CHAPTER 1. OPEN VIRTUAL NETWORK (OVN)

Open Virtual Network (OVN) is an Open vSwitch-based software-defined networking (SDN) solution for supplying network services to instances. OVN provides platform-agnostic support for the full OpenStack Networking API. OVN allows you to programatically connect groups of guest instances into private L2 and L3 networks. OVN uses a standard approach to virtual networking that is capable of extending to other Red Hat platforms and solutions.

NOTE

The minimum Open vSwitch (OVS) version required is OVS 2.9.

OVN uses Python 3.6 packages by default.

NOTE

OVN is supported only in an HA environment. We recommend that you deploy OVN with distributed virtual routing (DVR).

1.1. OVN ARCHITECTURE

The OVN architecture replaces the OVS ML2 plugin with the OVN Modular Layer 2 (ML2) plugin to support the Networking API. OVN provides robust networking services for the Red Hat OpenStack platform.

The OVN architecture consists of the following components and services:

**OVN ML2 plugin**

- Translates the OpenStack-specific networking configuration into the platform-agnostic OVN logical networking configuration. This plugin typically runs on the Controller node.

**OVN Northbound (NB) database (ovn-nb)**

- Stores the logical OVN networking configuration from the OVN ML2 plugin. This database typically runs on the Controller node and listens on TCP port 6641.

**OVN Northbound service (ovn-northd)**

- Converts the logical networking configuration from the OVN NB database to the logical data path flows and populates these on the OVN Southbound database. This service typically runs on the Controller node.

**OVN Southbound (SB) database (ovn-sb)**

- Stores the converted logical data path flows. This database typically runs on the Controller node and listens on TCP port 6642.

**OVN controller (ovn-controller)**

- Connects to the OVN SB database and acts as the open vSwitch controller to control and monitor network traffic. Runs on all Compute and gateway nodes where OS::Tripleo::Services::OVNController is defined.

**OVN metadata agent (ovn-metadata-agent)**

- Spawns the haproxy instances for managing the OVS interfaces, network namespaces and HAProxy processes used to proxy metadata API requests. Runs on all Compute and gateway nodes where OS::TripleO::Services::OVNMetadataAgent is defined.
Deploy OVN in HA deployments only. We recommend you deploy with distributed virtual routing (DVR) enabled.

**NOTE**
To use OVN, your director deployment must use Generic Network Virtualization Encapsulation (Geneve), and not VXLAN. Geneve allows OVN to identify the network using the 24-bit Virtual Network Identifier (VNI) field and an additional 32-bit Type Length Value (TLV) to specify both the source and destination logical ports. You should account for this larger protocol header when you determine your MTU setting.

**DVR HA with OVN**
Deploy OVN with DVR in an HA environment. OVN is supported only in an HA environment. The `neutron-ovn-dvr-ha.yaml` environment file configures the required DVR-specific parameters for deployments using OVN in an HA environment.

### 2.1. THE OVN-CONTROLLER ON COMPUTE NODES

The `ovn-controller` service runs on each Compute node and connects to the OVN SB database server to retrieve the logical flows. The `ovn-controller` translates these logical flows into physical OpenFlow flows and adds the flows to the OVS bridge (`br-int`). To communicate with `ovs-vswitchd` and install the OpenFlow flows, the `ovn-controller` connects to the local `ovsdb-server` (that hosts `conf.db`) using the UNIX socket path that was passed when `ovn-controller` was started (for example `unix:/var/run/openvswitch/db.sock`).

The `ovn-controller` service expects certain key-value pairs in the `external_ids` column of the `Open_vSwitch` table; `puppet-ovn` uses `puppet-vswitch` to populate these fields. Below are the key-value pairs that `puppet-vswitch` configures in the `external_ids` column:

```
hostname=<HOST NAME>
ovn-encap-ip=<IP OF THE NODE>
ovn-encap-type=geneve
ovn-remote=tcp:OVN_DBS_VIP:6642
```

### 2.2. THE OVN COMPOSABLE SERVICE

The director has a composable service for OVN named `ovn-dbs` with two profiles: the base profile and the pacemaker HA profile. The OVN northbound and southbound databases are hosted by the `ovsdb-server` service. Similarly, the `ovsdb-server` process runs alongside `ovs-vswitchd` to host the OVS database (`conf.db`).

