<code>camel.component.jetty.send-server-version</code>	If the option is true, jetty server will send the date header to the client which sends the request. NOTE please make sure there is no any other camel-jetty endpoint is share the same port, otherwise this option may not work as expected.	true	Boolean
<code>camel.component.jetty.socket-connector-properties</code>	A map which contains general HTTP connector properties. Uses the same principle as <code>sslSocketConnectorProperties</code> . The option is a <code>java.util.Map<java.lang.String,java.lang.Object></code> type.		String
<code>camel.component.jetty.socket-connectors</code>	A map which contains per port number specific HTTP connectors. Uses the same principle as <code>sslSocketConnectors</code> . The option is a <code>java.util.Map<java.lang.Integer,org.eclipse.jetty.server.Connector></code> type.		String
<code>camel.component.jetty.ssl-context-parameters</code>	To configure security using <code>SSLContextParameters</code> . The option is a <code>org.apache.camel.util.jsse.SSLContextParameters</code> type.		String
<code>camel.component.jetty.ssl-key-password</code>	The key password, which is used to access the certificate's key entry in the keystore (this is the same password that is supplied to the keystore command's <code>-keypass</code> option).		String

Name	Description	Default	Type
<code>camel.component.jetty.ssl-password</code>	The ssl password, which is required to access the keystore file (this is the same password that is supplied to the keystore command's <code>-storepass</code> option).		String
<code>camel.component.jetty.ssl-socket-connector-properties</code>	A map which contains general SSL connector properties. The option is a <code>java.util.Map<java.lang.String,java.lang.Object></code> type.		String
<code>camel.component.jetty.ssl-socket-connectors</code>	A map which contains per port number specific SSL connectors. The option is a <code>java.util.Map<java.lang.Integer,org.eclipse.jetty.server.Connector></code> type.		String
<code>camel.component.jetty.thread-pool</code>	To use a custom thread pool for the server. This option should only be used in special circumstances. The option is a <code>org.eclipse.jetty.util.thread.ThreadPool</code> type.		String
<code>camel.component.jetty.use-continuation</code>	Whether or not to use Jetty continuations for the Jetty Server.	true	Boolean
<code>camel.component.jetty.use-global-ssl-context-parameters</code>	Enable usage of global SSL context parameters	false	Boolean
<code>camel.component.jetty.use-x-forwarded-for-header</code>	To use the X-Forwarded-For header in <code>HttpServletRequest.getRemoteAddr</code> .	false	Boolean

173.4. MESSAGE HEADERS

Camel uses the same message headers as the [HTTP](#) component. From Camel 2.2, it also uses (`Exchange.HTTP_CHUNKED,CamelHttpChunked`) header to turn on or turn off the chunked encoding on the camel-jetty consumer.

Camel also populates `all` `request.parameter` and `request.headers`. For example, given a client request with the URL, <http://myserver/myserver?orderid=123>, the exchange will contain a header named `orderid` with the value 123.

Starting with Camel 2.2.0, you can get the `request.parameter` from the message header not only from `Get` Method, but also other HTTP method.

173.5. USAGE

The Jetty component supports both consumer and producer endpoints. Another option for producing to other HTTP endpoints, is to use the [HTTP Component](#)

173.6. PRODUCER EXAMPLE

WARNING

The producer is deprecated - do not use. We only recommend using jetty as consumer (eg from jetty)

The following is a basic example of how to send an HTTP request to an existing HTTP endpoint.

in Java DSL

```
from("direct:start")
  .to("jetty://http://www.google.com");
```

or in Spring XML

```
<route>
  <from uri="direct:start"/>
  <to uri="jetty://http://www.google.com"/>
</route>
```

173.7. CONSUMER EXAMPLE

In this sample we define a route that exposes a HTTP service at <http://localhost:8080/myapp/myervice>:

Usage of localhost

When you specify **localhost** in a URL, Camel exposes the endpoint only on the local TCP/IP network interface, so it cannot be accessed from outside the machine it operates on.

If you need to expose a Jetty endpoint on a specific network interface, the numerical IP address of this interface should be used as the host. If you need to expose a Jetty endpoint on all network interfaces, the **0.0.0.0** address should be used.

To listen across an entire URI prefix, see [How do I let Jetty match wildcards](#) .

If you actually want to expose routes by HTTP and already have a Servlet, you should instead refer to the [Servlet Transport](#).

Our business logic is implemented in the **MyBookService** class, which accesses the HTTP request contents and then returns a response.

Note: The **assert** call appears in this example, because the code is part of an unit test.

The following sample shows a content-based route that routes all requests containing the URI parameter, **one**, to the endpoint, **mock:one**, and all others to **mock:other**.

So if a client sends the HTTP request, <http://serverUri?one=hello>, the Jetty component will copy the HTTP request parameter, **one** to the exchange's **in.header**. We can then use the **simple** language to route exchanges that contain this header to a specific endpoint and all others to another. If we used a language more powerful than **Simple** (such as **OGNL**) we could also test for the parameter value and do routing based on the header value as well.

173.8. SESSION SUPPORT

The session support option, **sessionSupport**, can be used to enable a **HttpSession** object and access the session object while processing the exchange. For example, the following route enables sessions:

```
<route>
  <from uri="jetty:http://0.0.0.0/myapp/myservice/?sessionSupport=true"/>
  <processRef ref="myCode"/>
</route>
```

The **myCode** Processor can be instantiated by a Spring **bean** element:

```
<bean id="myCode" class="com.mycompany.MyCodeProcessor"/>
```

Where the processor implementation can access the **HttpSession** as follows:

```
public void process(Exchange exchange) throws Exception {
    HttpSession session = exchange.getIn(HttpMessage.class).getRequest().getSession();
    ...
}
```

173.9. SSL SUPPORT (HTTPS)

Using the JSSE Configuration Utility

As of Camel 2.8, the Jetty component supports SSL/TLS configuration through the [Camel JSSE Configuration Utility](#). This utility greatly decreases the amount of component specific code you need to write and is configurable at the endpoint and component levels. The following examples demonstrate how to use the utility with the Jetty component.

Programmatic configuration of the component

```
KeyStoreParameters ksp = new KeyStoreParameters();
ksp.setResource("/users/home/server/keystore.jks");
ksp.setPassword("keystorePassword");

KeyManagersParameters kmp = new KeyManagersParameters();
kmp.setKeyStore(ksp);
kmp.setKeyPassword("keyPassword");

SSLContextParameters scp = new SSLContextParameters();
scp.setKeyManagers(kmp);

JettyComponent jettyComponent = getContext().getComponent("jetty", JettyComponent.class);
jettyComponent.setSslContextParameters(scp);
```

Spring DSL based configuration of endpoint

```

...
<camel:sslContextParameters
  id="sslContextParameters">
  <camel:keyManagers
    keyPassword="keyPassword">
    <camel:keyStore
      resource="/users/home/server/keystore.jks"
      password="keystorePassword"/>
    </camel:keyManagers>
  </camel:sslContextParameters>...
...
<to uri="jetty:https://127.0.0.1/mail?sslContextParameters=#sslContextParameters"/>
...

```

Configuring Jetty Directly

Jetty provides SSL support out of the box. To enable Jetty to run in SSL mode, simply format the URI with the **https://** prefix---for example:

```
<from uri="jetty:https://0.0.0.0/myapp/myservice/" />
```

Jetty also needs to know where to load your keystore from and what passwords to use in order to load the correct SSL certificate. Set the following JVM System Properties:

until Camel 2.2

- **jetty.ssl.keystore** specifies the location of the Java keystore file, which contains the Jetty server's own X.509 certificate in a *key entry*. A key entry stores the X.509 certificate (effectively, the *public key*) and also its associated private key.
- **jetty.ssl.password** the store password, which is required to access the keystore file (this is the same password that is supplied to the **keystore** command's **-storepass** option).
- **jetty.ssl.keypassword** the key password, which is used to access the certificate's key entry in the keystore (this is the same password that is supplied to the **keystore** command's **-keypass** option).

from Camel 2.3 onwards

- **org.eclipse.jetty.ssl.keystore** specifies the location of the Java keystore file, which contains the Jetty server's own X.509 certificate in a *key entry*. A key entry stores the X.509 certificate (effectively, the *public key*) and also its associated private key.
- **org.eclipse.jetty.ssl.password** the store password, which is required to access the keystore file (this is the same password that is supplied to the **keystore** command's **-storepass** option).
- **org.eclipse.jetty.ssl.keypassword** the key password, which is used to access the certificate's key entry in the keystore (this is the same password that is supplied to the **keystore** command's **-keypass** option).

