Abstract

This guide contains important planning information and describes the configuration procedures for single root input/output virtualization (SR-IOV) and dataplane development kit (DPDK) for network functions virtualization infrastructure (NFVI) in your Red Hat OpenStack Platform deployment.

PREFACE

Red Hat OpenStack Platform provides the foundation to build a private or public cloud on top of Red Hat Enterprise Linux. It offers a massively scalable, fault-tolerant platform for the development of cloud-enabled workloads.

This guide describes the steps to plan and configure single root input/output virtualization (SR-IOV) and Open vSwitch with Data Plane Development Kit (OVS-DPDK) using the Red Hat OpenStack Platform director for NFV deployments.
CHAPTER 1. OVERVIEW OF NFV

Network Functions Virtualization (NFV) is a software solution that virtualizes a network function, such as a network switch, on general purpose, cloud-based infrastructure. NFV allows the Communication Service Provider to move away from traditional or proprietary hardware.

For a high-level overview of NFV concepts, see the Network Functions Virtualization Product Guide.

NOTE

OVS-DPDK and SR-IOV configuration depends on your hardware and topology. This guide provides examples for CPU assignments, memory allocation, and NIC configurations that might vary from your topology and use case.

Use Red Hat OpenStack Platform director to isolate specific network types, for example, external, tenant, internal API, and so on. You can deploy a network on a single network interface, or distributed over a multiple-host network interface. With Open vSwitch you can create bonds by assigning multiple interfaces to a single bridge. Configure network isolation in a Red Hat OpenStack Platform installation with template files. If you do not provide template files, the service networks deploy on the provisioning network. There are two types of template configuration files:

- network-environment.yaml - this file contains network details, such as subnets and IP address ranges, for the overcloud nodes. This file also contains the different settings that override the default parameter values for various scenarios.

- Host network templates, for example, compute.yaml and controller.yaml - define the network interface configuration for the overcloud nodes. The values of the network details are provided by the network-environment.yaml file.

These heat template files are located at /usr/share/openstack-tripleo-heat-templates/ on the undercloud node.

The Hardware requirements and Software requirements sections provide more details on how to plan and configure the heat template files for NFV using the Red Hat OpenStack Platform director.

NOTE

You can edit YAML files to configure NFV. For an introduction to the YAML file format, see: YAML in a Nutshell.
CHAPTER 2. HARDWARE REQUIREMENTS

This section describes the hardware requirements for NFV.

You can use Red Hat Technologies Ecosystem to check for a list of certified hardware, software, cloud providers, and components. Choose the category and select the product version.

For a complete list of the certified hardware for Red Hat OpenStack Platform, see Red Hat OpenStack Platform certified hardware.

2.1. TESTED NICS

For a list of tested NICs for NFV, see Network Adapter Support.

If you configure OVS-DPDK on Mellanox ConnectX-4 or ConnectX-5 network interfaces, you must set the corresponding kernel driver in the compute-ovs-dpdk.yaml file:

```yaml
members
  - type: ovs_dpdk_port
    name: dpdk0
    driver: mlx5_core
    members:
      - type: interface
        name: enp3s0f0
```

2.2. DISCOVERING YOUR NUMA NODE TOPOLOGY

When you plan your deployment, you must understand the NUMA topology of your Compute node to partition the CPU and memory resources for optimum performance. To determine the NUMA information, perform one of the following tasks:

- Enable hardware introspection to retrieve this information from bare-metal nodes.
- Log on to each bare-metal node to manually collect the information.

**NOTE**

You must install and configure the undercloud before you can retrieve NUMA information through hardware introspection. For more information about undercloud configuration, see: Director Installation and Usage Guide.

Retrieving hardware introspection details

The Bare Metal service hardware-inspection-extras feature is enabled by default, and you can use it to retrieve hardware details for overcloud configuration. For more information about the inspection_extras parameter in the undercloud.conf file, see Configuring the Director.

For example, the numa_topology collector is part of the hardware-inspection extras and includes the following information for each NUMA node:

- RAM (in kilobytes)
- Physical CPU cores and their sibling threads
NICs associated with the NUMA node

To retrieve the information listed above, substitute <UUID> with the UUID of the bare-metal node to complete the following command:

```
# openstack baremetal introspection data save <UUID> | jq .numa_topology
```

The following example shows the retrieved NUMA information for a bare-metal node:

```json
{
  "cpus": [
    {
      "cpu": 1,
      "thread_siblings": [1, 17],
      "numa_node": 0
    },
    {
      "cpu": 2,
      "thread_siblings": [10, 26],
      "numa_node": 1
    },
    {
      "cpu": 0,
      "thread_siblings": [0, 16],
      "numa_node": 0
    },
    {
      "cpu": 5,
      "thread_siblings": [13, 29],
      "numa_node": 1
    },
    {
      "cpu": 7,
      "thread_siblings": [15, 31],
      "numa_node": 1
    },
    {
      "cpu": 7,
      "thread_siblings": [7,
```

2.3. BIOS SETTINGS

The following table describes the required BIOS settings for NFV:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Setting</th>
</tr>
</thead>
<tbody>
<tr>
<td>C3 Power State</td>
<td>Disabled.</td>
</tr>
<tr>
<td>C6 Power State</td>
<td>Disabled.</td>
</tr>
<tr>
<td>MLC Streamer</td>
<td>Enabled.</td>
</tr>
<tr>
<td>MLC Spacial Prefetcher</td>
<td>Enabled.</td>
</tr>
<tr>
<td>DCU Data Prefetcher</td>
<td>Enabled.</td>
</tr>
<tr>
<td>DCA</td>
<td>Enabled.</td>
</tr>
<tr>
<td>CPU Power and Performance</td>
<td>Performance.</td>
</tr>
<tr>
<td>Memory RAS and Performance Config → NUMA Optimized</td>
<td>Enabled.</td>
</tr>
</tbody>
</table>
### Turbo Boost
- Setting: Disabled.

### VT-d
- Setting: Enabled for Intel cards if VFIO functionality is needed.
CHAPTER 3. SOFTWARE REQUIREMENTS

This section describes the supported configurations and drivers, and subscription details necessary for NFV.

3.1. REGISTERING AND ENABLING REPOSITORIES

To install Red Hat OpenStack Platform, you must register Red Hat OpenStack Platform director using the Red Hat Subscription Manager, and subscribe to the required channels. For more information about registering and updating your undercloud, see Registering your system.

Procedure

1. Register your system with the Content Delivery Network, entering your Customer Portal user name and password when prompted.

   [stack@director ~]$ sudo subscription-manager register

2. Determine the entitlement pool ID for Red Hat OpenStack Platform director, for example {Pool ID} from the following command and output:

   [stack@director ~]$ sudo subscription-manager list --available --all --matches="Red Hat OpenStack"

   Subscription Name:   Name of SKU
   Provides:            Red Hat Single Sign-On
   Red Hat Enterprise Linux Workstation
   Red Hat CloudForms
   Red Hat OpenStack
   Red Hat Software Collections (for RHEL Workstation)
   Red Hat Virtualization
   SKU:                 SKU-Number
   Contract:            Contract-Number
   Pool ID:             {Pool-ID}-123456
   Provides Management: Yes
   Available:           1
   Suggested:           1
   Service Level:       Support-level
   Service Type:        Service-Type
   Subscription Type:   Sub-type
   Ends:                End-date
   System Type:         Physical

3. Include the Pool ID value in the following command to attach the Red Hat OpenStack Platform 16.1 entitlement.

   [stack@director ~]$ sudo subscription-manager attach --pool={Pool-ID}-123456

4. Disable the default repositories.

   subscription-manager repos --disable=*

5. Enable the required repositories for Red Hat OpenStack Platform with NFV.
6. Update your system so you have the latest base system packages.

```
[stack@director ~]$ sudo dnf update -y
[stack@director ~]$ sudo reboot
```

**NOTE**

To register your overcloud nodes, see [Ansible Based Registration](#).

### 3.2. SUPPORTED CONFIGURATIONS FOR NFV DEPLOYMENTS

Red Hat OpenStack Platform (RHOSP) supports the following NFV deployments using director:

- Single root I/O virtualization (SR-IOV)
- Open vSwitch with Data Plane Development Kit (OVS-DPDK)

Additionally, you can deploy RHOSP with any of the following features:

- **Composable roles**
- **Hyper-converged infrastructure**
- **Real-time KVM**
- **OVS hardware offload**

**NOTE**

Red Hat’s embedded OpenDaylight SDN solution was deprecated in RHOSP 14. Red Hat support, including bug fixes, for OpenDaylight ends with the RHOSP 13 lifecycle, planned for June 27, 2021.

RHOSP NFV deployments with Open Virtual Network (OVN) as the default Software Defined Networking (SDN) solution are unsupported. Use the following steps to deploy RHOSP with the OVS mechanism driver:

**Procedure**

1. Modify the `containers-prepare-parameter.yaml` file so that the `neutron_driver` parameter is set to `null`.

```yaml
parameter_defaults:
  ContainerImagePrepare:
    ...
```

```bash
$ sudo subscription-manager repos --enable=rhel-8-for-x86_64-baseos-eus-rpms \
--enable=rhel-8-for-x86_64-appstream-eus-rpms \
--enable=rhel-8-for-x86_64-highavailability-eus-rpms \
--enable=ansible-2.9-for-rhel-8-x86_64-rpms \
--enable=openstack-16.1-for-rhel-8-x86_64-rpms \
--enable=rhel-8-for-x86_64-nfv-rpms \
--enable=advanced-virt-for-rhel-8-x86_64-rpms \
--enable=fast-datapath-for-rhel-8-x86_64-rpms
```
- push_destination: true
  set:
    neutron_driver: null
...

2. Include the neutron-ovs.yaml environment file in the /usr/share/openstack-tripleo-heat-templates/environments/services directory with your deployment script.

```bash
TEMPLATES=/usr/share/openstack-tripleo-heat-templates
openstack overcloud deploy --templates \
  -e ${TEMPLATES}/environments/network-environment.yaml \
  -e ${TEMPLATES}/environments/network-isolation.yaml \
  -e ${TEMPLATES}/environments/services/neutron-ovs.yaml \
  -e ${TEMPLATES}/environments/services/neutron-ovs-dpdk.yaml \
  -e ${TEMPLATES}/environments/services/neutron-sriov.yaml \
  -e /home/stack/containers-prepare-parameter.yaml
```

### 3.3. SUPPORTED DRIVERS

For a complete list of supported drivers, see Component, Plug-In, and Driver Support in Red Hat OpenStack Platform.

For a list of NICs tested for Red Hat OpenStack Platform deployments with NFV, see Tested NICs.

### 3.4. COMPATIBILITY WITH THIRD-PARTY SOFTWARE

For a complete list of products and services tested, supported, and certified to perform with Red Hat OpenStack Platform, see Third Party Software compatible with Red Hat OpenStack Platform. You can filter the list by product version and software category.

For a complete list of products and services tested, supported, and certified to perform with Red Hat Enterprise Linux, see Third Party Software compatible with Red Hat Enterprise Linux. You can filter the list by product version and software category.
CHAPTER 4. NETWORK CONSIDERATIONS

The undercloud host requires at least the following networks:

- **Provisioning network** - Provides DHCP and PXE-boot functions to help discover bare-metal systems for use in the overcloud.

- **External network** - A separate network for remote connectivity to all nodes. The interface connecting to this network requires a routable IP address, either defined statically, or generated dynamically from an external DHCP service.

The minimal overcloud network configuration includes the following NIC configurations:

- **Single NIC configuration** - One NIC for the provisioning network on the native VLAN and tagged VLANs that use subnets for the different overcloud network types.

- **Dual NIC configuration** - One NIC for the provisioning network and the other NIC for the external network.

- **Dual NIC configuration** - One NIC for the provisioning network on the native VLAN, and the other NIC for tagged VLANs that use subnets for different overcloud network types.

- **Multiple NIC configuration** - Each NIC uses a subnet for a different overcloud network type.

For more information on the networking requirements, see **Networking requirements**.
CHAPTER 5. PLANNING AN SR-IOV DEPLOYMENT

Optimize single root I/O virtualization (SR-IOV) deployments for NFV by setting individual parameters based on your Compute node hardware.

See Discovering your NUMA node topology to evaluate your hardware impact on the SR-IOV parameters.

5.1. HARDWARE PARTITIONING FOR AN SR-IOV DEPLOYMENT

To achieve high performance with SR-IOV, partition the resources between the host and the guest.

A typical topology includes 14 cores per NUMA node on dual socket Compute nodes. Both hyper-threading (HT) and non-HT cores are supported. Each core has two sibling threads. One core is dedicated to the host on each NUMA node. The virtual network function (VNF) handles the SR-IOV interface bonding. All the interrupt requests (IRQs) are routed on the host cores. The VNF cores are dedicated to the VNFs. They provide isolation from other VNFs and isolation from the host. Each VNF must use resources on a single NUMA node. The SR-IOV NICs used by the VNF must also be associated with that same NUMA node. This topology does not have a virtualization overhead. The host, OpenStack Networking (neutron), and Compute (nova) configuration parameters are exposed in a single file for ease, consistency, and to avoid incoherence that is fatal to proper isolation, causing preemption, and packet loss. The host and virtual machine isolation depend on a tuned profile, which defines the boot parameters and any Red Hat OpenStack Platform modifications based on the list of isolated CPUs.

5.2. TOPOLOGY OF AN NFV SR-IOV DEPLOYMENT

The following image has two VNFs each with the management interface represented by mgt and the data plane interfaces. The management interface manages the ssh access, and so on. The data plane interfaces bond the VNFs to DPDK to ensure high availability, as VNFs bond the data plane interfaces using the DPDK library. The image also has two provider networks for redundancy. The Compute node has two regular NICs bonded together and shared between the VNF management and the Red Hat OpenStack Platform API management.
The image shows a VNF that uses DPDK at an application level, and has access to SR-IOV virtual functions (VFs) and physical functions (PFs), for better availability or performance, depending on the fabric configuration. DPDK improves performance, while the VF/PF DPDK bonds provide support for failover, and high availability. The VNF vendor must ensure that the DPDK poll mode driver (PMD) supports the SR-IOV card that is being exposed as a VF/PF. The management network uses OVS, therefore the VNF sees a mgmt network device using the standard virtIO drivers. You can use that device to initially connect to the VNF, and ensure that the DPDK application bonds the two VF/PFs.

5.2.1. Topology for NFV SR-IOV without HCI

Observe the topology for SR-IOV without hyper-converged infrastructure (HCI) for NFV in the image below. It consists of compute and controller nodes with 1 Gbps NICs, and the director node.
CHAPTER 6. DEPLOYING SR-IOV TECHNOLOGIES

In your Red Hat OpenStack Platform NFV deployment, you can achieve higher performance with single root I/O virtualization (SR-IOV), when you configure direct access from your instances to a shared PCIe resource through virtual resources.

6.1. PREREQUISITES

- For details on how to install and configure the undercloud before deploying the overcloud, see the Director Installation and Usage Guide.

**NOTE**

Do not manually edit any values in `/etc/tuned/cpu-partitioning-variables.conf` that director heat templates modify.

6.2. CONFIGURING SR-IOV

**NOTE**

The following CPU assignments, memory allocation, and NIC configurations are examples, and might be different from your use case.