**NOTE**
The schema file for the NB database is located in `/usr/share/openvswitch/ovn-nb.ovsschema`, and the SB database schema file is in `/usr/share/openvswitch/ovn-sb.ovsschema`.

### 2.3. HIGH AVAILABILITY WITH PACEMAKER AND DVR
In addition to the required HA profile, Red Hat recommends that you deploy OVN with DVR to ensure the availability of networking services. With the HA profile enabled, the OVN database servers start on all the Controllers, and pacemaker then selects one controller to serve in the master role.

The `ovsdb-server` service does not currently support active-active mode. It does support HA with the master-slave mode, which is managed by Pacemaker using the resource agent Open Cluster Framework (OCF) script. Having `ovsdb-server` run in master mode allows write access to the database, while all the other slave `ovsdb-server` services replicate the database locally from the master, and do not allow write access.

The YAML file for this profile is the `tripleo-heat-templates/environments/services/neutron-ovn-dvr-ha.yaml` file. When enabled, the OVN database servers are managed by Pacemaker, and `puppet-tripleo` creates a pacemaker OCF resource named `ovn:ovndb-servers`.

The OVN database servers are started on each Controller node, and the controller owning the virtual IP address (OVN_DBS_VIP) runs the OVN DB servers in master mode. The OVN ML2 mechanism driver and `ovn-controller` then connect to the database servers using the OVN_DBS_VIP value. In the event of a failover, Pacemaker moves the virtual IP address (OVN_DBS_VIP) to another controller, and also promotes the OVN database server running on that node to master.

2.4. LAYER 3 HIGH AVAILABILITY WITH OVN

OVN supports Layer 3 high availability (L3 HA) without any special configuration. OVN automatically schedules the router port to all available gateway nodes that can act as an L3 gateway on the specified external network. OVN L3 HA uses the gateway_chassis column in the OVN Logical_Router_Port table. Most functionality is managed by OpenFlow rules with bundled active_passive outputs. The `ovn-controller` handles the Address Resolution Protocol (ARP) responder and router enablement and disablement. Gratuitous ARPs for FIPs and router external addresses are also periodically sent by the `ovn-controller`.

**NOTE**

L3HA uses OVN to balance the routers back to the original gateway nodes to avoid any nodes becoming a bottleneck.

**BFD monitoring**

OVN uses the Bidirectional Forwarding Detection (BFD) protocol to monitor the availability of the gateway nodes. This protocol is encapsulated on top of the Geneve tunnels established from node to node.

Each gateway node monitors all the other gateway nodes in a star topology in the deployment. Gateway nodes also monitor the compute nodes to let the gateways enable and disable routing of packets and ARP responses and announcements.

Each compute node uses BFD to monitor each gateway node and automatically steers external traffic, such as source and destination Network Address Translation (SNAT and DNAT), through the active gateway node for a given router. Compute nodes do not need to monitor other compute nodes.

**NOTE**

External network failures are not detected as would happen with an ML2-OVS configuration.

L3 HA for OVN supports the following failure modes:
• The gateway node becomes disconnected from the network (tunneling interface).

• **ovs-vswitchd** stops (**ovs-switchd** is responsible for BFD signaling)

• **ovn-controller** stops (**ovn-controller** removes itself as a registered node).

**NOTE**

This BFD monitoring mechanism only works for link failures, not for routing failures.
CHAPTER 3. MIGRATING FROM ML2/OVS TO ML2/OVN

In a director-managed deployment, you can use the script `ovn_migration.sh` to migrate from ML2/OVS to ML2/OVN.

You can migrate from the ML2/OVS to the ML2/OVN mechanism driver in either mode:

- ovs-firewall
- ovs-hybrid

You cannot use the `ovn_migration.sh` script in deployments that are not managed by RHOSP director. To migrate to ML2/OVN in a deployment that is not managed by RHOSP director, see the file `migration/README.rst` and the Ansible playbook `migration/migrate-to-ovn.yml`.

3.1. LIMITS OF THE ML2/OVN MECHANISM DRIVER

Some features available with the ML2/OVS mechanism driver are not yet supported with the ML2/OVN mechanism driver.

