Abstract

This guide contains important planning information and describes the configuration procedures for single root input/output virtualization (SR-IOV) and dataplane development kit (DPDK) for network functions virtualization infrastructure (NFVI) in your Red Hat OpenStack Platform deployment.

PREFACE

Red Hat OpenStack Platform provides the foundation to build a private or public cloud on top of Red Hat Enterprise Linux. It offers a massively scalable, fault-tolerant platform for the development of cloud-enabled workloads.

This guide describes the steps to plan and configure single root input/output virtualization (SR-IOV) and Open vSwitch with Data Plane Development Kit (OVS-DPDK) using the Red Hat OpenStack Platform director for NFV deployments.
CHAPTER 1. OVERVIEW OF NFV

Network Functions Virtualization (NFV) is a software solution that virtualizes a network function, such as a network switch, on general purpose, cloud-based infrastructure. NFV allows the Communication Service Provider to move away from traditional or proprietary hardware.

For a high-level overview of NFV concepts, see the Network Functions Virtualization Product Guide.

**NOTE**

OVS-DPDK and SR-IOV configuration depends on your hardware and topology. This guide provides examples for CPU assignments, memory allocation, and NIC configurations that might vary from your topology and use case.

Use Red Hat OpenStack Platform director to isolate specific network types, for example, external, tenant, internal API, and so on. You can deploy a network on a single network interface, or distributed over a multiple-host network interface. With Open vSwitch you can create bonds by assigning multiple interfaces to a single bridge. Configure network isolation in a Red Hat OpenStack Platform installation with template files. If you do not provide template files, the service networks deploy on the provisioning network. There are two types of template configuration files:

- **network-environment.yaml** - this file contains network details, such as subnets and IP address ranges, for the overcloud nodes. This file also contains the different settings that override the default parameter values for various scenarios.

- Host network templates, for example, `compute.yaml` and `controller.yaml` - define the network interface configuration for the overcloud nodes. The values of the network details are provided by the `network-environment.yaml` file.

These heat template files are located at `/usr/share/openstack-tripleo-heat-templates` on the undercloud node.

The Hardware requirements and Software requirements sections provide more details on how to plan and configure the heat template files for NFV using the Red Hat OpenStack Platform director.

**NOTE**

You can edit YAML files to configure NFV. For an introduction to the YAML file format, see: YAML in a Nutshell.
CHAPTER 2. HARDWARE REQUIREMENTS

This section describes the hardware requirements for NFV.

You can use Red Hat Technologies Ecosystem to check for a list of certified hardware, software, cloud providers, and components. Choose the category and select the product version.

For a complete list of the certified hardware for Red Hat OpenStack Platform, see Red Hat OpenStack Platform certified hardware.

2.1. TESTED NICS

For a list of tested NICs for NFV, see Network Adapter Support.

If you configure OVS-DPDK on Mellanox ConnectX-4 or ConnectX-5 network interfaces, you must set the corresponding kernel driver in the compute-ovs-dpdk.yaml file:

```yaml
members
  - type: ovs_dpdk_port
    name: dpdk0
    driver: mlx5_core
    members:
      - type: interface
        name: enp3s0f0
```

2.2. DISCOVERING YOUR NUMA NODE TOPOLOGY

When you plan your deployment, you must understand the NUMA topology of your Compute node to partition the CPU and memory resources for optimum performance. To determine the NUMA information, perform one of the following tasks:

- Enable hardware introspection to retrieve this information from bare-metal nodes.
- Log on to each bare-metal node to manually collect the information.

**NOTE**

You must install and configure the undercloud before you can retrieve NUMA information through hardware introspection. For more information about undercloud configuration, see: Director Installation and Usage Guide.

Retrieving hardware introspection details

The Bare Metal service hardware-inspection-extras feature is enabled by default, and you can use it to retrieve hardware details for overcloud configuration. For more information on the inspection_extras parameter in the undercloud.conf file, see: Configuring the Director.

For example, the numa_topology collector is part of these hardware-inspection extras and includes the following information for each NUMA node:

- RAM (in kilobytes)
- Physical CPU cores and their sibling threads
- NICs associated with the NUMA node

To retrieve the information listed above, substitute `<UUID>` with the UUID of the bare-metal node to complete the following command:

```bash
# openstack baremetal introspection data save <UUID> | jq .numa_topology
```

The following example shows the retrieved NUMA information for a bare-metal node:

```json
{
  "cpus": [
    {
      "cpu": 1,
      "thread_siblings": [1, 17],
      "numa_node": 0
    },
    {
      "cpu": 2,
      "thread_siblings": [10, 26],
      "numa_node": 1
    },
    {
      "cpu": 0,
      "thread_siblings": [0, 16],
      "numa_node": 0
    },
    {
      "cpu": 5,
      "thread_siblings": [13, 29],
      "numa_node": 1
    },
    {
      "cpu": 7,
      "thread_siblings": [15, 31],

</tbody>
</table>
CHAPTER 3. SOFTWARE REQUIREMENTS

This section describes the supported configurations and drivers, and subscription details necessary for NFV.

3.1. REGISTERING AND ENABLING REPOSITORIES

To install Red Hat OpenStack Platform, you must register Red Hat OpenStack Platform director using the Red Hat Subscription Manager, and subscribe to the required channels. See Registering your system for details.

Procedure

1. Register your system with the Content Delivery Network, entering your Customer Portal user name and password when prompted.

   [stack@director ~]$ sudo subscription-manager register

2. Determine the entitlement pool ID for Red Hat OpenStack Platform director, for example {Pool ID} from the following command and output:

   [stack@director ~]$ sudo subscription-manager list --available --all --matches="Red Hat OpenStack"

   Subscription Name:   Name of SKU
   Provides:            Red Hat Single Sign-On
   Red Hat Enterprise Linux Workstation
   Red Hat CloudForms
   Red Hat OpenStack
   Red Hat Software Collections (for RHEL Workstation)
   Red Hat Virtualization
   SKU:                 SKU-Number
   Contract:            Contract-Number
   Pool ID:             {Pool-ID}-123456
   Provides Management: Yes
   Available:           1
   Suggested:           1
   Service Level:       Support-level
   Service Type:        Service-Type
   Subscription Type:   Sub-type
   Ends:                End-date
   System Type:         Physical

3. Include the Pool ID value in the following command to attach the Red Hat OpenStack Platform 15 entitlement.

   [stack@director ~]$ sudo subscription-manager attach --pool={Pool-ID}-123456

4. Disable the default repositories.

   subscription-manager repos --disable=*

5. Enable the required repositories for Red Hat OpenStack Platform with NFV.
6. Update your system so you have the latest base system packages.

   [stack@director ~]$ sudo dnf update -y
   [stack@director ~]$ sudo reboot

**NOTE**

To register your overcloud nodes, see [Ansible Based Registration](#).

### 3.2. SUPPORTED CONFIGURATIONS FOR NFV DEPLOYMENTS

Red Hat OpenStack Platform (RHOSP) supports the following NFV deployments using director:

- Single root I/O virtualization (SR-IOV)
- Open vSwitch with Data Plane Development Kit (OVS-DPDK)

Additionally, you can deploy RHOSP with any of the following features:

- Composable roles
- Hyper-converged infrastructure (limited support)
- Real-time KVM
- OVS hardware offload (Technology preview)

**NOTE**

Red Hat’s embedded OpenDaylight SDN solution was deprecated in RHOSP 14. Red Hat support, including bug fixes, for OpenDaylight ends with the RHOSP 13 lifecycle, planned for June 27, 2021.

RHOSP NFV deployments with Open Virtual Network (OVN) as the default Software Defined Networking (SDN) solution are unsupported. Use the following steps to deploy RHOSP with the OVS mechanism driver:

**Procedure**

1. Modify the `containers-prepare-parameter.yaml` file so that the `neutron_driver` parameter is set to `null`.

   ```yaml
   parameter_defaults:
   ContainerImagePrepare:
   ```
- push_destination: true
set:
  neutron_driver: null
...

2. Include the `neutron-ovs.yaml` environment file in the `/usr/share/openstack-tripleo-heat-templates/environments/services` directory with your deployment script.

```bash
TEMPLATES=/usr/share/openstack-tripleo-heat-templates

openstack overcloud deploy --templates \
-e ${TEMPLATES}/environments/network-environment.yaml \
-e ${TEMPLATES}/environments/network-isolation.yaml \
-e ${TEMPLATES}/environments/services/neutron-ovs.yaml \
-e ${TEMPLATES}/environments/services/neutron-ovs-dpdk.yaml \
-e ${TEMPLATES}/environments/services/neutron-sriov.yaml \
-e /home/stack/containers-prepare-parameter.yaml
```

### 3.3. SUPPORTED DRIVERS

For a complete list of supported drivers, see [Component, Plug-In, and Driver Support in Red Hat OpenStack Platform](#).

For a list of NICs tested for Red Hat OpenStack Platform deployments with NFV, see [Tested NICs](#).

### 3.4. COMPATIBILITY WITH THIRD-PARTY SOFTWARE

For a complete list of products and services tested, supported, and certified to perform with Red Hat OpenStack Platform, see [Third Party Software compatible with Red Hat OpenStack Platform](#). You can filter the list by product version and software category.

For a complete list of products and services tested, supported, and certified to perform with Red Hat Enterprise Linux, see [Third Party Software compatible with Red Hat Enterprise Linux](#). You can filter the list by product version and software category.
CHAPTER 4. NETWORK CONSIDERATIONS

The undercloud host requires at least the following networks:

- **Provisioning network** - Provides DHCP and PXE-boot functions to help discover bare-metal systems for use in the overcloud.

- **External network** - A separate network for remote connectivity to all nodes. The interface connecting to this network requires a routable IP address, either defined statically, or generated dynamically from an external DHCP service.

The minimal overcloud network configuration includes the following NIC configurations:

- **Single NIC configuration** - One NIC for the provisioning network on the native VLAN and tagged VLANs that use subnets for the different overcloud network types.

- **Dual NIC configuration** - One NIC for the provisioning network and the other NIC for the external network.

- **Dual NIC configuration** - One NIC for the provisioning network on the native VLAN, and the other NIC for tagged VLANs that use subnets for different overcloud network types.

- **Multiple NIC configuration** - Each NIC uses a subnet for a different overcloud network type.

For more information on the networking requirements, see Networking requirements.
CHAPTER 5. PLANNING AN SR-IOV DEPLOYMENT

Optimize single root I/O virtualization (SR-IOV) deployments for NFV by setting individual parameters based on your Compute node hardware.

See Discovering your NUMA node topology to evaluate your hardware impact on the SR-IOV parameters.

5.1. HARDWARE PARTITIONING FOR AN SR-IOV DEPLOYMENT

To achieve high performance with SR-IOV, partition the resources between the host and the guest.

A typical topology includes 14 cores per NUMA node on dual socket Compute nodes. Both hyper-threading (HT) and non-HT cores are supported. Each core has two sibling threads. One core is dedicated to the host on each NUMA node. The virtual network function (VNF) handles the SR-IOV interface bonding. All the interrupt requests (IRQs) are routed on the host cores. The VNF cores are dedicated to the VNFs. They provide isolation from other VNFs and isolation from the host. Each VNF must use resources on a single NUMA node. The SR-IOV NICs used by the VNF must also be associated with that same NUMA node. This topology does not have a virtualization overhead. The host, OpenStack Networking (neutron), and Compute (nova) configuration parameters are exposed in a single file for ease, consistency, and to avoid incoherence that is fatal to proper isolation, causing preemption, and packet loss. The host and virtual machine isolation depend on a tuned profile, which defines the boot parameters and any Red Hat OpenStack Platform modifications based on the list of isolated CPUs.

5.2. TOPOLOGY OF AN NFV SR-IOV DEPLOYMENT

The following image has two VNFs each with the management interface represented by mgt and the data plane interfaces. The management interface manages the ssh access, and so on. The data plane interfaces bond the VNFs to DPDK to ensure high availability, as VNFs bond the data plane interfaces using the DPDK library. The image also has two provider networks for redundancy. The Compute node has two regular NICs bonded together and shared between the VNF management and the Red Hat OpenStack Platform API management.
The image shows a VNF that uses DPDK at an application level, and has access to SR-IOV virtual functions (VFs) and physical functions (PFs), for better availability or performance, depending on the fabric configuration. DPDK improves performance, while the VF/PF DPDK bonds provide support for failover, and high availability. The VNF vendor must ensure that the DPDK poll mode driver (PMD) supports the SR-IOV card that is being exposed as a VF/PF. The management network uses OVS, therefore the VNF sees a mgmt network device using the standard virtIO drivers. You can use that device to initially connect to the VNF, and ensure that the DPDK application bonds the two VF/PFs.

5.2.1. Topology for NFV SR-IOV without HCI

Observe the topology for SR-IOV without hyper-converged infrastructure (HCl) for NFV in the image below. It consists of compute and controller nodes with 1 Gbps NICs, and the director node.
CHAPTER 6. DEPLOYING SR-IOV TECHNOLOGIES

In your Red Hat OpenStack Platform NFV deployment, you can achieve higher performance with single root I/O virtualization (SR-IOV), when you configure direct access from your instances to a shared PCIe resource through virtual resources.

6.1. PREREQUISITES

- For details on how to install and configure the undercloud before deploying the overcloud, see the Director Installation and Usage Guide.

**NOTE**

Do not manually edit any values in `/etc/tuned/cpu-partitioning-variables.conf` that director heat templates modify.

6.2. CONFIGURING SR-IOV

**NOTE**

The following CPU assignments, memory allocation, and NIC configurations are examples, and might be different from your use case.

1. Generate the built-in `ComputeSriov` to define nodes in the OpenStack cluster that run `NeutronSriovAgent`, `NeutronSriovHostConfig`, and default compute services.

   ```bash
   # openstack overcloud roles generate \
   -o /home/stack/templates/roles_data.yaml \
   Controller ComputeSriov
   ```

2. To prepare the SR-IOV containers, include the `neutron-sriov.yaml` and `roles_data.yaml` files when you generate the `overcloud_images.yaml` file.

   ```bash
   SERVICES=\n   /usr/share/openstack-tripleo-heat-templates/environments/services

