Abstract

This guide provides information on configuring logging and monitoring for a Red Hat OpenStack Platform environment.

Table of Contents

CHAPTER 1. INTRODUCTION	3
CHAPTER 2. ARCHITECTURE	4
2.1. CENTRALIZED LOGGING	4
2.2. AVAILABILITY MONITORING	4
CHAPTER 3. INSTALLING THE CLIENT-SIDE TOOLS	8
3.1. SETTING CENTRALIZED LOGGING CLIENT PARAMETERS	8
3.2. SETTING MONITORING CLIENT PARAMETERS	8
3.3. YAML FILES	9
CHAPTER 4. MONITOR THE OPENSTACK PLATFORM	10
CHAPTER 5. VALIDATE THE SENSU CLIENT INSTALLATION	11
CHAPTER 6. REVIEW THE STATE OF A NODE	12
CHAPTER 7. REVIEW THE STATE OF AN OPENSTACK SERVICE	13

CHAPTER 1. INTRODUCTION

Monitoring tools are an optional suite of tools designed to help operators maintain an OpenStack environment. The tools perform the following functions:

- **Centralized logging:** Allows you gather logs from all components in the OpenStack environment in one central location. You can identify problems across all nodes and services, and optionally, export the log data to Red Hat for assistance in diagnosing problems.
- **Availability monitoring:** Allows you to monitor all components in the OpenStack environment and determine if any components are currently experiencing outages or are otherwise not functional. You can also configure the system to alert you when problems are identified.

CHAPTER 2. ARCHITECTURE

Monitoring tools use a client-server model with the client deployed onto the Red Hat OpenStack Platform overcloud nodes. The Rsyslog service provides client-side centralized logging (CL) and the Sensu client service provides client-side availability monitoring (AM).

2.1. CENTRALIZED LOGGING

In your Red Hat OpenStack environment, collecting the logs from all services in one central location simplifies debugging and administration. These logs come from the operating system, such as syslog and audit log files, infrastructure components such as RabbitMQ and MariaDB, and OpenStack services such as Identity, Compute, and others.

The centralized logging toolchain consists of the following components: * Log Collection Agent (Rsyslog) * Data Store (Elasticsearch) * API/Presentation Layer (Kibana)

NOTE

The director does not deploy the server-side components for centralized logging. Red Hat does not support the server-side components, including the Elasticsearch database and Kibana.

2.2. AVAILABILITY MONITORING

Availability monitoring allows you to have one central place to monitor the high-level functionality of all components across your entire OpenStack environment.

The availability monitoring toolchain consists of a number of components, including:

- Monitoring Agent (Sensu client)
- Monitoring Relay/Proxy (RabbitMQ)
- Monitoring Controller/Server (Sensu server)
- API/Presentation Layer (Uchiwa)

NOTE

The director does not deploy the server-side components for availability monitoring. Red Hat does not support the server-side components, including Uchiwa, Sensu Server, the Sensu API plus RabbitMQ, and a Redis instance running on a monitoring node.