3.1.1. ML2/OVS features not yet supported by ML2/OVN

<table>
<thead>
<tr>
<th>Feature</th>
<th>Notes</th>
<th>Track this Feature</th>
</tr>
</thead>
<tbody>
<tr>
<td>Fragmentation / Jumbo Frames</td>
<td>OVN does not yet support sending ICMP &quot;fragmentation needed&quot; packets. Larger ICMP/UDP packets that require fragmentation do not work with ML2/OVN as they would with the ML2/OVS driver implementation. TCP traffic is handled by maximum segment sized (MSS) clamping.</td>
<td><a href="https://bugzilla.redhat.com/show_bug.cgi?id=1547074">https://bugzilla.redhat.com/show_bug.cgi?id=1547074</a> (ovn-network) <a href="https://bugzilla.redhat.com/show_bug.cgi?id=1702331">https://bugzilla.redhat.com/show_bug.cgi?id=1702331</a> (Core ovn)</td>
</tr>
<tr>
<td>Port Forwarding</td>
<td>OVN does not support port forwarding.</td>
<td><a href="https://bugzilla.redhat.com/show_bug.cgi?id=1654608">https://bugzilla.redhat.com/show_bug.cgi?id=1654608</a> <a href="https://blueprints.launchpad.net/neutron/+spec/port-forwarding">https://blueprints.launchpad.net/neutron/+spec/port-forwarding</a></td>
</tr>
<tr>
<td>Security Groups Logging API</td>
<td>ML2/OVN does not provide a log file that logs security group events such as an instance trying to execute restricted operations or access restricted ports in remote servers.</td>
<td><a href="https://bugzilla.redhat.com/show_bug.cgi?id=1619266">https://bugzilla.redhat.com/show_bug.cgi?id=1619266</a></td>
</tr>
<tr>
<td>Multicast</td>
<td>When using ML2/OVN as the integration bridge, multicast traffic is treated as broadcast traffic. The integration bridge operates in FLOW mode, so IGMP snooping is not available. To support this, core OVN must support IGMP snooping.</td>
<td><a href="https://bugzilla.redhat.com/show_bug.cgi?id=1672278">https://bugzilla.redhat.com/show_bug.cgi?id=1672278</a></td>
</tr>
</tbody>
</table>
Provisioning Baremetal Machines with OVN DHCP

The built-in DHCP server on OVN presently cannot provision baremetal nodes. It cannot serve DHCP for the provisioning networks. Chainbooting iPXE requires tagging (\texttt{--dhcp-match} in dnsmasq), which is not supported in the OVN DHCP server.

OVS_DPDK

OVS_DPDK is presently not supported with OVN.

SR-IOV

When using SR-IOV with native OVN DHCP:

- All external ports are scheduled on a single gateway node because there is only one HA Chassis Group for all of the ports.

- Routing on VLAN tenant network does not work with SR-IOV because the external ports are not co-located with the logical router's gateway ports.

3.2. ML2/OVS TO ML2/OVN MIGRATION EXCEPTIONS

Migration from ML2/OVS to ML2/OVN is not supported yet in certain scenarios.

Do not attempt the ML2/OVS to ML2/OVN migration in the following scenarios.

OVS uses trunk ports

If you have an ML2/OVS deployment that uses trunk ports, do not perform an ML2/OVS to ML2/OVN migration. The migration does not properly set up the trunked ports. Red Hat plans to fix this migration problem in a future release. To track progress of this work, see https://bugzilla.redhat.com/show_bug.cgi?id=1857652.

Centralized routing and VLAN project (tenant) networks

If your ML2/OVS deployment uses centralized routing and VLAN project (tenant) networks, do not migrate to ML2/OVN with DVR. You can migrate to ML2/OVN with centralized routing. To track progress on this limitation, see https://bugzilla.redhat.com/show_bug.cgi?id=1704596.

3.3. PREPARING TO MIGRATE FROM ML2/OVS TO ML2/OVN

Prerequisites

- You are working with Red Hat OpenStack Platform (RHOSP) 16.0 or later.

- You have the latest openstack/neutron version in the undercloud and overcloud.
Your RHOSP deployment is up to date. In other words, if you need to upgrade or update your OpenStack version, perform the upgrade or update first, and then perform the ML2/OVS to ML2/OVN migration.

You have the docker-podman package installed on your undercloud and overcloud. This package might not be installed if you performed a Fast Forward Upgrade from RHOSP 13 to RHOSP 16.1.1.