1. Generate the built-in `ComputeSriov` to define nodes in the OpenStack cluster that run `NeutronSriovAgent`, `NeutronSriovHostConfig`, and default compute services.

```
# openstack overcloud roles generate \
-o /home/stack/templates/roles_data.yaml \
Controller ComputeSriov
```

2. To prepare the SR-IOV containers, include the `neutron-sriov.yaml` and `roles_data.yaml` files when you generate the `overcloud_images.yaml` file.

```
sudo openstack tripleo container image prepare \
--roles-file ~/templates/roles_data.yaml \
-e /usr/share/openstack-tripleo-heat-templates/environments/services/neutron-sriov.yaml \
-e ~/containers-prepare-parameter.yaml \
--output-env-file=/home/stack/templates/overcloud_images.yaml
```

For more information on container image preparation, see Director Installation and Usage.

3. Configure the parameters for the SR-IOV nodes under `parameter_defaults` appropriately for your cluster, and your hardware configuration. Typically, you add these settings to the `network-environment.yaml` file.

```
NeutronNetworkType: 'vlan'
NeutronNetworkVLANRanges:
  - tenant:22:22
  - tenant:25:25
NeutronTunnelTypes: ''
```

4. In the same file, configure role specific parameters for SR-IOV compute nodes.
NOTE

The `numvfs` parameter replaces the `NeutronSriovNumVFs` parameter in the network configuration templates. Red Hat does not support modification of the `NeutronSriovNumVFs` parameter or the `numvfs` parameter after deployment. If you modify either parameter after deployment, it might cause a disruption for the running instances that have an SR-IOV port on that physical function (PF). In this case, you must hard reboot these instances to make the SR-IOV PCI device available again. The `NovaVcpuPinSet` parameter is now deprecated, and is replaced by `NovaComputeCpuDedicatedSet` for dedicated, pinned workflows.

```
ComputeSriovParameters:
  IsolCpusList: "1-19,21-39"
  KernelArgs: "default_hugepagesz=1GB hugepagesz=1G hugepages=32 iommu=pt
              intel_iommu=on isolcpus=1-19,21-39"
  TunedProfileName: "cpu-partitioning"
  NeutronBridgeMappings:
    - tenant:br-link0
  NeutronPhysicalDevMappings:
    - tenant:p7p1
    - tenant:p7p2
  NovaPCIPassthrough:
    - devname: "p7p1"
      physical_network: "tenant"
    - devname: "p7p2"
      physical_network: "tenant"
  NovaComputeCpuDedicatedSet: ’1-19,21-39’
  NovaReservedHostMemory: 4096
```

5. Configure the SR-IOV enabled interfaces in the `compute.yaml` network configuration template. To create SR-IOV virtual functions (VFs), configure the interfaces as standalone NICs:

```
- type: sriov_pf
  name: p7p3
  mtu: 9000
  numvfs: 10
  use_dhcp: false
  defroute: false
  nm_controlled: true
  hotplug: true
  promisc: false

- type: sriov_pf
  name: p7p4
  mtu: 9000
  numvfs: 10
  use_dhcp: false
  defroute: false
  nm_controlled: true
  hotplug: true
  promisc: false
```

6. Ensure that the list of default filters includes the value `AggreateInstanceExtraSpecsFilter`.

```
NovaSchedulerDefaultFilters:
```
7. Run the overcloud_deploy.sh script.

### 6.3. NIC PARTITIONING

This feature is available in this release as a *Technology Preview*, and therefore is not fully supported by Red Hat. It should only be used for testing, and should not be deployed in a production environment. For more information about Technology Preview features, see [Scope of Coverage Details](#).

You can configure single root I/O virtualization (SR-IOV) so that an Red Hat OpenStack Platform host can use virtual functions (VFs).

When you partition a single, high-speed NIC into multiple VFs, you can use the NIC for both control and data plane traffic. You can then apply a QoS (Quality of Service) priority value to VF interfaces as desired.

**Procedure**

Ensure that you complete the following steps when creating the templates for an overcloud deployment:

1. Use the interface type `sriov_pf` in an `os-net-config` role file to configure a physical function that the host can use.

   ```yaml
   - type: sriov_pf
     name: <interface name>
     use_dhcp: false
     numvfs: <number of vfs>
     promisc: <true/false> #optional (Defaults to true)
   ```

   **NOTE**

   The `numvfs` parameter replaces the `NeutronSriovNumVFs` parameter in the network configuration templates. Red Hat does not support modification of the `NeutronSriovNumVFs` parameter or the `numvfs` parameter after deployment. If you modify either parameter after deployment, it might cause a disruption for the running instances that have an SR-IOV port on that physical function (PF). In this case, you must hard reboot these instances to make the SR-IOV PCI device available again.

2. Use the interface type `sriov_vf` to configure virtual functions in a bond that the host can use.

   ```yaml
   - type: linux_bond
     name: internal_bond
     bonding_options: mode=active-backup
     use_dhcp: false
     members:
       - type: sriov_vf
         device: nic7
         vfid: 1
       - type: sriov_vf
         device: nic8
         vfid: 1
   ```
The VLAN tag must be unique across all VFs that belong to a common PF device. You must assign VLAN tags to an interface type:

- `linux_bond`
- `ovs_bridge`
- `ovs_dpdk_port`

The applicable VF ID range starts at zero, and ends at the maximum number of VFs minus one.

3. To reserve virtual functions for VMs, use the `NovaPCIPassthrough` parameter. You must assign a regex value to the `address` parameter to identify the VFs that you want to pass through to Nova, to be used by virtual instances, and not by the host.
You can obtain these values from `lspci`, so, if necessary, boot a compute node into a Linux environment to obtain this information.

The `lspci` command returns the address of each device in the format `<bus>:<device>:<slot>`. Enter these address values in the `NovaPCIPassthrough` parameter in the following format:

```
NovaPCIPassthrough:
  - physical_network: "sriovnet2"
    address: {"domain": ".*", "bus": "06", "slot": "11", "function": "[5-7]"}
  - physical_network: "sriovnet2"
    address: {"domain": ".*", "bus": "06", "slot": "10", "function": "[5]"}
```

4. Ensure that IOMMU is enabled on all nodes that require NIC partitioning. For example, if you want NIC Partitioning for compute nodes, enable IOMMU using the `KernelArgs` parameter for that role:

```
parameter_defaults:
  ComputeParameters:
    KernelArgs: "intel_iommu=on iommu=pt"
```

**Validation**

1. Check the number of VFs.

```
[root@overcloud-compute-0 heat-admin]# cat /sys/class/net/p4p1/device/sriov_numvfs
10
[root@overcloud-compute-0 heat-admin]# cat /sys/class/net/p4p2/device/sriov_numvfs
10
```

2. Check Linux bonds.
[root@overcloud-compute-0 heat-admin]# cat /proc/net/bonding/intapi_bond
Ethernet Channel Bonding Driver: v3.7.1 (April 27, 2011)

Bonding Mode: fault-tolerance (active-backup)
Primary Slave: None
Currently Active Slave: p4p1_1
MII Status: up
MII Polling Interval (ms): 0
Up Delay (ms): 0
Down Delay (ms): 0
Slave Interface: p4p1_1
MII Status: up
Speed: 10000 Mbps
Duplex: full
Link Failure Count: 0
Permanent HW addr: 16:b4:4c:aa:f0:a8
Slave queue ID: 0
Slave Interface: p4p2_1
MII Status: up
Speed: 10000 Mbps
Duplex: full
Link Failure Count: 0
Permanent HW addr: b6:be:82:ac:51:98
Slave queue ID: 0

[root@overcloud-compute-0 heat-admin]# cat /proc/net/bonding/st_bond
Ethernet Channel Bonding Driver: v3.7.1 (April 27, 2011)

Bonding Mode: fault-tolerance (active-backup)
Primary Slave: None
Currently Active Slave: p4p1_3
MII Status: up
MII Polling Interval (ms): 0
Up Delay (ms): 0
Down Delay (ms): 0
Slave Interface: p4p1_3
MII Status: up
Speed: 10000 Mbps
Duplex: full
Link Failure Count: 0
Permanent HW addr: 9a:86:b7:cc:17:e4
Slave queue ID: 0
Slave Interface: p4p2_3
MII Status: up
Speed: 10000 Mbps
Duplex: full
Link Failure Count: 0
Permanent HW addr: d6:07:f8:78:dd:5b
Slave queue ID: 0

3. List OVS bonds.
Show OVS connections.

[root@overcloud-compute-0 heat-admin]# ovs-vsctl show

cec12069-9d4c-4fa8-bfe4-decfdf258f49
Manager "ptcp:6640:127.0.0.1"

    Interface "dpdk2"
    type: dpdk
If you used **NovaPCIPassthrough** to pass VFs to instances, test by deploying an SR-IOV instance.

The following bond modes are supported:

- balance-slb
- active-backup

### 6.4. Configuring OVS Hardware Offload

The procedure for OVS hardware offload configuration shares many of the same steps as configuring SR-IOV.

**Procedure**

1. Generate the **ComputeSriov** role:
   
   ```bash
   openstack overcloud roles generate -o roles_data.yaml Controller ComputeSriov
   ```

2. Add the **OvsHwOffload** parameter under role-specific parameters with a value of **true**.

3. To configure neutron to use the iptables/hybrid firewall driver implementation, include the line:
NeutronOVSFirewallDriver: iptables_hybrid. For more information about NeutronOVSFirewallDriver, see Using the Open vSwitch Firewall in the Advanced Overcloud Customization Guide.

4. Configure the **physical_network** parameter to match your environment.
   - For VLAN, set the **physical_network** parameter to the name of the network you create in neutron after deployment. This value should also be in NeutronBridgeMappings.
   - For VXLAN, set the **physical_network** parameter to the string value **null**.
   Example:

```
parameter_defaults:
  NeutronOVSFirewallDriver: iptables_hybrid
  ComputeSriovParameters:
    IsolCpusList: 2-9,21-29,11-19,31-39
    KernelArgs: "default_hugepagesz=1GB hugepagesz=1G hugepages=128 intel_iommu=on iommu=pt"
  OvsHwOffload: true
  TunedProfileName: "cpu-partitioning"
  NeutronBridgeMappings:
    - tenant:br-tenant
  NeutronPhysicalDevMappings:
    - tenant:p7p1
    - tenant:p7p2
  NovaPCIPassthrough:
    - devname: "p7p1"
      physical_network: "null"
    - devname: "p7p2"
      physical_network: "null"
  NovaReservedHostMemory: 4096
  NovaComputeCpuDedicatedSet: 1-9,21-29,11-19,31-39
```

5. Ensure that the list of default filters includes **NUMATopologyFilter**:

```
NovaSchedulerDefaultFilters:
  ["RetryFilter","AvailabilityZoneFilter","ComputeFilter","ComputeCapabilitiesFilter","ImagePropertiesFilter","ServerGroupAntiAffinityFilter","ServerGroupAffinityFilter","PciPassthroughFilter","NUMATopologyFilter"]
```

6. Configure one or more network interfaces intended for hardware offload in the **compute-sriov.yaml** configuration file:

```
NOTE

Do not use the **NeutronSriovNumVFs** parameter when configuring Open vSwitch hardware offload. The **numvfs** parameter specifies the number of VFs in a network configuration file used by **os-net-config**.

- type: ovs_bridge
  name: br-tenant
  mtu: 9000
  members:
    - type: sriov_pf
```
name: p7p1
numvfs: 5
mtu: 9000
primary: true
promisc: true
use_dhcp: false
link_mode: switchdev

**NOTE**
Do not configure Mellanox network interfaces as a nic-config interface type ovs-vlan because this prevents tunnel endpoints such as VXLAN from passing traffic due to driver limitations.

7. Include the ovs-hw-offload.yaml file in the overcloud deploy command:

```sh
openstack overcloud deploy --templates \
-r ${CUSTOM_TEMPLATES}/roles_data.yaml \
-e ${TEMPLATES_HOME}/environments/ovs-hw-offload.yaml \
-e ${CUSTOM_TEMPLATES}/network-environment.yaml \
-e ${CUSTOM_TEMPLATES}/neutron-ovs.yaml
```

6.4.1. Verifying OVS hardware offload

1. Confirm that a PCI device is in switchdev mode:

   ```sh
   # devlink dev eswitch show pci/0000:03:00.0
   pci/0000:03:00.0: mode switchdev inline-mode none encap enable
   ```

2. Verify if offload is enabled in OVS:

   ```sh
   # ovs-vsctl get Open_vSwitch . other_config:hw-offload
   "true"
   ```

6.5. TUNING EXAMPLES FOR OVS HARDWARE OFFLOAD

For optimal performance you must complete additional configuration steps.

**Adjusting the number of channels for each network interface to improve performance**

A channel includes an interrupt request (IRQ) and the set of queues that trigger the IRQ. When you set the mlx5_core driver to switchdev mode, the mlx5_core driver defaults to one combined channel, which might not deliver optimal performance.

**Procedure**

- On the PF representors, enter the following command to adjust the number of CPUs available to the host. Replace $(nproc) with the number of CPUs you want to make available:

  ```sh
  $ sudo ethtool -L enp3s0f0 combined $(nproc)
  ```
CPU pinning

To prevent performance degradation from cross-NUMA operations, locate NICs, their applications, the VF guest, and OVS in the same NUMA node. For more information, see: Configuring CPU pinning on the Compute node in the Instances and Images Guide.

6.6. COMPONENTS OF OVS HARDWARE OFFLOAD

A reference for configuring and troubleshooting the components of OVS HW Offload with Mellanox smart NICs.

Nova

Configure the Nova scheduler to use the NovaPCIPassthrough filter with the NUMATopologyFilter and DerivePciWhitelistEnabled parameters. When you enable OVS HW Offload, the Nova scheduler operates similarly to SR-IOV passthrough for instance spawning.

Neutron

When you enable OVS HW Offload, use the devlink cli tool to set the NIC e-switch mode to switchdev. Switchdev mode establishes representor ports on the NIC that are mapped to the VFs.

Procedure

1. To allocate a port from a switchdev-enabled NIC, create a neutron port and set the value of binding-profile to capabilities:

   ```bash
   $ openstack port create --network private --vnic-type=direct --binding-profile '{"capabilities": ["switchdev"]}' direct_port1
   ```

   Pass this port information when you create the instance. You associate the representor port with the instance VF interface and connect the representor port to OVS bridge br-int for one-time OVS datapath processing. A VF port representor functions like a software version of a physical “patch panel” front-end. For more information about new instance creation, see: Deploying an Instance for SR-IOV

OVS

In an environment with hardware offload configured, the first packet transmitted traverses the OVS kernel path, and this packet journey establishes the ml2 OVS rules for incoming and outgoing traffic for the instance traffic. When the flows of the traffic stream are established, OVS uses the traffic control (TC) Flower utility to push these flows on the NIC hardware.

Procedure

1. Use director to apply the following configuration on OVS:

   ```bash
   $ sudo ovs-vsctl set Open_vSwitch . other_config:hw-offload=true
   ```

2. Restart to enable HW Offload.

Traffic Control (TC) subsystems

When you enable the hw-offload flag, OVS uses the TC datapath. TC Flower is an iproute2 utility that writes datapath flows on hardware. This ensures that the flow is programmed on both the hardware and software datapaths, for redundancy.
Procedure

1. Apply the following configuration. This is the default option if you do not explicitly configure `tc-policy`:

   ```
   $ sudo ovs-vsctl set Open_vSwitch . other_config:tc-policy=none
   ```

2. Restart OVS.

NIC PF and VF drivers

Mlx5_core is the PF and VF driver for the Mellanox ConnectX-5 NIC. The mlx5_core driver performs the following tasks:

- Creates routing tables on hardware.
- Manages network flow management.
- Configures the Ethernet switch device driver model, `switchdev`.
- Creates block devices.