For details of how to configure SSL on a Jetty endpoint, read the following documentation at the Jetty Site: <http://docs.codehaus.org/display/JETTY/How+to+configure+SSL>

Some SSL properties aren't exposed directly by Camel, however Camel does expose the underlying `SslSocketConnector`, which will allow you to set properties like `needClientAuth` for mutual authentication requiring a client certificate or `wantClientAuth` for mutual authentication where a client doesn't need a

certificate but can have one. There's a slight difference between the various Camel versions:

Up to Camel 2.2

```
<bean id="jetty" class="org.apache.camel.component.jetty.JettyHttpComponent">
  <property name="sslSocketConnectors">
    <map>
      <entry key="8043">
        <bean class="org.mortbay.jetty.security.SslSocketConnector">
          <property name="password" value="..."/>
          <property name="keyPassword" value="..."/>
          <property name="keystore" value="..."/>
          <property name="needClientAuth" value="..."/>
          <property name="truststore" value="..."/>
        </bean>
      </entry>
    </map>
  </property>
</bean>
```

Camel 2.3, 2.4

```
<bean id="jetty" class="org.apache.camel.component.jetty.JettyHttpComponent">
  <property name="sslSocketConnectors">
    <map>
      <entry key="8043">
        <bean class="org.eclipse.jetty.server.ssl.SslSocketConnector">
          <property name="password" value="..."/>
          <property name="keyPassword" value="..."/>
          <property name="keystore" value="..."/>
          <property name="needClientAuth" value="..."/>
          <property name="truststore" value="..."/>
        </bean>
      </entry>
    </map>
  </property>
</bean>
```

*From Camel 2.5 we switch to use SslSelectChannelConnector *

```
<bean id="jetty" class="org.apache.camel.component.jetty.JettyHttpComponent">
  <property name="sslSocketConnectors">
    <map>
      <entry key="8043">
        <bean class="org.eclipse.jetty.server.ssl.SslSelectChannelConnector">
          <property name="password" value="..."/>
          <property name="keyPassword" value="..."/>
          <property name="keystore" value="..."/>
          <property name="needClientAuth" value="..."/>
          <property name="truststore" value="..."/>
        </bean>
      </entry>
    </map>
  </property>
</bean>
```

The value you use as keys in the above map is the port you configure Jetty to listen on.

173.9.1. Configuring camel-jetty9 with TLS security on IBM Java

The default TLS security settings in the **camel-jetty9** component are not compatible with the IBM Java VM. All ciphers in IBM Java starts with **prefix SSL_***, even ciphers for TLS protocol starts with **SSL_***. **camel-jetty9** supports only RFC Cipher Suite names and all **SSL_* cipher** are not secured and are excluded. Jetty excludes all **SSL_*** ciphers, so there is no negotiable cipher usable for TLS 1.2 and connection fails. As there is no way to change behavior of Jetty's ssl context, only workaround is to override the default TLS security configuration on the Jetty9 component. To achieve this, add the following code at the end of the method "sslContextParameters()" in the **Application.java** file.

```
FilterParameters fp = new FilterParameters();
    fp.getInclude().add(".*");

    // Exclude weak / insecure ciphers
    fp.getExclude().add("^.*_(MD5|SHA|SHA1)$");
    // Exclude ciphers that don't support forward secrecy
    fp.getExclude().add("^TLS_RSA_.*$");
    // The following exclusions are present to cleanup known bad cipher
    // suites that may be accidentally included via include patterns.
    // The default enabled cipher list in Java will not include these
    // (but they are available in the supported list).
    /* SSL_ ciphers are not excluded
    fp.getExclude().add("^SSL_.*$"); */
    fp.getExclude().add("^NULL.$");
    fp.getExclude().add("^anon.$");

    p.setCipherSuitesFilter(fp);
```

This code overrides excluded ciphers defined in Jetty by removing exclusion of all **SSL_*** ciphers.

173.9.2. Configuring general SSL properties

Available as of Camel 2.5

Instead of a per port number specific SSL socket connector (as shown above) you can now configure general properties which applies for all SSL socket connectors (which is not explicit configured as above with the port number as entry).

```
<bean id="jetty" class="org.apache.camel.component.jetty.JettyHttpComponent">
  <property name="sslSocketConnectorProperties">
    <map>
      <entry key="password" value="..."/>
      <entry key="keyPassword" value="..."/>
      <entry key="keystore" value="..."/>
      <entry key="needClientAuth" value="..."/>
      <entry key="truststore" value="..."/>
    </map>
  </property>
</bean>
```

173.9.3. How to obtain reference to the X509Certificate

Jetty stores a reference to the certificate in the `HttpServletRequest` which you can access from code as follows:

```
HttpServletRequest req = exchange.getIn().getBody(HttpServletRequest.class);
X509Certificate cert = (X509Certificate) req.getAttribute("javax.servlet.request.X509Certificate")
```

173.9.4. Configuring general HTTP properties

Available as of Camel 2.5

Instead of a per port number specific HTTP socket connector (as shown above) you can now configure general properties which applies for all HTTP socket connectors (which is not explicit configured as above with the port number as entry).

```
<bean id="jetty" class="org.apache.camel.component.jetty.JettyHttpComponent">
  <property name="socketConnectorProperties">
    <map>
      <entry key="acceptors" value="4"/>
      <entry key="maxIdleTime" value="300000"/>
    </map>
  </property>
</bean>
```

173.9.5. Obtaining X-Forwarded-For header with `HttpServletRequest.getRemoteAddr()`

If the HTTP requests are handled by an Apache server and forwarded to jetty with `mod_proxy`, the original client IP address is in the X-Forwarded-For header and the `HttpServletRequest.getRemoteAddr()` will return the address of the Apache proxy.

Jetty has a `forwarded` property which takes the value from X-Forwarded-For and places it in the `HttpServletRequest.remoteAddr` property. This property is not available directly through the endpoint configuration but it can be easily added using the `socketConnectors` property:

```
<bean id="jetty" class="org.apache.camel.component.jetty.JettyHttpComponent">
  <property name="socketConnectors">
    <map>
      <entry key="8080">
        <bean class="org.eclipse.jetty.server.nio.SelectChannelConnector">
          <property name="forwarded" value="true"/>
        </bean>
      </entry>
    </map>
  </property>
</bean>
```

This is particularly useful when an existing Apache server handles TLS connections for a domain and proxies them to application servers internally.

173.10. DEFAULT BEHAVIOR FOR RETURNING HTTP STATUS CODES

The default behavior of HTTP status codes is defined by the **org.apache.camel.component.http.DefaultHttpBinding** class, which handles how a response is written and also sets the HTTP status code.

If the exchange was processed successfully, the 200 HTTP status code is returned. If the exchange failed with an exception, the 500 HTTP status code is returned, and the stacktrace is returned in the body. If you want to specify which HTTP status code to return, set the code in the **Exchange.HTTP_RESPONSE_CODE** header of the OUT message.

173.11. CUSTOMIZING HTTPBINDING

By default, Camel uses the **org.apache.camel.component.http.DefaultHttpBinding** to handle how a response is written. If you like, you can customize this behavior either by implementing your own **HttpBinding** class or by extending **DefaultHttpBinding** and overriding the appropriate methods.

The following example shows how to customize the **DefaultHttpBinding** in order to change how exceptions are returned:

We can then create an instance of our binding and register it in the Spring registry as follows:

```
<bean id="mybinding" class="com.mycompany.MyHttpBinding"/>
```

And then we can reference this binding when we define the route:

```
<route>
  <from uri="jetty:http://0.0.0.0:8080/myapp/myservice?httpBindingRef=mybinding"/>
  <to uri="bean:doSomething"/>
</route>
```

173.12. JETTY HANDLERS AND SECURITY CONFIGURATION

You can configure a list of Jetty handlers on the endpoint, which can be useful for enabling advanced Jetty security features. These handlers are configured in Spring XML as follows:

```
<!-- Jetty Security handling -->
<bean id="userRealm" class="org.mortbay.jetty.plus.jaas.JAASUserRealm">
  <property name="name" value="tracker-users"/>
  <property name="loginModuleName" value="ldaploginmodule"/>
</bean>

<bean id="constraint" class="org.mortbay.jetty.security.Constraint">
  <property name="name" value="BASIC"/>
  <property name="roles" value="tracker-users"/>
  <property name="authenticate" value="true"/>
</bean>

<bean id="constraintMapping" class="org.mortbay.jetty.security.ConstraintMapping">
  <property name="constraint" ref="constraint"/>
  <property name="pathSpec" value="/*"/>
</bean>

<bean id="securityHandler" class="org.mortbay.jetty.security.SecurityHandler">
```

```

    <property name="userRealm" ref="userRealm"/>
    <property name="constraintMappings" ref="constraintMapping"/>
  </bean>