Procedure

In the undercloud, perform the following steps:

1. If your deployment uses VXLAN or GRE tenant networks, schedule for a 24-hour waiting period after the setup-mtu-t1 step.
   - This wait allows the VMs to catch up with the new MTU timing. During this time you may need to manually set MTUs on some instances and reboot some instances.
   - 24 hours is the time based on default configuration of 86400 seconds. The actual time depends on /var/lib/config-data/puppet-generated/neutron/etc/neutron/dhcp_agent.ini DHCP_renewal_time and /var/lib/config-data/puppet-generated/neutron/etc/neutron/neutron.conf dhcp_lease_duration parameters.

2. Install python3-networking-ovn-migration-tool.
   ```bash
dnf install python3-networking-ovn-migration-tool
   ```

3. Create a directory on the undercloud, and copy the Ansible playbooks:
   ```bash
   mkdir ~/ovn_migration
cd ~/ovn_migration
cp -rfp /usr/share/ansible/networking-ovn-migration/playbooks .
   ```

4. In your overcloud-deploy.sh script, remove any references to files specific to neutron ovs, such as neutron-ovs-dvr.yaml and neutron-ovs-dpdk.yaml.

5. Create the overcloud-deploy-ovn.sh script in your $HOME. This script sources your stackrc file and executes an openstack overcloud deploy with your original deployment parameters plus the files in the following environment. Note that migration tool automatically creates the ovn-extras.yaml file.

6. Find your migration scenario in the following list and perform the appropriate steps.

   **Scenario 1: DVR to DVR, compute nodes have connectivity to the external network**
   - Add the following environment files to the openstack deploy command in the order shown:
     ```bash
     * -e /usr/share/openstack-tripleo-heat-templates/environments/services/neutron-ovn-dvr-ha.yaml
     * -e $HOME/ovn-extras.yaml
     ```

   **Scenario 2: Centralized routing to centralized routing (no DVR)**
   - Add the following environment files to the openstack deploy command in the order shown:
     ```bash
     ```
-e /usr/share/openstack-tripleo-heat-templates/environments/services/neutron-ovn-ha.yaml \
-e $HOME/ovn-extras.yaml

- Leave custom network modifications the same as they were before migration. For instance, in the following example, the NeutronBridgeMappings parameter in /usr/share/openstack-tripleo-heat-templates/environments/services/neutron-ovn-ha.yaml.

  ComputeParameters:
    NeutronBridgeMappings: "tenant:br-isolated"

**Scenario 3: Centralized routing to DVR, with Geneve type driver, and compute nodes connected to external networks through br-ex**

**WARNING**

If your ML2/OVS deployment uses centralized routing and VLAN project (tenant) networks, do not migrate to ML2/OVN with DVR. You can migrate to ML2/OVN with centralized routing. To track progress on this limitation, see [https://bugzilla.redhat.com/show_bug.cgi?id=1704596](https://bugzilla.redhat.com/show_bug.cgi?id=1704596).

- Ensure that compute nodes are connected to the external network through the br-ex bridge. For example, in an environment file such as compute-dvr.yaml, set the following:

  ```yaml
  type: ovs_bridge
  # Defaults to br-ex, anything else requires specific # bridge mapping entries for it to be used.
  name: bridge_name
  use_dhcp: false
  members:
    -
      type: interface
      name: nic3
      # force the MAC address of the bridge to this interface
      primary: true
  ```

7. Ensure that all users have execution privileges on ovn_migration.sh/ansible. The script requires execution privileges during the migration process.

   ```bash
   $ chmod a+x ~/overcloud-deploy-ovn.sh
   ```

8. Ensure that the `overcloud-deploy-ovn.sh` script does not contain any references to files specific to neutron ovs, such as `neutron-ovs-dvr.yaml` and `neutron-ovs-dpdk.yaml`.

9. To configure the parameters of your migration, set the environment variables that `ovn_migration.sh` uses. You can skip setting any values matching the defaults.
- STACKRC_FILE - must point to your stackrc file in your undercloud.
  Default: ~/stackrc

- OVERCLOUDRC_FILE - must point to your overcloudrc file in your undercloud.
  Default: ~/overcloudrc

- OVERCLOUD_OVN_DEPLOY_SCRIPT - must point to the deployment script.
  Default: ~/overcloud-deploy-ovn.sh

- PUBLIC_NETWORK_NAME - Name of your public network.
  Default: public.