Procedure

- Use the following `devlink` commands to query the mode of the PCI device.

  ```
  $ sudo devlink dev eswitch set pci/0000:03:00.0 mode switchdev
  $ sudo devlink dev eswitch show pci/0000:03:00.0
  pci/0000:03:00.0: mode switchdev inline-mode none encap enable
  ```

NIC firmware

The NIC firmware performs the following tasks:

- Maintains routing tables and rules.
- Fixes the pipelines of the tables.
- Manages hardware resources.
- Creates VFs.

The firmware works with the driver for optimal performance.

Although the NIC firmware is non-volatile and persists after you reboot, you can modify the configuration during run time.

Procedure

- Apply the following configuration on the interfaces, and the representor ports, to ensure that TC Flower pushes the flow programming at the port level:

  ```
  $ sudo ethtool -K enp3s0f0 hw-tc-offload on
  ```

NOTE
6.7. TROUBLESHOOTING OVS HARDWARE OFFLOAD

Prerequisites

- Linux Kernel 4.13 or newer
- OVS 2.8 or newer
- RHOSP 12 or newer
- Iproute 4.12 or newer
- Mellanox NIC firmware:
  - FW ConnectX-5 16.21.0338 or newer
  - FW ConnectX-4 14.21.0338 or newer

NOTE

Mellanox ConnectX-5 and ConnectX-4Lx NICs support both VLAN and VXLAN Offload. Mellanox ConnectX-4 supports VLAN Offload only.

For more information about supported prerequisites, see https://access.redhat.com/articles/3538141

Configuring the network in an OVS HW offload deployment

In a HW offload deployment, you can choose one of the following scenarios for your network configuration according to your requirements:

- You can base guest VMs on VXLAN and VLAN by using either the same set of interfaces attached to a bond or a different set of NICs for each type.
- You can bond two ports of a Mellanox NIC by using Linux bond.
- You can host tenant VXLAN networks on VLAN interfaces on top of the Linux bond.
- You can host a VLAN network on an ovs-bridge which has Linux bond as a member.

Refer to the below example network configuration:

```
- type: ovs_bridge
  name: br-offload
  mtu: 9000
  use_dhcp: false
  members:
    - type: linux_bond
      name: bond-pf
      bonding_options: "mode=active-backup miimon=100"
      members:
        - type: sriov_pf
```
name: p5p1
numvfs: 3
primary: true
promisc: true
use_dhcp: false
defroute: false
link_mode: switchdev
- type: sriov_pf
  name: p5p2
  numvfs: 3
  promisc: true
  use_dhcp: false
defroute: false
  link_mode: switchdev
- type: vlan
  vlan_id:
    get_param: TenantNetworkVlanID
device: bond-pf
addresses:
  - ip_netmask:
    get_param: TenantIpSubnet

Refer to the below validated bonding configurations:

- active-backup - mode=1
- active-active or balance-xor - mode=2
- 802.3ad (LACP) - mode=4

Verifying the interface configuration

Verify the interface configuration with the following procedure.

Procedure

1. During deployment, use the host network configuration tool `os-net-config` to enable `hw-tc-offload`.

2. Enable `hw-tc-offload` on the `sriov_config` service any time you reboot the Compute node.

3. Set the `hw-tc-offload` parameter to `on` for the NICs that are attached to the bond:

   ```
   [root@overcloud-computesriov-0 ~]# ethtool -k ens1f0 | grep tc-offload
   hw-tc-offload: on
   ```

Verifying the interface mode

Verify the interface mode with the following procedure.

Procedure

1. Set the eswitch mode to `switchdev` for the interfaces you use for HW offload.

2. Use the host network configuration tool `os-net-config` to enable `eswitch` during deployment.
3. Enable `eswitch` on the `sriov_config` service any time you reboot the Compute node.

   ```bash
   [root@overcloud-computesriov-0 ~]# devlink dev eswitch show pci/$(ethtool -i ens1f0 | grep bus-info | cut -d ':' -f 2,3,4 | awk '{$1=$1};1')
   ```

   **NOTE**
   The driver of the PF interface is set to "mlx5e_rep", to show that it is a representor of the e-switch uplink port. This does not affect the functionality.

### Verifying the offload state in OVS

Verify the offload state in OVS with the following procedure.

- Enable hardware offload in OVS in the Compute node.

   ```bash
   [root@overcloud-computesriov-0 ~]# ovs-vsctl get Open_vSwitch . other_config:hw-offload "true"
   ```

### Verifying the name of the VF representor port

To ensure consistent naming of VF representor ports, `os-net-config` uses udev rules to rename the ports in the `<PF-name>_<VF_id>` format.

**Procedure**

- After deployment, verify that the VF representor ports are named correctly.

   ```bash
   [root@overcloud-computesriov-0 ~]# cat /etc/udev/rules.d/80-persistent-os-net-config.rules
   # This file is autogenerated by os-net-config
   SUBSYSTEM=="net", ACTION=="add", ATTR{phys_switch_id}="", ATTR{phys_port_name}="pf*vf*", ENV[NM_UNMANAGED]="1"
   SUBSYSTEM=="net", ACTION=="add", DRIVERS="?***", KERNELS="0000:65:00.0", NAME="ens1f0"
   SUBSYSTEM=="net", ACTION=="add", ATTR{phys_switch_id}="98039b7f9e48", ATTR{phys_port_name}="pf0vf*", IMPORT{program}="/etc/udev/rep-link-name.sh $attr{phys_port_name}", NAME="ens1f0_$env{NUMBER}"
   SUBSYSTEM=="net", ACTION=="add", DRIVERS="?***", KERNELS="0000:65:00.1", NAME="ens1f1"
   SUBSYSTEM=="net", ACTION=="add", ATTR{phys_switch_id}="98039b7f9e49", ATTR{phys_port_name}="pf1vf*", IMPORT{program}="/etc/udev/rep-link-name.sh $attr{phys_port_name}", NAME="ens1f1_$env{NUMBER}"
   ```

### Examining network traffic flow

HW offloaded network flow functions in a similar way to physical switches or routers with application-specific integrated circuit (ASIC) chips. You can access the ASIC shell of a switch or router to examine the routing table and for other debugging. The following procedure uses a Broadcom chipset from a Cumulus Linux switch as an example. Replace the values that are appropriate to your environment.

**Procedure**

1. To get Broadcom chip table content, use the `bcmcmd` command.
2. Inspect the Traffic Control (TC) Layer.

```bash
# tc -s filter show dev p5p1_1 ingress
...
filter block 94 protocol ip pref 3 flower chain 5
target block 94 protocol ip pref 3 flower chain 5 handle 0x2
  eth_type ipv4
  src_ip 172.0.0.1
  ip_flags nofrag
  in_hw in_hw_count 1
  action order 1: mirred (Egress Redirect to device eth4) stolen
  index 3 ref 1 bind 1 installed 364 sec used 0 sec
  Action statistics:
  Sent 253991716224 bytes 169534118 pkt (dropped 0, overlimits 0 requeues 0)
  Sent software 43711874200 bytes 30161170 pkt
  Sent hardware 210279842024 bytes 139372948 pkt
  backlog 0b 0p requeues 0
  cookie 8beddad9a0430f0457e7e78db6e0af48
  no_percpu
```

3. Examine the **in_hw** flags and the statistics in this output. The word **hardware** indicates that the hardware processes the network traffic. If you use **tc-policy=none**, you can check this output or a **tcpdump** to investigate when hardware or software handles the packets. You can see a corresponding log message in **dmesg** or in **ovs-vswitch.log** when the driver is unable to offload packets.

4. For Mellanox, as an example, the log entries resemble syndrome messages in **dmesg**.

```bash
[13232.860484] mlx5_core 0000:3b:00.0: mlx5_cmd_check:756:(pid 131368):
  SET_FLOW_TABLE_ENTRY(0x936) op_mod(0x0) failed, status bad parameter(0x3),
  syndrome (0x6b1266)
```

In this example, the error code (0x6b1266) represents the following behavior:

```
0x6B1266 | set_flow_table_entry: pop vlan and forward to uplink is not allowed
```

**Validating systems**

Validate your system with the following procedure.

**Procedure**

1. Ensure SR-IOV and VT-d are enabled on the system.

2. Enable IOMMU in Linux by adding **intel_iommu=on** to kernel parameters, for example, using GRUB.

**Limitations**
You cannot use the OVS firewall driver with HW offload because the connection tracking properties of the flows are unsupported in the offload path in OVS 2.11.

## 6.8. DEBUGGING HW OFFLOAD FLOW

You can use the following procedure if you encounter the following message in the `ovs-vswitch.log` file:

```
2020-01-31T06:22:11.257Z|00473|dpif_netlink(handler402)|ERR|failed to offload flow: Operation not supported: p6p1_5
```

### Procedure

1. To enable logging on the offload modules and to get additional log information for this failure, use the following commands on the Compute node:

   ```
   ovs-appctl vlog/set dpif_netlink:file:dbg
   # Module name changed recently (check based on the version used
   ovs-appctl vlog/set netdev_tc_offloads:file:dbg [OR] ovs-appctl vlog/set
   netdev_offload_tc:file:dbg
   ovs-appctl vlog/set tc:file:dbg
   ```

2. Inspect the `ovs-vswitchd` logs again to see additional details about the issue. In the following example logs, the offload failed because of an unsupported attribute mark.

   ```
   2020-01-31T06:22:11.218Z|00471|dpif_netlink(handler402)|DBG|system@ovs-system:
   [put[create] ufid:61bd016e-eb89-44fc-a17e-958bc8e45fda
   recirc_id(0),dp_hash(0/0),skb_priority(0/0),in_port(7),skb_mark(0),ct_state(0/0),ct_zone(0/0),ct
   _mark(0/0),ct_label(0/0),eth(src=fa:16:3e:d2:f5:f3,dst=fa:16:3e:c4:a3:eb),eth_type(0x0800),ipv
   4(src=10.1.1.8/0.0.0.0,dst=10.1.1.31/0.0.0.0,proto=1/0,tos=0/0x3,ttl=64/0,frag=no),icmp(type=0/
   0,code=0/0),
   actions:set(tunnel(tun_id=0x3d,src=10.10.141.107,dst=10.10.141.124,ttl=64,tp_dst=4789,flags(
   df|key)),6

### Debugging Mellanox NICs

Mellanox has provided a system information script, similar to a Red Hat SOS report.

When you run this command, you create a zip file of the relevant log information, which is useful for support cases.

### Procedure

- You can run this system information script with the following command:

  ```
  # ./sysinfo-snapshot.py --asap --asap_tc --ibdiagnet --openstack
  ```
You can also install Mellanox Firmware Tools (MFT), mlxconfig, mlxlink and the OpenFabrics Enterprise Distribution (OFED) drivers.

**Useful CLI commands**

Use the `ethtool` utility with the following options to gather diagnostic information:

- `ethtool -l <uplink representor>`: View the number of channels
- `ethtool -l <uplink/VFs>`: Check statistics
- `ethtool -i <uplink rep>`: View driver information
- `ethtool -g <uplink rep>`: Check ring sizes
- `ethtool -k <uplink/VFs>`: View enabled features

Use the `tcpdump` utility at the representor and PF ports to similarly check traffic flow.

- Any changes you make to the link state of the representor port, affect the VF link state also.
- Representor port statistics present VF statistics also.

Use the below commands to get useful diagnostic information:

```
$ovs-dpctl dump-flows -m type=offloaded
$tc filter show dev ens1_0 ingress
$tc -s filter show dev ens1_0 ingress
$ tc monitor
```

6.9. DEPLOYING AN INSTANCE FOR SR-IOV

Use host aggregates to separate high performance compute hosts. For information on creating host aggregates and associated flavors for scheduling see [Creating host aggregates](#).

**NOTE**

Pinned CPU instances can be located on the same Compute node as unpinned instances. For more information, see [Configuring CPU pinning on the Compute node](#) in the Instances and Images Guide.

Deploy an instance for single root I/O virtualization (SR-IOV) by performing the following steps:

1. Create a flavor.

```
# openstack flavor create <flavor> --ram <MB> --disk <GB> --vcpus <#>
```
TIP

You can specify the NUMA affinity policy for PCI passthrough devices and SR-IOV interfaces by adding the extra spec `hw:pci_numa_affinity_policy` to your flavor. For more information, see Update flavor metadata in the Instance and Images Guide.

2. Create the network.

```bash
# openstack network create net1 --provider-physical-network tenant --provider-network-type vlan --provider-segment <VLAN-ID>
# openstack subnet create subnet1 --network net1 --subnet-range 192.0.2.0/24 --dhcp
```

3. Create the port.

- Use vnic-type `direct` to create an SR-IOV virtual function (VF) port.

  ```bash
  # openstack port create --network net1 --vnic-type direct sriov_port
  ```

- Use the following command to create a virtual function with hardware offload.

  ```bash
  # openstack port create --network net1 --vnic-type direct --binding-profile '{"capabilities": ['switchdev']} sriov_hwoffload_port
  ```

- Use vnic-type `direct-physical` to create an SR-IOV PF port.

  ```bash
  # openstack port create --network net1 --vnic-type direct-physical sriov_port
  ```

4. Deploy an instance.

```bash
# openstack server create --flavor <flavor> --image <image> --nic port-id=<id> <instance name>
```

### 6.10. CREATING HOST AGGREGATES

For better performance, deploy guests that have cpu pinning and hugepages. You can schedule high performance instances on a subset of hosts by matching aggregate metadata with flavor metadata.

1. Ensure that the `AggregateInstanceExtraSpecsFilter` value is included in the `scheduler_default_filters` parameter in the `nova.conf` file. This configuration can be set through the heat parameter `NovaSchedulerDefaultFilters` under role-specific parameters before deployment.

   ```
   ComputeOvsDpdkSriovParameters:
   ```

NOTE

To add this parameter to the configuration of an exiting cluster, you can add it to the heat templates, and run the original deployment script again.
2. Create an aggregate group for SR-IOV, and add relevant hosts. Define metadata, for example, `sriov=true`, that matches defined flavor metadata.

```bash
# openstack aggregate create sriov_group
# openstack aggregate add host sriov_group compute-sriov-0.localdomain
# openstack aggregate set sriov=true sriov_group
```

3. Create a flavor.

```bash
# openstack flavor create <flavor> --ram <MB> --disk <GB> --vcpus <#>
```

4. Set additional flavor properties. Note that the defined metadata, `sriov=true`, matches the defined metadata on the SR-IOV aggregate.