   openstack tripleo container image prepare \n   --namespace=registry.redhat.io/rhosp-rhel8 \n   --push-destination=192.168.24.1:8787 \n   --prefix=\n   --tag-from-label {version}-{release} \n   -e \$({SERVICES})/neutron-sriov.yaml \n   --roles-file /home/stack/templates/roles_data.yaml \n   --output-env-file=/home/stack/templates/overcloud_images.yaml \n   --output-images-file=/home/stack/local_registry_images.yaml
   ```

**NOTE**

The push-destination IP address is the address that you previously set with the `local_ip` parameter in the `undercloud.conf` configuration file.

For more information on container image preparation, see Director Installation and Usage.
3. Configure the parameters for the SR-IOV nodes under `parameter_defaults` appropriately for your cluster, and your hardware configuration. Typically, you add these settings to the `network-environment.yaml` file.

```yaml
NeutronNetworkType: 'vlan'
NeutronNetworkVLANRanges:
  - tenant:22:22
  - tenant:25:25
NeutronTunnelTypes: "
```

4. In the same file, configure role specific parameters for SR-IOV compute nodes.

**NOTE**

The `numvfs` parameter replaces the `NeutronSriovNumVFs` parameter in the network configuration templates. Red Hat does not support modification of the `NeutronSriovNumVFs` parameter or the `numvfs` parameter after deployment. If you modify either parameter after deployment, it might cause a disruption for the running instances that have an SR-IOV port on that physical function (PF). In this case, you must hard reboot these instances to make the SR-IOV PCI device available again. The `NovaVcpuPinSet` parameter is now deprecated, and is replaced by `NovaComputeCpuDedicatedSet` for dedicated, pinned workflows.

```yaml
ComputeSriovParameters:
  IsolCpusList: "1-19,21-39"
  KernelArgs: "default_hugepagesz=1GB hugepagesz=1G hugepages=32 iommu=pt intel_iommu=onisolcpus=1-19,21-39"
  TunedProfileName: "cpu-partitioning"
  NeutronBridgeMappings:
    - tenant:br-link0
  NeutronPhysicalDevMappings:
    - tenant:p7p1
    - tenant:p7p2
  NeutronSriovNumVFs:
    - p7p1:5
    - p7p2:5
  NovaPCIPassthrough:
    - devname: "p7p1"
      physical_network: "tenant"
    - devname: "p7p2"
      physical_network: "tenant"
  NovaComputeCpuDedicatedSet: '1-19,21-39'
  NovaReservedHostMemory: 4096
```

5. Configure the SR-IOV enabled interfaces in the `compute.yaml` network configuration template. To create SR-IOV virtual functions (VFs), configure the interfaces as standalone NICs:

```yaml
- type: interface
  name: p7p3
  mtu: 9000
  use_dhcp: false
  defroute: false
  nm_controlled: true
  hotplug: true
```
6. Ensure that the list of default filters includes the value `AggregateInstanceExtraSpecsFilter`.

```python
NovaSchedulerDefaultFilters:
```

7. Run the `overcloud_deploy.sh` script.

### 6.3. NIC PARTITIONING

This feature is available in this release as a **Technology Preview**, and therefore is not fully supported by Red Hat. It should only be used for testing, and should not be deployed in a production environment. For more information about Technology Preview features, see [Scope of Coverage Details](#). You can configure single root I/O virtualization (SR-IOV) so that an Red Hat OpenStack Platform host can use virtual functions (VFs).

When you partition a single, high-speed NIC into multiple VFs, you can use the NIC for both control and data plane traffic. You can then apply a QoS (Quality of Service) priority value to VF interfaces as desired.

**Procedure**

Ensure that you complete the following steps when creating the templates for an overcloud deployment:

1. Use the interface type `sriov_pf` in an `os-net-config` role file to configure a physical function that the host can use.

   ```yaml
   - type: sriov_pf
     name: <interface name>
     use_dhcp: false
     numvfs: <number of vfs>
     promisc: <true/false> #optional (Defaults to true)
   ```

**NOTE**

The `numvfs` parameter replaces the `NeutronSriovNumVFs` parameter in the network configuration templates. Red Hat does not support modification of the `NeutronSriovNumVFs` parameter or the `numvfs` parameter after deployment. If you modify either parameter after deployment, it might cause a disruption for the running instances that have an SR-IOV port on that physical function (PF). In this case, you must hard reboot these instances to make the SR-IOV PCI device available again.
2. Use the interface type `sriov_vf` to configure virtual functions in a bond that the host can use.

```yaml
- type: linux_bond
  name: internal_bond
  bonding_options: mode=active-backup
  use_dhcp: false
  members:
    - type: sriov_vf
      device: nic7
      vfid: 1
    - type: sriov_vf
      device: nic8
      vfid: 1

- type: vlan
  vlan_id:
    get_param: InternalApiNetworkVlanID
  device: internal_bond
  addresses:
    - ip_netmask:
        get_param: InternalApiIpSubnet
```

- The VLAN tag must be unique across all VFs that belong to a common PF device. You must assign VLAN tags to an interface type:
  - `linux_bond`
  - `ovs_bridge`
  - `ovs_dpdk_port`

- The applicable VF ID range starts at zero, and ends at the maximum number of VFs minus one.

3. To reserve virtual functions for VMs, use the `NovaPCIPassthrough` parameter. You must assign a regex value to the `address` parameter to identify the VFs that you want to pass through to Nova, to be used by virtual instances, and not by the host. You can obtain these values from `lspci`, so, if necessary, boot a compute node into a Linux environment to obtain this information.

The `lspci` command returns the address of each device in the format `<bus>:<device>:<slot>`. Enter these address values in the `NovaPCIPassthrough` parameter in the following format:

```yaml
NovaPCIPassthrough:
  - physical_network: "sriovnet2"
    address: {"domain": ".*", "bus": "06", "slot": "11", "function": ":[5-7]"}
  - physical_network: "sriovnet2"
    address: {"domain": ".*", "bus": "06", "slot": "10", "function": ":[5]"}
```

4. Ensure that IOMMU is enabled on all nodes that require NIC partitioning. For example, if you want NIC Partitioning for compute nodes, enable IOMMU using the `KernelArgs` parameter for that role:

```bash
parameter_defaults:
  ComputeParameters:
    KernelArgs: "intel_iommu=on iommu=pt"
```
Validation

1. Check the number of VFs.

   
   
   
   ```
   [root@overcloud-compute-0 heat-admin]# cat /sys/class/net/p4p1/device/sriov_numvfs
   10
   [root@overcloud-compute-0 heat-admin]# cat /sys/class/net/p4p2/device/sriov_numvfs
   10
   ```

2. Check Linux bonds.

   
   
   
   ```
   [root@overcloud-compute-0 heat-admin]# cat /proc/net/bonding/intapi_bond
   Ethernet Channel Bonding Driver: v3.7.1 (April 27, 2011)
   Bonding Mode: fault-tolerance (active-backup)
   Primary Slave: None
   Currently Active Slave: p4p1_1
   MII Status: up
   MII Polling Interval (ms): 0
   Up Delay (ms): 0
   Down Delay (ms): 0
   Slave Interface: p4p1_1
   MII Status: up
   Speed: 10000 Mbps
   Duplex: full
   Link Failure Count: 0
   Permanent HW addr: 16:b4:4c:aa:f0:a8
   Slave queue ID: 0
   Slave Interface: p4p2_1
   MII Status: up
   Speed: 10000 Mbps
   Duplex: full
   Link Failure Count: 0
   Permanent HW addr: b6:be:82:ac:51:98
   Slave queue ID: 0
   ```

   
   
   
   ```
   [root@overcloud-compute-0 heat-admin]# cat /proc/net/bonding/st_bond
   Ethernet Channel Bonding Driver: v3.7.1 (April 27, 2011)
   Bonding Mode: fault-tolerance (active-backup)
   Primary Slave: None
   Currently Active Slave: p4p1_3
   MII Status: up
   MII Polling Interval (ms): 0
   Up Delay (ms): 0
   Down Delay (ms): 0
   Slave Interface: p4p1_3
   MII Status: up
   Speed: 10000 Mbps
   Duplex: full
   Link Failure Count: 0
   Permanent HW addr: 9a:86:b7:cc:17:e4
   ```
Slave queue ID: 0
Slave Interface: p4p2_3
MII Status: up
Speed: 10000 Mbps
Duplex: full
Link Failure Count: 0
Permanent HW addr: d6:07:f8:78:dd:5b
Slave queue ID: 0

3. List OVS bonds.

[root@overcloud-compute-0 heat-admin]# ovs-appctl bond/show
---- bond_prov ----
bond_mode: active-backup
bond may use recirculation: no, Recirc-ID : -1
bond-hash-basis: 0
updelay: 0 ms
downdelay: 0 ms
lacp_status: off
lacp_fallback_ab: false
active slave mac: f2:ad:c7:00:f5:c7(dpdk2)
slave dpdk2: enabled
active slave
may_enable: true

slave dpdk3: enabled
may_enable: true

---- bond_tnt ----
bond_mode: active-backup
bond may use recirculation: no, Recirc-ID : -1
bond-hash-basis: 0
updelay: 0 ms
downdelay: 0 ms
lacp_status: off
lacp_fallback_ab: false
active slave mac: b2:7e:b8:75:72:e8(dpdk0)
slave dpdk0: enabled
active slave
may_enable: true
slave dpdk1: enabled
may_enable: true

4. Show OVS connections.

[root@overcloud-compute-0 heat-admin]# ovs-vsctl show
cec12069-9d4c-4fa8-bfe4-decfdf258f49
Manager "ptcp:6640:127.0.0.1"

If you used **NovaPCIPassthrough** to pass VFs to instances, test by deploying an SR-IOV instance.

### 6.4. CONFIGURING OVS HARDWARE OFFLOAD

This feature is available in this release as a **Technology Preview**, and therefore is not fully supported by Red Hat. It should only be used for testing, and should not be deployed in a production environment. For more information about Technology Preview features, see **Scope of Coverage Details**.

The procedure for OVS hardware offload configuration shares many of the same steps as configuring SR-IOV.
Procedure

1. Generate the `ComputeSriov` role:

   openstack overcloud roles generate -o roles_data.yaml Controller ComputeSriov

2. Add the `OvsHwOffload` parameter under role-specific parameters with a value of `true`.

3. Configure the `physical_network` parameter to match your environment.
   - For VLAN, set the `physical_network` parameter to the name of the network you create in neutron after deployment. This value should also be in `NeutronBridgeMappings`.
   - For VXLAN, set the `physical_network` parameter to the string value `null`.

   Example:

   ```yaml
   parameter_defaults:
   ComputeSriovParameters:
     IsolCpusList: 2-9,21-29,11-19,31-39
     KernelArgs: "defaulthugepagesz=1GB hugepagesz=1G hugepages=128 intel_iommu=on iommu=pt"
   OvsHwOffload: true
   TunedProfileName: "cpu-partitioning"
   NeutronBridgeMappings:
     - tenant:br-tenant
   NeutronPhysicalDevMappings:
     - tenant:p7p1
     - tenant:p7p2
   NovaPCIPassthrough:
     - devname: "p7p1"
       physical_network: "null"
     - devname: "p7p2"
       physical_network: "null"
   NovaReservedHostMemory: 4096
   NovaComputeCpuDedicatedSet: 1-9,21-29,11-19,31-39
   
   4. Ensure that the list of default filters includes `NUMATopologyFilter`:

   ```yaml
   NovaSchedulerDefaultFilters:
   [\'RetryFilter',\'AvailabilityZoneFilter',\'ComputeFilter',\'ComputeCapabilitiesFilter',\'ImagePropertiesFilter',\'ServerGroupAntiAffinityFilter',\'ServerGroupAffinityFilter',\'PciPassthroughFilter',\'NUMATopologyFilter']
   ```

5. Configure one or more network interfaces intended for hardware offload in the `compute-sriov.yaml` configuration file:

   ```yaml
   - type: ovs_bridge
     name: br-tenant
   ```

   **NOTE**

   Do not use the `NeutronSriovNumVFs` parameter when configuring Open vSwitch hardware offload. The `numvfs` parameter specifies the number of VFs in a network configuration file used by `os-net-config`.  