```

And from Camel 2.3 onwards you can configure a list of Jetty handlers as follows:

```

<!-- Jetty Security handling -->
<bean id="constraint" class="org.eclipse.jetty.http.security.Constraint">
  <property name="name" value="BASIC"/>
  <property name="roles" value="tracker-users"/>
  <property name="authenticate" value="true"/>
</bean>

<bean id="constraintMapping" class="org.eclipse.jetty.security.ConstraintMapping">
  <property name="constraint" ref="constraint"/>
  <property name="pathSpec" value="/*"/>
</bean>

<bean id="securityHandler" class="org.eclipse.jetty.security.ConstraintSecurityHandler">
  <property name="authenticator">
    <bean class="org.eclipse.jetty.security.authentication.BasicAuthenticator"/>
  </property>
  <property name="constraintMappings">
    <list>
      <ref bean="constraintMapping"/>
    </list>
  </property>
</bean>

```

You can then define the endpoint as:

```

from("jetty:http://0.0.0.0:9080/myservice?handlers=securityHandler")

```

If you need more handlers, set the **handlers** option equal to a comma-separated list of bean IDs.

173.13. HOW TO RETURN A CUSTOM HTTP 500 REPLY MESSAGE

You may want to return a custom reply message when something goes wrong, instead of the default reply message Camel [Jetty](#) replies with.

You could use a custom **HttpBinding** to be in control of the message mapping, but often it may be easier to use Camel's Exception Clause to construct the custom reply message. For example as show here, where we return **Dude something went wrong** with HTTP error code 500:

173.14. MULTI-PART FORM SUPPORT

From Camel 2.3.0, camel-jetty support to multipart form post out of box. The submitted form-data are mapped into the message header. Camel-jetty creates an attachment for each uploaded file. The file name is mapped to the name of the attachment. The content type is set as the content type of the attachment file name. You can find the example here.

Note: `getName()` functions as shown below in versions 2.5 and higher. In earlier versions you receive the temporary file name for the attachment instead

173.15. JETTY JMX SUPPORT

From Camel 2.3.0, camel-jetty supports the enabling of Jetty's JMX capabilities at the component and endpoint level with the endpoint configuration taking priority. Note that JMX must be enabled within the Camel context in order to enable JMX support in this component as the component provides Jetty with a reference to the MBeanServer registered with the Camel context. Because the camel-jetty component caches and reuses Jetty resources for a given protocol/host/port pairing, this configuration option will only be evaluated during the creation of the first endpoint to use a protocol/host/port pairing. For example, given two routes created from the following XML fragments, JMX support would remain enabled for all endpoints listening on "https://0.0.0.0".

```
<from uri="jetty:https://0.0.0.0/myapp/myservice1/?enableJmx=true"/>
```

```
<from uri="jetty:https://0.0.0.0/myapp/myservice2/?enableJmx=false"/>
```

The camel-jetty component also provides for direct configuration of the Jetty MBeanContainer. Jetty creates MBean names dynamically. If you are running another instance of Jetty outside of the Camel context and sharing the same MBeanServer between the instances, you can provide both instances with a reference to the same MBeanContainer in order to avoid name collisions when registering Jetty MBeans.

CHAPTER 174. JGROUPS COMPONENT

Available as of Camel version 2.13

JGroups is a toolkit for reliable multicast communication. The **jgroups:** component provides exchange of messages between Camel infrastructure and **JGroups** clusters.

Maven users will need to add the following dependency to their **pom.xml** for this component.

```
<dependency>
  <groupId>org.apache-extras.camel-extra</groupId>
  <artifactId>camel-jgroups</artifactId>
  <!-- use the same version as your Camel core version -->
  <version>x.y.z</version>
</dependency>
```

Starting from the Camel **2.13.0**, JGroups component has been moved from Camel Extra under the umbrella of the Apache Camel. If you are using Camel **2.13.0** or higher, please use the following POM entry instead.

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-jgroups</artifactId>
  <!-- use the same version as your Camel core version -->
  <version>x.y.z</version>
</dependency>
```

174.1. URI FORMAT

```
jgroups:clusterName[?options]
```

Where **clusterName** represents the name of the JGroups cluster the component should connect to.

174.2. OPTIONS

The JGroups component supports 4 options, which are listed below.

Name	Description	Default	Type
channel (common)	Channel to use		JChannel
channelProperties (common)	Specifies configuration properties of the JChannel used by the endpoint.		String
enableViewMessages (consumer)	If set to true, the consumer endpoint will receive org.jgroups.View messages as well (not only org.jgroups.Message instances). By default only regular messages are consumed by the endpoint.	false	boolean

Name	Description	Default	Type
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The JGroups endpoint is configured using URI syntax:

```
jgroups:clusterName
```

with the following path and query parameters:

174.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
clusterName	Required The name of the JGroups cluster the component should connect to.		String

174.2.2. Query Parameters (6 parameters):

Name	Description	Default	Type
channelProperties (common)	Specifies configuration properties of the JChannel used by the endpoint.		String
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
enableViewMessages (consumer)	If set to true, the consumer endpoint will receive <code>org.jgroups.View</code> messages as well (not only <code>org.jgroups.Message</code> instances). By default only regular messages are consumed by the endpoint.	false	boolean

Name	Description	Default	Type
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

174.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 9 options, which are listed below.

Name	Description	Default	Type
camel.component.jgroups.channel	Channel to use. The option is a org.jgroups.JChannel type.		String
camel.component.jgroups.channel-properties	Specifies configuration properties of the JChannel used by the endpoint.		String
camel.component.jgroups.enable-view-messages	If set to true, the consumer endpoint will receive org.jgroups.View messages as well (not only org.jgroups.Message instances). By default only regular messages are consumed by the endpoint.	false	Boolean
camel.component.jgroups.enabled	Enable jgroups component	true	Boolean
camel.component.jgroups.lock.cluster.service.enabled	Sets if the jgroups lock cluster service should be enabled or not, default is false.	false	Boolean
camel.component.jgroups.lock.cluster.service.id	Cluster Service ID		String

Name	Description	Default	Type
camel.component.jgroups.lock.cluster.service.jgroups-cluster-name	JGroups Cluster name		String
camel.component.jgroups.lock.cluster.service.jgroups-config	JGroups configuration File name		String
camel.component.jgroups.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

174.4. HEADERS

Header	Constant	Since version	Description
JGROUPS_ORIGINAL_MESSAGE	JGroupsEndpoint.HEADER_JGROUPS_ORIGINAL_MESSAGE	2.13.0	The original org.jgroups.Message instance from which the body of the consumed message has been extracted.
JGROUPS_SRC	<code>~JGroupsEndpoint.HEADER_JGROUPS_SRC</code>	2.10.0	Consumer : The org.jgroups.Address instance extracted by org.jgroups.Message .getSrc() method of the consumed message. Producer : The custom source org.jgroups.Address of the message to be sent.
JGROUPS_DEST	<code>~JGroupsEndpoint.HEADER_JGROUPS_DEST</code>	2.10.0	Consumer : The org.jgroups.Address instance extracted by org.jgroups.Message .getDest() method of the consumed message. Producer : The custom destination org.jgroups.Address of the message to be sent.

Header	Constant	Since version	Description
JGROUPS_CHANNEL_ADDRESS	<code>`JGroupsEndpoint.HEADER_JGROUPS_CHANNEL_ADDRESS</code>	2.13.0	Address (org.jgroups.Address) of the channel associated with the endpoint.

Usage

Using **jgroups** component on the consumer side of the route will capture messages received by the **JChannel** associated with the endpoint and forward them to the Camel route. JGroups consumer processes incoming messages [asynchronously](#).

```
// Capture messages from cluster named
// 'clusterName' and send them to Camel route.
from("jgroups:clusterName").to("seda:queue");
```

Using **jgroups** component on the producer side of the route will forward body of the Camel exchanges to the **JChannel** instance managed by the endpoint.

```
// Send message to the cluster named 'clusterName'
from("direct:start").to("jgroups:clusterName");
```

174.5. PREDEFINED FILTERS

Starting from version 2.13.0 of Camel, JGroups component comes with predefined filters factory class named **JGroupsFilters**.

If you would like to consume only view changes notifications sent to coordinator of the cluster (and ignore these sent to the "slave" nodes), use the **JGroupsFilters.dropNonCoordinatorViews()** filter. This filter is particularly useful when you want a single Camel node to become the master in the cluster, because messages passing this filter notifies you when given node has become a coordinator of the cluster. The snippet below demonstrates how to collect only messages received by the master node.