```bash
openstack flavor set --property sriov=true --property hw:cpu_policy=dedicated --property hw:mem_page_size=1GB <flavor>
```
CHAPTER 7. PLANNING YOUR OVS-DPDK DEPLOYMENT

To optimize your OVS-DPDK deployment, you should understand how to configure the OVS-DPDK parameters relative to your Compute node hardware. For more information about CPUs and NUMA topology, see: NFV performance considerations.

7.1. OVS-DPDK WITH CPU PARTITIONING AND NUMA TOPOLOGY

OVS-DPDK partitions the hardware resources for host, guests, and itself. The OVS-DPDK Poll Mode Drivers (PMDs) run DPDK active loops, which require dedicated CPU cores. Therefore you must allocate some CPUs, and huge pages, to OVS-DPDK.

A sample partitioning includes 16 cores per NUMA node on dual-socket Compute nodes. The traffic requires additional NICs because you cannot share NICs between the host and OVS-DPDK.

NOTE

You must reserve DPDK PMD threads on both NUMA nodes, even if a NUMA node does not have an associated DPDK NIC.

For optimum OVS-DPDK performance, reserve a block of memory local to the NUMA node. Choose NICs associated with the same NUMA node that you use for memory and CPU pinning. Ensure that both bonded interfaces are from NICs on the same NUMA node.

7.2. WORKFLOWS AND DERIVED PARAMETERS

This feature is available in this release as a Technology Preview, and therefore is not fully supported by Red Hat. It should only be used for testing, and should not be deployed in a production environment. For more information about Technology Preview features, see Scope of Coverage Details.

You can use the Red Hat OpenStack Platform Workflow (mistral) service to derive parameters based on the capabilities of your available bare-metal nodes. Workflows use a YAML file to define a set of tasks and actions to perform. You can use a pre-defined workbook, derive_params.yaml, in the directory tripleo-common/workbooks/. This workbook provides workflows to derive each supported parameter.
from the results of Bare Metal introspection. The `derive_params.yaml` workflows use the formulas from `tripleo-common/workbooks/derive_params_formulas.yaml` to calculate the derived parameters.

**NOTE**

You can modify `derive_params_formulas.yaml` to suit your environment.

The `derive_params.yaml` workbook assumes all nodes for a particular composable role have the same hardware specifications. The workflow considers the flavor-profile association and nova placement scheduler to match nodes associated with a role, then uses the introspection data from the first node that matches the role.

For more information about Workflows, see Troubleshooting Workflows and Executions.

You can use the `-p` or `--plan-environment-file` option to add a custom `plan_environment.yaml` file, containing a list of workbooks and any input values, to the `openstack overcloud deploy` command. The resultant workflows merge the derived parameters back into the custom `plan_environment.yaml`, where they are available for the overcloud deployment.

For details on how to use the `--plan-environment-file` option in your deployment, see Plan Environment Metadata.

### 7.3. DERIVED OVS-DPDK PARAMETERS

The workflows in `derive_params.yaml` derive the DPDK parameters associated with the role that uses the `ComputeNeutronOvsDpdk` service.

The workflows can automatically derive the following parameters for OVS-DPDK. The `NovaVcpuPinSet` parameter is now deprecated, and is replaced by `NovaComputeCpuDedicatedSet` for dedicated, pinned workflows:

- `IsolCpusList`
- `KernelArgs`
- `NovaReservedHostMemory`
- `NovaComputeCpuDedicatedSet`
- `OvsDpdkCoreList`
- `OvsDpdkSocketMemory`
- `OvsPmdCoreList`

The `OvsDpdkMemoryChannels` parameter cannot be derived from the introspection memory bank data because the format of memory slot names are inconsistent across different hardware environments.

In most cases, the default number of `OvsDpdkMemoryChannels` is four. Consult your hardware manual to determine the number of memory channels per socket, and update the default number with this value.

For more information about workflow parameters, see Section 8.1, "Deriving DPDK parameters with workflows".
7.4. CALCULATING OVS-DPDK PARAMETERS MANUALLY

This section describes how OVS-DPDK uses parameters within the director network_environment.yaml heat templates to configure the CPU and memory for optimum performance. Use this information to evaluate the hardware support on your Compute nodes and how to partition the hardware to optimize your OVS-DPDK deployment.

NOTE

For more information on how to generate these values with the derived_parameters.yaml workflow instead, see Overview of workflows and derived parameters.

NOTE

Always pair CPU sibling threads, or logical CPUs, together in the physical core when allocating CPU cores.

For details on how to determine the CPU and NUMA nodes on your Compute nodes, see Discovering your NUMA node topology. Use this information to map CPU and other parameters to support the host, guest instance, and OVS-DPDK process needs.

7.4.1. CPU parameters

OVS-DPDK uses the following parameters for CPU partitioning:

OvsPmdCoreList

Provides the CPU cores that are used for the DPDK poll mode drivers (PMD). Choose CPU cores that are associated with the local NUMA nodes of the DPDK interfaces. Use OvsPmdCoreList for the pmd-cpu-mask value in OVS. Observe the following recommendations for OvsPmdCoreList:

- Pair the sibling threads together.
- Exclude all cores from the OvsDpdkCoreList
- Avoid allocating the logical CPUs of both thread siblings on the first physical core to both NUMA nodes as these should be used for the OvsDpdkCoreList parameter.
- Performance depends on the number of physical cores allocated for this PMD Core list. On the NUMA node which is associated with DPDK NIC, allocate the required cores.
- For NUMA nodes with a DPDK NIC, determine the number of physical cores required based on the performance requirement, and include all the sibling threads or logical CPUs for each physical core.
- For NUMA nodes without DPDK NICs, allocate the sibling threads or logical CPUs of any physical core except the first physical core of the NUMA node. You need a minimal DPDK poll mode driver on the NUMA node without DPDK NICs present to properly create guest instances.
NOTE
You must reserve DPDK PMD threads on both NUMA nodes, even if a NUMA node does not have an associated DPDK NIC.

NovaComputeCpuDedicatedSet
A comma-separated list or range of physical host CPU numbers to which processes for pinned instance CPUs can be scheduled. For example, `NovaComputeCpuDedicatedSet: [4-12, ^8, 15]` reserves cores from 4-12 and 15, excluding 8.

- Exclude all cores from the `OvsPmdCoreList` and the `OvsDpdkCoreList`.
- Include all remaining cores.
- Pair the sibling threads together.

NovaComputeCpuSharedSet
A comma-separated list or range of physical host CPU numbers used to determine the host CPUs for instance emulator threads. The recommended value for this parameter matches the value set for `OvsDpdkCoreList`.

IsolCpusList
A set of CPU cores isolated from the host processes. `IsolCpusList` is the `isolated_cores` value in the `cpu-partitioning-variable.conf` file for the `tuned-profiles-cpu-partitioning` component. Observe the following recommendations for `IsolCpusList`:

- Match the list of cores in `OvsPmdCoreList` and `NovaComputeCpuDedicatedSet`.
- Pair the sibling threads together.

OvsDpdkCoreList
Provides CPU cores for non data path OVS-DPDK processes, such as handler and revalidator threads. This parameter has no impact on overall data path performance on multi-NUMA node hardware. `OvsDpdkCoreList` is the `dpdk-lcore-mask` value in OVS, and these cores are shared with the host. Observe the following recommendations for `OvsDpdkCoreList`:

- Allocate the first physical core, and sibling thread, from each NUMA node, even if the NUMA node has no associated DPDK NIC.
- These cores must be mutually exclusive from the list of cores in `OvsPmdCoreList` and `NovaComputeCpuDedicatedSet`.

DerivePciWhitelistEnabled
To reserve virtual functions (VF) for VMs, use the `NovaPCIPassthrough` parameter to create a list of VFs passed through to Nova. VMs excluded from the list remain available for the host. Red Hat recommends that you change the `DerivePciWhitelistEnabled` value to `false` from the default of `true`, and then manually configure the list in the `NovaPCIPassthrough` parameter.

For each VF in the list, populate the address parameter with a regular expression that resolves to the address value.

The following is an example of the manual list creation process. If NIC partitioning is enabled in a device named `eno2`, list the PCI addresses of the VFs with the following command:

```
[heat-admin@compute-0 ~]$ ls -lh /sys/class/net/eno2/device/ | grep virtfn
```
In this case, the VFs 0, 4, and 6 are used by eno2 for NIC Partitioning. Manually configure `NovaPCIPassthrough` to include VFs 1-3, 5, and 7, and consequently exclude VFs 0, 4, and 6, as in the following example:

```bash
NovaPCIPassthrough:
- physical_network: "sriovnet2"
  address: {"domain": ".*", "bus": "18", "slot": "06", "function": "[1-3]"}
- physical_network: "sriovnet2"
  address: {"domain": ".*", "bus": "18", "slot": "06", "function": "[5]"}
- physical_network: "sriovnet2"
  address: {"domain": ".*", "bus": "18", "slot": "06", "function": "[7]"}
```

### 7.4.2. Memory parameters

OVS-DPDK uses the following memory parameters:

#### OvsDpdkMemoryChannels
Maps memory channels in the CPU per NUMA node. `OvsDpdkMemoryChannels` is the `other_config:dpdk-extra="-n <value>"` value in OVS. Observe the following recommendations for `OvsDpdkMemoryChannels`:

- Use `dmidecode -t memory` or your hardware manual to determine the number of memory channels available.
- Use `ls /sys/devices/system/node/node* -d` to determine the number of NUMA nodes.
- Divide the number of memory channels available by the number of NUMA nodes.

#### NovaReservedHostMemory
Reserves memory in MB for tasks on the host. `NovaReservedHostMemory` is the `reserved_host_memory_mb` value for the Compute node in `nova.conf`. Observe the following recommendation for `NovaReservedHostMemory`:

- Use the static recommended value of 4096 MB.

#### OvsDpdkSocketMemory
Specifies the amount of memory in MB to pre-allocate from the hugepage pool, per NUMA node. `OvsDpdkSocketMemory` is the `other_config:dpdk-socket-mem` value in OVS. Observe the following recommendations for `OvsDpdkSocketMemory`:

- Provide as a comma-separated list.
- For a NUMA node without a DPDK NIC, use the static recommendation of 1024 MB (1GB)
• Calculate the **OvsDpdkSocketMemory** value from the MTU value of each NIC on the NUMA node.

• The following equation approximates the value for **OvsDpdkSocketMemory**:
  - **MEMORY_REQD_PER_MTU** = (ROUNDUP_PER_MTU + 800) * (4096 * 64) Bytes
  - 800 is the overhead value.
  - 4096 * 64 is the number of packets in the mempool.

• Add the **MEMORY_REQD_PER_MTU** for each of the MTU values set on the NUMA node and add another 512 MB as buffer. Round the value up to a multiple of 1024.

**Sample Calculation - MTU 2000 and MTU 9000**

DPDK NICs dpdk0 and dpdk1 are on the same NUMA node 0, and configured with MTUs 9000, and 2000 respectively. The sample calculation to derive the memory required is as follows:

1. Round off the MTU values to the nearest multiple of 1024 bytes.
   - The MTU value of 9000 becomes 9216 bytes.
   - The MTU value of 2000 becomes 2048 bytes.

2. Calculate the required memory for each MTU value based on these rounded byte values.
   - Memory required for 9000 MTU = (9216 + 800) * (4096*64) = 2625634304
   - Memory required for 2000 MTU = (2048 + 800) * (4096*64) = 746586112

3. Calculate the combined total memory required, in bytes.
   - 2625634304 + 746586112 + 536870912 = 3909091328 bytes.
   - This calculation represents (Memory required for MTU of 9000) + (Memory required for MTU of 2000) + (512 MB buffer).

4. Convert the total memory required into MB.
   - 3909091328 / (1024*1024) = 3728 MB.

5. Round this value up to the nearest 1024.
   - 3724 MB rounds up to 4096 MB.

6. Use this value to set **OvsDpdkSocketMemory**.
   - **OvsDpdkSocketMemory**: “4096,1024”

**Sample Calculation - MTU 2000**

DPDK NICs dpdk0 and dpdk1 are on the same NUMA node 0, and each are configured with MTUs of 2000. The sample calculation to derive the memory required is as follows:

1. Round off the MTU values to the nearest multiple of 1024 bytes.
The MTU value of 2000 becomes 2048 bytes.

2. Calculate the required memory for each MTU value based on these rounded byte values.

   Memory required for 2000 MTU = (2048 + 800) * (4096*64) = 746586112

3. Calculate the combined total memory required, in bytes.

   746586112 + 536870912 = 1283457024 bytes.

   This calculation represents (Memory required for MTU of 2000) + (512 MB buffer).

4. Convert the total memory required into MB.

   1283457024 / (1024*1024) = 1224 MB.

5. Round this value up to the nearest multiple of 1024.

   1224 MB rounds up to 2048 MB.

6. Use this value to set OvsDpdkSocketMemory.

   OvsDpdkSocketMemory: "2048,1024"

7.4.3. Networking parameters

NeutronDpdkDriverType

Sets the driver type used by DPDK. Use the default value of vfio-pci.

NeutronDatapathType

Datapath type for OVS bridges. DPDK uses the default value of netdev.

NeutronVhostuserSocketDir

Sets the vhost-user socket directory for OVS. Use /var/lib/vhost_sockets for vhost client mode.

7.4.4. Other parameters

NovaSchedulerDefaultFilters

Provides an ordered list of filters that the Compute node uses to find a matching Compute node for a requested guest instance.

VhostuserSocketGroup

Sets the vhost-user socket directory group. The default value is qemu. Set VhostuserSocketGroup to hugetlbs so that the ovs-vswitchd and qemu processes can access the shared huge pages and unix socket that configures the virtio-net device. This value is role-specific and should be applied to any role leveraging OVS-DPDK.

KernelArgs

Provides multiple kernel arguments to /etc/default/grub for the Compute node at boot time. Add the following values based on your configuration:

- hugepagesz: Sets the size of the huge pages on a CPU. This value can vary depending on the CPU hardware. Set it to 1G for OVS-DPDK deployments (default_hugepagesz=1GB hugepagesz=1G). Use this command to check for the pdpe1gb CPU flag that confirms your
CPU supports 1G.