   ```yaml
   ```
mtu: 9000
members:
- type: sriov_pf
  name: p7p1
  numvfs: 5
  mtu: 9000
  primary: true
  promisc: true
  use_dhcp: false
  link_mode: switchdev

NOTE
Do not configure Mellanox network interfaces as a nic-config interface type **ovs-vlan** because this prevents tunnel endpoints such as VXLAN from passing traffic due to driver limitations.

6. Include the **ovs-hw-offload.yaml** file in the **overcloud deploy** command:

```bash
TEMPLATES_HOME="/usr/share/openstack-tripleo-heat-templates"
CUSTOM_TEMPLATES="/home/stack/templates"

openstack overcloud deploy --templates \
  -r ${CUSTOM_TEMPLATES}/roles_data.yaml \
  -e ${TEMPLATES_HOME}/environments/ovs-hw-offload.yaml \
  -e ${CUSTOM_TEMPLATES}/network-environment.yaml \
  -e ${CUSTOM_TEMPLATES}/neutron-ovs.yaml
```

6.4.1. Verifying OVS hardware offload

1. Confirm that a PCI device is in **switchdev** mode:

```bash
# devlink dev eswitch show pci/0000:03:00.0
pci/0000:03:00.0: mode switchdev inline-mode none encap enable
```

2. Verify if offload is enabled in OVS:

```bash
# ovs-vsctl get Open_vSwitch . other_config:hw-offload
"true"
```

6.5. DEPLOYING AN INSTANCE FOR SR-IOV

Use host aggregates to separate high performance compute hosts. For information on creating host aggregates and associated flavors for scheduling see **Creating host aggregates**.

NOTE
Pinned CPU instances can be located on the same Compute node as unpinned instances. For more information, see **Configuring CPU pinning on the Compute node** in the Instances and Images Guide.

Deploy an instance for single root I/O virtualization (SR-IOV) by performing the following steps:
1. Create a flavor.

   # openstack flavor create <flavor> --ram <MB> --disk <GB> --vcpus <#>

**TIP**

You can specify the NUMA affinity policy for PCI passthrough devices and SR-IOV interfaces by adding the extra spec `hw:pci_numa_affinity_policy` to your flavor. For more information, see Update flavor metadata in the Instance and Images Guide.

2. Create the network.

   # openstack network create net1 --provider-physical-network tenant --provider-network-type vlan --provider-segment <VLAN-ID>
   # openstack subnet create subnet1 --network net1 --subnet-range 192.0.2.0/24 --dhcp

3. Create the port.

   - Use vnic-type **direct** to create an SR-IOV virtual function (VF) port.

     # openstack port create --network net1 --vnic-type direct sriov_port

   - Use the following command to create a virtual function with hardware offload.

     # openstack port create --network net1 --vnic-type direct --binding-profile '{"capabilities": ["switchdev"]}' sriov_hwoffload_port

   - Use vnic-type **direct-physical** to create an SR-IOV PF port.

     # openstack port create --network net1 --vnic-type direct-physical sriov_port

4. Deploy an instance.

   # openstack server create --flavor <flavor> --image <image> --nic port-id=<id> <instance name>

---

**6.6. CREATING HOST AGGREGATES**

For better performance, deploy guests that have cpu pinning and hugepages. You can schedule high performance instances on a subset of hosts by matching aggregate metadata with flavor metadata.

1. Ensure that the `AggregateInstanceExtraSpecsFilter` value is included in the `scheduler_default_filters` parameter in the `nova.conf` file. This configuration can be set through the heat parameter `NovaSchedulerDefaultFilters` under role-specific parameters before deployment.

   ComputeOvsDpdkSriovParameters:
NOTE

To add this parameter to the configuration of an existing cluster, you can add it to the heat templates, and run the original deployment script again.

2. Create an aggregate group for SR-IOV, and add relevant hosts. Define metadata, for example, `sriov=true`, that matches defined flavor metadata.

```bash
# openstack aggregate create sriov_group
# openstack aggregate add host sriov_group compute-sriov-0.localdomain
# openstack aggregate set sriov_group sriov=true
```

3. Create a flavor.

```bash
# openstack flavor create <flavor> --ram <MB> --disk <GB> --vcpus <#>
```

4. Set additional flavor properties. Note that the defined metadata, `sriov=true`, matches the defined metadata on the SR-IOV aggregate.

```bash
openstack flavor set --property sriov=true --property hw:cpu_policy=dedicated --property hw:mem_page_size=1GB <flavor>
```
CHAPTER 7. PLANNING YOUR OVS-DPDK DEPLOYMENT

To optimize your OVS-DPDK deployment, you should understand how to configure the OVS-DPDK parameters relative to your Compute node hardware. For more information about CPUs and NUMA topology, see: NFV performance considerations.

7.1. OVS-DPDK WITH CPU PARTITIONING AND NUMA TOPOLOGY

OVS-DPDK partitions the hardware resources for host, guests, and itself. The OVS-DPDK Poll Mode Drivers (PMDs) run DPDK active loops, which require dedicated CPU cores. Therefore you must allocate some CPUs, and huge pages, to OVS-DPDK.

A sample partitioning includes 16 cores per NUMA node on dual-socket Compute nodes. The traffic requires additional NICs because you cannot share NICs between the host and OVS-DPDK.

**NOTE**

You must reserve DPDK PMD threads on both NUMA nodes, even if a NUMA node does not have an associated DPDK NIC.

For optimum OVS-DPDK performance, reserve a block of memory local to the NUMA node. Choose NICs associated with the same NUMA node that you use for memory and CPU pinning. Ensure that both bonded interfaces are from NICs on the same NUMA node.

7.2. WORKFLOWS AND DERIVED PARAMETERS

This feature is available in this release as a Technology Preview, and therefore is not fully supported by Red Hat. It should only be used for testing, and should not be deployed in a production environment. For more information about Technology Preview features, see Scope of Coverage Details.

You can use the OpenStack Workflow (mistral) service to derive parameters based on the capabilities of your available bare-metal nodes. Workflows use a YAML file to define a set of tasks and actions to perform. You can use a pre-defined workbook, `derive_params.yaml`, in the directory `tripleo-common/workbooks/`. This workbook provides workflows to derive each supported parameter from the results of Bare Metal introspection. The `derive_params.yaml` workflows use the formulas from `tripleo-common/workbooks/derive_params_formulas.yaml` to calculate the derived parameters.
NOTE
You can modify `derive_params_formulas.yaml` to suit your environment.

The `derive_params.yaml` workbook assumes all nodes for a particular composable role have the same hardware specifications. The workflow considers the flavor-profile association and nova placement scheduler to match nodes associated with a role, then uses the introspection data from the first node that matches the role.

For more information about Red Hat OpenStack Platform workflows, see Troubleshooting workflows and executions.

You can use the `-p` or `--plan-environment-file` option to add a custom `plan_environment.yaml` file, containing a list of workbooks and any input values, to the `openstack overcloud deploy` command. The resultant workflows merge the derived parameters back into the custom `plan_environment.yaml`, where they are available for the overcloud deployment.

For details on how to use the `--plan-environment-file` option in your deployment, see Plan Environment Metadata.

### 7.3. DERIVED OVS-DPDK PARAMETERS

The workflows in `derive_params.yaml` derive the DPDK parameters associated with the role that uses the `ComputeNeutronOvsDpdk` service.

The workflows can automatically derive the following parameters for OVS-DPDK. The `NovaVcpuPinSet` parameter is now deprecated, and is replaced by `NovaComputeCpuDedicatedSet` for dedicated, pinned workflows:

- `IsolCpusList`
- `KernelArgs`
- `NovaReservedHostMemory`
- `NovaComputeCpuDedicatedSet`
- `OvsDpdkCoreList`
- `OvsDpdkSocketMemory`
- `OvsPmdCoreList`

The `OvsDpdkMemoryChannels` parameter cannot be derived from the introspection memory bank data because the format of memory slot names are inconsistent across different hardware environments.

In most cases, the default number of `OvsDpdkMemoryChannels` is four. Consult your hardware manual to determine the number of memory channels per socket, and update the default number with this value.

For more information about workflow parameters, see Section 8.1, “Deriving DPDK parameters with workflows”.

### 7.4. CALCULATING OVS-DPDK PARAMETERS MANUALLY
This section describes how OVS-DPDK uses parameters within the director `network_environment.yaml` heat templates to configure the CPU and memory for optimum performance. Use this information to evaluate the hardware support on your Compute nodes and how to partition the hardware to optimize your OVS-DPDK deployment.

**NOTE**

For more information on an how to generate these values with the `derived_parameters.yaml` workflow instead, see Overview of workflows and derived parameters.

**NOTE**

Always pair CPU sibling threads, or logical CPUs, together in the physical core when allocating CPU cores.

For details on how to determine the CPU and NUMA nodes on your Compute nodes, see Discovering your NUMA node topology. Use this information to map CPU and other parameters to support the host, guest instance, and OVS-DPDK process needs.

### 7.4.1. CPU parameters

OVS-DPDK uses the following parameters for CPU partitioning:

**OvsPmdCoreList**

Provides the CPU cores that are used for the DPDK poll mode drivers (PMD). Choose CPU cores that are associated with the local NUMA nodes of the DPDK interfaces. Use `OvsPmdCoreList` for the `pmd-cpu-mask` value in OVS. Observe the following recommendations for `OvsPmdCoreList`:

- Pair the sibling threads together.
- Exclude all cores from the `OvsDpdkCoreList`.
- Avoid allocating the logical CPUs of both thread siblings on the first physical core to both NUMA nodes as these should be used for the `OvsDpdkCoreList` parameter.
- Performance depends on the number of physical cores allocated for this PMD Core list. On the NUMA node which is associated with DPDK NIC, allocate the required cores.
- For NUMA nodes with a DPDK NIC, determine the number of physical cores required based on the performance requirement, and include all the sibling threads or logical CPUs for each physical core.
- For NUMA nodes without DPDK NICs, allocate the sibling threads or logical CPUs of any physical core except the first physical core of the NUMA node. You need a minimal DPDK poll mode driver on the NUMA node without DPDK NICs present to properly create guest instances.

**NOTE**

You must reserve DPDK PMD threads on both NUMA nodes, even if a NUMA node does not have an associated DPDK NIC.
NovaComputeCpuDedicatedSet
A comma-separated list or range of physical host CPU numbers to which processes for pinned instance CPUs can be scheduled. For example, `NovaComputeCpuDedicatedSet: [4-12,^8,15]` reserves cores from 4-12 and 15, excluding 8.

- Exclude all cores from the `OvsPmdCoreList` and the `OvsDpdkCoreList`.
- Include all remaining cores.
- Pair the sibling threads together.

NovaComputeCpuSharedSet
A comma-separated list or range of physical host CPU numbers used to determine the host CPUs for instance emulator threads. The recommended value for this parameter matches the value set for `OvsDpdkCoreList`.

IsolCpusList
A set of CPU cores isolated from the host processes. `IsolCpusList` is the `isolated_cores` value in the `cpu-partitioning-variable.conf` file for the tuned-profiles-cpu-partitioning component. Observe the following recommendations for `IsolCpusList`:

- Match the list of cores in `OvsPmdCoreList` and `NovaComputeCpuDedicatedSet`.
- Pair the sibling threads together.

OvsDpdkCoreList
Provides CPU cores for non data path OVS-DPDK processes, such as handler and revalidator threads. This parameter has no impact on overall data path performance on multi-NUMA node hardware. `OvsDpdkCoreList` is the `dpdk-lcore-mask` value in OVS, and these cores are shared with the host. Observe the following recommendations for `OvsDpdkCoreList`:

- Allocate the first physical core, and sibling thread, from each NUMA node, even if the NUMA node has no associated DPDK NIC.
- These cores must be mutually exclusive from the list of cores in `OvsPmdCoreList` and `NovaComputeCpuDedicatedSet`.