```
import static org.apache.camel.component.jgroups.JGroupsFilters.dropNonCoordinatorViews;
...
from("jgroups:clusterName?enableViewMessages=true").
    filter(dropNonCoordinatorViews()).
    to("seda:masterNodeEventsQueue");
```

174.6. PREDEFINED EXPRESSIONS

Starting from version 2.13.0 of Camel, JGroups component comes with predefined expressions factory class named **JGroupsExpressions**.

If you would like to create a delayer that would affect the route only if the Camel context has not been started yet, use the **JGroupsExpressions.delayIfContextNotStarted(long delay)** factory method. The expression created by this factory method will return given delay value only if the Camel context is in the state different than **started**. This expression is particularly useful if you would like to use JGroups component for keeping singleton (master) route within the cluster. **Control Bus start** command won't initialize the singleton route if the Camel Context hasn't been yet started. So you need to delay a startup of the master route, to be sure that it has been initialized after the Camel Context startup. Because such scenario can happen only during the initialization of the cluster, we don't want to delay startup of the slave node becoming the new master - that's why we need a conditional delay expression.

The snippet below demonstrates how to use conditional delaying with the JGroups component to delay the initial startup of master node in the cluster.

```
import static java.util.concurrent.TimeUnit.SECONDS;
import static org.apache.camel.component.jgroups.JGroupsExpressions.delayIfContextNotStarted;
import static org.apache.camel.component.jgroups.JGroupsFilters.dropNonCoordinatorViews;
...
from("jgroups:clusterName?enableViewMessages=true").
    filter(dropNonCoordinatorViews()).
    threads().delay(delayIfContextNotStarted(SECONDS.toMillis(5))). // run in separated and delayed
    thread. Delay only if the context hasn't been started already.
    to("controlbus:route?routeId=masterRoute&action=start&async=true");

from("timer://master?repeatCount=1").routeId("masterRoute").autoStartup(false).to(masterMockUri);
```

174.7. EXAMPLES

174.7.1. Sending (receiving) messages to (from) the JGroups cluster

In order to send message to the JGroups cluster use producer endpoint, just as demonstrated on the snippet below.

```
from("direct:start").to("jgroups:myCluster");
...
producerTemplate.sendBody("direct:start", "msg")
```

To receive the message from the snippet above (on the same or the other physical machine) listen on the messages coming from the given cluster, just as demonstrated on the code fragment below.

```
mockEndpoint.setExpectedMessageCount(1);
mockEndpoint.message(0).body().isEqualTo("msg");
...
from("jgroups:myCluster").to("mock:messagesFromTheCluster");
...
mockEndpoint.assertIsSatisfied();
```

174.7.2. Receive cluster view change notifications

The snippet below demonstrates how to create the consumer endpoint listening to the notifications regarding cluster membership changes. By default only regular messages are consumed by the endpoint.

```
mockEndpoint.setExpectedMessageCount(1);
```

```
mockEndpoint.message(0).body().isInstanceOf(org.jgroups.View.class);  
...  
from("jgroups:clusterName?enableViewMessages=true").to(mockEndpoint);  
...  
mockEndpoint.assertIsSatisfied();
```

174.7.3. Keeping singleton route within the cluster

The snippet below demonstrates how to keep the singleton consumer route in the cluster of Camel Contexts. As soon as the master node dies, one of the slaves will be elected as a new master and started. In this particular example we want to keep singleton `jetty` instance listening for the requests on address `http://localhost:8080/orders`.

```
JGroupsLockClusterService service = new JGroupsLockClusterService();  
service.setId("uniqueNodeId");  
...  
context.addService(service);  
  
from("master:mycluster:jetty:http://localhost:8080/orders").to("jms:orders");
```

CHAPTER 175. JIBX DATAFORMAT

Available as of Camel version 2.6

JiBX is a Data Format which uses the [JiBX library](#) to marshal and unmarshal Java objects to and from XML.

```
// lets turn Object messages into XML then send to MQSeries
from("activemq:My.Queue").
  marshal().jibx().
  to("mqseries:Another.Queue");
```

Please note that marshaling process can recognize the message type at the runtime. However while unmarshaling message from XML we need to specify target class explicitly.

```
// lets turn XML into PurchaseOrder message
from("mqseries:Another.Queue").
  unmarshal().jibx(PurchaseOrder.class).
  to("activemq:My.Queue");
```

175.1. OPTIONS

The JiBX dataformat supports 3 options, which are listed below.

Name	Default	Java Type	Description
<code>unmarshallClass</code>		String	Class name to use when unmarshalling from XML to Java.
<code>bindingName</code>		String	To use a custom binding factory
<code>contentTypeHeader</code>	false	Boolean	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSon etc.

175.2. SPRING BOOT AUTO-CONFIGURATION

The component supports 4 options, which are listed below.

Name	Description	Default	Type
<code>camel.dataformat.jibx.binding-name</code>	To use a custom binding factory		String

Name	Description	Default	Type
<code>camel.dataformat.jibx.content-type-header</code>	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example <code>application/xml</code> for data formats marshalling to XML, or <code>application/json</code> for data formats marshalling to JSON etc.	false	Boolean
<code>camel.dataformat.jibx.enabled</code>	Enable jibx dataformat	true	Boolean
<code>camel.dataformat.jibx.unmarshall-class</code>	Class name to use when unmarshalling from XML to Java.		String

ND

175.3. JIBX SPRING DSL

JiBX data format is also supported by Camel Spring DSL.

```

<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">

  <!-- Define data formats -->
  <dataFormats>
    <jibx id="jibx" unmarshallClass="org.apache.camel.dataformat.jibx.PurchaseOrder"/>
  </dataFormats>

  <!-- Marshal message to XML -->
  <route>
    <from uri="direct:marshal"/>
    <marshal ref="jibx"/>
    <to uri="mock:result"/>
  </route>

  <!-- Unmarshal message from XML -->
  <route>
    <from uri="direct:unmarshal"/>
    <unmarshal ref="jibx"/>
    <to uri="mock:result"/>
  </route>

</camelContext>

```

175.4. DEPENDENCIES

To use JiBX in your camel routes you need to add the a dependency on **camel-jibx** which implements this data format.

If you use maven you could just add the following to your pom.xml, substituting the version number for the latest & greatest release (see the download page for the latest versions).

```
<dependency>  
  <groupId>org.apache.camel</groupId>  
  <artifactId>camel-jibx</artifactId>  
  <version>2.6.0</version>  
</dependency>
```

CHAPTER 176. JING COMPONENT

Available as of Camel version 1.1

The Jing component uses the [Jing Library](#) to perform XML validation of the message body using either

- [RelaxNG XML Syntax](#)
- [RelaxNG Compact Syntax](#)

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-jing</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

Note that the [MSV](#) component can also support RelaxNG XML syntax.

176.1. URI FORMAT CAMEL 2.16

```
jing:someLocalOrRemoteResource
```

From Camel 2.16 the component use jing as name, and you can use the option compactSyntax to turn on either RNG or RNC mode.

176.2. OPTIONS

The Jing component has no options.

The Jing endpoint is configured using URI syntax:

```
jing:resourceUri
```

with the following path and query parameters:

176.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
resourceUri	Required URL to a local resource on the classpath or a full URL to a remote resource or resource on the file system which contains the schema to validate against.		String

176.2.2. Query Parameters (2 parameters):

Name	Description	Default	Type
compactSyntax (producer)	Whether to validate using RelaxNG compact syntax or not. By default this is false for using RelaxNG XML Syntax (rng) And true is for using RelaxNG Compact Syntax (rnc)	false	boolean
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

176.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.component.jing.enabled	Enable jing component	true	Boolean
camel.component.jing.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

176.4. EXAMPLE

The following [example](#) shows how to configure a route from the endpoint **direct:start** which then goes to one of two endpoints, either **mock:valid** or **mock:invalid** based on whether or not the XML matches the given [RelaxNG Compact Syntax](#) schema (which is supplied on the classpath).

176.5. SEE ALSO

- [Configuring Camel](#)
- [Component](#)
- [Endpoint](#)
- [Getting Started](#)

CHAPTER 177. JIRA COMPONENT (DEPRECATED)

Available as of Camel version 2.15

The JIRA component interacts with the JIRA API by encapsulating Atlassian's [REST Java Client for JIRA](#). It currently provides polling for new issues and new comments. It is also able to create new issues.

Rather than webhooks, this endpoint relies on simple polling. Reasons include:

- Concern for reliability/stability
- The types of payloads we're polling aren't typically large (plus, paging is available in the API)
- The need to support apps running somewhere not publicly accessible where a webhook would fail

Note that the JIRA API is fairly expansive. Therefore, this component could be easily expanded to provide additional interactions.

Maven users will need to add the following dependency to their pom.xml for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-jira</artifactId>
  <version>${camel-version}</version>
</dependency>
```

177.1. URI FORMAT

```
jira://endpoint[?options]
```

177.2. JIRA OPTIONS

The JIRA component has no options.