  To support migration validation, this network must have available floating IP addresses, and those floating IP addresses must be pingable from the undercloud. If that is not possible, configure VALIDATE_MIGRATION to False.

- IMAGE_NAME - Name/ID of the glance image to use for booting a test server.
  Default: cirros.

  The image is automatically downloaded during the pre-validation / post-validation process.

- VALIDATE_MIGRATION - Create migration resources to validate the migration. Before starting the migration, the migration script boots a server and validates that the server is reachable after the migration.
  Default: True.

- SERVER_USER_NAME - User name to use for logging to the migration instances.
  Default: cirros.

- DHCP_RENEWAL_TIME - DHCP renewal time in seconds to configure in DHCP agent configuration file.
  Default: 30

**WARNING**

VALIDATE_MIGRATION requires enough quota (2 available floating IP addresses, 2 networks, 2 subnets, 2 instances, and 2 routers as admin).

For example:

$ export PUBLIC_NETWORK_NAME=my-public-network
$ ovn_migration.sh .........

10. Run `ovn_migration.sh generate-inventory` to generate the inventory file `hosts_for_migration` and the `ansible.cfg` file. Review `hosts_for_migration` for correctness.

$ ovn_migration.sh generate-inventory
11. Run `ovn_migration.sh setup-mtu-t1`. This lowers the T1 parameter of the internal neutron DHCP servers that configure the `dhcp_renewal_time` in `/var/lib/config-data/puppet-generated/neutron/etc/neutron/dhcp_agent.ini` in all the nodes where DHCP agent is running.

```
$ ovn_migration.sh setup-mtu-t1
```

12. If your deployment uses VLAN tenant networks, skip to step 17.

13. If your deployment uses VXLAN or GRE tenant networking, wait at least 24 hours before continuing.

14. If you have any instances with static IP assignment on VXLAN or GRE tenant networks, you must manually modify the configuration of those instances to configure the new Geneve MTU, which is the current VXLAN MTU minus 8 bytes. For instance, if the VXLAN-based MTU was 1450, change it to 1442.

15. If your instances don’t honor the T1 parameter of DHCP, reboot them.

16. [Optional] Verify that the T1 parameter has propagated to existing VMs.
   
   - Connect to one of the compute nodes.
   
   - Run `tcpdump` over one of the VM taps attached to a tenant network.
     
     If T1 propagation is successful, you should see that requests happen on an interval of approximately 30 seconds:

     ```
     [heat-admin@overcloud-novacompute-0 ~]$ sudo tcpdump -i tap52e872c2-e6 port 67 or
     port 68 -n
     tcpdump: verbose output suppressed, use -v or -vv for full protocol decode
     listening on tap52e872c2-e6, link-type EN10MB (Ethernet), capture size 262144 bytes
     Request from fa:16:3e:6b:41:3d, length 300
     length 355
     13:17:56.241156 IP 192.168.99.5.bootpc > 192.168.99.3.bootps: BOOTP/DHCP,
     Request from fa:16:3e:6b:41:3d, length 30013:17:56.249899 IP 192.168.99.3.bootps >
     192.168.99.5.bootpc: BOOTP/DHCP, Reply, length 355
     ```

     NOTE This verification is not possible with cirros VMs. The cirros udhcpc implementation does not obey DHCP option 58 (T1). Try this verification on a port that belongs to a full Linux VM. Red Hat recommends that you check all the different types of workloads that your system runs (Windows, different flavors of Linux, etc.).

17. Lower the MTU of the:pre-migration VXLAN and GRE networks:

   ```
   $ ovn_migration.sh reduce-mtu
   ```

   This step reduces the MTU network by network and tags the completed network with `adapted_mtu`. The tool ignores non-VXLAN/GRE networks, so if you use VLAN for tenant networks, this step is not expected to change any values.

18. Make Tripleo prepare the new container images for OVN.

   If your deployment did not have a `containers-prepare-parameter.yaml`, you can create one with the following command:
1. Run `ovn_migration.sh start-migration` to kick-start the migration process.

   ```bash
   $ ovn_migration.sh start-migration
   ```

   The script performs the following actions.