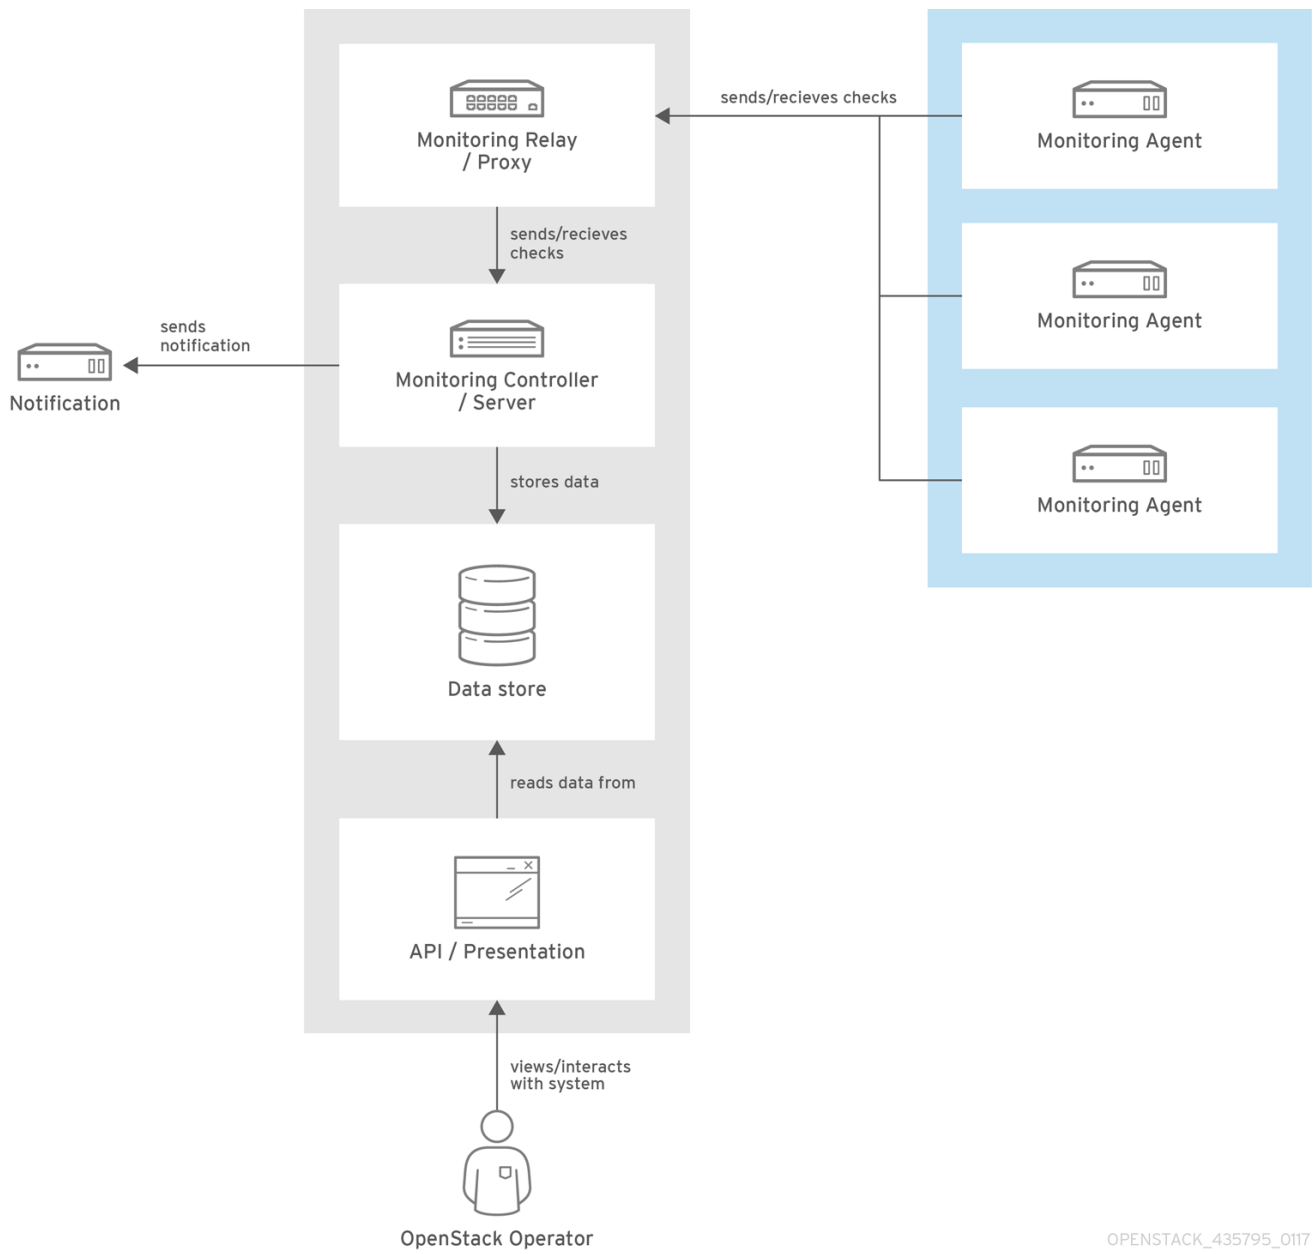

The availability monitoring components and their interactions are laid out in the following diagrams:

NOTE

Items shown in blue denote Red Hat-supported components.

OPENSTACK_435795_017

Figure 2.3. HA deployment for Red Hat OpenStack Platform

OPENSTACK_435795_017

CHAPTER 3. INSTALLING THE CLIENT-SIDE TOOLS

Before you deploy the overcloud, you need to determine the configuration settings to apply to each client. Copy the example environment files from the heat template collection and modify the files to suit your environment.

3.1. SETTING CENTRALIZED LOGGING CLIENT PARAMETERS

For more information, see [Enabling centralized logging during deployment](#).

3.2. SETTING MONITORING CLIENT PARAMETERS

The monitoring solution collects system information periodically and provides a mechanism to store and monitor the values in a variety of ways using a data collecting agent. Red Hat supports collectd as a collection agent. You can use Service Telemetry Framework (STF) to store the data, and in turn, monitor systems, find performance bottlenecks, and predict future system load.