7.4.2. Memory parameters
OVS-DPDK uses the following memory parameters:

OvsDpdkMemoryChannels
Maps memory channels in the CPU per NUMA node. `OvsDpdkMemoryChannels` is the `other_config:dpdk-extra="-n <value>"` value in OVS. Observe the following recommendations for `OvsDpdkMemoryChannels`:

- Use `dmidecode -t memory` or your hardware manual to determine the number of memory channels available.
- Use `ls /sys/devices/system/node/node* -d` to determine the number of NUMA nodes.
- Divide the number of memory channels available by the number of NUMA nodes.

NovaReservedHostMemory
Reserves memory in MB for tasks on the host. **NovaReservedHostMemory** is the `reserved_host_memory_mb` value for the Compute node in `nova.conf`. Observe the following recommendation for **NovaReservedHostMemory**:

- Use the static recommended value of 4096 MB.

**OvsDpdkSocketMemory**

Specifies the amount of memory in MB to pre-allocate from the hugepage pool, per NUMA node. **OvsDpdkSocketMemory** is the `other_config:dpdk-socket-mem` value in OVS. Observe the following recommendations for **OvsDpdkSocketMemory**:

- Provide as a comma-separated list.
- For a NUMA node without a DPDK NIC, use the static recommendation of 1024 MB (1GB)
- Calculate the **OvsDpdkSocketMemory** value from the MTU value of each NIC on the NUMA node.
- The following equation approximates the value for **OvsDpdkSocketMemory**:
  
  \[
  \text{MEMORY\_REQD\_PER\_MTU} = (\text{ROUNDUP\_PER\_MTU} + 800) \times (4096 \times 64) \text{ Bytes}
  \]
  
  800 is the overhead value.
  
  4096 * 64 is the number of packets in the mempool.
- Add the MEMORY\_REQD\_PER\_MTU for each of the MTU values set on the NUMA node and add another 512 MB as buffer. Round the value up to a multiple of 1024.

**Sample Calculation - MTU 2000 and MTU 9000**

DPDK NICs dpdk0 and dpdk1 are on the same NUMA node 0, and configured with MTUs 900, and 2000 respectively. The sample calculation to derive the memory required is as follows:

1. Round off the MTU values to the nearest multiple of 1024 bytes.

   - The MTU value of 9000 becomes 9216 bytes.
   - The MTU value of 2000 becomes 2048 bytes.

2. Calculate the required memory for each MTU value based on these rounded byte values.

   Memory required for 9000 MTU = (9216 + 800) * (4096*64) = 2625634304
   
   Memory required for 2000 MTU = (2048 + 800) * (4096*64) = 746586112

3. Calculate the combined total memory required, in bytes.

   \[2625634304 + 746586112 + 536870912 = 3909091328 \text{ bytes} \]

   This calculation represents (Memory required for MTU of 9000) + (Memory required for MTU of 2000) + (512 MB buffer).

4. Convert the total memory required into MB.

   \[3909091328 / (1024*1024) = 3728 \text{ MB}\]
5. Round this value up to the nearest 1024.
   
   3724 MB rounds up to 4096 MB.

6. Use this value to set OvsDpdkSocketMemory.
   
   OvsDpdkSocketMemory: "4096,1024"

**Sample Calculation - MTU 2000**

DPDK NICs dpdk0 and dpdk1 are on the same NUMA node 0, and each are configured with MTUs of 2000. The sample calculation to derive the memory required is as follows:

1. Round off the MTU values to the nearest multiple of 1024 bytes.
   
   The MTU value of 2000 becomes 2048 bytes.

2. Calculate the required memory for each MTU value based on these rounded byte values.
   
   Memory required for 2000 MTU = (2048 + 800) * (4096*64) = 746586112

3. Calculate the combined total memory required, in bytes.
   
   746586112 + 536870912 = 1283457024 bytes.
   
   This calculation represents (Memory required for MTU of 2000) + (512 MB buffer).

4. Convert the total memory required into MB.
   
   1283457024 / (1024*1024) = 1224 MB.

5. Round this value up to the nearest multiple of 1024.
   
   1224 MB rounds up to 2048 MB.

6. Use this value to set OvsDpdkSocketMemory.
   
   OvsDpdkSocketMemory: "2048,1024"

### 7.4.3. Networking parameters

**NeutronDpdkDriverType**

Sets the driver type used by DPDK. Use the default value of vfio-pci.

**NeutronDatapathType**

Datapath type for OVS bridges. DPDK uses the default value of netdev.

**NeutronVhostuserSocketDir**

Sets the vhost-user socket directory for OVS. Use /var/lib/vhost_sockets for vhost client mode.

### 7.4.4. Other parameters

**NovaSchedulerDefaultFilters**
Provides an ordered list of filters that the Compute node uses to find a matching Compute node for a requested guest instance.

VhostuserSocketGroup
Sets the vhost-user socket directory group. The default value is qemu. Set VhostuserSocketGroup to hugetlbfs so that the ovs-vswitchd and qemu processes can access the shared huge pages and unix socket that configures the virtio-net device. This value is role-specific and should be applied to any role leveraging OVS-DPDK.

KernelArgs
Provides multiple kernel arguments to /etc/default/grub for the Compute node at boot time. Add the following values based on your configuration:

- **hugepagesz**: Sets the size of the huge pages on a CPU. This value can vary depending on the CPU hardware. Set to 1G for OVS-DPDK deployments (default_hugepagesz=1GB hugepagesz=1G). Use this command to check for the pdpe1gb CPU flag that confirms your CPU supports 1G.

  ```bash
  lshw -class processor | grep pdpe1gb
  ```

- **hugepages count**: Sets the number of huge pages available based on available host memory. Use most of your available memory, except NovaReservedHostMemory. You must also configure the huge pages count value within the flavor of your Compute nodes.

- **iommu**: For Intel CPUs, add “intel_iommu=on iommu=pt”

- **isolcpus**: Sets the CPU cores for tuning. This value matches IsolCpusList.

7.4.5. Instance extra specifications

Before deploying instances in an NFV environment, create a flavor that utilizes CPU pinning, huge pages, and emulator thread pinning.

**hw:cpu_policy**
When this parameter is set to dedicated, the guest uses pinned CPUs. Instances created from a flavor with this parameter set have an effective overcommit ratio of 1:1. The default value is shared.

**hw:mem_page_size**
Set this parameter to a valid string of a specific value with standard suffix (For example, 4KB, 8MB, or 1GB). Use 1GB to match the hugepagesz boot parameter. Calculate the number of huge pages available for the virtual machines by subtracting OvsDpdkSocketMemory from the boot parameter. The following values are also valid:

- small (default) - The smallest page size is used
- large - Only use large page sizes. (2MB or 1GB on x86 architectures)
- any - The compute driver can attempt to use large pages, but defaults to small if none available.

**hw:emulator_threads_policy**
Set the value of this parameter to share so that emulator threads are locked to CPUs that you’ve identified in the heat parameter, NovaComputeCpuSharedSet. If an emulator thread is running on a vCPU with the poll mode driver (PMD) or real-time processing, you can experience negative effects, such as packet loss.
7.5. TWO NUMA NODE EXAMPLE OVS-DPDK DEPLOYMENT

The Compute node in the following example includes two NUMA nodes:

- NUMA 0 has cores 0-7. The sibling thread pairs are (0,1), (2,3), (4,5), and (6,7).
- NUMA 1 has cores 8-15. The sibling thread pairs are (8,9), (10,11), (12,13), and (14,15).
- Each NUMA node connects to a physical NIC, namely NIC1 on NUMA 0, and NIC2 on NUMA 1.

NOTE

Reserve the first physical cores or both thread pairs on each NUMA node (0,1 and 8,9) for non-datapath DPDK processes, such as OvsDpdkCoreList.

This example also assumes a 1500 MTU configuration, so the OvsDpdkSocketMemory is the same for all use cases:

- OvsDpdkSocketMemory: “1024,1024”

NIC 1 for DPDK, with one physical core for PMD

In this use case, you allocate one physical core on NUMA 0 for PMD. You must also allocate one physical core on NUMA 1, even though DPDK is not enabled on the NIC for that NUMA node. The remaining cores, not reserved for OvsDpdkCoreList, are allocated for guest instances. The resulting parameter settings are:

- OvsPmdCoreList: “2,3,10,11”
- NovaComputeCpuDedicatedSet: “4,5,6,7,12,13,14,15”

NIC 1 for DPDK, with two physical cores for PMD

In this use case, you allocate two physical cores on NUMA 0 for PMD. You must also allocate one physical core on NUMA 1, even though DPDK is not enabled on the NIC for that NUMA node. The remaining cores, not reserved for OvsDpdkCoreList, are allocated for guest instances. The resulting parameter settings are:

- OvsPmdCoreList: “2,3,4,5,10,11”
- NovaComputeCpuDedicatedSet: “6,7,12,13,14,15”

NIC 2 for DPDK, with one physical core for PMD

In this use case, you allocate one physical core on NUMA 1 for PMD. You must also allocate one physical core on NUMA 0, even though DPDK is not enabled on the NIC for that NUMA node. The remaining
cores, not reserved for OvsDpdkCoreList, are allocated for guest instances. The resulting parameter settings are:

OvsPmdCoreList: “2,3,10,11”
NovaComputeCpuDedicatedSet: “4,5,6,7,12,13,14,15”

**NIC 2 for DPDK, with two physical cores for PMD**

In this use case, you allocate two physical cores on NUMA 1 for PMD. You must also allocate one physical core on NUMA 0, even though DPDK is not enabled on the NIC for that NUMA node. The remaining cores, not reserved for OvsDpdkCoreList, are allocated for guest instances. The resulting parameter settings are:

OvsPmdCoreList: “2,3,10,11,12,13”
NovaComputeCpuDedicatedSet: “4,5,6,7,14,15”

**NIC 1 and NIC2 for DPDK, with two physical cores for PMD**

In this use case, you allocate two physical cores on each NUMA node for PMD. The remaining cores, not reserved for OvsDpdkCoreList, are allocated for guest instances. The resulting parameter settings are:

OvsPmdCoreList: “2,3,4,5,10,11,12,13”
NovaComputeCpuDedicatedSet: “6,7,14,15”

### 7.6. TOPOLOGY OF AN NFV OVS-DPDK DEPLOYMENT

This example deployment shows an OVS-DPDK configuration and consists of two virtual network functions (VNFs) with two interfaces each:

- The management interface, represented by mgt.
- The data plane interface.

In the OVS-DPDK deployment, the VNFs operate with inbuilt DPDK that supports the physical interface. OVS-DPDK enables bonding at the vSwitch level. For improved performance in your OVS-DPDK deployment, it is recommended that you separate kernel and OVS-DPDK NICs. To separate the management (mgt) network, connected to the Base provider network for the virtual machine, ensure you have additional NICs. The Compute node consists of two regular NICs for the Red Hat OpenStack Platform API management that can be reused by the Ceph API but cannot be shared with any OpenStack tenant.
**NFV OVS-DPDK topology**

The following image shows the topology for OVS-DPDK for NFV. It consists of Compute and Controller nodes with 1 or 10 Gbps NICs, and the director node.
CHAPTER 8. CONFIGURING AN OVS-DPDK DEPLOYMENT

This section deploys OVS-DPDK within the Red Hat OpenStack Platform environment. The overcloud usually consists of nodes in predefined roles such as Controller nodes, Compute nodes, and different storage node types. Each of these default roles contains a set of services defined in the core heat templates on the director node.

You must install and configure the undercloud before you can deploy the overcloud. See the Director Installation and Usage Guide for details.

IMPORTANT
You must determine the best values for the OVS-DPDK parameters found in the network-environment.yaml file to optimize your OpenStack network for OVS-DPDK.

NOTE
Do not manually edit or change isolated_cores or other values in etc/tuned/cpu-partitioning-variables.conf that the director heat templates modify.

8.1. DERIVING DPDK PARAMETERS WITH WORKFLOWS

IMPORTANT
This feature is available in this release as a Technology Preview, and therefore is not fully supported by Red Hat. It should only be used for testing, and should not be deployed in a production environment. For more information about Technology Preview features, see Scope of Coverage Details.

See Section 7.2, “Workflows and derived parameters” for an overview of the Mistral workflow for DPDK.

Prerequisites
You must have bare metal introspection, including hardware inspection extras (inspection_extras) enabled to provide the data retrieved by this workflow. Hardware inspection extras are enabled by default. For more information about hardware of the nodes, see: Inspecting the Hardware of Nodes.