```
lshw -class processor | grep pdpe1gb
```

- **hugepages count**: Sets the number of huge pages available based on available host memory. Use most of your available memory, except `NovaReservedHostMemory`. You must also configure the huge pages count value within the flavor of your Compute nodes.

- **iommu**: For Intel CPUs, add “`intel_iommu=on iommu=pt`”

- **isolcpus**: Sets the CPU cores for tuning. This value matches `IsolCpusList`.

### 7.4.5. Instance extra specifications

Before deploying instances in an NFV environment, create a flavor that utilizes CPU pinning, huge pages, and emulator thread pinning.

**hw:cpu_policy**

When this parameter is set to `dedicated`, the guest uses pinned CPUs. Instances created from a flavor with this parameter set have an effective overcommit ratio of 1:1. The default value is `shared`.

**hw:mem_page_size**

Set this parameter to a valid string of a specific value with standard suffix (For example, `4KB`, `8MB`, or `1GB`). Use 1GB to match the `hugepagesz` boot parameter. Calculate the number of huge pages available for the virtual machines by subtracting `OvsDpdkSocketMemory` from the boot parameter.

The following values are also valid:

- **small** (default) - The smallest page size is used
- **large** - Only use large page sizes. (2MB or 1GB on x86 architectures)
- **any** - The compute driver can attempt to use large pages, but defaults to small if none available.

**hw:emulator_threads_policy**

Set the value of this parameter to `share` so that emulator threads are locked to CPUs that you’ve identified in the heat parameter, `NovaComputeCpuSharedSet`. If an emulator thread is running on a vCPU with the poll mode driver (PMD) or real-time processing, you can experience negative effects, such as packet loss.

### 7.5. TWO NUMA NODE EXAMPLE OVS-DPDK DEPLOYMENT

The Compute node in the following example includes two NUMA nodes:

- **NUMA 0** has cores 0-7. The sibling thread pairs are (0,1), (2,3), (4,5), and (6,7)
- **NUMA 1** has cores 8-15. The sibling thread pairs are (8,9), (10,11), (12,13), and (14,15).
- Each NUMA node connects to a physical NIC, namely NIC1 on NUMA 0, and NIC2 on NUMA 1.
NOTE

Reserve the first physical cores or both thread pairs on each NUMA node (0,1 and 8,9) for non-datapath DPDK processes, such as OvsDpdkCoreList.

This example also assumes a 1500 MTU configuration, so the OvsDpdkSocketMemory is the same for all use cases:

- **NIC 1 for DPDK, with one physical core for PMD**
  In this use case, you allocate one physical core on NUMA 0 for PMD. You must also allocate one physical core on NUMA 1, even though DPDK is not enabled on the NIC for that NUMA node. The remaining cores, not reserved for OvsDpdkCoreList, are allocated for guest instances. The resulting parameter settings are:

  - OvsPmdCoreList: “2,3,10,11”
  - NovaComputeCpuDedicatedSet: “4,5,6,7,12,13,14,15”

- **NIC 1 for DPDK, with two physical cores for PMD**
  In this use case, you allocate two physical cores on NUMA 0 for PMD. You must also allocate one physical core on NUMA 1, even though DPDK is not enabled on the NIC for that NUMA node. The remaining cores, not reserved for OvsDpdkCoreList, are allocated for guest instances. The resulting parameter settings are:

  - OvsPmdCoreList: “2,3,4,5,10,11”
  - NovaComputeCpuDedicatedSet: “6,7,12,13,14,15”

- **NIC 2 for DPDK, with one physical core for PMD**
  In this use case, you allocate one physical core on NUMA 1 for PMD. You must also allocate one physical core on NUMA 0, even though DPDK is not enabled on the NIC for that NUMA node. The remaining cores, not reserved for OvsDpdkCoreList, are allocated for guest instances. The resulting parameter settings are:

  - OvsPmdCoreList: “2,3,10,11”
  - NovaComputeCpuDedicatedSet: “4,5,6,7,12,13,14,15”

- **NIC 2 for DPDK, with two physical cores for PMD**
  In this use case, you allocate two physical cores on NUMA 1 for PMD. You must also allocate one physical
core on NUMA 0, even though DPDK is not enabled on the NIC for that NUMA node. The remaining cores, not reserved for \textit{OvsDpdkCoreList}, are allocated for guest instances. The resulting parameter settings are:

- \textit{OvsPmdCoreList}: “2,3,10,11,12,13”
- \textit{NovaComputeCpuDedicatedSet}: “4,5,6,7,14,15”

**NIC 1 and NIC2 for DPDK, with two physical cores for PMD**

In this use case, you allocate two physical cores on each NUMA node for PMD. The remaining cores, not reserved for \textit{OvsDpdkCoreList}, are allocated for guest instances. The resulting parameter settings are:

- \textit{OvsPmdCoreList}: “2,3,4,5,10,11,12,13”
- \textit{NovaComputeCpuDedicatedSet}: “6,7,14,15”

### 7.6. TOPOLOGY OF AN NFV OVS-DPDK DEPLOYMENT

This example deployment shows an OVS-DPDK configuration and consists of two virtual network functions (VNFs) with two interfaces each:

- The management interface, represented by \textit{mgt}.
- The data plane interface.

In the OVS-DPDK deployment, the VNFs operate with inbuilt DPDK that supports the physical interface. OVS-DPDK enables bonding at the vSwitch level. For improved performance in your OVS-DPDK deployment, it is recommended that you separate kernel and OVS-DPDK NICs. To separate the management (\textit{mgt}) network, connected to the Base provider network for the virtual machine, ensure you have additional NICs. The Compute node consists of two regular NICs for the Red Hat OpenStack Platform API management that can be reused by the Ceph API but cannot be shared with any OpenStack tenant.
NFV OVS-DPDK topology

The following image shows the topology for OVS-DPDK for NFV. It consists of Compute and Controller nodes with 1 or 10 Gbps NICs, and the director node.
CHAPTER 8. CONFIGURING AN OVS-DPDK DEPLOYMENT

This section deploys OVS-DPDK within the Red Hat OpenStack Platform environment. The overcloud usually consists of nodes in predefined roles such as Controller nodes, Compute nodes, and different storage node types. Each of these default roles contains a set of services defined in the core heat templates on the director node.

You must install and configure the undercloud before you can deploy the overcloud. See the Director Installation and Usage Guide for details.

**IMPORTANT**
You must determine the best values for the OVS-DPDK parameters found in the network-environment.yaml file to optimize your OpenStack network for OVS-DPDK.

**NOTE**
Do not manually edit or change isolated_cores or other values in etc/tuned/cpu-partitioning-variables.conf that the director heat templates modify.

8.1. DERIVING DPDK PARAMETERS WITH WORKFLOWS

**IMPORTANT**
This feature is available in this release as a Technology Preview, and therefore is not fully supported by Red Hat. It should only be used for testing, and should not be deployed in a production environment. For more information about Technology Preview features, see Scope of Coverage Details.

See Section 7.2, “Workflows and derived parameters” for an overview of the Mistral workflow for DPDK.

**Prerequisites**
You must have bare metal introspection, including hardware inspection extras (inspection_extras) enabled to provide the data retrieved by this workflow. Hardware inspection extras are enabled by default. For more information about hardware of the nodes, see: Inspecting the hardware of nodes.

**Define the Workflows and Input Parameters for DPDK**

The following list outlines the input parameters you can provide to the OVS-DPDK workflows:

- **num_phy_cores_per_numa_node_for_pmd**
  This input parameter specifies the required minimum number of cores for the NUMA node associated with the DPDK NIC. One physical core is assigned for the other NUMA nodes not associated with DPDK NIC. Ensure that this parameter is set to 1.

- **huge_page_allocation_percentage**
  This input parameter specifies the required percentage of total memory, excluding NovaReservedHostMemory, that can be configured as huge pages. The KernelArgs parameter is derived using the calculated huge pages based on the huge_page_allocation_percentage specified. Ensure that this parameter is set to 50.

The workflows calculate appropriate DPDK parameter values from these input parameters and the bare-metal introspection details.
To define the workflows and input parameters for DPDK:

1. Copy the `usr/share/openstack-tripleo-heat-templates/plan-samples/plan-environment-derived-params.yaml` file to a local directory and set the input parameters to suit your environment.

```yaml
workflow_parameters:
  tripleo.derive_params.v1.derive_parameters:
    # DPDK Parameters
    # Specifies the minimum number of CPU physical cores to be allocated for DPDK
    # PMD threads. The actual allocation will be based on network config, if
    # the a DPDK port is associated with a numa node, then this configuration
    # will be used, else 1.
    num_phy_cores_per_numa_node_for_pmd: 1
    # Amount of memory to be configured as huge pages in percentage. Out of the
    # total available memory (excluding the NovaReservedHostMemory), the
    # specified percentage of the remaining is configured as huge pages.
    huge_page_allocation_percentage: 50
```

2. Run the `openstack overcloud deploy` command and include the following information:

- The **update-plan-only** option

- The role file and all environment files specific to your environment

- The `plan-environment-derived-parms.yaml` file with the **--plan-environment-file** optional argument

```
$ openstack overcloud deploy --templates --update-plan-only \
-r /home/stack/roles_data.yaml \
-e /home/stack/<environment-file> \
... #repeat as necessary ... \
**-p /home/stack/plan-environment-derived-params.yaml**
```

The output of this command shows the derived results, which are also merged into the `plan-environment.yaml` file.

 Started Mistral Workflow tripleo.validations.v1.check_pre_deployment_validations. Execution ID: 55ba73f2-2ef4-4da1-94e9-eae2fddc35535
 Waiting for messages on queue '472a4180-e91b-4f9e-bd4c-1fbd6b6f414f' with no timeout.
 Removing the current plan files
 Uploading new plan files
 Started Mistral Workflow tripleo.plan_management.v1.update_deployment_plan. Execution ID: 7fa995f3-7e0f-4c9e-9234-dd5292e8c722
 Plan updated.
 Processing templates in the directory /tmp/tripleoclient-SY6RcY/tripleo-heat-templates
 Invoking workflow (tripleo.derive_params.v1.derive_parameters) specified in plan-environment file
 Started Mistral Workflow tripleo.derive_params.v1.derive_parameters. Execution ID: 2d4572bf-4c5b-41f8-8981-c84a363dd95b
 Workflow execution is completed. result:
 ComputeOvsDpdkParameters:
 IsolCpusList: 1,2,3,4,5,6,7,9,10,17,18,19,20,21,22,23,11,12,13,14,15,25,26,27,28,29,30,31
 KernelArgs: default_hugepagesz=1GB hugepagesz=1G hugepages=32 iommu=pt intel_iommu=on
 isolcpus=1,2,3,4,5,6,7,9,10,17,18,19,20,21,22,23,11,12,13,14,15,25,26,27,28,29,30,31
 NovaReservedHostMemory: 4096
NOTE

The **OvsDpdkMemoryChannels** parameter cannot be derived from introspection details. In most cases, this value should be 4.

Deploy the overcloud with the derived parameters

To deploy the overcloud with these derived parameters:

1. Copy the derived parameters from the deploy command output to the `network-environment.yaml` file.

```yaml
# DPDK compute node.
ComputeOvsDpdkParameters:
  KernelArgs: default_hugepagesz=1GB hugepagesz=1G hugepages=32 iommu=pt
  intel_iommu=on
  TunedProfileName: "cpu-partitioning"
  IsolCpusList:
    "1,2,3,4,5,6,7,9,10,17,18,19,20,21,22,23,11,12,13,14,15,25,26,27,28,29,30,31"
  NovaComputeCpuDedicatedSet:
    [2,3,4,5,6,7,18,19,20,21,22,23,10,11,12,13,14,15,26,27,28,29,30,31]
  NovaReservedHostMemory: 4096
  OvsDpdkSocketMemory: "1024,1024"
  OvsDpdkMemoryChannels: "4"
  OvsPmdCoreList: "0,16,8,24"
  OvsPmdCoreList: "1,17,9,25"
```

NOTE

You must assign at least one CPU with sibling thread on each NUMA node with or without DPDK NICs present for DPDK PMD to avoid failures in creating guest instances.

NOTE

These parameters apply to the specific role, ComputeOvsDpdk. You can apply these parameters globally, but role-specific parameters overwrite any global parameters.

2. Deploy the overcloud using the role file and all environment files specific to your environment.

```bash
openstack overcloud deploy --templates
- r /home/stack/roles_data.yaml
- e /home/stack/<environment-file>
... #repeat as necessary ...
```
NOTE

In a cluster with Compute, ComputeOvsDpdk, and ComputeSriov, the workflow applies the formula only for the ComputeOvsDpdk role, not Compute or ComputeSriovs.

8.2. OVS-DPDK TOPOLOGY

With Red Hat OpenStack Platform, you can create custom deployment roles, using the composable roles feature to add or remove services from each role. For more information on Composable Roles, see Composable Services and Custom Roles in Advanced Overcloud Customization.

This image shows an example OVS-DPDK topology with two bonded ports for the control plane and data plane:

To configure OVS-DPDK, perform the following tasks:

- If you use composable roles, copy and modify the roles_data.yaml file to add the custom role for OVS-DPDK.
Update the appropriate `network-environment.yaml` file to include parameters for kernel arguments, and DPDK arguments.

Update the `compute.yaml` file to include the bridge for DPDK interface parameters.

Update the `controller.yaml` file to include the same bridge details for DPDK interface parameters.

Run the `overcloud_deploy.sh` script to deploy the overcloud with the DPDK parameters.

**NOTE**
This guide provides examples for CPU assignments, memory allocation, and NIC configurations that can vary from your topology and use case. For more information on hardware and configuration options, see: *Network Functions Virtualization Product Guide* and *Chapter 2, Hardware requirements*.

### Prerequisites

- OVS 2.10
- DPDK 17
- A supported NIC. To view the list of supported NICs for NFV, see *Section 2.1, “Tested NICs”*.

**NOTE**
The Red Hat OpenStack Platform operates in OVS client mode for OVS-DPDK deployments.

### 8.3. SETTING THE MTU VALUE FOR OVS-DPDK INTERFACES

Red Hat OpenStack Platform supports jumbo frames for OVS-DPDK. To set the maximum transmission unit (MTU) value for jumbo frames you must:

- Set the global MTU value for networking in the `network-environment.yaml` file.

- Set the physical DPDK port MTU value in the `compute.yaml` file. This value is also used by the vhost user interface.

- Set the MTU value within any guest instances on the Compute node to ensure that you have a comparable MTU value from end to end in your configuration.

**NOTE**

VXLAN packets include an extra 50 bytes in the header. Calculate your MTU requirements based on these additional header bytes. For example, an MTU value of 9000 means the VXLAN tunnel MTU value is 8950 to account for these extra bytes.
NOTE
You do not need any special configuration for the physical NIC because the NIC is controlled by the DPDK PMD, and has the same MTU value set by the `compute.yaml` file. You cannot set an MTU value larger than the maximum value supported by the physical NIC.

To set the MTU value for OVS-DPDK interfaces:

```yaml
parameter_defaults:
  # MTU global configuration
  NeutronGlobalPhysnetMtu: 9000
```

NOTE
Ensure that the `NeutronDpdkSocketMemory` value in the `network-environment.yaml` file is large enough to support jumbo frames. For details, see Section 7.4.2, “Memory parameters”.

2. Set the MTU value on the bridge to the Compute node in the `controller.yaml` file.

```yaml
- type: ovs_bridge
  name: br-link0
  use_dhcp: false
  members:
    - type: interface
      name: nic3
      mtu: 9000
```

3. Set the MTU values for an OVS-DPDK bond in the `compute.yaml` file:

```yaml
- type: ovs_user_bridge
  name: br-link0
  use_dhcp: false
  members:
    - type: ovs_dpdk_bond
      name: dpdkbond0
      mtu: 9000
      rx_queue: 2
      members:
        - type: ovs_dpdk_port
          name: dpdk0
          mtu: 9000
          members:
            - type: interface
              name: nic4
            - type: ovs_dpdk_port
              name: dpdk1
              mtu: 9000
```
8.4. CONFIGURING A FIREWALL FOR SECURITY GROUPS

Dataplane interfaces require high performance in a stateful firewall. To protect these interfaces, consider deploying a telco-grade firewall as a virtual network function (VNF).

To configure control plane interfaces, set the `NeutronOVSFirewallDriver` parameter to `openvswitch`. To use the flow-based OVS firewall driver, modify the `network-environment.yaml` file under `parameter_defaults`.

Example:

```yaml
parameter_defaults:
  NeutronOVSFirewallDriver: openvswitch
```

Use the `openstack port set` command to disable the OVS firewall driver for dataplane interfaces.

Example:

```bash
openstack port set --no-security-group --disable-port-security ${PORT}
```

8.5. SETTING MULTIQUEUE FOR OVS-DPDK INTERFACES

**NOTE**

Multiqueue is experimental and unsupported.

To set the same number of queues for interfaces in OVS-DPDK on the Compute node, modify the `compute.yaml` file:

```yaml
- type: ovs_user_bridge
  name: br-link0
  use_dhcp: false
members:
  - type: ovs_dpdk_bond
    name: dpdkbond0
    mtu: 9000
    rx_queue: 2
members:
  - type: ovs_dpdk_port
    name: dpdk0
    mtu: 9000
members:
  - type: interface
    name: nic4
  - type: ovs_dpdk_port
    name: dpdk1
    mtu: 9000
```
members:
- type: interface
  name: nic5

8.6. KNOWN LIMITATIONS

Observe the following limitations when configuring OVS-DPDK with Red Hat OpenStack Platform for NFV:

- Use Linux bonds for control plane networks. Ensure that both the PCI devices used in the bond are on the same NUMA node for optimum performance. Neutron Linux bridge configuration is not supported by Red Hat.

- You require huge pages for every instance running on the hosts with OVS-DPDK. If huge pages are not present in the guest, the interface appears but does not function.

- With OVS-DPDK, there is a performance degradation of services that use tap devices, such as Distributed Virtual Routing (DVR). The resulting performance is not suitable for a production environment.

- When using OVS-DPDK, all bridges on the same Compute node must be of type **ovs_user_bridge**. The director may accept the configuration, but Red Hat OpenStack Platform does not support mixing **ovs_bridge** and **ovs_user_bridge** on the same node.

8.7. CREATING A FLAVOR AND DEPLOYING AN INSTANCE FOR OVS-DPDK

After you configure OVS-DPDK for your Red Hat OpenStack Platform deployment with NFV, you can create a flavor, and deploy an instance using the following steps:

1. Create an aggregate group, and add relevant hosts for OVS-DPDK. Define metadata, for example **dpdk=true**, that matches defined flavor metadata.

   ```
   # openstack aggregate create dpdk_group
   # openstack aggregate add host dpdk_group [compute-host]
   # openstack aggregate set --property dpdk=true dpdk_group
   ```

   **NOTE**

   Pinned CPU instances can be located on the same Compute node as unpinned instances. For more information, see Configuring CPU pinning on the Compute node in the Instances and Images Guide.

2. Create a flavor.

   ```
   # openstack flavor create <flavor> --ram <MB> --disk <GB> --vcpus <#>
   ```

3. Set flavor properties. Note that the defined metadata, **dpdk=true**, matches the defined metadata in the DPDK aggregate.

   ```
   # openstack flavor set <flavor> --property dpdk=true --property hw:cpu_policy=dedicated --property hw:mem_page_size=1GB --property hw:emulator_threads_policy=isolate
   ```
For details on the emulator threads policy for performance improvements, see: Configure Emulator Threads to run on a Dedicated Physical CPU.

4. Create the network.