The JIRA endpoint is configured using URI syntax:

```
jira:type
```

with the following path and query parameters:

177.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
type	Required Operation to perform such as create a new issue or a new comment	t	JIRAType

177.2.2. Query Parameters (9 parameters):

Name	Description	Default	Type
password (common)	Password for login		String
serverUrl (common)	Required URL to the JIRA server		String
username (common)	Username for login		String
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
delay (consumer)	Delay in seconds when querying JIRA using the consumer.	6000	int
jql (consumer)	JQL is the query language from JIRA which allows you to retrieve the data you want. For example jql=project=MyProject Where MyProject is the product key in Jira.		String
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

177.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.jira.enabled</code>	Enable jira component	true	Boolean
<code>camel.component.jira.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

177.4. JQL:

The JQL URI option is used by both consumer endpoints. Theoretically, items like "project key", etc. could be URI options themselves. However, by requiring the use of JQL, the consumers become much more flexible and powerful.

At the bare minimum, the consumers will require the following:

```
jira://[endpoint]?[required options]&jql=project=[project key]
```

One important thing to note is that the newIssue consumer will automatically append "ORDER BY key desc" to your JQL. This is in order to optimize startup processing, rather than having to index every single issue in the project.

Another note is that, similarly, the newComment consumer will have to index every single issue **and** comment in the project. Therefore, for large projects, it's **vital** to optimize the JQL expression as much as possible. For example, the JIRA Toolkit Plugin includes a "Number of comments" custom field – use "'Number of comments' > 0" in your query. Also try to minimize based on state (status=Open), increase the polling delay, etc. Example:

```
jira://[endpoint]?[required options]&jql=RAW(project=[project key] AND status in (Open, \"Coding In Progress\") AND \"Number of comments\">0)"
```

CHAPTER 178. JMS COMPONENT

178.1. JMS COMPONENT

TIP

Using ActiveMQ

If you are using [Apache ActiveMQ](#), you should prefer the ActiveMQ component as it has been optimized for ActiveMQ. All of the options and samples on this page are also valid for the ActiveMQ component.

NOTE

Transacted and caching

See section *Transactions and Cache Levels* below if you are using transactions with [JMS](#) as it can impact performance.

NOTE

Request/Reply over JMS

Make sure to read the section *Request-reply over JMS* further below on this page for important notes about request/reply, as Camel offers a number of options to configure for performance, and clustered environments.

This component allows messages to be sent to (or consumed from) a [JMS](#) Queue or Topic. It uses Spring's JMS support for declarative transactions, including Spring's **JmsTemplate** for sending and a **MessageListenerContainer** for consuming.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-jms</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

178.2. URI FORMAT

```
jms:[queue:|topic:]destinationName[?options]
```

Where **destinationName** is a JMS queue or topic name. By default, the **destinationName** is interpreted as a queue name. For example, to connect to the queue, **FOO.BAR** use:

```
jms:FOO.BAR
```

You can include the optional **queue:** prefix, if you prefer:

```
jms:queue:FOO.BAR
```

To connect to a topic, you *must* include the **topic:** prefix. For example, to connect to the topic, **Stocks.Prices**, use:

```
jms:topic:Stocks.Prices
```

You append query options to the URI by using the following format, **?option=value&option=value&...**

178.3. NOTES

178.3.1. Using ActiveMQ

The JMS component reuses Spring 2's **JmsTemplate** for sending messages. This is not ideal for use in a non-J2EE container and typically requires some caching in the JMS provider to avoid [poor performance](#).

If you intend to use [Apache ActiveMQ](#) as your message broker, the recommendation is that you do one of the following:

- Use the ActiveMQ component, which is already optimized to use ActiveMQ efficiently
- Use the **PoolingConnectionFactory** in ActiveMQ.

178.3.2. Transactions and Cache Levels

If you are consuming messages and using transactions (**transacted=true**) then the default settings for cache level can impact performance.

If you are using XA transactions then you cannot cache as it can cause the XA transaction to not work properly.

If you are **not** using XA, then you should consider caching as it speeds up performance, such as setting **cacheLevelName=CACHE_CONSUMER**.

Through Camel 2.7.x, the default setting for **cacheLevelName** is **CACHE_CONSUMER**. You will need to explicitly set **cacheLevelName=CACHE_NONE**.

In Camel 2.8 onwards, the default setting for **cacheLevelName** is **CACHE_AUTO**. This default auto detects the mode and sets the cache level accordingly to:

- **CACHE_CONSUMER** if **transacted=false**
- **CACHE_NONE** if **transacted=true**

So you can say the default setting is conservative. Consider using **cacheLevelName=CACHE_CONSUMER** if you are using non-XA transactions.

178.3.3. Durable Subscriptions

If you wish to use durable topic subscriptions, you need to specify both **clientId** and **durableSubscriptionName**. The value of the **clientId** must be unique and can only be used by a single JMS connection instance in your entire network. You may prefer to use [Virtual Topics](#) instead to avoid this limitation. More background on durable messaging [here](#).

178.3.4. Message Header Mapping

When using message headers, the JMS specification states that header names must be valid Java identifiers. So try to name your headers to be valid Java identifiers. One benefit of doing this is that you can then use your headers inside a JMS Selector (whose SQL92 syntax mandates Java identifier syntax for headers).

A simple strategy for mapping header names is used by default. The strategy is to replace any dots and hyphens in the header name as shown below and to reverse the replacement when the header name is restored from a JMS message sent over the wire. What does this mean? No more losing method names to invoke on a bean component, no more losing the filename header for the File Component, and so on.

The current header name strategy for accepting header names in Camel is as follows:

- Dots are replaced by ***DOT*** and the replacement is reversed when Camel consume the message
- Hyphen is replaced by ***HYPHEN*** and the replacement is reversed when Camel consumes the message

178.4. OPTIONS

You can configure many different properties on the JMS endpoint which map to properties on the [JMSSConfiguration POJO](#).

WARNING

Mapping to Spring JMS

Many of these properties map to properties on Spring JMS, which Camel uses for sending and receiving messages. So you can get more information about these properties by consulting the relevant Spring documentation.

178.4.1. Component options

The JMS component supports 81 options which are listed below.

Name	Description	Default	Type
configuration (advanced)	To use a shared JMS configuration		JmsConfiguration

Name	Description	Default	Type
acceptMessagesWhileStopping (consumer)	Specifies whether the consumer accept messages while it is stopping. You may consider enabling this option, if you start and stop JMS routes at runtime, while there are still messages enqueued on the queue. If this option is false, and you stop the JMS route, then messages may be rejected, and the JMS broker would have to attempt redeliveries, which yet again may be rejected, and eventually the message may be moved at a dead letter queue on the JMS broker. To avoid this its recommended to enable this option.	false	boolean
allowReplyManagerQuickStop (consumer)	Whether the DefaultMessageListenerContainer used in the reply managers for request-reply messaging allow the DefaultMessageListenerContainer.runningAllowed flag to quick stop in case JmsConfiguration#isAcceptMessagesWhileStopping is enabled, and org.apache.camel.CamelContext is currently being stopped. This quick stop ability is enabled by default in the regular JMS consumers but to enable for reply managers you must enable this flag.	false	boolean
acknowledgmentMode (consumer)	The JMS acknowledgement mode defined as an Integer. Allows you to set vendor-specific extensions to the acknowledgment mode. For the regular modes, it is preferable to use the acknowledgmentModeName instead.		int
eagerLoadingOfProperties (consumer)	Enables eager loading of JMS properties as soon as a message is loaded which generally is inefficient as the JMS properties may not be required but sometimes can catch early any issues with the underlying JMS provider and the use of JMS properties	false	boolean
acknowledgmentModeName (consumer)	The JMS acknowledgement name, which is one of: SESSION_TRANSACTED, CLIENT_ACKNOWLEDGE, AUTO_ACKNOWLEDGE, DUPES_OK_ACKNOWLEDGE	AUTO_ACKNOWLEDGE	String
autoStartup (consumer)	Specifies whether the consumer container should auto-startup.	true	boolean
cacheLevel (consumer)	Sets the cache level by ID for the underlying JMS resources. See cacheLevelName option for more details.		int