Define the Workflows and Input Parameters for DPDK

The following list outlines the input parameters you can provide to the OVS-DPDK workflows:

num_phy_cores_per_numa_node_for_pmd
This input parameter specifies the required minimum number of cores for the NUMA node associated with the DPDK NIC. One physical core is assigned for the other NUMA nodes not associated with DPDK NIC. Ensure that this parameter is set to 1.

huge_page_allocation_percentage
This input parameter specifies the required percentage of total memory, excluding NovaReservedHostMemory, that can be configured as huge pages. The KernelArgs parameter is derived using the calculated huge pages based on the huge_page_allocation_percentage specified. Ensure that this parameter is set to 50.

The workflows calculate appropriate DPDK parameter values from these input parameters and the bare-metal introspection details.
To define the workflows and input parameters for DPDK:

1. Copy the `usr/share/openstack-tripleo-heat-templates/plan-samples/plan-environment-derived-params.yaml` file to a local directory and set the input parameters to suit your environment.

   ```yaml
   workflow_parameters:
   tripleo.derive_params.v1.derive_parameters:
   # DPDK Parameters #
   # Specifies the minimum number of CPU physical cores to be allocated for DPDK
   # PMD threads. The actual allocation will be based on network config, if
   # the a DPDK port is associated with a numa node, then this configuration
   # will be used, else 1.
   num_phy_cores_per_numa_node_for_pmd: 1
   # Amount of memory to be configured as huge pages in percentage. Out the
   # total available memory (excluding the NovaReservedHostMemory), the
   # specified percentage of the remaining is configured as huge pages.
   huge_page_allocation_percentage: 50
   ```

2. Run the `openstack overcloud deploy` command and include the following information:

   - The `update-plan-only` option
   - The role file and all environment files specific to your environment
   - The `plan-environment-derived-parms.yaml` file with the `--plan-environment-file` optional argument

   ```bash
   $ openstack overcloud deploy --templates --update-plan-only
   -r /home/stack/roles_data.yaml
   -e /home/stack/<environment-file>
   ... #repeat as necessary ...
   **-p /home/stack/plan-environment-derived-params.yaml**
   ```

   The output of this command shows the derived results, which are also merged into the `plan-environment.yaml` file.

   Started Mistral Workflow tripleo.validations.v1.check_pre_deployment_validations. Execution ID: 55ba73f2-2ef4-4da1-94e9-eae2fdcf35535
   Waiting for messages on queue '472a4180-e91b-4f9e-bd4c-1fbdfbcf414f' with no timeout.
   Removing the current plan files
   Uploading new plan files
   Started Mistral Workflow tripleo.plan_management.v1.update_deployment_plan. Execution ID: 7fa995f3-7e0f-4c9e-9234-dd5292e8c722
   Plan updated.
   Processing templates in the directory /tmp/tripleoclient-SY6RcY/tripleo-heat-templates
   Invoking workflow (tripleo.derive_params.v1.derive_parameters) specified in plan-environment file
   Started Mistral Workflow tripleo.derive_params.v1.derive Parameters. Execution ID: 2d4572bf-4c5b-41f8-8981-c84a363dd95b
   Workflow execution is completed. result:
   ComputeOvsDpdkParameters:
   IsolCpusList: 1, 2, 3, 4, 5, 6, 7, 9, 10, 17, 18, 19, 20, 21, 22, 23, 11, 12, 13, 14, 15, 25, 26, 27, 28, 29, 30, 31
   KernelArgs: default_hugepagesz=1GB hugepagesz=1G hugepages=32 iommu=pt intel_iommu=on
   isolcpus=1, 2, 3, 4, 5, 6, 7, 9, 10, 17, 18, 19, 20, 21, 22, 23, 11, 12, 13, 14, 15, 25, 26, 27, 28, 29, 30, 31
   NovaReservedHostMemory: 4096
NOTE

The **OvsDpdkMemoryChannels** parameter cannot be derived from introspection details. In most cases, this value should be 4.

**Deploy the overcloud with the derived parameters**

To deploy the overcloud with these derived parameters:

1. Copy the derived parameters from the deploy command output to the **network-environment.yaml** file.

```yaml
# DPDK compute node.
ComputeOvsDpdkParameters:
    KernelArgs: default_hugepagesz=1GB hugepagesz=1G hugepages=32 iommu=pt
    intel_iommu=on
    TunedProfileName: "cpu-partitioning"
    IsolCpusList: "1,2,3,4,5,6,7,9,10,13,14,15,16,23,25,26,27,28,29,30,31"
    NovaComputeCpuDedicatedSet: ['2,3,4,5,6,7,18,19,20,21,22,23,11,12,13,14,15,26,27,28,29,30,31']
    NovaReservedHostMemory: 4096
    OvsDpdkSocketMemory: "1024,1024"
    OvsDpdkMemoryChannels: "4"
    OvsPmdCoreList: "0,16,8,24"
    OvsPmdCoreList: "1,17,9,25"
```

2. Deploy the overcloud using the role file and all environment files specific to your environment.

```
openstack overcloud deploy --templates \
-r /home/stack/roles_data.yaml \
-e /home/stack/<environment-file> \
... #repeat as necessary ...
```
NOTE

In a cluster with Compute, ComputeOvsDpdk, and ComputeSriov, the workflow applies the formula only for the ComputeOvsDpdk role, not Compute or ComputeSriovs.

8.2. OVS-DPDK TOPOLOGY

With Red Hat OpenStack Platform, you can create custom deployment roles, using the composable roles feature to add or remove services from each role. For more information on Composable Roles, see Composable Services and Custom Roles in Advanced Overcloud Customization.

This image shows a example OVS-DPDK topology with two bonded ports for the control plane and data plane:

To configure OVS-DPDK, perform the following tasks:

- If you use composable roles, copy and modify the roles_data.yaml file to add the custom role for OVS-DPDK.
- Update the appropriate `network-environment.yaml` file to include parameters for kernel arguments, and DPDK arguments.

- Update the `compute.yaml` file to include the bridge for DPDK interface parameters.

- Update the `controller.yaml` file to include the same bridge details for DPDK interface parameters.

- Run the `overcloud_deploy.sh` script to deploy the overcloud with the DPDK parameters.

**NOTE**

This guide provides examples for CPU assignments, memory allocation, and NIC configurations that can vary from your topology and use case. For more information on hardware and configuration options, see: Network Functions Virtualization Product Guide and Chapter 2, Hardware requirements.

**Prerequisites**

- OVS 2.10

- DPDK 17

- A supported NIC. To view the list of supported NICs for NFV, see Section 2.1, “Tested NICs”.

**NOTE**

The Red Hat OpenStack Platform operates in OVS client mode for OVS-DPDK deployments.

### 8.3. Setting the MTU Value for OVS-DPDK Interfaces

Red Hat OpenStack Platform supports jumbo frames for OVS-DPDK. To set the maximum transmission unit (MTU) value for jumbo frames you must:

- Set the global MTU value for networking in the `network-environment.yaml` file.

- Set the physical DPDK port MTU value in the `compute.yaml` file. This value is also used by the vhost user interface.

- Set the MTU value within any guest instances on the Compute node to ensure that you have a comparable MTU value from end to end in your configuration.

**NOTE**

VXLAN packets include an extra 50 bytes in the header. Calculate your MTU requirements based on these additional header bytes. For example, an MTU value of 9000 means the VXLAN tunnel MTU value is 8950 to account for these extra bytes.
NOTE

You do not need any special configuration for the physical NIC because the NIC is controlled by the DPDK PMD, and has the same MTU value set by the `compute.yaml` file. You cannot set an MTU value larger than the maximum value supported by the physical NIC.

To set the MTU value for OVS-DPDK interfaces:

   ```yaml
   parameter_defaults:
     # MTU global configuration
     NeutronGlobalPhysnetMtu: 9000
   
   NOTE

   Ensure that the NeutronDpdkSocketMemory value in the `network-environment.yaml` file is large enough to support jumbo frames. For details, see Section 7.4.2, "Memory parameters".

2. Set the MTU value on the bridge to the Compute node in the `controller.yaml` file.

   ```yaml
   -
     type: ovs_bridge
     name: br-link0
     use_dhcp: false
     members:
       -
         type: interface
         name: nic3
         mtu: 9000
   
3. Set the MTU values for an OVS-DPDK bond in the `compute.yaml` file:

   ```yaml
   - type: ovs_user_bridge
     name: br-link0
     use_dhcp: false
     members:
       - type: ovs_dpdk_bond
         name: dpdkbond0
         mtu: 9000
         rx_queue: 2
         members:
           - type: ovs_dpdk_port
             name: dpdk0
             mtu: 9000
             members:
               - type: interface
                 name: nic4
               - type: ovs_dpdk_port
                 name: dpdk1
                 mtu: 9000
   ```
8.4. CONFIGURING A FIREWALL FOR SECURITY GROUPS

Dataplane interfaces require high performance in a stateful firewall. To protect these interfaces, consider deploying a telco-grade firewall as a virtual network function (VNF).

To configure control plane interfaces, set the `NeutronOVSFirewallDriver` parameter to `openvswitch`. To use the flow-based OVS firewall driver, modify the `network-environment.yaml` file under `parameter_defaults`.

Example:

```
parameter_defaults:
  NeutronOVSFirewallDriver: openvswitch
```

Use the `openstack port set` command to disable the OVS firewall driver for dataplane interfaces.

Example:

```
openstack port set --no-security-group --disable-port-security ${PORT}
```

8.5. SETTING MULTIQUEUE FOR OVS-DPDK INTERFACES

To set the same number of queues for interfaces in OVS-DPDK on the Compute node, modify the `compute.yaml` file:

```
- type: ovs_user_bridge
  name: br-link0
  use_dhcp: false
  members:
    - type: ovs_dpdk_bond
      name: dpdkbond0
      mtu: 9000
      rx_queue: 2
      members:
        - type: ovs_dpdk_port
          name: dpdk0
          mtu: 9000
          members:
            - type: interface
              name: nic4
        - type: ovs_dpdk_port
          name: dpdk1
          mtu: 9000
          members:
            - type: interface
              name: nic5
```

8.6. KNOWN LIMITATIONS
Observe the following limitations when configuring OVS-DPDK with Red Hat OpenStack Platform for NFV:

- Use Linux bonds for control plane networks. Ensure that both the PCI devices used in the bond are on the same NUMA node for optimum performance. Neutron Linux bridge configuration is not supported by Red Hat.

- You require huge pages for every instance running on the hosts with OVS-DPDK. If huge pages are not present in the guest, the interface appears but does not function.

- With OVS-DPDK, there is a performance degradation of services that use tap devices, such as Distributed Virtual Routing (DVR). The resulting performance is not suitable for a production environment.

- When using OVS-DPDK, all bridges on the same Compute node must be of type `ovs_user_bridge`. The director may accept the configuration, but Red Hat OpenStack Platform does not support mixing `ovs_bridge` and `ovs_user_bridge` on the same node.

### 8.7. Creating a Flavor and Deploying an Instance for OVS-DPDK

After you configure OVS-DPDK for your Red Hat OpenStack Platform deployment with NFV, you can create a flavor, and deploy an instance using the following steps:

1. Create an aggregate group, and add relevant hosts for OVS-DPDK. Define metadata, for example `dpdk=true`, that matches defined flavor metadata.

   ```bash
   # openstack aggregate create dpdk_group
   # openstack aggregate add host dpdk_group [compute-host]
   # openstack aggregate set --property dpdk=true dpdk_group
   ```

   **NOTE**
   Pinned CPU instances can be located on the same Compute node as unpinned instances. For more information, see Configuring CPU pinning on the Compute node in the Instances and Images Guide.

2. Create a flavor.

   ```bash
   # openstack flavor create <flavor> --ram <MB> --disk <GB> --vcpus <#>
   ```

3. Set additional flavor properties. Note that the defined metadata, `dpdk=true`, matches the defined metadata in the DPDK aggregate.

   ```bash
   # openstack flavor set <flavor> --property dpdk=true --property hw:cpu_policy=dedicated --property hw:mem_page_size=1GB --property hw:emulator_threads_policy=isolate
   ```

   In this example, `m1.medium_huge_4cpu` is the flavor name, and the remaining parameters set the other properties for the flavor.

   For details on the emulator threads policy for performance improvements, see: Configure Emulator Threads to run on a Dedicated Physical CPU.

4. Create the network.
5. Deploy an instance.

```bash
# openstack server create --flavor <flavor> --image <glance image> --nic net-id=<network ID>
```

With multi-queue in OVS-DPDK, set the `hw_vif_multiqueue_enabled` property on an image before you set the `hw.vif_multiqueue_enabled` property on a flavor:

6. Set the image properties.

```bash
# openstack image set --property hw_vif_multiqueue_enabled=true <image>
```

7. Set additional flavor properties.

```bash
# openstack flavor set --property hw:vif_multiqueue_enabled=true <flavor>
```

8.8. TROUBLESHOOTING THE CONFIGURATION

This section describes the steps to troubleshoot the OVS-DPDK configuration.