```bash
# openstack network create net1 --provider-physical-network tenant --provider-network-type vlan --provider-segment <VLAN-ID>
# openstack subnet create subnet1 --network net1 --subnet-range 192.0.2.0/24 --dhcp
```

5. Optional: If you use multiqueue with OVS-DPDK, set the `hw_vif_multiqueue_enabled` property on the image that you want to use to create a instance:

```bash
# openstack image set --property hw_vif_multiqueue_enabled=true <image>
```

6. Deploy an instance.

```bash
# openstack server create --flavor <flavor> --image <glance image> --nic net-id=<network ID> <server_name>
```

8.8. TROUBLESHOOTING THE CONFIGURATION

This section describes the steps to troubleshoot the OVS-DPDK configuration.

1. Review the bridge configuration, and confirm that the bridge has `datapath_type=netdev`.

```bash
# ovs-vsctl list bridge br0
_uuid               : bdce0825-e263-4d15-b256-f01222df96f3
auto_attach         : []
controller          : []
datapath_id         : "00002608cebd154d"
datapath_type       : netdev
datapath_version    : "<built-in>"
external_ids        : {}
fail_mode           : []
flood_vlans         : []
flow_tables         : {}
ipfix               : []
mcast_snooping_enable: false
mirrors             : []
name                : "br0"
netflow             : []
other_config        : {}
ports               : [52725b91-de7f-41e7-bb49-3b7e50354138]
protocols           : []
rstp_enable         : false
rstp_status         : {}
sflow               : []
status              : {}
stp_enable          : false
```

2. Confirm that the docker container `neutron_ovs_agent` is configured to start automatically.
3. Optionally, you can view logs for errors, such as if the container fails to start.

```
# less /var/log/containers/neutron/openvswitch-agent.log
```

4. Confirm that the Poll Mode Driver CPU mask of the ovs-dpdk is pinned to the CPUs. In case of hyper threading, use sibling CPUs.
   For example, to check the sibling of CPU4, run the following command:

```
# cat /sys/devices/system/cpu/cpu4/topology/thread_siblings_list
```

The sibling of CPU4 is CPU20, therefore proceed with the following command:

```
# ovs-vsctl set Open_vSwitch . other_config:pmd-cpu-mask=0x100010
```

Display the status:

```
# tuna -t ovs-vswitchd -CP
thread  ctxt_switches pid SCHED rtpri affinity voluntary nonvoluntary       cmd
3161 OTHER  0  6 765023   614 ovs-vswitchd
3219 OTHER  0  6  1  0   handler24
3220 OTHER  0  6  1  0   handler21
3221 OTHER  0  6  1  0   handler22
3222 OTHER  0  6  1  0   handler23
3223 OTHER  0  6  1  0   handler25
3224 OTHER  0  6  1  0   handler26
3225 OTHER  0  6  1  0   handler27
3226 OTHER  0  6  1  0   handler28
3227 OTHER  0  6  2  0   handler31
3228 OTHER  0  6  2  4   handler30
3229 OTHER  0  6  2  5   handler32
3230 OTHER  0  6 953538  431 revalidator29
3231 OTHER  0  6 1424258  976 revalidator33
3232 OTHER  0  6 1424693  836 revalidator34
3233 OTHER  0  6 951678  503 revalidator36
3234 OTHER  0  6 1425128  498 revalidator35
*3235 OTHER  0  4 151123  51      pmd37*
*3236 OTHER  0 20 298967  48      pmd38*
3164 OTHER  0  6 47575  0   dpdk_watchdog3

```
CHAPTER 9. TUNING A RED HAT OPENSTACK PLATFORM ENVIRONMENT

9.1. PINNING EMULATOR THREADS

Emulator threads handle interrupt requests and non-blocking processes for virtual machine hardware emulation. These threads float across the CPUs that the guest uses for processing. If threads used for the poll mode driver (PMD) or real-time processing run on these guest CPUs, you can experience packet loss or missed deadlines.

You can separate emulator threads from VM processing tasks by pinning the threads to their own guest CPUs, increasing performance as a result.

9.1.1. Configuring CPUs to host emulator threads

To improve performance, reserve a subset of host CPUs identified in the `OvsDpdkCoreList` parameter for hosting emulator threads.

Procedure

1. Deploy an overcloud with `NovaComputeCpu Shared Set` defined for a given role. The value of `NovaComputeCpu Shared Set` applies to the `cpu_shared_set` parameter in the `nova.conf` file for hosts within that role.

```
parameter_defaults:
    ComputeOvsDpdkParameters:
        OvsDpdkCoreList: “0-1,16-17”
        NovaComputeCpuSharedSet: “0-1,16-17”
        NovaComputeCpuDedicatedSet: “2-15,18-31”
```

2. Create a flavor to build instances with emulator threads separated into a shared pool.

```
openstack flavor create --ram <size_mb> --disk <size_gb> --vcpus <vcpus> <flavor>
```

3. Add the `hw:emulator_threads_policy` extra specification, and set the value to `share`. Instances created with this flavor will use the instance CPUs defined in the `cpu_share_set` parameter in the `nova.conf` file.

```
openstack flavor set <flavor> --property hw:emulator_threads_policy=share
```

**NOTE**

You must set the `cpu_share_set` parameter in the `nova.conf` file to enable the share policy for this extra specification. You should use heat for this preferably, as editing `nova.conf` manually might not persist across redeployments.

9.1.2. Verify the emulator thread pinning

Procedure

1. Identify the host and name for a given instance.
openstack server show <instance_id>

2. Use SSH to log on to the identified host as heat-admin.

ssh heat-admin@compute-1

[compute-1]$ sudo virsh dumpxml instance-0001 | grep `emulatorpin cpuset`

9.2. ENABLING RT-KVM FOR NFV WORKLOADS

To facilitate installing and configuring Red Hat Enterprise Linux 8.0 Real Time KVM (RT-KVM), Red Hat OpenStack Platform provides the following features:

- A real-time Compute node role that provisions Red Hat Enterprise Linux for real-time.
- The additional RT-KVM kernel module.
- Automatic configuration of the Compute node.

9.2.1. Planning for your RT-KVM Compute nodes

You must use Red Hat certified servers for your RT-KVM Compute nodes. For more information, see: Red Hat Enterprise Linux for Real Time 7 certified servers.

For details on how to enable the rhel-8-server-nfv-rpms repository for RT-KVM, and ensuring your system is up to date, see: Registering and updating your undercloud.

NOTE

You need a separate subscription to a Red Hat OpenStack Platform for Real Time SKU before you can access this repository.

Building the real-time image

1. Install the libguestfs-tools package on the undercloud to get the virt-customize tool:

(undercloud) [stack@undercloud-0 ~]$ sudo dnf install libguestfs-tools

2. Extract the images:

(undercloud) [stack@undercloud-0 ~]$ tar -xf /usr/share/rhosp-director-images/overcloud-full.tar
(undercloud) [stack@undercloud-0 ~]$ tar -xf /usr/share/rhosp-director-images/ironic-python-agent.tar

3. Copy the default image:

(undercloud) [stack@undercloud-0 ~]$ cp overcloud-full.qcow2 overcloud-realtime-compute.qcow2

4. Register your image to enable Red Hat repositories relevant to your customizations. Replace [username] and [password] with valid credentials in the following example.
virt-customize -a overcloud-realtime-compute.qcow2 --run-command \
'subscription-manager register --username=[username] --password=[password]' \
subscription-manager release --set 8.1

NOTE
For security, you can remove credentials from the history file if they are used on
the command prompt. You can delete individual lines in history using the history
-d command followed by the line number.

5. Find a list of pool IDs from your account’s subscriptions, and attach the appropriate pool ID to
your image.

    sudo subscription-manager list --all --available | less
    ...
    virt-customize -a overcloud-realtime-compute.qcow2 --run-command \
    'subscription-manager attach --pool [pool-ID]'

6. Add the repositories necessary for Red Hat OpenStack Platform with NFV.

    virt-customize -a overcloud-realtime-compute.qcow2 --run-command \
    'sudo subscription-manager repos --enable=rhel-8-for-x86_64-baseos-eus-rpms \  
    --enable=rhel-8-for-x86_64-appstream-eus-rpms \  
    --enable=rhel-8-for-x86_64-highavailability-eus-rpms \  
    --enable=ansible-2.9-for-rhel-8-x86_64-rpms \  
    --enable=openstack-16.1-for-rhel-8-x86_64-rpms \  
    --enable=rhel-8-for-x86_64-nfv-rpms \  
    --enable=advanced-virt-for-rhel-8-x86_64-rpms \  
    --enable=fast-datapath-for-rhel-8-x86_64-rpms'

7. Create a script to configure real-time capabilities on the image.

    (undercloud) [stack@undercloud-0 ~]$ cat <<'EOF' > rt.sh
    #!/bin/bash
    set -eux
    dnf -v -y --setopt=protected_packages= erase kernel.$(uname -m)
    dnf -v -y install kernel-rt kernel-rt-kvm tuned-profiles-nfv-host
    EOF

8. Run the script to configure the real-time image:

    (undercloud) [stack@undercloud-0 ~]$ virt-customize -a overcloud-realtime-compute.qcow2 -v --run rt.sh 2>&1 | tee virt-customize.log

NOTE
If you see the following line in the rt.sh script output, "grubby fatal error:
unable to find a suitable template", you can ignore this error.
9. Examine the `virt-customize.log` file that resulted from the previous command, to check that the packages installed correctly using the `rt.sh` script.

```bash
(undercloud) [stack@undercloud-0 ~]$ cat virt-customize.log | grep Verifying
Verifying : kernel-3.10.0-957.el7.x86_64                                 1/1
Verifying : 10:qemu-kvm-tools-rhev-2.12.0-18.el7_6.1.x86_64              1/8
Verifying : tuned-profiles-realtime-2.10.0-6.el7_6.3.noarch            2/8
Verifying : linux-firmware-20180911-69.git85c5d90.el7.noarch             3/8
Verifying : tuned-profiles-nfv-host-2.10.0-6.el7_6.3.noarch          4/8
Verifying : kernel-rt-kvm-3.10.0-957.10.1.rt56.921.el7.x86_64          5/8
Verifying : tuned-profiles.realtime-2.10.0-6.el7_6.3.noarch         6/8
Verifying : kernel-rt-3.10.0-957.10.1.rt56.921.el7.x86_64            7/8
Verifying : rt-setup-2.0-6.el7.x86_64                                  8/8
```

10. Relabel SELinux:

```bash
(undercloud) [stack@undercloud-0 ~]$ virt-customize -a overcloud-realtime-compute.qcow2 -selinux-relabel
```

11. Extract vmlinuz and initrd:

```bash
(undercloud) [stack@undercloud-0 ~]$ mkdir image
(undercloud) [stack@undercloud-0 ~]$ guestmount -a overcloud-realtime-compute.qcow2 -i -ro image
(undercloud) [stack@undercloud-0 ~]$ cp image/boot/vmlinuz-3.10.0-862.rt56.804.el7.x86_64 ./overcloud-realtime-compute.vmlinuz
(undercloud) [stack@undercloud-0 ~]$ cp image/boot/initramfs-3.10.0-862.rt56.804.el7.x86_64.img ./overcloud-realtime-compute.initrd
(undercloud) [stack@undercloud-0 ~]$ guestunmount image
```

**NOTE**

The software version in the `vmlinuz` and `initramfs` filenames vary with the kernel version.

12. Upload the image:

```bash
(undercloud) [stack@undercloud-0 ~]$ openstack overcloud image upload --update-existing -os-image-name overcloud-realtime-compute.qcow2
```

You now have a real-time image you can use with the `ComputeOvsDpdkRT` composable role on your selected Compute nodes.

**Modifying BIOS settings on RT-KVM Compute nodes**

To reduce latency on your RT-KVM Compute nodes, disable all options for the following parameters in your Compute node BIOS settings:

- Power Management
- Hyper-Threading
- CPU sleep states
Logical processors

See Setting BIOS parameters for descriptions of these settings and the impact of disabling them. See your hardware manufacturer documentation for complete details on how to change BIOS settings.

9.2.2. Configuring OVS-DPDK with RT-KVM

NOTE

You must determine the best values for the OVS-DPDK parameters that you set in the network-environment.yaml file to optimize your OpenStack network for OVS-DPDK. For more details, see Section 8.1, “Deriving DPDK parameters with workflows”.

9.2.2.1. Generating the ComputeOvsDpdk composable role

Use the ComputeOvsDpdkRT role to specify Compute nodes for the real-time compute image. Generate roles_data.yaml for the ComputeOvsDpdkRT role.

# (undercloud) [stack@undercloud-0 ~]$ openstack overcloud roles generate -o roles_data.yaml
Controller ComputeOvsDpdkRT

9.2.2.2. Configuring the OVS-DPDK parameters

IMPORTANT

Determine the best values for the OVS-DPDK parameters in the network-environment.yaml file to optimize your deployment. For more information, see Section 8.1, “Deriving DPDK parameters with workflows”.

1. Add the NIC configuration for the OVS-DPDK role you use under resource_registry:

resource_registry:
   # Specify the relative/absolute path to the config files you want to use for override the default.
   OS::TripleO::ComputeOvsDpdkRT::Net::SoftwareConfig: nic-configs/compute-ovs-dpdk.yaml
   OS::TripleO::Controller::Net::SoftwareConfig: nic-configs/controller.yaml

2. Under parameter_defaults, set the OVS-DPDK, and RT-KVM parameters:

   # DPDK compute node.
   ComputeOvsDpdkRTParameters:
      KernelArgs: "default_hugepagesz=1GB hugepagesz=1G hugepages=32 iommu=pt
      intel_iommu=on isolcpus=1-7,17-23,9-15,25-31"
      TunedProfileName: "realtime-virtual-host"
      IsolCpusList: "1,2,3,4,5,6,7,9,10,17,18,19,20,21,22,23,11,12,13,14,15,25,26,27,28,29,30,31"
   NovaComputeCpuDedicatedSet: 
      ["2,3,4,5,6,7,18,19,20,21,22,23,10,11,12,13,14,15,26,27,28,29,30,31"]
   NovaReservedHostMemory: 4096
   OvsDpdkSocketMemory: "1024,1024"
   OvsDpdkMemoryChannels: "4"
9.2.3.1. Launching an RT-KVM instance

Perform the following steps to launch an RT-KVM instance on a real-time enabled Compute node:

1. Create an RT-KVM flavor on the overcloud:

```
# openstack flavor create r1.small 99 4096 20 4
# openstack flavor set --property hw:cpu_policy=dedicated 99
# openstack flavor set --property hw:cpu_realtime=yes 99
# openstack flavor set --property hw:mem_page_size=1GB 99
# openstack flavor set --property hw:cpu_realtime_mask="^0-1" 99
# openstack flavor set --property hw:cpu_emulator_threads=isolate 99
```

2. Launch an RT-KVM instance:

```
# openstack server create --image <rhel> --flavor r1.small --nic net-id=<dpdk-net> test-rt
```

3. To verify that the instance uses the assigned emulator threads, run the following command:

```
# virsh dumpxml <instance-id> | grep vcpu -A1
<vcpu placement='static'>4</vcpu>
<cputune>
  <vcpupin vcpu='0' cpuset='1'/>
  <vcpupin vcpu='1' cpuset='3'/>
  <vcpupin vcpu='2' cpuset='5'/>
  <vcpupin vcpu='3' cpuset='7'/>
  <emulatorpin cpuset='0-1'/>
  <vcpusched vcpus='2-3' scheduler='fifo' priority='1'/>
</cputune>
```

9.3. TRUSTED VIRTUAL FUNCTIONS

You can configure trust between physical functions (PFs) and virtual functions (VFs), so that VFs can perform privileged actions, such as enabling promiscuous mode, or modifying a hardware address.
9.3.1. Configuring trust between virtual and physical functions

Prerequisites

- An operational installation of Red Hat OpenStack Platform including director

Procedure

Complete the following steps to configure and deploy the overcloud with trust between physical and virtual functions:

1. Add the `NeutronPhysicalDevMappings` parameter in the `parameter_defaults` section to link between the logical network name and the physical interface.

   ```yaml
   parameter_defaults:
   NeutronPhysicalDevMappings:
   - sriov2:p5p2
   ```

2. Add the new property, `trusted`, to the SR-IOV parameters.

   ```yaml
   parameter_defaults:
   NeutronPhysicalDevMappings:
   - sriov2:p5p2
   NovaPCIPassthrough:
   - devname: "p5p2"
     physical_network: "sriov2"
     trusted: "true"
   ```

   **NOTE**

   You must include double quotation marks around the value "true".

   **IMPORTANT**

   Complete the following step in trusted environments, as it allows trusted port binding by non-administrative accounts.

3. Modify permissions to allow users to create and update port bindings.

   ```yaml
   parameter_defaults:
   NeutronApiPolicies: {
     operator_create_binding_profile: { key: 'create_port:binding:profile', value: 'rule:admin_or_network_owner' },
     operator_get_binding_profile: { key: 'get_port:binding:profile', value: 'rule:admin_or_network_owner' },
     operator_update_binding_profile: { key: 'update_port:binding:profile', value: 'rule:admin_or_network_owner' }
   }
   ```

9.3.2. Utilizing trusted VF networks

1. Create a network of type `vlan`. 
openstack network create trusted_vf_network --provider-network-type vlan \
--provider-segment 111 --provider-physical-network sriov2 \
--external --disable-port-security

2. Create a subnet.

openstack subnet create --network trusted_vf_network \
--ip-version 4 --subnet-range 192.168.111.0/24 --no-dhcp \
subnet-trusted_vf_network

3. Create a port. Set the `vnic-type` option to `direct`, and the `binding-profile` option to `true`.

openstack port create --network sriov111 \
--vnic-type direct --binding-profile trusted=true \
sriov111_port_trusted

4. Create an instance, and bind it to the previously-created trusted port.

openstack server create --image rhel --flavor dpdk 
 --network internal --port trusted_vf_network_port_trusted --config-drive True --wait rhel-dpdk-sriov_trusted

Verify the trusted VF configuration on the hypervisor

1. On the compute node that you created the instance, run the following command:

```
# ip link
7: p5p2: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 9000 qdisc mq state UP mode
DEFAULT group default qlen 1000
    link/ether b4:96:91:1c:40:fa brd ff:ff:ff:ff:ff:ff
  vf 6 MAC fa:16:3e:b8:91:c2, vlan 111, spoof checking off, link-state auto, trust on, query_rss off
  vf 7 MAC fa:16:3e:84:cf:c8, vlan 111, spoof checking off, link-state auto, trust off, query_rss off
```

1. Verify that the trust status of the VF is `trust on`. The example output contains details of an environment that contains two ports. Note that `vf 6` contains the text `trust on`.

9.4. CONFIGURING RX/TX QUEUE SIZE

You can experience packet loss at high packet rates above 3.5 million packets per second (mpps) for many reasons, such as:

- a network interrupt
- a SMI
- packet processing latency in the Virtual Network Function

To prevent packet loss, increase the queue size from the default of 512 to a maximum of 1024.

**Prerequisites**

- To configure RX, ensure that you have libvirt v2.3 and QEMU v2.7.
- To configure TX, ensure that you have libvirt v3.7 and QEMU v2.10.
Procedure

- To increase the RX and TX queue size, include the following lines to the `parameter_defaults:` section of a relevant director role. Here is an example with ComputeOvsDpdk role:

```plaintext
parameter_defaults:
  ComputeOvsDpdkParameters:
    -NovaLibvirtRxQueueSize: 1024
    -NovaLibvirtTxQueueSize: 1024
```

Testing

- You can observe the values for RX queue size and TX queue size in the nova.conf file:

```plaintext
[libvirt]
  rx_queue_size=1024
  tx_queue_size=1024
```

- You can check the values for RX queue size and TX queue size in the VM instance XML file generated by libvirt on the compute host.

```xml
<devices>
  <interface type='vhostuser'>
    <mac address='56:48:4f:4d:5e:6f'/>
    <source type='unix' path='/tmp/vhost-user1' mode='server'/>
    <model type='virtio'/>
    <driver name='vhost' rx_queue_size='1024' tx_queue_size='1024'/>
    <address type='pci' domain='0x0000' bus='0x00' slot='0x10' function='0x0'/>
  </interface>
</devices>
```

To verify the values for RX queue size and TX queue size, use the following command on a KVM host:

```
$ virsh dumpxml <vm name> | grep queue_size
```

- You can check for improved performance, such as 3.8 mpps/core at 0 frame loss.

9.5. CONFIGURING A NUMA-AWARE VSWITCH

**IMPORTANT**

This feature is available in this release as a Technology Preview, and therefore is not fully supported by Red Hat. It should only be used for testing, and should not be deployed in a production environment. For more information about Technology Preview features, see Scope of Coverage Details.

Before you implement a NUMA-aware vSwitch, examine the following components of your hardware configuration:

- The number of physical networks.
- The placement of PCI cards.
The physical architecture of the servers.

Memory-mapped I/O (MMIO) devices, such as PCIe NICs, are associated with specific NUMA nodes. When a VM and the NIC are on different NUMA nodes, there is a significant decrease in performance. To increase performance, align PCIe NIC placement and instance processing on the same NUMA node.

Use this feature to ensure that instances that share a physical network are located on the same NUMA node. To optimize datacenter hardware, you can leverage load-sharing VMs by using multiple networks, different network types, or bonding.

**IMPORTANT**

To architect NUMA-node load sharing and network access correctly, you must understand the mapping of the PCIe slot and the NUMA node. For detailed information on your specific hardware, refer to your vendor’s documentation.

To prevent a cross-NUMA configuration, place the VM on the correct NUMA node, by providing the location of the NIC to Nova.

**Prerequisites**

- You have enabled the filter “NUMATopologyFilter”

**Procedure**

- Set a new `NeutronPhysnetNUMANodesMapping` parameter to map the physical network to the NUMA node that you associate with the physical network.

- If you use tunnels, such as VxLAN or GRE, you must also set the `NeutronTunnelNUMANodes` parameter.

```parameter_defaults:
    NeutronPhysnetNUMANodesMapping: {<physnet_name>: [<NUMA_NODE>]}
    NeutronTunnelNUMANodes: <NUMA_NODE>,<NUMA_NODE>
```

Here is an example with two physical networks tunneled to NUMA node 0:

- one tenant network associated with NUMA node 0
- one management network without any affinity

```parameter_defaults:
    NeutronBridgeMappings:
    - tenant:br-link0
    NeutronPhysnetNUMANodesMapping: {tenant: [1], mgmt: [0,1]}
    NeutronTunnelNUMANodes: 0
```

**Testing**

- Observe the configuration in the file `/var/lib/config-data/puppet-generated/nova_libvirt/etc/nova/nova.conf`

```[neutron_physnet_tenant]
    numa_nodes=1
[neutron_tunnel]```
numa_nodes=1

- Confirm the new configuration with the `lscpu` command:

  ```
  $ lscpu
  ```

- Launch a VM, with the NIC attached to the appropriate network

### 9.6. Configuring Quality of Service (QoS) in an NFVI Environment

For details on Configuring QoS, see Configure Quality-of-Service (QoS). Support is limited to QoS rule type `bandwidth-limit` on SR-IOV and OVS-DPDK egress interfaces.

### 9.7. Deploying an Overcloud with HCI and DPDK

You can deploy your NFV infrastructure with hyper-converged nodes, by co-locating and configuring Compute and Ceph Storage services for optimized resource usage.

For more information about hyper-converged infrastructure (HCI), see: [Hyper Converged Infrastructure Guide](https://your-document-url)

**Prerequisites**

- Red Hat OpenStack Platform 16.1.
- Ceph 12.2.12-79 (luminous) or newer.
- Ceph-ansible 3.2.38 or newer.

**Procedure**

1. Install `ceph-ansible` on the undercloud.

   ```
   $ sudo yum install ceph-ansible -y
   ```

2. Generate the `roles_data.yaml` file for the ComputeHCI role.

   ```
   $ openstack overcloud roles generate -o ~/<templates>/roles_data.yaml Controller \ ComputeHCIOvsDpdk
   ```

3. Create and configure a new flavor with the `openstack flavor create` and `openstack flavor set` commands. For more information about creating a flavor, see Creating a new role in the Advanced Overcloud Customization Guide.

4. Deploy the overcloud with the custom `roles_data.yaml` file that you generated.

   ```
   # time openstack overcloud deploy --templates \ --timeout 360 \ -r ~/<templates>/roles_data.yaml \ -e /usr/share/openstack-tripleo-heat-templates/environments/ceph-ansible/ceph-ansible.yaml \ -e /usr/share/openstack-tripleo-heat-templates/environments/network-isolation.yaml \ -e /usr/share/openstack-tripleo-heat-templates/environments/services-docker/neutron-ovs-
For increased performance, place the tenant network and Ceph object service daemon (OSD)s in one
NUMA node, such as NUMA-0, and the VNF and any non-NFV VMs in another NUMA node, such as
NUMA-1.

### CPU allocation:

<table>
<thead>
<tr>
<th>NUMA-0</th>
<th>NUMA-1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of Ceph OSDs * 4 HT</td>
<td>Guest vCPU for the VNF and non-NFV VMs</td>
</tr>
<tr>
<td>DPDK lcore – 2 HT</td>
<td>DPDK lcore – 2 HT</td>
</tr>
<tr>
<td>DPDK PMD – 2 HT</td>
<td>DPDK PMD – 2 HT</td>
</tr>
</tbody>
</table>

#### Example of CPU allocation:

<table>
<thead>
<tr>
<th>NUMA-0</th>
<th>NUMA-1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ceph OSD</td>
<td>32,34,36,38,40,42,76,78,80,82,84,86</td>
</tr>
<tr>
<td>DPDK-lcore</td>
<td>0,44</td>
</tr>
<tr>
<td>DPDK-pmd</td>
<td>2,46</td>
</tr>
</tbody>
</table>

### 9.7.2. Example ceph configuration file

```yaml
parameter_defaults:
  CephPoolDefaultSize: 3
  CephPoolDefaultPgNum: 64
  CephPools:
    - {"name": backups, "pg_num": 128, "pgp_num": 128, "application": "rbd"}
    - {"name": volumes, "pg_num": 256, "pgp_num": 256, "application": "rbd"}
    - {"name": vms, "pg_num": 64, "pgp_num": 64, "application": "rbd"}
    - {"name": images, "pg_num": 32, "pgp_num": 32, "application": "rbd"}
  CephConfigOverrides:
    osd_recovery_op_priority: 3
    osd_recovery_max_active: 3
    osd_max_backfills: 1
  CephAnsibleExtraConfig:
```

---

3. For increased performance, place the tenant network and Ceph object service daemon (OSD)s in one
NUMA node, such as NUMA-0, and the VNF and any non-NFV VMs in another NUMA node, such as
NUMA-1.

### CPU allocation:

<table>
<thead>
<tr>
<th>NUMA-0</th>
<th>NUMA-1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Number of Ceph OSDs * 4 HT</td>
<td>Guest vCPU for the VNF and non-NFV VMs</td>
</tr>
<tr>
<td>DPDK lcore – 2 HT</td>
<td>DPDK lcore – 2 HT</td>
</tr>
<tr>
<td>DPDK PMD – 2 HT</td>
<td>DPDK PMD – 2 HT</td>
</tr>
</tbody>
</table>

#### Example of CPU allocation:

<table>
<thead>
<tr>
<th>NUMA-0</th>
<th>NUMA-1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ceph OSD</td>
<td>32,34,36,38,40,42,76,78,80,82,84,86</td>
</tr>
<tr>
<td>DPDK-lcore</td>
<td>0,44</td>
</tr>
<tr>
<td>DPDK-pmd</td>
<td>2,46</td>
</tr>
</tbody>
</table>

### 9.7.2. Example ceph configuration file

```yaml
parameter_defaults:
  CephPoolDefaultSize: 3
  CephPoolDefaultPgNum: 64
  CephPools:
    - {"name": backups, "pg_num": 128, "pgp_num": 128, "application": "rbd"}
    - {"name": volumes, "pg_num": 256, "pgp_num": 256, "application": "rbd"}
    - {"name": vms, "pg_num": 64, "pgp_num": 64, "application": "rbd"}
    - {"name": images, "pg_num": 32, "pgp_num": 32, "application": "rbd"}
  CephConfigOverrides:
    osd_recovery_op_priority: 3
    osd_recovery_max_active: 3
    osd_max_backfills: 1
  CephAnsibleExtraConfig:
```
Assign CPU resources for ceph OSD processes with the following parameters. Adjust the values based on the workload and hardware in this hyperconverged environment.

1. **ceph_osd_docker_cpuset_cpus**: Allocate 4 CPU threads for each OSD for SSD disks, or 1 CPU for each OSD for HDD disks. Include the list of cores and sibling threads from the NUMA node associated with ceph, and the CPUs not found in the three lists: NovaVcpuPinSet, OvsDpdkCoreList, and OvsPmdCoreList.

2. **ceph_osd_docker_cpu_limit**: Set this value to 0, to pin the ceph OSDs to the CPU list from ceph_osd_docker_cpuset_cpus.

3. **ceph_osd_numactl_opts**: Set this value to preferred for cross-NUMA operations, as a precaution.

### 9.7.3. Example DPDK configuration file