   - Creates pre-migration resources (network and VM) to validate existing deployment and final migration.
   - Updates the overcloud stack to deploy OVN alongside reference implementation services using the temporary bridge br-migration instead of br-int.
   - Starts the migration process, which includes the following actions:
     - Generates the OVN north db by running `neutron-ovn-db-sync` util.
     - Clones the existing resources from br-int to br-migration, to allow ovn to find the same resource UUIDs over br-migration.
     - Re-assigns ovn-controller to br-int instead of br-migration.
- Cleans up network namespaces (fip, snat, qrouter, qdhcp).
- Removes any unnecessary patch ports on br-int.
- Removes br-tun and br-migration ovs bridges.
- Deletes qr-, ha- and qg-* ports from br-int (via neutron netns cleanup).
- Deletes neutron agents and neutron HA internal networks from the database via API.
- Validates connectivity on pre-migration resources.
- Deletes pre-migration resources.
- Creates post-migration resources.
- Validates connectivity on post-migration resources.
- Cleans up post-migration resources.
- Re-runs the deployment tool to update OVN on br-int.
CHAPTER 4. DEPLOYING OVN WITH DIRECTOR

The following events are triggered when you deploy OVN on the Red Hat OpenStack Platform:

1. Enables the OVN ML2 plugin and generates the necessary configuration options.
2. Deploys the OVN databases and the `ovn-northd` service on the controller node(s).
3. Deploys `ovn-controller` on each Compute node.
4. Deploys `neutron-ovn-metadata-agent` on each Compute node.

4.1. DEPLOYING OVN WITH DVR

**NOTE**

This guide deploys OVN with DVR in an HA environment.

To deploy OVN with DVR in an HA environment:

1. Verify that the value for `OS::TripleO::Compute::Net::SoftwareConfig` in the `environments/services/neutron-ovn-dvr-ha.yaml` file is the same as the `OS::TripleO::Controller::Net::SoftwareConfig` value in use. This can normally be found in the network environment file in use when deploying the overcloud, for example, in the `environments/net-multiple-nics.yaml` file. This creates the appropriate external network bridge on the Compute node.

**NOTE**

If customizations have been made to the network configuration of the Compute node, it may be necessary to add the appropriate configuration to those files instead.

2. Configure a Networking port for the Compute node on the external network by modifying `OS::TripleO::Compute::Ports::ExternalPort` to an appropriate value, such as `OS::TripleO::Compute::Ports::ExternalPort: ../network/ports/external.yaml`

3. Include `environments/services/neutron-ovn-dvr-ha.yaml` as an environment file when deploying the overcloud. For example:

```bash
$ openstack overcloud deploy \
  --templates /usr/share/openstack-tripleo-heat-templates \
  ... \
  -e /usr/share/openstack-tripleo-heat-templates/environments/services/neutron-ovn-dvr-ha.yaml
```

For production environments (or test environments that require special customization, such as network isolation or dedicated NICs, you can use the example environments as a guide. Pay special attention to the bridge mapping type parameters used, for example, by OVS and any reference to external facing bridges.

4.2. DEPLOYING THE OVN METADATA AGENT ON COMPUTE NODES
The OVN metadata agent is configured in the `tripleo-heat-templates/deployment/ovn/ovn-metadata-container-puppet.yaml` file and included in the default Compute role through `OS::TripleO::Services::OVNMetadataAgent`. As such, the OVN metadata agent with default parameters is deployed as part of the OVN deployment. See Chapter 4, *Deploying OVN with director*.

OpenStack guest instances access the Networking metadata service available at the link-local IP address: 169.254.169.254. The `neutron-ovn-metadata-agent` has access to the host networks where the Compute metadata API exists. Each HAProxy is in a network namespace that is not able to reach the appropriate host network. HaProxy adds the necessary headers to the metadata API request and then forwards the request to the `neutron-ovn-metadata-agent` over a UNIX domain socket.

The OVN Networking service creates a unique network namespace for each virtual network that enables the metadata service. Each network accessed by the instances on the Compute node has a corresponding metadata namespace (`ovnmeta-<net_uuid>`).

### 4.2.1. Troubleshooting Metadata issues

You can use metadata namespaces for troubleshooting to access the local instances on the Compute node. To troubleshoot metadata namespace issues, run the following command as root on the Compute node:

```
# ip netns exec ovnmeta-fd706b96-a591-409e-83be-33caea824114 ssh
USER@INSTANCE_IP_ADDRESS
```

`USER@INSTANCE_IP_ADDRESS` is the user name and IP address for the local instance you want to troubleshoot.