Name	Description	Default	Type
cacheLevelName (consumer)	Sets the cache level by name for the underlying JMS resources. Possible values are: <code>CACHE_AUTO</code> , <code>CACHE_CONNECTION</code> , <code>CACHE_CONSUMER</code> , <code>CACHE_NONE</code> , and <code>CACHE_SESSION</code> . The default setting is <code>CACHE_AUTO</code> . See the Spring documentation and Transactions Cache Levels for more information.	<code>CACHE_AUTO</code>	String
replyToCacheLevelName (producer)	Sets the cache level by name for the reply consumer when doing request/reply over JMS. This option only applies when using fixed reply queues (not temporary). Camel will by default use: <code>CACHE_CONSUMER</code> for exclusive or shared w/ <code>replyToSelectorName</code> . And <code>CACHE_SESSION</code> for shared without <code>replyToSelectorName</code> . Some JMS brokers such as IBM WebSphere may require to set the <code>replyToCacheLevelName=CACHE_NONE</code> to work. Note: If using temporary queues then <code>CACHE_NONE</code> is not allowed, and you must use a higher value such as <code>CACHE_CONSUMER</code> or <code>CACHE_SESSION</code> .		String
clientId (common)	Sets the JMS client ID to use. Note that this value, if specified, must be unique and can only be used by a single JMS connection instance. It is typically only required for durable topic subscriptions. If using Apache ActiveMQ you may prefer to use Virtual Topics instead.		String
concurrentConsumers (consumer)	Specifies the default number of concurrent consumers when consuming from JMS (not for request/reply over JMS). See also the <code>maxMessagesPerTask</code> option to control dynamic scaling up/down of threads. When doing request/reply over JMS then the option <code>replyToConcurrentConsumers</code> is used to control number of concurrent consumers on the reply message listener.	1	int
replyToConcurrentConsumers (producer)	Specifies the default number of concurrent consumers when doing request/reply over JMS. See also the <code>maxMessagesPerTask</code> option to control dynamic scaling up/down of threads.	1	int
connectionFactory (common)	The connection factory to be use. A connection factory must be configured either on the component or endpoint.		ConnectionFactory

Name	Description	Default	Type
username (security)	Username to use with the ConnectionFactory. You can also configure username/password directly on the ConnectionFactory.		String
password (security)	Password to use with the ConnectionFactory. You can also configure username/password directly on the ConnectionFactory.		String
deliveryPersistent (producer)	Specifies whether persistent delivery is used by default.	true	boolean
deliveryMode (producer)	Specifies the delivery mode to be used. Possible values are those defined by javax.jms.DeliveryMode. NON_PERSISTENT = 1 and PERSISTENT = 2.		Integer
durableSubscriptionName (common)	The durable subscriber name for specifying durable topic subscriptions. The clientId option must be configured as well.		String
exceptionListener (advanced)	Specifies the JMS Exception Listener that is to be notified of any underlying JMS exceptions.		ExceptionListener
errorHandler (advanced)	Specifies a org.springframework.util.ErrorHandler to be invoked in case of any uncaught exceptions thrown while processing a Message. By default these exceptions will be logged at the WARN level, if no errorHandler has been configured. You can configure logging level and whether stack traces should be logged using errorHandlerLogLevel and errorHandlerLogStackTrace options. This makes it much easier to configure, than having to code a custom errorHandler.		ErrorHandler
errorHandlerLogLevel (logging)	Allows to configure the default errorHandler logging level for logging uncaught exceptions.	WARN	LogLevel
errorHandlerLogStackTrace (logging)	Allows to control whether stacktraces should be logged or not, by the default errorHandler.	true	boolean

Name	Description	Default	Type
explicitQosEnabled (producer)	Set if the deliveryMode, priority or timeToLive qualities of service should be used when sending messages. This option is based on Spring's JmsTemplate. The deliveryMode, priority and timeToLive options are applied to the current endpoint. This contrasts with the preserveMessageQos option, which operates at message granularity, reading QoS properties exclusively from the Camel In message headers.	false	boolean
exposeListenerSession (consumer)	Specifies whether the listener session should be exposed when consuming messages.	false	boolean
idleTaskExecutionLimit (advanced)	Specifies the limit for idle executions of a receive task, not having received any message within its execution. If this limit is reached, the task will shut down and leave receiving to other executing tasks (in the case of dynamic scheduling; see the maxConcurrentConsumers setting). There is additional doc available from Spring.	1	int
idleConsumerLimit (advanced)	Specify the limit for the number of consumers that are allowed to be idle at any given time.	1	int
maxConcurrentConsumers (consumer)	Specifies the maximum number of concurrent consumers when consuming from JMS (not for request/reply over JMS). See also the maxMessagesPerTask option to control dynamic scaling up/down of threads. When doing request/reply over JMS then the option replyToMaxConcurrentConsumers is used to control number of concurrent consumers on the reply message listener.		int
replyToMaxConcurrentConsumers (producer)	Specifies the maximum number of concurrent consumers when using request/reply over JMS. See also the maxMessagesPerTask option to control dynamic scaling up/down of threads.		int
replyOnTimeoutToMaxConcurrentConsumers (producer)	Specifies the maximum number of concurrent consumers for continue routing when timeout occurred when using request/reply over JMS.	1	int
maxMessagesPerTask (advanced)	The number of messages per task. -1 is unlimited. If you use a range for concurrent consumers (eg min max), then this option can be used to set a value to eg 100 to control how fast the consumers will shrink when less work is required.	-1	int

Name	Description	Default	Type
messageConverter (advanced)	To use a custom Spring <code>org.springframework.jms.support.converter.MessageConverter</code> so you can be in control how to map to/from a <code>javax.jms.Message</code> .		MessageConverter
mapJmsMessage (advanced)	Specifies whether Camel should auto map the received JMS message to a suited payload type, such as <code>javax.jms.TextMessage</code> to a String etc. See section about how mapping works below for more details.	true	boolean
messageIdEnabled (advanced)	When sending, specifies whether message IDs should be added. This is just an hint to the JMS Broker. If the JMS provider accepts this hint, these messages must have the message ID set to null; if the provider ignores the hint, the message ID must be set to its normal unique value	true	boolean
messageTimestampEnabled (advanced)	Specifies whether timestamps should be enabled by default on sending messages.	true	boolean
alwaysCopyMessage (producer)	If true, Camel will always make a JMS message copy of the message when it is passed to the producer for sending. Copying the message is needed in some situations, such as when a <code>replyToDestinationSelectorName</code> is set (incidentally, Camel will set the <code>alwaysCopyMessage</code> option to true, if a <code>replyToDestinationSelectorName</code> is set)	false	boolean
useMessageIDAsCorrelationID (advanced)	Specifies whether <code>JMSMessageID</code> should always be used as <code>JMSCorrelationID</code> for InOut messages.	false	boolean
priority (producer)	Values greater than 1 specify the message priority when sending (where 0 is the lowest priority and 9 is the highest). The <code>explicitQosEnabled</code> option must also be enabled in order for this option to have any effect.	4	int
pubSubNoLocal (advanced)	Specifies whether to inhibit the delivery of messages published by its own connection.	false	boolean
receiveTimeout (advanced)	The timeout for receiving messages (in milliseconds).	1000	long
recoveryInterval (advanced)	Specifies the interval between recovery attempts, i.e. when a connection is being refreshed, in milliseconds. The default is 5000 ms, that is, 5 seconds.	5000	long

Name	Description	Default	Type
taskExecutor (consumer)	Allows you to specify a custom task executor for consuming messages.		TaskExecutor
deliveryDelay (producer)	Sets delivery delay to use for send calls for JMS. This option requires JMS 2.0 compliant broker.	-1	long
timeToLive (producer)	When sending messages, specifies the time-to-live of the message (in milliseconds).	-1	long
transacted (transaction)	Specifies whether to use transacted mode	false	boolean
lazyCreateTransactionManager (transaction)	If true, Camel will create a JmsTransactionManager, if there is no transactionManager injected when option transacted=true.	true	boolean
transactionManager (transaction)	The Spring transaction manager to use.		PlatformTransactionManager
transactionName (transaction)	The name of the transaction to use.		String
transactionTimeout (transaction)	The timeout value of the transaction (in seconds), if using transacted mode.	-1	int
testConnectionOnStartup (common)	Specifies whether to test the connection on startup. This ensures that when Camel starts that all the JMS consumers have a valid connection to the JMS broker. If a connection cannot be granted then Camel throws an exception on startup. This ensures that Camel is not started with failed connections. The JMS producers is tested as well.	false	boolean
asyncStartListener (advanced)	Whether to startup the JmsConsumer message listener asynchronously, when starting a route. For example if a JmsConsumer cannot get a connection to a remote JMS broker, then it may block while retrying and/or failover. This will cause Camel to block while starting routes. By setting this option to true, you will let routes startup, while the JmsConsumer connects to the JMS broker using a dedicated thread in asynchronous mode. If this option is used, then beware that if the connection could not be established, then an exception is logged at WARN level, and the consumer will not be able to receive messages; You can then restart the route to retry.	false	boolean

