conf** file of each Controller node.

After creating the environment file, see [Chapter 5, Re-Deploy the OpenStack](#) for instructions on deploying its settings to the overcloud.

CHAPTER 5. RE-DEPLOY THE OVERCLOUD

Once you have created the [environment file](#) in `/home/stack/templates/`, log in as the `stack` user. Then, deploy the configuration by running:

```
$ openstack overcloud deploy --templates -e /home/stack/templates/gcs-backup.yaml
```

IMPORTANT

If you passed any extra environment files when you created the Overcloud, pass them again here using the `-e` option to avoid making undesired changes to the Overcloud.

For more information, see [Scaling the Overcloud](#) and [Updating the Overcloud Packages](#).
