Centralized Logging and Monitoring of an OpenStack Environment

OpenStack Team
Centralized Logging and Monitoring of an OpenStack Environment

OpenStack Team
rhos-docs@redhat.com
Abstract

This document describes the installation and configuration of the operational tools that provide centralized logging, availability monitoring, and performance monitoring.
Table of Contents

  4.2. INSTALLING THE PERFORMANCE MONITORING COLLECTION AGENT ON ALL NODES ... 30
Red Hat OpenStack Platform comes with an optional suite of tools designed to help operators maintain an OpenStack environment. The tools perform the following functions:

- Centralized logging
- Availability monitoring
- Performance monitoring

This document describes the preparation and installation of these tools.

**Warning**

The Red Hat OpenStack Platform Operational Tool Suite is currently a Technology Preview. For more information on Red Hat Technology Previews, see Technology Preview Features Support Scope.
CHAPTER 1. ARCHITECTURE

1.1. CENTRALIZED LOGGING

The centralized logging toolchain consists of a number of components, including:

- A Log Collection Agent (Fluentd)
- A Log Relay/Transformer (Fluentd)
- A Data Store (Elasticsearch)
- An API/Presentation Layer (Kibana)

These components and their interactions are laid out in the following diagrams:

Figure 1.1. Centralized logging architecture at a high level

Figure 1.2. Single-node deployment for Red Hat OpenStack Platform
1.2. AVAILABILITY MONITORING

Figure 1.3. HA deployment for Red Hat OpenStack Platform
1.2. AVAILABILITY MONITORING

The availability monitoring toolchain consists of a number of components, including:

- A Monitoring Agent (Sensu)
- A Monitoring Relay/Proxy (RabbitMQ)
- A Monitoring Controller/Server (Sensu)
- An API/Presentation Layer (Uchiwa)

These components and their interactions are laid out in the following diagrams:

Figure 1.4. Availability monitoring architecture at a high level

Figure 1.5. Single-node deployment for Red Hat OpenStack Platform
Figure 1.6. HA deployment for Red Hat OpenStack Platform
1.3. PERFORMANCE MONITORING

The performance monitoring toolchain consists of a number of components, including:

- A Collection Agent (collectd)
- A Collection Aggregator/Relay (Graphite)
- A Data Store (whisperdb)
- An API/Presentation Layer (Grafana)

These components and their interactions are laid out in the following diagrams:

Figure 1.7. Performance monitoring architecture at a high level
Figure 1.8. Single-node deployment for Red Hat OpenStack Platform
Figure 1.9. HA deployment for Red Hat OpenStack Platform
CHAPTER 2. INSTALLING THE CENTRALIZED LOGGING SUITE

2.1. INSTALLING THE CENTRALIZED LOG RELAY/TRANSFORMER

1. Locate a bare metal system that meets the following minimum specifications:
   - 8 GB of memory
   - Single-socket Xeon class CPU
   - 500 GB of disk space

2. Install Red Hat Enterprise Linux 7.

3. Allow the system to access the Operational Tools packages:
   1. Register the system and subscribe it:
      ```bash
      # subscription-manager register
      # subscription-manager list --consumed
      ```
      If an OpenStack subscription is not attached automatically, see the documentation for manually attaching subscriptions.
   2. Disable initially enabled repositories and enable only the ones appropriate for the Operational Tools:
      ```bash
      # subscription-manager repos --disable=*  
      # subscription-manager repos --enable=rhel-7-server-rpms --enable=rhel-7-server-optional-rpms --enable=rhel-7-server-openstack-8-optools-rpms
      ```

   **Note**
   The base OpenStack repository (rhel-7-server-openstack-8-rpms) must not be enabled on this node. This repository may contain newer versions of certain Operational Tools dependencies which may be incompatible with the Operational Tools packages.

4. Install the Elasticsearch, Fluentd, and Kibana software by running the following command:
   ```bash
   # yum install elasticsearch fluentd rubygem-fluent-plugin-elasticsearch kibana httpd
   ```

5. Enable Cross-origin resource sharing (CORS) in Elasticsearch. To do so, edit `/etc/elasticsearch/elasticsearch.yml` and add the following lines to the end of the file:
http.cors.enabled: true
http.cors.allow-origin: "/.*"

Note

This will allow the Elasticsearch JavaScript applications to be called from any web page on any web server. To allow CORS from your Kibana server only, use:

http.cors.allow-origin: "http://LOGGING_SERVER"

Replace LOGGING_SERVER with the IP address or the host name of your Kibana server, depending on whether you are going to access Kibana using the IP address or the host name. However, if the Elasticsearch service is only accessible from trusted hosts, it is safe to use "/.*".