Name	Description	Default	Type
asyncStopListener (advanced)	Whether to stop the JmsConsumer message listener asynchronously, when stopping a route.	false	boolean
forceSendOriginal Message (producer)	When using mapJmsMessage=false Camel will create a new JMS message to send to a new JMS destination if you touch the headers (get or set) during the route. Set this option to true to force Camel to send the original JMS message that was received.	false	boolean
requestTimeout (producer)	The timeout for waiting for a reply when using the InOut Exchange Pattern (in milliseconds). The default is 20 seconds. You can include the header CamelJmsRequestTimeout to override this endpoint configured timeout value, and thus have per message individual timeout values. See also the requestTimeoutCheckerInterval option.	20000	long
requestTimeoutChecker Interval (advanced)	Configures how often Camel should check for timed out Exchanges when doing request/reply over JMS. By default Camel checks once per second. But if you must react faster when a timeout occurs, then you can lower this interval, to check more frequently. The timeout is determined by the option requestTimeout.	1000	long
transferExchange (advanced)	You can transfer the exchange over the wire instead of just the body and headers. The following fields are transferred: In body, Out body, Fault body, In headers, Out headers, Fault headers, exchange properties, exchange exception. This requires that the objects are serializable. Camel will exclude any non-serializable objects and log it at WARN level. You must enable this option on both the producer and consumer side, so Camel knows the payloads is an Exchange and not a regular payload.	false	boolean
transferException (advanced)	If enabled and you are using Request Reply messaging (InOut) and an Exchange failed on the consumer side, then the caused Exception will be send back in response as a javax.jms.ObjectMessage. If the client is Camel, the returned Exception is rethrown. This allows you to use Camel JMS as a bridge in your routing - for example, using persistent queues to enable robust routing. Notice that if you also have transferExchange enabled, this option takes precedence. The caught exception is required to be serializable. The original Exception on the consumer side can be wrapped in an outer exception such as org.apache.camel.RuntimeCamelException when returned to the producer.	false	boolean

Name	Description	Default	Type
transferFault (advanced)	If enabled and you are using Request Reply messaging (InOut) and an Exchange failed with a SOAP fault (not exception) on the consumer side, then the fault flag on <code>org.apache.camel.Message#isFault()</code> will be send back in the response as a JMS header with the key <code>JmsConstants#JMS_TRANSFER_FAULT</code> . If the client is Camel, the returned fault flag will be set on the <code>org.apache.camel.Message#setFault(boolean)</code> . You may want to enable this when using Camel components that support faults such as SOAP based such as cxf or spring-ws.	false	boolean
jmsOperations (advanced)	Allows you to use your own implementation of the <code>org.springframework.jms.core.JmsOperations</code> interface. Camel uses <code>JmsTemplate</code> as default. Can be used for testing purpose, but not used much as stated in the spring API docs.		JmsOperations
destinationResolver (advanced)	A pluggable <code>org.springframework.jms.support.destination.DestinationResolver</code> that allows you to use your own resolver (for example, to lookup the real destination in a JNDI registry).		DestinationResolver
replyToType (producer)	Allows for explicitly specifying which kind of strategy to use for replyTo queues when doing request/reply over JMS. Possible values are: Temporary, Shared, or Exclusive. By default Camel will use temporary queues. However if replyTo has been configured, then Shared is used by default. This option allows you to use exclusive queues instead of shared ones. See Camel JMS documentation for more details, and especially the notes about the implications if running in a clustered environment, and the fact that Shared reply queues has lower performance than its alternatives Temporary and Exclusive.		ReplyToType

Name	Description	Default	Type
preserveMessageQos (producer)	Set to true, if you want to send message using the QoS settings specified on the message, instead of the QoS settings on the JMS endpoint. The following three headers are considered JMSPriority, JMSDeliveryMode, and JMSExpiration. You can provide all or only some of them. If not provided, Camel will fall back to use the values from the endpoint instead. So, when using this option, the headers override the values from the endpoint. The explicitQosEnabled option, by contrast, will only use options set on the endpoint, and not values from the message header.	false	boolean
asyncConsumer (consumer)	Whether the JmsConsumer processes the Exchange asynchronously. If enabled then the JmsConsumer may pickup the next message from the JMS queue, while the previous message is being processed asynchronously (by the Asynchronous Routing Engine). This means that messages may be processed not 100% strictly in order. If disabled (as default) then the Exchange is fully processed before the JmsConsumer will pickup the next message from the JMS queue. Note if transacted has been enabled, then asyncConsumer=true does not run asynchronously, as transaction must be executed synchronously (Camel 3.0 may support async transactions).	false	boolean
allowNullBody (producer)	Whether to allow sending messages with no body. If this option is false and the message body is null, then an JMSException is thrown.	true	boolean
includeSentJMSMessageID (producer)	Only applicable when sending to JMS destination using InOnly (eg fire and forget). Enabling this option will enrich the Camel Exchange with the actual JMSMessageID that was used by the JMS client when the message was sent to the JMS destination.	false	boolean
includeAllJMSXProperties (advanced)	Whether to include all JMSXxxx properties when mapping from JMS to Camel Message. Setting this to true will include properties such as JMSXAppID, and JMSXUserID etc. Note: If you are using a custom headerFilterStrategy then this option does not apply.	false	boolean

Name	Description	Default	Type
defaultTaskExecutor Type (consumer)	Specifies what default TaskExecutor type to use in the DefaultMessageListenerContainer, for both consumer endpoints and the ReplyTo consumer of producer endpoints. Possible values: SimpleAsync (uses Spring's SimpleAsyncTaskExecutor) or ThreadPool (uses Spring's ThreadPoolTaskExecutor with optimal values - cached threadpool-like). If not set, it defaults to the previous behaviour, which uses a cached thread pool for consumer endpoints and SimpleAsync for reply consumers. The use of ThreadPool is recommended to reduce thread trash in elastic configurations with dynamically increasing and decreasing concurrent consumers.		DefaultTaskExecutor Type
jmsKeyFormatStrategy (advanced)	Pluggable strategy for encoding and decoding JMS keys so they can be compliant with the JMS specification. Camel provides two implementations out of the box: default and passthrough. The default strategy will safely marshal dots and hyphens (. and -). The passthrough strategy leaves the key as is. Can be used for JMS brokers which do not care whether JMS header keys contain illegal characters. You can provide your own implementation of the org.apache.camel.component.jms.JmsKeyFormatStrategy and refer to it using the # notation.		JmsKeyFormatStrategy
allowAdditionalHeaders (producer)	This option is used to allow additional headers which may have values that are invalid according to JMS specification. For example some message systems such as WMQ do this with header names using prefix JMS_IBM_MQMD_ containing values with byte array or other invalid types. You can specify multiple header names separated by comma, and use as suffix for wildcard matching.		String
queueBrowseStrategy (advanced)	To use a custom QueueBrowseStrategy when browsing queues		QueueBrowseStrategy
messageCreatedStrategy (advanced)	To use the given MessageCreatedStrategy which are invoked when Camel creates new instances of javax.jms.Message objects when Camel is sending a JMS message.		MessageCreatedStrategy
waitForProvisionCorrelationToBeUpdated Counter (advanced)	Number of times to wait for provisional correlation id to be updated to the actual correlation id when doing request/reply over JMS and when the option useMessageIDAsCorrelationID is enabled.	50	int