### 4.3. DEPLOYING INTERNAL DNS WITH OVN

To deploy internal DNS with OVN:

1. Enable DNS with the `NeutronPluginExtensions` parameter:

   ```yaml
   parameter_defaults:
     NeutronPluginExtensions: "dns"
   ```

2. Set the DNS domain before you deploy the overcloud:

   ```yaml
   NeutronDnsDomain: "mydns-example.org"
   ```

3. Deploy the overcloud:

   ```bash
   $ openstack overcloud deploy \
   --templates /usr/share/openstack-tripleo-heat-templates \
   ...
   -e /usr/share/openstack-tripleo-heat-templates/environments/services/neutron-ovn-dvr-ha.yaml
   ```
CHAPTER 5. MONITORING OVN

You can use the `ovn-trace` command to monitor and troubleshoot OVN logical flows, and you can use the `ovs-ofctl dump-flows` command to monitor and troubleshoot OpenFlows.

### 5.1. MONITORING OVN LOGICAL FLOWS

OVN uses logical flows that are tables of flows with a priority, match, and actions. These logical flows are distributed to the `ovn-controller` running on each Compute node. You can use the `ovn-sbctl lflow-list` command on the Controller node to view the full set of logical flows, as shown in this example.

```bash
$ ovn-sbctl --db=tcp:172.17.1.10:6642 lflow-list
  Datapath: "sw0" (d7bf6a7b-e915-4502-8f9d-5995d33f5d10) Pipeline: ingress
  table=0 (ls_in_port_sec_l2 ), priority=100 , match=(eth.src[40]), action=(drop;)
table=0 (ls_in_port_sec_l2 ), priority=100 , match=(vlan.present), action=(drop;)
table=0 (ls_in_port_sec_l2 ), priority=50 , match=(import == "sw0-port1" && eth.src ==
  (00:00:00:00:00:01), action=(next;)
table=0 (ls_in_port_sec_l2 ), priority=50 , match=(import == "sw0-port2" && eth.src ==
  (00:00:00:00:00:02), action=(next;)
table=1 (ls_in_port_sec_ip ), priority=0 , match=(1), action=(next;)
table=2 (ls_in_port_sec_nd ), priority=90 , match=(import == "sw0-port1" && eth.src ==
  00:00:00:00:00:01 & & arp.sha == 00:00:00:00:00:01), action=(next;)
table=2 (ls_in_port_sec_nd ), priority=90 , match=(import == "sw0-port1" && eth.src ==
  00:00:00:00:00:02 & & ip6 & & nd & & ((nd.sll == 00:00:00:00:00:00 || nd.sll == 00:00:00:00:00:01)) ||
  ((nd.tll == 00:00:00:00:00:00 || nd.tll == 00:00:00:00:00:01))) , action=(next;)
table=2 (ls_in_port_sec_nd ), priority=90 , match=(import == "sw0-port2" && eth.src ==
  00:00:00:00:00:02 & & arp.sha == 00:00:00:00:00:02), action=(next;)
table=2 (ls_in_port_sec_nd ), priority=90 , match=(import == "sw0-port2" && eth.src ==
  00:00:00:00:00:02 & & ip6 & & nd & & ((nd.sll == 00:00:00:00:00:00 || nd.sll == 00:00:00:00:00:02)) ||
  ((nd.tll == 00:00:00:00:00:00 || nd.tll == 00:00:00:00:00:01))) , action=(next;)
table=2 (ls_in_port_sec_nd ), priority=80 , match=(import == "sw0-port1" && (arp || nd)), action=(
  drop;)
table=2 (ls_in_port_sec_nd ), priority=80 , match=(import == "sw0-port2" && (arp || nd)), action=(
  drop;)
table=2 (ls_in_port_sec_nd ), priority=0 , match=(1), action=(next;)
table=3 (ls_in_pre_acl    ), priority=0 , match=(1), action=(next;)
table=4 (ls_in_pre_lb     ), priority=0 , match=(1), action=(next;)
table=5 (ls_in_pre_stateful), priority=100 , match=(reg0[0] == 1), action=(ct_next;)
table=5 (ls_in_pre_stateful), priority=0 , match=(1), action=(next;)
table=6 (ls_in_acl        ), priority=0 , match=(1), action=(next;)
table=7 (ls_in_qos_mark    ), priority=0 , match=(1), action=(next;)
table=8 (ls_in_lb         ), priority=0 , match=(1), action=(next;)
table=9 (ls_in_stateful   ), priority=100 , match=(reg0[1] == 1), action=(ct_commit(ct_label=0/1);
  next;)
table=9 (ls_in_stateful   ), priority=100 , match=(reg0[2] == 1), action=(ct_lb;)
table=9 (ls_in_stateful   ), priority=0 , match=(1), action=(next;)
table=10(ls_in_arp_rsp     ), priority=0 , match=(1), action=(next;)
table=11(ls_in_dhcp_options), priority=0 , match=(1), action=(next;)
table=12(ls_in_dhcp_response), priority=0 , match=(1), action=(next;)
table=13(ls_in_l2_lkup     ), priority=100 , match=(eth.mcast), action=(outport = ",_MC_flood";
  output;)
table=13(ls_in_l2_lkup     ), priority=50 , match=(eth.dst == 00:00:00:00:00:01), action=(outport
  = "sw0-port1"; output;)
table=13(ls_in_l2_lkup     ), priority=50 , match=(eth.dst == 00:00:00:00:00:02), action=(outport
  = "sw0-port2"; output;)
```
Key differences between OVN and OpenFlow include:

- OVN ports are logical entities that reside somewhere on a network, not physical ports on a single switch.
- OVN gives each table in the pipeline a name in addition to its number. The name describes the purpose of that stage in the pipeline.
- The OVN match syntax supports complex Boolean expressions.
- The actions supported in OVN logical flows extend beyond those of OpenFlow. You can implement higher level features, such as DHCP, in the OVN logical flow syntax.

**ovn-trace**

The `ovn-trace` command can simulate how a packet travels through the OVN logical flows, or help you determine why a packet is dropped. Provide the `ovn-trace` command with the following parameters:

**DATAPATH**

The logical switch or logical router where the simulated packet starts.

**MICROFLOW**

The simulated packet, in the syntax used by the `ovn-sb` database.

This example displays the `--minimal` output option on a simulated packet and shows that the packet reaches its destination:

```bash
$ ovn-trace --minimal sw0 'inport == "sw0-port1" && eth.src == 00:00:00:00:00:01 && eth.dst == 00:00:00:00:00:02'
```

In more detail, the `--summary` output for this same simulated packet shows the full execution pipeline:

```bash
$ ovn-trace --summary sw0 'inport == "sw0-port1" && eth.src == 00:00:00:00:00:01 && eth.dst == 00:00:00:00:00:02'
```
The example output shows:

- The packet enters the sw0 network from the sw0-port1 port and runs the ingress pipeline.
- The outport variable is set to sw0-port2 indicating that the intended destination for this packet is sw0-port2.
- The packet is output from the ingress pipeline, which brings it to the egress pipeline for sw0 with the outport variable set to sw0-port2.
- The output action is executed in the egress pipeline, which outputs the packet to the current value of the outport variable, which is sw0-port2.

See the ovn-trace man page for complete details.

5.2. MONITORING OPENFLOWS

You can use ovs-ofctl dump-flows command to monitor the OpenFlow flows on a logical switch in your network.

```bash
$ ovs-ofctl dump-flows br-int
NXST_FLOW reply (xid=0x4):
  cookie=0x0, duration=72.132s, table=0, n_packets=0, n_bytes=0, idle_age=72,
  priority=10,in_port=1,dl_src=00:00:00:00:00:01 actions=resubmit(,1)
  cookie=0x0, duration=60.565s, table=0, n_packets=0, n_bytes=0, idle_age=60,
  priority=10,in_port=2,dl_src=00:00:00:00:00:02 actions=resubmit(,1)
  cookie=0x0, duration=28.127s, table=0, n_packets=0, n_bytes=0, idle_age=28, priority=0
  actions=drop
  cookie=0x0, duration=13.887s, table=1, n_packets=0, n_bytes=0, idle_age=13, priority=0,in_port=1
  actions=output:2
  cookie=0x0, duration=4.023s, table=1, n_packets=0, n_bytes=0, idle_age=4, priority=0,in_port=2
  actions=output:1
```