```yaml
nb_retry_wait_osd_up: 60
delay_wait_osd_up: 20
is_hci: true

# 3 OSDs * 4 vCPUs per SSD = 12 vCPUs (list below not used for VNF)
ceph_osd_docker_cpuset_cpus: "32,34,36,38,40,42,76,78,80,82,84,86"  # ①
# cpu_limit 0 means no limit as we are limiting CPUs with cpuset above
ceph_osd_docker_cpu_limit: 0  # ②
# numactl preferred to cross the numa boundary if we have to
# but try to only use memory from numa node0
# cpuset-mems would not let it cross numa boundary
# lots of memory so NUMA boundary crossing unlikely
ceph_osd_numactl_opts: "-N 0 --preferred=0"  # ③

CephAnsibleDisksConfig:
    osds_per_device: 1
    osd_scenario: lvm
    osd_objectstore: bluestore
    devices:
        - /dev/sda
        - /dev/sdb
        - /dev/sdc
```
1. **KernelArgs**: To calculate hugepages, subtract the value of the `NovaReservedHostMemory` parameter from total memory.

2. **IsolCpusList**: Assign a set of CPU cores that you want to isolate from the host processes with this parameter. Add the value of the `OvsPmdCoreList` parameter to the value of the `NovaVcpuPinSet` parameter to calculate the value for the `IsolCpusList` parameter.

3. **OvsDpdkSocketMemory**: Specify the amount of memory in MB to pre-allocate from the hugepage pool per NUMA node with the `OvsDpdkSocketMemory` parameter. For more information about calculating OVS-DPDK parameters, see: [ovsdpdk parameters](#).

4. **OvsPmdCoreList**: Specify the CPU cores that are used for the DPDK poll mode drivers (PMD) with this parameter. Choose CPU cores that are associated with the local NUMA nodes of the DPDK interfaces. Allocate 2 HT sibling threads for each NUMA node to calculate the value for the `OvsPmdCoreList` parameter.

5. **OvsDpdkCoreList**: Specify CPU cores for non-data path OVS-DPDK processes, such as handler, and revalidator threads, with this parameter. Allocate 2 HT sibling threads for each NUMA node to calculate the value for the `OvsDpdkCoreList` parameter.

### 9.7.4. Example nova configuration file

```
parameter_defaults:
ComputeHClExtraConfig:
nova::cpu_allocation_ratio: 16 # 2
NovaReservedHugePages: # 1
  - node:0, size:1GB, count:4
  - node:1, size:1GB, count:4
NovaReservedHostMemory: 123904 # 2
# All left over cpus from NUMA-1
NovaVcpuPinSet: # 3
[53,55,57,59,61,63,65,67,69,71,73,75,77,79,81,83,85,87]
```

1. **NovaReservedHugePages**: Pre-allocate memory in MB from the hugepage pool with the `NovaReservedHugePages` parameter. It is the same memory total as the value for the `OvsDpdkSocketMemory` parameter.

2. **NovaReservedHostMemory**: Reserve memory in MB for tasks on the host with the `NovaReservedHostMemory` parameter. Use the following guidelines to calculate the amount of memory that you must reserve:
   - 5 GB for each OSD.
   - 0.5 GB overhead for each VM.
   - 4GB for general host processing. Ensure that you allocate sufficient memory to prevent potential performance degradation caused by cross-NUMA OSD operation.

3. **NovaVcpuPinSet**: List the CPUs not found in `OvsPmdCoreList`, `OvsDpdkCoreList`, or `Ceph osd docker cniuset cnius` with the `NovaVcpuPinSet` parameter. The CPUs must be in the
Ceph_osd_docker_cpuset_cpus with the Nova_vcpu_pinset parameter. The CPUs must be in the same NUMA node as the DPDK NICs.

9.7.5. Recommended configuration for HCI-DPDK deployments

Table 9.1. Tunable parameters for HCI deployments

<table>
<thead>
<tr>
<th>Block Device Type</th>
<th>OSDs, Memory, vCPUs per device</th>
</tr>
</thead>
<tbody>
<tr>
<td>NVMe</td>
<td>Memory: 5GB per OSD&lt;br&gt;OSDs per device: 4&lt;br&gt;vCPUs per device: 3</td>
</tr>
<tr>
<td>SSD</td>
<td>Memory: 5GB per OSD&lt;br&gt;OSDs per device: 1&lt;br&gt;vCPUs per device: 4</td>
</tr>
<tr>
<td>HDD</td>
<td>Memory: 5GB per OSD&lt;br&gt;OSDs per device: 1&lt;br&gt;vCPUs per device: 1</td>
</tr>
</tbody>
</table>

Use the same NUMA node for the following functions:

- Disk controller
- Storage networks
- Storage CPU and memory

Allocate another NUMA node for the following functions of the DPDK provider network:

- NIC
- PMD CPUs
- Socket memory
CHAPTER 10. EXAMPLE: CONFIGURING OVS-DPDK AND SR-IOV WITH VXLAN TUNNELLING

This section describes how to deploy Compute nodes with both OVS-DPDK and SR-IOV interfaces. The cluster includes ML2/OVS and VXLAN tunnelling.

IMPORTANT

You must determine the best values for the OVS-DPDK parameters that you set in the network-environment.yaml file to optimize your OpenStack network for OVS-DPDK. For details, see: Deriving DPDK parameters with workflows.

10.1. CONFIGURING ROLES DATA

Red Hat OpenStack Platform provides a set of default roles in the roles_data.yaml file. You can create your own roles_data.yaml file to support the roles you require.

For the purposes of this example, the ComputeOvsDpdkSriov role is created. For information on creating roles in Red Hat OpenStack Platform, see Advanced Overcloud Customization. For details on the specific role used for this example, see roles_data.yaml.

10.2. CONFIGURING OVS-DPDK PARAMETERS

IMPORTANT

You must determine the best values for the OVS-DPDK parameters that you set in the network-environment.yaml file to optimize your OpenStack network for OVS-DPDK. For details, see Deriving DPDK parameters with workflows.

1. Add the custom resources for OVS-DPDK under resource_registry:

```
resource_registry:
  # Specify the relative/absolute path to the config files you want to use for override the default.
  OS::TripleO::ComputeOvsDpdkSriov::Net::SoftwareConfig: nic-configs/computeovsdpdksirov.yaml
  OS::TripleO::Controller::Net::SoftwareConfig: nic-configs/controller.yaml
```

2. Under parameter_defaults, set the tunnel type to vxlan, and the network type to vxlan,vlan:

```
NeutronTunnelTypes: 'vxlan'
NeutronNetworkType: 'vxlan,vlan'
```

3. Under parameters_defaults, set the bridge mapping:

```
# The OVS logical->physical bridge mappings to use.
NeutronBridgeMappings:
  - dpdk-mgmt:br-link0
```

4. Under parameter_defaults, set the role-specific parameters for the ComputeOvsDpdkSriov role:

```
NOTE

To prevent failures during guest creation, assign at least one CPU with sibling thread on each NUMA node. In the example, the values for the `OvsPmdCoreList` parameter denote cores 2 and 22 from NUMA 0, and cores 3 and 23 from NUMA 1.

NOTE

These huge pages are consumed by the virtual machines, and also by OVS-DPDK using the `OvsDpdkSocketMemory` parameter as shown in this procedure. The number of huge pages available for the virtual machines is the `boot` parameter minus the `OvsDpdkSocketMemory`.

You must also add `hw:mem_page_size=1GB` to the flavor you associate with the DPDK instance.

NOTE

`OvsDPDKCoreList` and `OvsDpdkMemoryChannels` are the required settings for this procedure. For optimum operation, ensure you deploy DPDK with appropriate parameters and values.

5. Configure the role-specific parameters for SR-IOV:

```
NovaPCIPassthrough:
  - devname: "p7p3"
    trusted: "true"
    physical_network: "sriov-1"
- devname: "p7p4"
  trusted: "true"
  physical_network: "sriov-2"
```

10.3. CONFIGURING THE CONTROLLER NODE
1. Create the control-plane Linux bond for an isolated network.

   - type: linux_bond
     name: bond_api
     bonding_options: "mode=active-backup"
     use_dhcp: false
     dns_servers:
       - get_param: DnsServers
     members:
       - type: interface
         name: nic2
         primary: true

2. Assign VLANs to this Linux bond.

   - type: vlan
     vlan_id:
       - get_param: InternalApiNetworkVlanID
     device: bond_api
     addresses:
       - ip_netmask:
         get_param: InternalApiIpSubnet

   - type: vlan
     vlan_id:
       - get_param: StorageNetworkVlanID
     device: bond_api
     addresses:
       - ip_netmask:
         get_param: StorageIpSubnet

   - type: vlan
     vlan_id:
       - get_param: StorageMgmtNetworkVlanID
     device: bond_api
     addresses:
       - ip_netmask:
         get_param: StorageMgmtIpSubnet

   - type: vlan
     vlan_id:
       - get_param: ExternalNetworkVlanID
     device: bond_api
     addresses:
       - ip_netmask:
         get_param: ExternalIpSubnet
     routes:
       - default: true
         next_hop:
           get_param: ExternalInterfaceDefaultRoute

3. Create the OVS bridge to access neutron-dhcp-agent and neutron-metadata-agent services.

   - type: ovs_bridge
     name: br-link0
10.4. CONFIGURING THE COMPUTE NODE FOR DPDK AND SR-IOV

Create the `computeovsdpdksriov.yaml` file from the default `compute.yaml` file, and make the following changes:

1. Create the control-plane Linux bond for an isolated network.

   ```yaml
   - type: linux_bond
     name: bond_api
     bonding_options: "mode=active-backup"
     use_dhcp: false
     dns_servers:
       get_param: DnsServers
     members:
       - type: interface
         name: nic3
         primary: true
       - type: interface
         name: nic4
   ```

2. Assign VLANs to this Linux bond.

   ```yaml
   - type: vlan
     vlan_id:
       get_param: InternalApiNetworkVlanID
     device: bond_api
     addresses:
       - ip_netmask:
           get_param: InternalApiIpSubnet

   - type: vlan
     vlan_id:
       get_param: StorageNetworkVlanID
     device: bond_api
     addresses:
       - ip_netmask:
           get_param: StorageIpSubnet
   ```

3. Set a bridge with a DPDK port to link to the controller.
- type: ovs_user_bridge
  name: br-link0
  use_dhcp: false
  ovs_extra:
    - str_replace:
        template: set port br-link0 tag=_VLAN_TAG_
        params:
          _VLAN_TAG_: get_param: TenantNetworkVlanID
  addresses:
    - ip_netmask:
        get_param: TenantIpSubnet
  members:
    - type: ovs_dpdk_bond
      name: dpdkbond0
      mtu: 9000
      rx_queue: 2
      members:
        - type: ovs_dpdk_port
          name: dpdk0
          members:
            - type: interface
              name: nic7
        - type: ovs_dpdk_port
          name: dpdk1
          members:
            - type: interface
              name: nic8

NOTE
To include multiple DPDK devices, repeat the type code section for each DPDK device that you want to add.

NOTE
When using OVS-DPDK, all bridges on the same Compute node must be of type ovs_user_bridge. Red Hat OpenStack Platform does not support both ovs_bridge and ovs_user_bridge located on the same node.

10.5. DEPLOYING THE OVERCLOUD

1. Run the overcloud_deploy.sh script:
CHAPTER 11. UPGRADING RED HAT OPENSTACK PLATFORM WITH NFV

There are additional considerations and steps required to upgrade Red Hat OpenStack Platform when you have OVS-DPDK configured. For more information, see Preparing an NFV-Configured Overcloud in the Upgrading Red Hat OpenStack Platform Guide.
CHAPTER 12. NFV PERFORMANCE

Red Hat OpenStack Platform director configures the Compute nodes to enforce resource partitioning and fine tuning to achieve line rate performance for the guest virtual network functions (VNFs). The key performance factors in the NFV use case are throughput, latency, and jitter.

You can enable high-performance packet switching between physical NICs and virtual machines using data plane development kit (DPDK) accelerated virtual machines. OVS 2.10 embeds support for DPDK 17 and includes support for vhost-user multiqueue, allowing scalable performance. OVS-DPDK provides line-rate performance for guest VNFs.

Single root I/O virtualization (SR-IOV) networking provides enhanced performance, including improved throughput for specific networks and virtual machines.

Other important features for performance tuning include huge pages, NUMA alignment, host isolation, and CPU pinning. VNF flavors require huge pages and emulator thread isolation for better performance. Host isolation and CPU pinning improve NFV performance and prevent spurious packet loss.

For a high-level introduction to CPUs and NUMA topology, see: NFV Performance Considerations and Configure Emulator Threads to run on a Dedicated Physical CPU.
The following table includes additional Red Hat documentation for reference:

The Red Hat OpenStack Platform documentation suite can be found here: [Red Hat OpenStack Platform Documentation Suite](https://www.redhat.com/openstack)

### Table 13.1. List of Available Documentation

<table>
<thead>
<tr>
<th>Component</th>
<th>Reference</th>
</tr>
</thead>
<tbody>
<tr>
<td>Red Hat Enterprise Linux</td>
<td>Red Hat OpenStack Platform is supported on Red Hat Enterprise Linux 8.0. For information on installing Red Hat Enterprise Linux, see the corresponding installation guide at: <a href="https://www.redhat.com">Red Hat Enterprise Linux Documentation Suite</a></td>
</tr>
<tr>
<td>Red Hat OpenStack Platform</td>
<td>To install OpenStack components and their dependencies, use the Red Hat OpenStack Platform director. The director uses a basic OpenStack installation as the undercloud to install, configure, and manage the OpenStack nodes in the final overcloud. You need one extra host machine for the installation of the undercloud, in addition to the environment necessary for the deployed overcloud. For detailed instructions, see <a href="https://www.redhat.com">Red Hat OpenStack Platform Director Installation and Usage</a>. For information on configuring advanced features for a Red Hat OpenStack Platform enterprise environment using the Red Hat OpenStack Platform director such as network isolation, storage configuration, SSL communication, and general configuration method, see <a href="https://www.redhat.com">Advanced Overcloud Customization</a>.</td>
</tr>
<tr>
<td>NFV Documentation</td>
<td>For a high level overview of the NFV concepts, see the <a href="https://www.redhat.com">Network Functions Virtualization Product Guide</a></td>
</tr>
</tbody>
</table>
This section provides sample yaml files as a reference to add single root I/O virtualization (SR-IOV) and Data Plane Development Kit (DPDK) interfaces on the same compute node.

NOTE

These templates are from a fully-configured environment, and include parameters unrelated to NFV, that might not apply to your deployment.

A.1. SAMPLE VXLAN DPDK SRIOV YAML FILES

A.1.1. roles_data.yaml

1. Run the `openstack overcloud roles generate` command to generate the `roles_data.yaml` file. Include role names in the command according to the roles that you want to deploy in your environment, such as `Controller`, `ComputeSriov`, `ComputeOvsDpdkRT`, `ComputeOvsDpdkSriov`, or other roles. For example, to generate a `roles_data.yaml` file that contains the roles `Controller` and `ComputeOvsDpdkSriov`, run the following command:

```
$ openstack overcloud roles generate -o roles_data.yaml Controller ComputeOvsDpdkSriov
```

```
# File generated by TripleO
#
# Role: Controller
#
- name: Controller