6. Start the Elasticsearch instance and enable it at boot:

```sh
# systemctl start elasticsearch
# systemctl enable elasticsearch
```

To confirm the Elasticsearch instance is working, run the following command:

```sh
# curl http://localhost:9200/
```

This should give a response similar to the following:

```json
{
  "status": 200,
  "name": "elasticsearch.example.com",
  "cluster_name": "elasticsearch",
  "version": {
    "number": "1.5.2",
    "build_hash": "c88f77ffcc81301dfa9dfdd81ca2232f09588bd512",
    "build_timestamp": "2015-02-19T13:05:36Z",
    "build_snapshot": false,
    "lucene_version": "4.10.3"
  },
  "tagline": "You Know, for Search"
}
```

7. Configure Fluentd to accept log data and write it to Elasticsearch. Edit `/etc/fluentd/fluent.conf` and replace its content with the following:

```ppt
# In v1 configuration, type and id are @ prefix parameters.
# @type and @id are recommended. type and id are still available for backward compatibility

<source>
  @type forward
  port 4000
  bind 0.0.0.0
</source>
```
8. Start Fluentd and enable it at boot:

```
# systemctl start fluentd
# systemctl enable fluentd
```

Tip

Check the journal for Fluentd and ensure it has no errors at start:

```
# journalctl -u fluentd -l -f
```

9. Configure Kibana to point to the Elasticsearch instance. Create `/etc/httpd/conf.d/kibana3.conf` and place the following content inside:

```
<VirtualHost *:80>
  DocumentRoot /usr/share/kibana
  <Directory /usr/share/kibana>
    Require all granted
    Options -Multiviews
  </Directory>
</VirtualHost>
```

10. If you want to restrict access to Kibana and Elasticsearch to authorized users only, for example, because these services are running on a system in an open network, secure the virtual host using HTTP Basic authentication and move Elasticsearch behind a proxy. To do so, follow these steps:

1. Create (or rewrite) the `/etc/httpd/conf.d/kibana3.conf` file with the following content:

```
<VirtualHost *:80>
  DocumentRoot /usr/share/kibana
  <Directory /usr/share/kibana>
    Options -Multiviews
    AuthUserFile /etc/httpd/conf/htpasswd-kibana
    AuthName "Restricted Kibana Server"
    AuthType Basic
    Require valid-user
  </Directory>
</VirtualHost>
```

# Proxy for Elasticsearch
<LocationMatch ^/(_nodes/_aliases|.*/_aliases|_search|.*/_search|_mapping |.*/_mapping)$">
    ProxyPassMatch http://127.0.0.1:9200/$1
    ProxyPassReverse http://127.0.0.1:9200/$1
</LocationMatch>

# Proxy for kibana-int/{dashboard,temp}
<LocationMatch "^/(kibana-int/dashboard/|kibana-int/temp) (.*$)"
    ProxyPassMatch http://127.0.0.1:9200/$1$2
    ProxyPassReverse http://127.0.0.1:9200/$1$2
</LocationMatch>
</Virtualhost>

Note

You can use a different path for the AuthUserFile option as well as any other description for the AuthName option.

2. Create a pair of user name and password which will be allowed to access Kibana. To do so, run the following command:

# htpasswd -c /etc/httpd/conf/htpasswd-kibana user_name

Note

If you are using a different path for the AuthUserFile option, change the command accordingly.

Replace user_name with a user name of your choice. When prompted, enter the password that will be used with this user name. You will be prompted to re-type the password.

3. Optionally, create more users with their own passwords by running the following command:

# htpasswd /etc/httpd/conf/htpasswd-kibana another_user_name

4. Configure Elasticsearch to listen on the localhost interface only. To do so, open the /etc/elasticsearch/elasticsearch.yml file in an editor and append the following option:

network.host: 127.0.0.1

5. You must also configure Elasticsearch to allow using HTTP Basic authentication data with CORS by appending the following option to /etc/elasticsearch/elasticsearch.yml:

Red Hat OpenStack Platform 8 Red Hat OpenStack Platform Operational Tools
http.cors.allow-credentials: true

6. Restart **Elasticsearch** for these changes to take effect:

```
# systemctl restart elasticsearch
```

7. Finally, ensure that the **Elasticsearch** files are downloaded using the proxy, and that the HTTP Basic authentication data is sent by the browser. To do so, edit the `/usr/share/kibana/config.js` file. Find the following line in this file:

```
elasticsearch: "http://"+window.location.hostname+":9200",
```

and change it as follows:

```
elasticsearch: {server: "http://"+window.location.hostname, withCredentials: true},
```