1. Review the bridge configuration, and confirm that the bridge has `datapath_type=netdev`.

```bash
# ovs-vsctl list bridge br0
   _uuid               : bdce0825-e263-4d15-b256-f01222df96f3
   auto_attach         : []
   controller          : []
   datapath_id         : "00002608cebd154d"
   datapath_type       : netdev
   datapath_version    : "<built-in>"
   external_ids        : {}
   fail_mode           : []
   flood_vlans         : []
   flow_tables         : {}
   ipfix               : []
   mcast_snooping_enable: false
   mirrors             : []
   name                : "br0"
   netflow             : []
   other_config        : {}
   ports               : [52725b91-de7f-41e7-bb49-3b7e50354138]
   protocols           : []
   rstp_enable         : false
   rstp_status         : {}
   sflow               : []
   status              : {}
   stp_enable          : false
```

2. Confirm that the docker container `neutron_ovs_agent` is configured to start automatically.
# docker inspect neutron_ovs_agent | grep -A1 RestartPolicy
"RestartPolicy": {
    "Name": "always",
}

3. Optionally, you can view logs for errors, such as if the container fails to start.

```
# less /var/log/containers/neutron/openvswitch-agent.log
```

4. Confirm that the Poll Mode Driver CPU mask of the `ovs-dpdk` is pinned to the CPUs. In case of hyper threading, use sibling CPUs.
   For example, to check the sibling of `CPU4`, run the following command:

```
# cat /sys/devices/system/cpu/cpu4/topology/thread_siblings_list
```

The sibling of `CPU4` is `CPU20`, therefore proceed with the following command:

```
# ovs-vsctl set Open_vSwitch . other_config:pmd-cpu-mask=0x100010
```

Display the status:

```
# tuna -t ovs-vswitchd -CP
thread  ctxt_switches pid  SCHED_  rtpri  affinity voluntary nonvoluntary  cmd
   3161 OTHER  0  6 765023     614 ovs-vswitchd
   3219 OTHER  0  6  1     0     0 handler24
   3220 OTHER  0  6  1     0     0 handler21

```
CHAPTER 9. TUNING A RED HAT OPENSTACK PLATFORM ENVIRONMENT

9.1. PINNING EMULATOR THREADS

Emulator threads handle interrupt requests and non-blocking processes for virtual machine hardware emulation. These threads float across the CPUs that the guest uses for processing. If threads used for the poll mode driver (PMD) or real-time processing run on these guest CPUs, you can experience packet loss or missed deadlines.

You can separate emulator threads from VM processing tasks by pinning the threads to their own guest CPUs, increasing performance as a result.

9.1.1. Configuring CPUs to host emulator threads

To improve performance, reserve a subset of host CPUs identified in the `OvsDpdkCoreList` parameter for hosting emulator threads.

Procedure

1. Deploy an overcloud with `NovaComputeCpuSharedSet` defined for a given role. The value of `NovaComputeCpuSharedSet` applies to the `cpu_shared_set` parameter in the `nova.conf` file for hosts within that role.

```plaintext
parameter_defaults:
    ComputeOvsDpdkParameters:
        OvsDpdkCoreList: "0-1,16-17"
        NovaComputeCpuSharedSet: "0-1,16-17"
        NovaComputeCpuDedicatedSet: "2-15,18-31"
```

2. Create a flavor to build instances with emulator threads separated into a shared pool.

```plaintext
openstack flavor create --ram <size_mb> --disk <size_gb> --vcpus <vcpus> <flavor>
```

3. Add the `hw:emulator_threads_policy` extra specification, and set the value to `share`. Instances created with this flavor will use the instance CPUs defined in the `cpu_share_set` parameter in the `nova.conf` file.

```plaintext
openstack flavor set <flavor> --property hw:emulator_threads_policy=share
```

**NOTE**

You must set the `cpu_share_set` parameter in the `nova.conf` file to enable the share policy for this extra specification. You should use heat for this preferably, as editing `nova.conf` manually might not persist across redeployments.

9.1.2. Verify the emulator thread pinning

Procedure

1. Identify the host and name for a given instance.
openstack server show <instance_id>

2. Use SSH to log on to the identified host as heat-admin.

ssh heat-admin@compute-1

[compute-1]$ sudo virsh dumpxml instance-00001 | grep `emulatorpin cpuset`

9.2. ENABLING RT-KVM FOR NFV WORK LOADS

To facilitate installing and configuring Red Hat Enterprise Linux 8.0 Real Time KVM (RT-KVM), Red Hat OpenStack Platform provides the following features:

- A real-time Compute node role that provisions Red Hat Enterprise Linux for real-time.
- The additional RT-KVM kernel module.
- Automatic configuration of the Compute node.

9.2.1. Planning for your RT-KVM Compute nodes

You must use Red Hat certified servers for your RT-KVM Compute nodes. For more information, see: Red Hat Enterprise Linux for Real Time 7 certified servers.

For details on how to enable the rhel-8-server-nfv-rpms repository for RT-KVM, and ensuring your system is up to date, see: Registering and updating your undercloud.

NOTE

You need a separate subscription to a Red Hat OpenStack Platform for Real Time SKU before you can access this repository.

Building the real-time image

1. Install the libguestfs-tools package on the undercloud to get the virt-customize tool:

   (undercloud) [stack@undercloud-0 ~]$ sudo dnf install libguestfs-tools

2. Extract the images:

   (undercloud) [stack@undercloud-0 ~]$ tar -xf /usr/share/rhosp-director-images/overcloud-full.tar
   (undercloud) [stack@undercloud-0 ~]$ tar -xf /usr/share/rhosp-director-images/ironic-python-agent.tar

3. Copy the default image:

   (undercloud) [stack@undercloud-0 ~]$ cp overcloud-full.qcow2 overcloud-realtime-compute.qcow2

4. Register your image to enable Red Hat repositories relevant to your customizations. Replace [username] and [password] with valid credentials in the following example.
virt-customize -a overcloud-realtime-compute.qcow2 --run-command 'subscription-manager register --username=[username] --password=[password]'

NOTE

For security, you can remove credentials from the history file if they are used on the command prompt. You can delete individual lines in history using the `history -d` command followed by the line number.

5. Find a list of pool IDs from your account’s subscriptions, and attach the appropriate pool ID to your image.

    sudo subscription-manager list --all --available | less
    ...
    virt-customize -a overcloud-realtime-compute.qcow2 --run-command 'subscription-manager attach --pool [pool-ID]'

6. Add the repositories necessary for Red Hat OpenStack Platform with NFV.

    virt-customize -a overcloud-realtime-compute.qcow2 --run-command 'sudo subscription-manager repos --enable=rhel-8-for-x86_64-baseos-rpms --enable=rhel-8-for-x86_64-appstream-rpms --enable=rhel-8-for-x86_64-highavailability-rpms --enable=ansible-2.8-for-rhel-8-x86_64-rpms --enable=openstack-16-for-rhel-8-x86_64-rpms --enable=rhel-8-for-x86_64-nfv-rpms --enable=advanced-virt-for-rhel-8-x86_64-rpms --enable=fast-datapath-for-rhel-8-x86_64-rpms'

7. Create a script to configure real-time capabilities on the image.

    (undercloud) [stack@undercloud-0 ~]$ cat <<'EOF' > rt.sh
    #!/bin/bash
    set -eux
    dnf -v -y --setopt=protected_packages= erase kernel.$(uname -m)
    dnf -v -y install kernel-rt kernel-rt-kvm tuned-profiles-nfv-host
    EOF

8. Run the script to configure the real-time image:

    (undercloud) [stack@undercloud-0 ~]$ virt-customize -a overcloud-realtime-compute.qcow2 -v --run rt.sh 2>&1 | tee virt-customize.log

NOTE

If you see the following line in the `rt.sh` script output, "grubby fatal error: unable to find a suitable template", you can ignore this error.

9. Examine the `virt-customize.log` file that resulted from the previous command, to check that the packages installed correctly using the `rt.sh` script.
10. Relabel SELinux:

```
(undercloud) [stack@undercloud-0 ~]$ virt-customize -a overcloud-realtime-compute.qcow2 -selinux-relabel
```

11. Extract vmlinux and initrd:

```
(undercloud) [stack@undercloud-0 ~]$ mkdir image
(undercloud) [stack@undercloud-0 ~]$ guestmount -a overcloud-realtime-compute.qcow2 -i -ro image
(undercloud) [stack@undercloud-0 ~]$ cp image/boot/vmlinuz-3.10.0-862.rt56.804.el7.x86_64 ./overcloud-realtime-compute.vmlinuz
(undercloud) [stack@undercloud-0 ~]$ cp image/boot/initramfs-3.10.0-862.rt56.804.el7.x86_64.img ./overcloud-realtime-compute.initrd
(undercloud) [stack@undercloud-0 ~]$ guestunmount image
```

**NOTE**

The software version in the `vmlinuz` and `initramfs` filenames vary with the kernel version.

12. Upload the image:

```
(undercloud) [stack@undercloud-0 ~]$ openstack overcloud image upload --update-existing -os-image-name overcloud-realtime-compute.qcow2
```

You now have a real-time image you can use with the `ComputeOvsDpdkRT` composable role on your selected Compute nodes.

**Modifying BIOS settings on RT-KVM Compute nodes**

To reduce latency on your RT-KVM Compute nodes, disable all options for the following parameters in your Compute node BIOS settings:

- Power Management
- Hyper-Threading
- CPU sleep states
- Logical processors
For descriptions of these settings and the impact of disabling them, see: Setting BIOS parameters. See your hardware manufacturer documentation for complete details on how to change BIOS settings.

9.2.2. Configuring OVS-DPDK with RT-KVM

NOTE

You must determine the best values for the OVS-DPDK parameters that you set in the network-environment.yaml file to optimize your OpenStack network for OVS-DPDK. For more details, see Section 8.1, “Deriving DPDK parameters with workflows”.

9.2.2.1. Generating the ComputeOvsDpdk composable role

Use the ComputeOvsDpdkRT role to specify Compute nodes for the real-time compute image.

Generate roles_data.yaml for the ComputeOvsDpdkRT role.

```bash
# (undercloud) [stack@undercloud-0 ~]$ openstack overcloud roles generate -o roles_data.yaml
Controller ComputeOvsDpdkRT
```

9.2.2.2. Configuring the OVS-DPDK parameters

IMPORTANT

Determine the best values for the OVS-DPDK parameters in the network-environment.yaml file to optimize your deployment. For more information, see Section 8.1, “Deriving DPDK parameters with workflows”.

1. Add the NIC configuration for the OVS-DPDK role you use under resource_registry:

   ```yaml
   resource_registry:
   # Specify the relative/absolute path to the config files you want to use for override the default.
   OS::TripleO::ComputeOvsDpdkRT::Net::SoftwareConfig: nic-configs/compute-ovs-dpdk.yaml
   OS::TripleO::Controller::Net::SoftwareConfig: nic-configs/controller.yaml
   # DPDK compute node.
   ComputeOvsDpdkRTParameters:
   KernelArgs: "default_hugepagesz=1GB hugepagesz=1G hugepages=32 iommu=pt intel_iommu=on isolcpus=1-7,17-23,9-15,25-31"
   TunedProfileName: "realtime-virtual-host"
   IsolCpusList:
   "1,2,3,4,5,6,7,9,10,17,18,19,20,21,22,23,11,12,13,14,15,25,26,27,28,29,30,31"
   NovaComputeCpuDedicatedSet:
   ["2,3,4,5,6,7,18,19,20,21,22,23,10,11,12,13,14,15,26,27,28,29,30,31"]
   NovaReservedHostMemory: 4096
   OvsDpdkSocketMemory: 1024,1024
   OvsDpdkMemoryChannels: 4
   OvsDpdkCoreList: 0,16,8,24"
   ```
9.2.2.3. Deploying the overcloud

Deploy the overcloud for ML2-OVS:

```
(undercloud) [stack@undercloud-0 ~]$ openstack overcloud deploy \
--templates \
-r /home/stack/ospd-16-vlan-dpdk-ctlplane-bonding-rt/roles_data.yaml \
-e /usr/share/openstack-tripleo-heat-templates/environments/network-isolation.yaml \
-e /usr/share/openstack-tripleo-heat-templates/environments/services/neutron-ovs.yaml \
-e /usr/share/openstack-tripleo-heat-templates/environments/services/neutron-ovs-dpdk.yaml \
-e /home/stack/ospd-16-vxlan-dpdk-data-bonding-rt-hybrid/containers-prepare-parameter.yaml \
```

9.2.3. Launching an RT-KVM instance

Perform the following steps to launch an RT-KVM instance on a real-time enabled Compute node:

1. Create an RT-KVM flavor on the overcloud:

   ```
   # openstack flavor create  r1.small 99 4096 20 4
   # openstack flavor set --property hw:cpu_policy=dedicated 99
   # openstack flavor set --property hw:cpu_realtime=yes 99
   # openstack flavor set --property hw:mem_page_size=1GB 99
   # openstack flavor set --property hw:cpu_realtime_mask="^0-1" 99
   # openstack flavor set --property hw:cpu_emulator_threads=isolate 99
   ```

2. Launch an RT-KVM instance:

   ```
   # openstack server create  --image <rhel> --flavor r1.small --nic net-id=<dpdk-net> test-rt
   ```

3. To verify that the instance uses the assigned emulator threads, run the following command:

   ```
   # virsh dumpxml <instance-id> | grep vcpu -A1
   <vcpu placement='static'>4</vcpu>
   <cputune>
     <vcpupin vcpu='0' cpuset='1'/>
     <vcpupin vcpu='1' cpuset='3'/>
     <vcpupin vcpu='2' cpuset='5'/>
     <vcpupin vcpu='3' cpuset='7'/>
     <emulatorpin cpuset='0-1'/>
     <vcpusched vcpu='2-3' scheduler='lifo'
       priority='1'/>
   </cputune>
   ```

9.3. TRUSTED VIRTUAL FUNCTIONS

You can configure trust between physical functions (PFs) and virtual functions (VFs), so that VFs can perform privileged actions, such as enabling promiscuous mode, or modifying a hardware address.
9.3.1. Configuring trust between virtual and physical functions

Prerequisites

- An operational installation of Red Hat OpenStack Platform including director

Procedure

Complete the following steps to configure and deploy the overcloud with trust between physical and virtual functions:

1. Add the `NeutronPhysicalDevMappings` parameter in the `parameter_defaults` section to link between the logical network name and the physical interface.