To configure collectd, complete the following steps:

1. Create **config.yaml** in your home directory, for example, **/home/templates/custom**, and configure the **MetricsQdrConnectors** parameter to point to the Service Telemetry Framework server side:

```
MetricsQdrConnectors:
  - host: qdr-normal-sa-telemetry.apps.remote.tld
    port: 443
    role: inter-router
    sslProfile: sslProfile
    verifyHostname: false
MetricsQdrSSLProfiles:
  - name: sslProfile
```

2. In the **config.yaml** file, list the plug-ins you want under **CollectdExtraPlugins**. You can also provide parameters in the **ExtraConfig** section. By default, collectd comes with the **cpu**, **df**, **disk**, **hugepages**, **interface**, **load**, **memory**, **processes**, **tcpconns**, **unixsock**, and **uptime** plug-ins. You can add additional plug-ins using the **CollectdExtraPlugins** parameter. You can also provide additional configuration information for the **CollectdExtraPlugins** using the **ExtraConfig** option as shown. For example, to enable the **virt** plug-in, and configure the connection string and the hostname format, use the following syntax:

```
parameter_defaults:
  CollectdExtraPlugins:
    - disk
    - df
    - virt

ExtraConfig:
  collectd::plugin::virt::connection: "qemu:/system"
  collectd::plugin::virt::hostname_format: "hostname uuid"
```

**NOTE**

Do not remove the **unixsock** plug-in. Removal results in the permanent marking of the collectd container as unhealthy.

3. Deploy the overcloud. Use **config.yaml**, **collectd-write-qdr.yaml**, and one of the **qdr-*.yaml** files in your overcloud deploy command. For example:

```
$ openstack overcloud deploy
-e /home/templates/custom/config.yaml
-e tripleo-heat-templates/environments/metrics/collectd-write-qdr.yaml
-e tripleo-heat-templates/environments/metrics/qdr-form-controller-mesh.yaml
```

4. Optional: To enable overcloud RabbitMQ monitoring, include the **collectd-read-rabbitmq.yaml** file in your overcloud deploy command. For more information about the YAML files, see [Section 3.3, "YAML files"](#).

3.3. YAML FILES

When you configure collectd, you can include the following YAML files in your overcloud deploy command:

- **Collectd-read-rabbitmq.yaml**: Enables `python-collect-rabbitmq` and configures it to monitor overcloud RabbitMQ instance.
- **Collectd-write-qdr.yaml**: Enables collectd to send telemetry and notification data through QPID dispatch routers.
- **Qdr-edge-only.yaml**: Enables deployment of QPID dispatch routers. Each overcloud node will have one local `qdrouterd` service running and operating in edge mode, for example, sending received data straight to defined `MetricsQdrConnectors`.
- **Qdr-form-controller-mesh.yaml**: Enables deployment of QPID dispatch routers. Each overcloud node will have one local `qdrouterd` service running and forming a mesh topology. For example, QDRs running on controllers operate in interior router mode, with connections to defined `MetricsQdrConnectors`, and QDRs running on other node types connect in edge mode to the interior routers running on the controllers.

CHAPTER 4. MONITOR THE OPENSTACK PLATFORM

See the Sensu documentation for further details about the Sensu stack infrastructure:

<https://docs.sensu.io/sensu-core/1.7/overview/architecture/>

Red Hat supplies a set of check scripts in the **osops-tools-monitoring-oschecks** package. The majority of the check scripts only check the API connection to the OpenStack component. However, certain scripts also perform additional OpenStack resource tests for OpenStack Compute (nova), OpenStack Block Storage (cinder), OpenStack Image (glance), and OpenStack Networking (neutron). For example, the OpenStack Identity (keystone) API check returns the following result when **keystone** is running:

OK: Got a token, Keystone API is working.

CHAPTER 5. VALIDATE THE SENSU CLIENT INSTALLATION

1. Check the status of the **sensu-client** on each overcloud node:

```
█ # podman ps | grep sensu-client
```

2. Review the error log for any issues: **/var/log/containers/sensu/sensu-client.log**
3. Verify that each overcloud node has the **/var/lib/config-data/puppet-generated/sensu/etc/sensu/conf.d/rabbitmq.json** file that sets the IP address of the monitoring server.

CHAPTER 6. REVIEW THE STATE OF A NODE

If you have a deployment of the Uchiwa dashboard, you can use it with the Sensu server to review the state of your nodes:

1. Login to the Uchiwa dashboard and click the **Data Center** tab to confirm that the Data Center is operational.

■ `http://<SERVER_IP_ADDRESS>/uchiwa`

2. Check that all overcloud nodes are in a **Connected** state.
3. At a suitable time, reboot one of the overcloud nodes and review the rebooted node's status in the Uchiwa dashboard. After the reboot completes, verify that the node successfully re-connects to the Sensu server and starts executing checks.

CHAPTER 7. REVIEW THE STATE OF AN OPENSTACK SERVICE

This example tests the monitoring of the **openstack-ceilometer-central** service.

1. Confirm that the **openstack-ceilometer-central** service is running:

```
docker ps -a | grep ceilometer
```

2. Connect to the Uchiwa dashboard and confirm that a successful **ceilometer** check is present and running as defined in the **ceilometer** JSON file.