11. Enable **Kibana** (inside Apache) to connect to **Elasticsearch**, and then start Apache and enable it at boot:

```
# setsebool -P httpd_can_network_connect 1
# systemctl start httpd
# systemctl enable httpd
```

12. Open the firewall on the system to allow connections to **Fluentd** and **httpd**:

```
# firewall-cmd --zone=public --add-port=4000/tcp --permanent
# firewall-cmd --zone=public --add-service=http --permanent
# firewall-cmd --reload
```

13. Moreover, if you have not configured HTTP authentication and **Elasticsearch** proxy, open the firewall to allow direct connections to **Elasticsearch**:

```
# firewall-cmd --zone=public --add-port=9200/tcp --permanent
# firewall-cmd --reload
```

**Important**

If you do not restrict access to **Kibana** and **Elasticsearch** using HTTP authentication, the information provided by Kibana and Elasticsearch is available to anyone without any authentication. To secure the data, ensure that the system or the open TCP ports (80, 4000, and 9200) are only accessible from trusted hosts.

## 2.2. INSTALLING THE LOG COLLECTION AGENT ON ALL NODES

To collect the logs from all the systems in the OpenStack environment and send them to your centralized logging server, run the following commands on all the OpenStack systems.

1. Enable the Operational Tools repository:
2. Install **fluentd** and **rubygem-fluent-plugin-add**:

```bash
# yum install fluentd rubygem-fluent-plugin-add
```

3. Configure the **Fluentd** user so it has permissions to read all the OpenStack log files. Do this by running the following command:

```bash
# for user in {keystone,nova,neutron,cinder,glance}; do usermod -a -G $user fluentd; done
```

Note that you may get an error on some nodes about missing groups. This can be disregarded as not all the nodes run all the services.

4. Configure **Fluentd**. Make sure `/etc/fluentd/fluent.conf` looks like the following; be sure to replace `LOGGING_SERVER` with the host name or IP address of your centralized logging server configured above:

```xml
# In v1 configuration, type and id are @ prefix parameters.
# @type and @id are recommended. type and id are still available for backward compatibility

# Nova compute
<source>
  @type tail
  path /var/log/nova/nova-compute.log

  \[(?<context>\.*\*)\] (?<message>\.*\*)/ 
  format /(?<time>[^\]*[^\]*) (?<pid>[^\]*) (?<loglevel>[^\]*) (?<class>[^\]*) \[(?<context>\.*\*)\] (?<message>\.*\*)/ 
  time_format %F %T.%L
</source>

<match cinder.volume>
  type add
  <pair>
    service cinder.volume
    hostname "#{Socket.gethostname}"
  </pair>
</match>

<match greped.**>
Now that **Fluentd** has been configured, start the **Fluentd** service and enable it at boot:

```
# systemctl start fluentd
# systemctl enable fluentd
```

You should now be able to access **Kibana** running at

http://`LOGGING_SERVER`/index.html#/dashboard/file/logstash.json

and see logs start to populate. If you have enabled HTTP Basic authentication in the **Kibana** configuration, you must enter a valid user name and password to access this page.

**Note**

By default, the front page of the logging server, http://`LOGGING_SERVER`/, is a **Kibana** welcome screen providing technical requirements and additional configuration information. If you want the logs to be available here, replace the `default.json` file in the **Kibana** application directory with `logstash.json`, but first create a backup copy of `default.json` in case you need this file again in the future:

```
# mv /usr/share/kibana/app/dashboards/default.json
/usr/share/kibana/app/dashboards/default.json.orig
# cp /usr/share/kibana/app/dashboards/logstash.json
/usr/share/kibana/app/dashboards/default.json
```
CHAPTER 3. INSTALLING THE AVAILABILITY MONITORING SUITE

3.1. INSTALLING THE MONITORING RELAY/CONTROLLER

1. Locate a bare metal system that meets the following minimum specifications:
   - 4 GB of memory
   - Single-socket Xeon class CPU
   - 100 GB of disk space
2. Install Red Hat Enterprise Linux 7.
3. Allow the system to access the Operational Tools packages:
   1. Register the system and subscribe it:
      ```bash
      # subscription-manager register
      # subscription-manager list --consumed
      ```
      If an OpenStack subscription is not attached automatically, see the documentation for manually attaching subscriptions.
   2. Disable initially enabled repositories and enable only the ones appropriate for the Operational Tools:
      ```bash
      # subscription-manager repos --disable=* 
      # subscription-manager repos --enable=rhel-7-server-rpms --enable=rhel-7-server-optional-rpms --enable=rhel-7-server-openstack-8-optools-rpms
      ```
      **Note**
      The base OpenStack repository (rhel-7-server-openstack-8-rpms) must not be enabled on this node. This repository may contain newer versions of certain Operational Tools dependencies which may be incompatible with the Operational Tools packages.
4. Open the firewall on the system to allow connections to RabbitMQ and Uchiwa:
   ```bash
   # firewall-cmd --zone=public --add-port=5672/tcp --permanent
   # firewall-cmd --zone=public --add-port=3000/tcp --permanent
   # firewall-cmd --reload
   ```
5. Install the components needed for the monitoring server:
   ```bash
   # yum install sensu uchiwa redis rabbitmq-server
   ```
6. Configure **RabbitMQ** and **Redis**, which are the backbone services. Start both **Redis** and **RabbitMQ** and enable them at boot:

   ```
   # systemctl start redis
   # systemctl enable redis
   # systemctl start rabbitmq-server
   # systemctl enable rabbitmq-server
   ```

7. Configure a new **RabbitMQ** virtual host for **sensu**, with a user name and password combination that can access the host:

   ```
   # rabbitmqctl add_vhost /sensu
   # rabbitmqctl add_user sensu sensu
   # rabbitmqctl set_permissions -p /sensu sensu ".*" ".*" ".*"
   ```

8. Now that the base services are running and configured, configure the **Sensu** monitoring server. Create `/etc/sensu/conf.d/rabbitmq.json` with the following contents:

   ```json
   {
   "rabbitmq": {
      "port": 5672,
      "host": "localhost",
      "user": "sensu",
      "password": "sensu",
      "vhost": "/sensu"
   }
   }
   ```

9. Next, create `/etc/sensu/conf.d/redis.json` with the following contents:

   ```json
   {
   "redis": {
      "port": 6379,
      "host": "localhost"
   }
   }
   ```

10. Finally, create `/etc/sensu/conf.d/api.json` with the following contents:

    ```json
    {
    "api": {
      "bind": "0.0.0.0",
      "port": 4567,
      "host": "localhost"
    }
    }
    ```

11. Start and enable all **Sensu** services:

    ```
    # systemctl start sensu-server
    # systemctl enable sensu-server
    # systemctl start sensu-api
    # systemctl enable sensu-api
    ```
12. Configure **Uchiwa**, which is the web interface for **Sensu**. To do this, edit `/etc/uchiwa/uchiwa.json` and replace its default contents with the following:

```json
{
  "sensu": [
    {
      "name": "Openstack",
      "host": "localhost",
      "port": 4567
    }
  ],
  "uchiwa": {
    "host": "0.0.0.0",
    "port": 3000,
    "refresh": 5
  }
}
```

13. Start and enable the **Uchiwa** web interface:

```bash
# systemctl start uchiwa
# systemctl enable uchiwa
```

### 3.2. INSTALLING THE AVAILABILITY MONITORING AGENT ON ALL NODES

To monitor all the systems in the OpenStack environment, run the following commands on all of them.

1. Enable the Operational Tools repository:

```bash
# subscription-manager repos --enable=rhel-7-server-openstack-8-optools-rpms
```

2. Install **Sensu**:

```bash
# yum install sensu
```

3. Configure the **Sensu** agent. Edit `/etc/sensu/conf.d/rabbitmq.json` to have the following content; remember to replace `MONITORING_SERVER` with the host name or IP address of your monitoring server configured in the previous section:

```json
{
  "rabbitmq": {
    "port": 5672,
    "host": "MONITORING_SERVER",
    "user": "sensu",
    "password": "sensu",
    "vhost": "/sensu"
  }
}
```
4. Edit `/etc/sensu/conf.d/client.json` to include the following content; remember to replace `FQDN` with the host name of the machine, and `ADDRESS` with the public IP address of the machine:

```json
{
    "client": {
        "name": "FQDN",
        "address": "ADDRESS",
        "subscriptions": [ "all" ]
    }
}
```

5. Finally, start and enable the Sensu client:

```
# systemctl start sensu-client
# systemctl enable sensu-client
```

You should now be able to access Uchiwa running at `http://MONITORING_SERVER:3000`. 

CHAPTER 4. INSTALLING THE PERFORMANCE MONITORING SUITE

4.1. INSTALLING THE COLLECTION AGGREGATOR/RELAY

1. Locate a bare metal system that meets the following minimum specifications:
   - 4 GB of memory
   - Single-socket Xeon class CPU
   - 500 GB of disk space

2. Install Red Hat Enterprise Linux 7.

3. Allow the system to access the Operational Tools packages:
   1. Register the system and subscribe it:
      ```bash
      # subscription-manager register
      # subscription-manager list --consumed
      
      If an OpenStack subscription is not attached automatically, see the documentation for manually attaching subscriptions.
      
      2. Disable initially enabled repositories and enable only the ones appropriate for the Operational Tools:
      ```bash
      # subscription-manager repos --disable=*  
      # subscription-manager repos --enable=rhel-7-server-rpms --enable=rhel-7-server-optional-rpms --enable=rhel-7-server-openstack-8-optools-rpms
      ```
      
      **Note**
      
      The base OpenStack repository (rhel-7-server-openstack-8-rpms) must not be enabled on this node. This repository may contain newer versions of certain Operational Tools dependencies which may be incompatible with the Operational Tools packages.

4. Open the firewall on the system to allow connections to **Graphite** and **Grafana**:
   ```bash
   # firewall-cmd --zone=public --add-port=2003/tcp --permanent
   # firewall-cmd --zone=public --add-port=3030/tcp --permanent
   # firewall-cmd --reload
   ```

5. Once that is done, install the **Graphite** and **Grafana** software by running the following command:
   ```bash
   # yum install python-carbon graphite-web grafana httpd
   ```
6. Configure the **Grafana** web interface to allow access. Edit `/etc/httpd/conf.d/graphite-web.conf` and modify the `Require` line as follows:

```
...<Directory "/usr/share/graphite/">
   <IfModule mod_authz_core.c>
      # Apache 2.4
      Require all granted
   </IfModule>
...```

7. Edit `/etc/grafana/grafana.ini`, and change `http_port` to `3030`.

8. Synchronize the database behind **Graphite** web. Run the following command; when prompted if you want to create a super user, choose `no`:

```
# sudo -u apache /usr/bin/graphite-manage syncdb --noinput
```

9. Start and enable all the **Graphite** and **Grafana** services:

```
# systemctl start httpd
# systemctl enable httpd
# systemctl start carbon-cache
# systemctl enable carbon-cache
# systemctl start grafana-server
# systemctl enable grafana-server
```

10. Configure **Grafana** to talk to your **Graphite** instance:

   a. Go to `http://PERFORMANCE_MONITORING_HOST:3030/`. You should be presented with the **Grafana** login page.

   b. Enter the default credentials of `admin/admin` to log in to the system.

   c. After you are logged in, click on the **Grafana** logo in the top left corner of the screen, then choose **Data Sources**.

   d. At the top of the page, click **Add new**, and enter the following details:

<table>
<thead>
<tr>
<th>Name</th>
<th>graphite</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default</td>
<td>yes (select)</td>
</tr>
<tr>
<td>Type</td>
<td>Graphite</td>
</tr>
<tr>
<td>Url</td>
<td><a href="http://localhost/">http://localhost/</a></td>
</tr>
</tbody>
</table>
4.2. INSTALLING THE PERFORMANCE MONITORING COLLECTION AGENT ON ALL NODES

To monitor the performance of all the systems in the OpenStack environment, run the following commands on all of them.

1. Enable the Operational Tools repository:

```bash
# subscription-manager repos --enable=rhel-7-server-openstack-8-optools-rpms
```

2. Install `collectd`:

```bash
# yum install collectd
```

3. Configure `collectd` to send the data to the performance monitoring aggregator/relay. To do so, create `/etc/collectd.d/10-write_graphite.conf` with the following contents, where `PERFORMANCE_MONITORING_HOST` is the host name or IP address of the host that was configured previously to be the performance monitoring aggregator/relay:

```xml
<LoadPlugin write_graphite>
  Globals false
</LoadPlugin>

<Plugin write_graphite>
  <Carbon>
    Host "PERFORMANCE_MONITORING_HOST"
    Port "2003"
    Prefix "collectd."
    EscapeCharacter "_"
    StoreRates true
    LogSendErrors true
    Protocol "tcp"
  </Carbon>
</Plugin>
```

4. If you are using SELinux, allow `collectd` to tcp network connect:

```bash
# setsebool -P collectd_tcp_network_connect=1
```

5. Start and enable `collectd`:
# systemctl start collectd
# systemctl enable collectd

After a while, you should see metrics in the **Graphite** web user interface running at **http://PERFORMANCE_MONITORING_HOST:3030/**.