   ```
   parameter_defaults:
   NeutronPhysicalDevMappings: "sriov2:p5p2"
   ```

2. Add the new property, `trusted`, to the SR-IOV parameters.

   ```
   parameter_defaults:
   NeutronPhysicalDevMappings: "sriov2:p5p2"
   NeutronSriovNumVFs: ["p5p2:8"]
   NovaPCIPassthrough:
   - devname: "p5p2"
     physical_network: "sriov2"
     trusted: "true"
   ```

   **NOTICE**

   You must include double quotation marks around the value "true".

   **IMPORTANT**

   Complete the following step in trusted environments, as it allows trusted port binding by non-administrative accounts.

3. Modify permissions to allow users to create and update port bindings.

   ```
   parameter_defaults:
   NeutronApiPolicies: {
     operator_create_binding_profile: { key: 'create_port:binding:profile', value: 'rule:admin_or_network_owner' },
     operator_get_binding_profile: { key: 'get_port:binding:profile', value: 'rule:admin_or_network_owner' },
     operator_update_binding_profile: { key: 'update_port:binding:profile', value: 'rule:admin_or_network_owner' }
   }
   ```

9.3.2. Utilizing trusted VF networks

1. Create a network of type `vlan`. 
openstack network create trusted_vf_network  --provider-network-type vlan \  --provider-segment 111 --provider-physical-network sriov2 \  --external --disable-port-security

2. Create a subnet.

openstack subnet create --network trusted_vf_network \  --ip-version 4 --subnet-range 192.168.111.0/24 --no-dhcp \ subnet-trusted_vf_network

3. Create a port. Set the vnic-type option to direct, and the binding-profile option to true.

openstack port create --network sriov111 \  --vnic-type direct --binding-profile trusted=true \ sriov111_port_trusted

4. Create an instance, and bind it to the previously-created trusted port.

openstack server create --image rhel --flavor dpdk  --network internal --port trusted_vf_network_port_trusted --config-drive True --wait rhel-dpdk-sriov_trusted

Verify the trusted VF configuration on the hypervisor

1. On the compute node that you created the instance, run the following command:

```
# ip link
7: p5p2: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 9000 qdisc mq state UP mode
DEFAULT group default qlen 1000
link/ether b4:96:91:1c:40:fa brd ff:ff:ff:ff:ff:ff
vf 6 MAC fa:16:3e:b8:91:c2, vlan 111, spoof checking off, link-state auto, trust on, query_rss off
vf 7 MAC fa:16:3e:84:cf:c8, vlan 111, spoof checking off, link-state auto, trust off, query_rss off
```

1. Verify that the trust status of the VF is trust on. The example output contains details of an environment that contains two ports. Note that vf 6 contains the text trust on.

9.4. CONFIGURING RX/TX QUEUE SIZE

You can experience packet loss at high packet rates above 3.5 million packets per second (mpps) for many reasons, such as:

- a network interrupt
- a SMI
- packet processing latency in the Virtual Network Function

To prevent packet loss, increase the queue size from the default of 512 to a maximum of 1024.

**Prerequisites**

- To configure RX, ensure that you have libvirt v2.3 and QEMU v2.7.
- To configure TX, ensure that you have libvirt v3.7 and QEMU v2.10.
Procedure

- To increase the RX and TX queue size, include the following lines to the `parameter_defaults:` section of a relevant director role. Here is an example with ComputeOvsDpdk role:

```yaml
parameter_defaults:
  ComputeOvsDpdkParameters:
  - NovaLibvirtRxQueueSize: 1024
  - NovaLibvirtTxQueueSize: 1024
```

Testing

- You can observe the values for RX queue size and TX queue size in the nova.conf file:

```plaintext
[libvirt]
rx_queue_size=1024
tx_queue_size=1024
```

- You can check the values for RX queue size and TX queue size in the VM instance XML file generated by libvirt on the compute host.

```xml
<devices>
  <interface type='vhostuser'>
    <mac address='56:48:4f:4d:5e:6f'/>
    <source type='unix' path='/tmp/vhost-user1' mode='server'/>
    <model type='virtio'/>
    <driver name='vhost' rx_queue_size='1024' tx_queue_size='1024' />
    <address type='pci' domain='0x0000' bus='0x00' slot='0x10' function='0x0'/>
  </interface>
</devices>
```

To verify the values for RX queue size and TX queue size, use the following command on a KVM host:

```bash
$ virsh dumpxml <vm name> | grep queue_size
```

- You can check for improved performance, such as 3.8 mpps/core at 0 frame loss.

9.5. CONFIGURING A NUMA-AWARE VSWITCH

Before you implement a NUMA-aware vSwitch, examine the following components of your hardware configuration:

- The number of physical networks.
- The placement of PCI cards.
- The physical architecture of the servers.

Memory-mapped I/O (MMIO) devices, such as PCIe NICs, are associated with specific NUMA nodes. When a VM and the NIC are on different NUMA nodes, there is a significant decrease in performance. To increase performance, align PCIe NIC placement and instance processing on the same NUMA node.
Use this feature to ensure that instances that share a physical network are located on the same NUMA node. To optimize datacenter hardware, you can leverage load-sharing VMs by using multiple networks, different network types, or bonding.

**IMPORTANT**

To architect NUMA-node load sharing and network access correctly, you must understand the mapping of the PCIe slot and the NUMA node. For detailed information on your specific hardware, refer to your vendor’s documentation.

To prevent a cross-NUMA configuration, place the VM on the correct NUMA node, by providing the location of the NIC to Nova.

**Prerequisites**

- You have enabled the filter “NUMATopologyFilter”

**Procedure**

- Set a new `NeutronPhysnetNUMANodesMapping` parameter to map the physical network to the NUMA node that you associate with the physical network.

- If you use tunnels, such as VxLAN or GRE, you must also set the `NeutronTunnelNUMANodes` parameter.

  ```
  parameter_defaults:
  NeutronPhysnetNUMANodesMapping: {<physnet_name>: [<NUMA_NODE>]}
  NeutronTunnelNUMANodes: <NUMA_NODE>,<NUMA_NODE>
  ```

Here is an example with two physical networks tunneled to NUMA node 0:

- one tenant network associated with NUMA node 0
- one management network without any affinity

  ```
  parameter_defaults:
  NeutronBridgeMappings:
  - tenant:br-link0
  NeutronPhysnetNUMANodesMapping: {tenant: [1], mgmt: [0,1]}
  NeutronTunnelNUMANodes: 0
  ```

**Testing**

- Observe the configuration in the file `/var/lib/config-data/puppet-generated/nova_libvirt/etc/nova/nova.conf`

  ```
  [neutron_physnet_tenant]
  numa_nodes=1
  [neutron_tunnel]
  numa_nodes=1
  ```

- Confirm the new configuration with the `lscpu` command:

  ```
  $ lscpu
  ```
Launch a VM, with the NIC attached to the appropriate network

9.6. CONFIGURING QUALITY OF SERVICE (QOS) IN AN NFVI ENVIRONMENT

For details on Configuring QoS, see Configuring Quality-of-Service (QoS) policies. Support is limited to QoS rule type bandwidth-limit on SR-IOV and OVS-DPDK egress interfaces.
CHAPTER 10. EXAMPLE: CONFIGURING OVS-DPDK AND SR-IOV WITH VXLAN TUNNELLING

This section describes how to deploy Compute nodes with both OVS-DPDK and SR-IOV interfaces. The cluster includes ML2/OVS and VXLAN tunnelling.

**IMPORTANT**

You must determine the best values for the OVS-DPDK parameters that you set in the `network-environment.yaml` file to optimize your OpenStack network for OVS-DPDK. For details, see: Deriving DPDK parameters with workflows.

### 10.1. CONFIGURING ROLES DATA

Red Hat OpenStack Platform provides a set of default roles in the `roles_data.yaml` file. You can create your own `roles_data.yaml` file to support the roles you require.

For the purposes of this example, the ComputeOvsDpdkSriov role is created. For information on creating roles in Red Hat OpenStack Platform, see Advanced Overcloud Customization. For details on the specific role used for this example, see `roles_data.yaml`.

### 10.2. CONFIGURING OVS-DPDK PARAMETERS

**IMPORTANT**

You must determine the best values for the OVS-DPDK parameters that you set in the `network-environment.yaml` file to optimize your OpenStack network for OVS-DPDK. For details, see Deriving DPDK parameters with workflows.

1. Add the custom resources for OVS-DPDK under `resource_registry`:

   ```yaml
   resource_registry:
   # Specify the relative/absolute path to the config files you want to use for override the default.
   OS::TripleO::ComputeOvsDpdkSriov::Net::SoftwareConfig: nic-configs/computeovsdpdksriov.yaml
   OS::TripleO::Controller::Net::SoftwareConfig: nic-configs/controller.yaml
   NeutronTunnelTypes: 'vxlan'
   NeutronNetworkType: 'vxlan,vlan'
   # The OVS logical->physical bridge mappings to use.
   NeutronBridgeMappings:
   - dpdk-mgmt:br-link0
   ``

2. Under `parameter_defaults`, set the tunnel type to `vxlan`, and the network type to `vxlan,vlan`:

   ```yaml
   NeutronTunnelTypes: 'vxlan'
   NeutronNetworkType: 'vxlan,vlan'
   ``

3. Under `parameters_defaults`, set the bridge mapping:

   ```yaml
   NeutronBridgeMappings:
   - dpdk-mgmt:br-link0
   ``

4. Under `parameter_defaults`, set the role-specific parameters for the `ComputeOvsDpdkSriov` role:

   ```yaml
   ```
NOTE
To prevent failures during guest creation, assign at least one CPU with sibling thread on each NUMA node. In the example, the values for the `OvsPmdCoreList` parameter denote cores 2 and 22 from NUMA 0, and cores 3 and 23 from NUMA 1.

NOTE
These huge pages are consumed by the virtual machines, and also by OVS-DPDK using the `OvsDpdkSocketMemory` parameter as shown in this procedure. The number of huge pages available for the virtual machines is the `boot` parameter minus the `OvsDpdkSocketMemory`.

You must also add `hw:mem_page_size=1GB` to the flavor you associate with the DPDK instance.

NOTE
`OvsDPDKCoreList` and `OvsDpdkMemoryChannels` are the required settings for this procedure. For optimum operation, ensure you deploy DPDK with appropriate parameters and values.

5. Configure the role-specific parameters for SR-IOV:

NovaPCIPassthrough:
- devname: "p7p3"
  trusted: "true"
  physical_network: "sriov-1"
- devname: "p7p4"
  trusted: "true"
  physical_network: "sriov-2"

10.3. CONFIGURING THE CONTROLLER NODE
1. Create the control-plane Linux bond for an isolated network.

   - type: linux_bond
     name: bond_api
     bonding_options: "mode=active-backup"
     use_dhcp: false
     dns_servers:
       get_param: DnsServers
     members:
       - type: interface
         name: nic2
         primary: true

2. Assign VLANs to this Linux bond.

   - type: vlan
     vlan_id:
       get_param: InternalApiNetworkVlanID
     device: bond_api
     addresses:
       - ip_netmask:
           get_param: InternalApiIpSubnet

   - type: vlan
     vlan_id:
       get_param: StorageNetworkVlanID
     device: bond_api
     addresses:
       - ip_netmask:
           get_param: StorageIpSubnet

   - type: vlan
     vlan_id:
       get_param: StorageMgmtNetworkVlanID
     device: bond_api
     addresses:
       - ip_netmask:
           get_param: StorageMgmtIpSubnet

   - type: vlan
     vlan_id:
       get_param: ExternalNetworkVlanID
     device: bond_api
     addresses:
       - ip_netmask:
           get_param: ExternalIpSubnet
     routes:
       - default: true
         next_hop:
           get_param: ExternalInterfaceDefaultRoute

3. Create the OVS bridge to access **neutron-dhcp-agent** and **neutron-metadata-agent** services.

   - type: ovs_bridge
     name: br-link0
10.4. CONFIGURING THE COMPUTE NODE FOR DPDK AND SR-IOV

Create the `computeovsdpdksriov.yaml` file from the default `compute.yaml` file, and make the following changes:

1. Create the control-plane Linux bond for an isolated network.

   ```yaml
   members:
   - type: interface
     name: nic3
     mtu: 9000
   - type: vlan
     vlan_id:
       get_param: TenantNetworkVlanID
     mtu: 9000
     addresses:
       - ip_netmask:
         get_param: TenantIpSubnet
   - type: interface
     name: nic4
     primary: true
   - type: vlan
     vlan_id:
       get_param: InternalApiNetworkVlanID
     device: bond_api
     addresses:
       - ip_netmask:
         get_param: InternalApiIpSubnet
   - type: vlan
     vlan_id:
       get_param: StorageNetworkVlanID
     device: bond_api
     addresses:
       - ip_netmask:
         get_param: StorageIpSubnet
   ```

2. Assign VLANs to this Linux bond.

   ```yaml
   members:
   - type: interface
     name: nic3
     mtu: 9000
     addresses:
       - ip_netmask:
         get_param: TenantIpSubnet
   ```

3. Set a bridge with a DPDK port to link to the controller.

   ```yaml
   use_dhcp: false
   mtu: 9000
   members:
   - type: interface
     name: nic3
     mtu: 9000
   - type: vlan
     vlan_id:
       get_param: TenantNetworkVlanID
     mtu: 9000
     addresses:
       - ip_netmask:
         get_param: TenantIpSubnet
   ```
- type: ovs_user_bridge
  name: br-link0

          members:
            - type: interface
              name: nic8

**NOTE**

To include multiple DPDK devices, repeat the **type** code section for each DPDK device that you want to add.

**NOTE**

When using OVS-DPDK, all bridges on the same Compute node must be of type `ovs_user_bridge`. Red Hat OpenStack Platform does not support both `ovs_bridge` and `ovs_user_bridge` located on the same node.

### 10.5. DEPLOYING THE OVERCLOUD

1. Run the `overcloud_deploy.sh` script:
There are additional considerations and steps required to upgrade Red Hat OpenStack Platform when you have OVS-DPDK configured. For more information, see Preparing an NFV-Configured Overcloud in the Upgrading Red Hat OpenStack Platform Guide.
CHAPTER 12. NFV PERFORMANCE

Red Hat OpenStack Platform director configures the Compute nodes to enforce resource partitioning and fine tuning to achieve line rate performance for the guest virtual network functions (VNFs). The key performance factors in the NFV use case are throughput, latency, and jitter.

You can enable high-performance packet switching between physical NICs and virtual machines using data plane development kit (DPDK) accelerated virtual machines. OVS 2.10 embeds support for DPDK 17 and includes support for vhost-user multiqueue, allowing scalable performance. OVS-DPDK provides line-rate performance for guest VNFs.

Single root I/O virtualization (SR-IOV) networking provides enhanced performance, including improved throughput for specific networks and virtual machines.

Other important features for performance tuning include huge pages, NUMA alignment, host isolation, and CPU pinning. VNF flavors require huge pages and emulator thread isolation for better performance. Host isolation and CPU pinning improve NFV performance and prevent spurious packet loss.

For a high-level introduction to CPUs and NUMA topology, see: [NFV Performance Considerations](#) and [Configure Emulator Threads to run on a Dedicated Physical CPU](#).
CHAPTER 13. FINDING MORE INFORMATION

The following table includes additional Red Hat documentation for reference:

The Red Hat OpenStack Platform documentation suite can be found here: Red Hat OpenStack Platform Documentation Suite

Table 13.1. List of Available Documentation

<table>
<thead>
<tr>
<th>Component</th>
<th>Reference</th>
</tr>
</thead>
<tbody>
<tr>
<td>Red Hat Enterprise Linux</td>
<td>Red Hat OpenStack Platform is supported on Red Hat Enterprise Linux 8.0. For information on installing Red Hat Enterprise Linux, see the corresponding installation guide at: Red Hat Enterprise Linux Documentation Suite.</td>
</tr>
<tr>
<td>Red Hat OpenStack Platform</td>
<td>To install OpenStack components and their dependencies, use the Red Hat OpenStack Platform director. The director uses a basic OpenStack installation as the undercloud to install, configure, and manage the OpenStack nodes in the final overcloud. You need one extra host machine for the installation of the undercloud, in addition to the environment necessary for the deployed overcloud. For detailed instructions, see Red Hat OpenStack Platform Director Installation and Usage. For information on configuring advanced features for a Red Hat OpenStack Platform enterprise environment using the Red Hat OpenStack Platform director such as network isolation, storage configuration, SSL communication, and general configuration method, see Advanced Overcloud Customization.</td>

APPENDIX A. SAMPLE DPDK SRIOV YAML FILES

This section provides sample yaml files as a reference to add single root I/O virtualization (SR-IOV) and Data Plane Development Kit (DPDK) interfaces on the same compute node.

**NOTE**

These templates are from a fully-configured environment, and include parameters unrelated to NFV, that might not apply to your deployment.

### A.1. SAMPLE VXLAN DPDK SRIOV YAML FILES

#### A.1.1. roles_data.yaml

1. Run the `openstack overcloud roles generate` command to generate the `roles_data.yaml` file. Include role names in the command according to the roles that you want to deploy in your environment, such as `Controller`, `ComputeSriov`, `ComputeOvsDpdkRT`, `ComputeOvsDpdkSriov`, or other roles. For example, to generate a `roles_data.yaml` file that contains the roles `Controller` and `ComputeOvsDpdkSriov`, run the following command:

   ```bash
   $ openstack overcloud roles generate -o roles_data.yaml Controller ComputeOvsDpdkSriov
   ```

   ```yaml
   # File generated by TripleO
   # Role: Controller
   
   - name: Controller
     description: Controller role that has all the controller services loaded and handles Database, Messaging and Network functions.

APPENDIX A. SAMPLE DPDK SRIOV YAML FILES
A.1.4. compute-ovs-dpdk.yaml

heat_template_version: rocky

description: >
  Software Config to drive os-net-config to configure VLANs for the compute role.

parameters:
  ControlPlaneIp:
    default: 
    description: IP address/subnet on the ctlplane network
    type: string
  ExternalIpSubnet:
    default: 
    description: The OsNetConfigImpl resource.
    get_resource: OsNetConfigImpl
description: IP address/subnet on the external network
type: string
ExternalInterfaceRoutes:
default: []
description: >
   Routes for the external network traffic.
   JSON route e.g. 
   ```
   [{'destination': '10.0.0.0/16', 'nexthop': '10.0.0.1'}]
   ```
   Unless the default is changed, the parameter is automatically resolved from the subnet host_routes attribute.
type: json
InternalApiIpSubnet:
default: 

description: IP address/subnet on the internal_api network
type: string
InternalApiInterfaceRoutes:
default: []
description: >
   Routes for the internal_api network traffic.
   JSON route e.g. 
   ```
   [{'destination': '10.0.0.0/16', 'nexthop': '10.0.0.1'}]
   ```
   Unless the default is changed, the parameter is automatically resolved from the subnet host_routes attribute.
type: json
StorageIpSubnet:
default: 

description: IP address/subnet on the storage network
type: string
StorageInterfaceRoutes:
default: []
description: >
   Routes for the storage network traffic.
   JSON route e.g. 
   ```
   [{'destination': '10.0.0.0/16', 'nexthop': '10.0.0.1'}]
   ```
   Unless the default is changed, the parameter is automatically resolved from the subnet host_routes attribute.
type: json
StorageMgmtIpSubnet:
default: 

description: IP address/subnet on the storage_mgmt network
type: string
StorageMgmtInterfaceRoutes:
default: []
description: >
   Routes for the storage_mgmt network traffic.
   JSON route e.g. 
   ```
   [{'destination': '10.0.0.0/16', 'nexthop': '10.0.0.1'}]
   ```
   Unless the default is changed, the parameter is automatically resolved from the subnet host_routes attribute.
type: json
TenantIpSubnet:
default: 

description: IP address/subnet on the tenant network
type: string
TenantInterfaceRoutes:
default: []
description: >
   Routes for the tenant network traffic.
   JSON route e.g. 
   ```
   [{'destination': '10.0.0.0/16', 'nexthop': '10.0.0.1'}]
   ```
   Unless the default is changed, the parameter is automatically resolved from the subnet host_routes attribute.
from the subnet host_routes attribute.
type: json
ManagementIpSubnet: # Only populated when including environments/network-management.yaml
default: "
description: IP address/subnet on the management network
type: string
ManagementInterfaceRoutes:
default: []
description: >
Routes for the management network traffic.
JSON route e.g. [{'destination': '10.0.0.0/16', 'nexthop': '10.0.0.1'}]
Unless the default is changed, the parameter is automatically resolved
from the subnet host_routes attribute.
type: json
BondInterfaceOvsOptions:
default: 'bond_mode=active-backup'
description: The ovs_options string for the bond interface. Set things like
  lacp=active and/or bond_mode=balance-slb using this option.
type: string
ExternalNetworkVlanID:
default: 10
description: Vlan ID for the external network traffic.
type: number
InternalApiNetworkVlanID:
default: 20
description: Vlan ID for the internal_api network traffic.
type: number
StorageNetworkVlanID:
default: 30
description: Vlan ID for the storage network traffic.
type: number
StorageMgmtNetworkVlanID:
default: 40
description: Vlan ID for the storage_mgmt network traffic.
type: number
TenantNetworkVlanID:
default: 50
description: Vlan ID for the tenant network traffic.
type: number
ManagementNetworkVlanID:
default: 60
description: Vlan ID for the management network traffic.
type: number
ExternalInterfaceDefaultRoute:
default: '10.0.0.1'
description: default route for the external network
type: string
ControlPlaneSubnetCidr:
default: "
description: >
The subnet CIDR of the control plane network. (The parameter is
automatically resolved from the ctlplane subnet's cidr attribute.)
type: string
ControlPlaneDefaultRoute:
default: "
description: The default route of the control plane network. (The parameter
is automatically resolved from the ctlplane subnet's `gateway_ip` attribute.)
type: string

dnsServers: # Override this via parameter_defaults
default: []
description: >
  DNS servers to use for the Overcloud (2 max for some implementations).
  If not set the nameservers configured in the ctlplane subnet's
dns_nameservers attribute will be used.
type: comma_delimited_list

EC2MetadataIp:
default: 

description: The IP address of the EC2 metadata server. (The parameter
  is automatically resolved from the ctlplane subnet's `host_routes` attribute.)
type: string

ControlPlaneStaticRoutes:
default: []
description: >
  Routes for the ctlplane network traffic. JSON route e.g. 
  `[{"destination":"10.0.0.0/16"," nexthop":"10.0.0.1"}]` Unless
  the default is changed, the parameter is automatically resolved from the subnet `host_routes`
  attribute.
type: json

ControlPlaneMtu:
default: 1500
description: The maximum transmission unit (MTU) size (in bytes) that is guaranteed to pass through the data
  path of the segments
  in the network. (The parameter is automatically resolved from the ctlplane network's `mtu`
  attribute.)
type: number

StorageMtu:
default: 1500
description: The maximum transmission unit (MTU) size (in bytes) that is guaranteed to pass through the data
  path of the segments
  in the Storage network.
type: number

InternalApiMtu:
default: 1500
description: The maximum transmission unit (MTU) size (in bytes) that is guaranteed to pass through the data
  path of the segments
  in the InternalApi network.
type: number

TenantMtu:
default: 1500
description: The maximum transmission unit (MTU) size (in bytes) that is guaranteed to pass through the data
  path of the segments
  in the Tenant network.
type: number