Name	Description	Default	Type
waitForProvisionCorrelationToBeUpdatedThreadSleepingTime (advanced)	Interval in millis to sleep each time while waiting for provisional correlation id to be updated.	100	long
correlationProperty (producer)	Use this JMS property to correlate messages in InOut exchange pattern (request-reply) instead of JMSCorrelationID property. This allows you to exchange messages with systems that do not correlate messages using JMSCorrelationID JMS property. If used JMSCorrelationID will not be used or set by Camel. The value of here named property will be generated if not supplied in the header of the message under the same name.		String
subscriptionDurable (consumer)	Set whether to make the subscription durable. The durable subscription name to be used can be specified through the subscriptionName property. Default is false. Set this to true to register a durable subscription, typically in combination with a subscriptionName value (unless your message listener class name is good enough as subscription name). Only makes sense when listening to a topic (pub-sub domain), therefore this method switches the pubSubDomain flag as well.	false	boolean
subscriptionShared (consumer)	Set whether to make the subscription shared. The shared subscription name to be used can be specified through the subscriptionName property. Default is false. Set this to true to register a shared subscription, typically in combination with a subscriptionName value (unless your message listener class name is good enough as subscription name). Note that shared subscriptions may also be durable, so this flag can (and often will) be combined with subscriptionDurable as well. Only makes sense when listening to a topic (pub-sub domain), therefore this method switches the pubSubDomain flag as well. Requires a JMS 2.0 compatible message broker.	false	boolean

Name	Description	Default	Type
subscriptionName (consumer)	Set the name of a subscription to create. To be applied in case of a topic (pub-sub domain) with a shared or durable subscription. The subscription name needs to be unique within this client's JMS client id. Default is the class name of the specified message listener. Note: Only 1 concurrent consumer (which is the default of this message listener container) is allowed for each subscription, except for a shared subscription (which requires JMS 2.0).		String
streamMessageTypeEnabled (producer)	Sets whether StreamMessage type is enabled or not. Message payloads of streaming kind such as files, InputStream, etc will either be sent as BytesMessage or StreamMessage. This option controls which kind will be used. By default BytesMessage is used which enforces the entire message payload to be read into memory. By enabling this option the message payload is read into memory in chunks and each chunk is then written to the StreamMessage until no more data.	false	boolean
formatDateHeadersToIso8601 (producer)	Sets whether date headers should be formatted according to the ISO 8601 standard.	false	boolean
headerFilterStrategy (filter)	To use a custom org.apache.camel.spi.HeaderFilterStrategy to filter header to and from Camel message.		HeaderFilterStrategy
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

178.4.2. Endpoint options

The JMS endpoint is configured using URI syntax:

```
jms:destinationType:destinationName
```

with the following path and query parameters:

178.4.3. Path Parameters (2 parameters):

Name	Description	Default	Type
destinationType	The kind of destination to use	queue	String

Name	Description	Default	Type
destinationName	Required Name of the queue or topic to use as destination		String

178.4.4. Query Parameters (92 parameters):

Name	Description	Default	Type
clientId (common)	Sets the JMS client ID to use. Note that this value, if specified, must be unique and can only be used by a single JMS connection instance. It is typically only required for durable topic subscriptions. If using Apache ActiveMQ you may prefer to use Virtual Topics instead.		String
connectionFactory (common)	Sets the default connection factory to be used if a connection factory is not specified for either <code>setTemplateConnectionFactory(ConnectionFactory)</code> or <code>setListenerConnectionFactory(ConnectionFactory)</code>		ConnectionFactory
disableReplyTo (common)	Specifies whether Camel ignores the JMSReplyTo header in messages. If true, Camel does not send a reply back to the destination specified in the JMSReplyTo header. You can use this option if you want Camel to consume from a route and you do not want Camel to automatically send back a reply message because another component in your code handles the reply message. You can also use this option if you want to use Camel as a proxy between different message brokers and you want to route message from one system to another.	false	boolean
durableSubscriptionName (common)	The durable subscriber name for specifying durable topic subscriptions. The <code>clientId</code> option must be configured as well.		String
jmsMessageType (common)	Allows you to force the use of a specific <code>javax.jms.Message</code> implementation for sending JMS messages. Possible values are: Bytes, Map, Object, Stream, Text. By default, Camel would determine which JMS message type to use from the In body type. This option allows you to specify it.		JmsMessageType

Name	Description	Default	Type
testConnectionOnStartup (common)	Specifies whether to test the connection on startup. This ensures that when Camel starts that all the JMS consumers have a valid connection to the JMS broker. If a connection cannot be granted then Camel throws an exception on startup. This ensures that Camel is not started with failed connections. The JMS producers is tested as well.	false	boolean
acknowledgmentModeName (consumer)	The JMS acknowledgement name, which is one of: SESSION_TRANSACTED, CLIENT_ACKNOWLEDGE, AUTO_ACKNOWLEDGE, DUPS_OK_ACKNOWLEDGE	AUTO_ACKNOWLEDGE	String
asyncConsumer (consumer)	Whether the JmsConsumer processes the Exchange asynchronously. If enabled then the JmsConsumer may pickup the next message from the JMS queue, while the previous message is being processed asynchronously (by the Asynchronous Routing Engine). This means that messages may be processed not 100% strictly in order. If disabled (as default) then the Exchange is fully processed before the JmsConsumer will pickup the next message from the JMS queue. Note if transacted has been enabled, then asyncConsumer=true does not run asynchronously, as transaction must be executed synchronously (Camel 3.0 may support async transactions).	false	boolean
autoStartup (consumer)	Specifies whether the consumer container should auto-startup.	true	boolean
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
cacheLevel (consumer)	Sets the cache level by ID for the underlying JMS resources. See cacheLevelName option for more details.		int

Name	Description	Default	Type
cacheLevelName (consumer)	Sets the cache level by name for the underlying JMS resources. Possible values are: <code>CACHE_AUTO</code> , <code>CACHE_CONNECTION</code> , <code>CACHE_CONSUMER</code> , <code>CACHE_NONE</code> , and <code>CACHE_SESSION</code> . The default setting is <code>CACHE_AUTO</code> . See the Spring documentation and Transactions Cache Levels for more information.	<code>CACHE_AUTO</code>	String
concurrentConsumers (consumer)	Specifies the default number of concurrent consumers when consuming from JMS (not for request/reply over JMS). See also the <code>maxMessagesPerTask</code> option to control dynamic scaling up/down of threads. When doing request/reply over JMS then the option <code>replyToConcurrentConsumers</code> is used to control number of concurrent consumers on the reply message listener.	1	int
maxConcurrentConsumers (consumer)	Specifies the maximum number of concurrent consumers when consuming from JMS (not for request/reply over JMS). See also the <code>maxMessagesPerTask</code> option to control dynamic scaling up/down of threads. When doing request/reply over JMS then the option <code>replyToMaxConcurrentConsumers</code> is used to control number of concurrent consumers on the reply message listener.		int
replyTo (consumer)	Provides an explicit <code>ReplyTo</code> destination, which overrides any incoming value of <code>Message.getJMSReplyTo()</code> .		String
replyToDeliveryPersistent (consumer)	Specifies whether to use persistent delivery by default for replies.	true	boolean
selector (consumer)	Sets the JMS selector to use		String
subscriptionDurable (consumer)	Set whether to make the subscription durable. The durable subscription name to be used can be specified through the <code>subscriptionName</code> property. Default is false. Set this to true to register a durable subscription, typically in combination with a <code>subscriptionName</code> value (unless your message listener class name is good enough as subscription name). Only makes sense when listening to a topic (pub-sub domain), therefore this method switches the <code>pubSubDomain</code> flag as well.	false	boolean

Name	Description	Default	Type
subscriptionName (consumer)	Set the name of a subscription to create. To be applied in case of a topic (pub-sub domain) with a shared or durable subscription. The subscription name needs to be unique within this client's JMS client id. Default is the class name of the specified message listener. Note: Only 1 concurrent consumer (which is the default of this message listener container) is allowed for each subscription, except for a shared subscription (which requires JMS 2.0).		String
subscriptionShared (consumer)	Set whether to make the subscription shared. The shared subscription name to be used can be specified through the subscriptionName property. Default is false. Set this to true to register a shared subscription, typically in combination with a subscriptionName value (unless your message listener class name is good enough as subscription name). Note that shared subscriptions may also be durable, so this flag can (and often will) be combined with subscriptionDurable as well. Only makes sense when listening to a topic (pub-sub domain), therefore this method switches the pubSubDomain flag as well. Requires a JMS 2.0 compatible message broker.	false	boolean
acceptMessagesWhileStopping (consumer)	Specifies whether the consumer accept messages while it is stopping. You may consider enabling this option, if you start and stop JMS routes at runtime, while there are still messages enqueued on the queue. If this option is false, and you stop the JMS route, then messages may be rejected, and the JMS broker would have to attempt redeliveries, which yet again may be rejected, and eventually the message may be moved at a dead letter queue on the JMS broker. To avoid this its recommended to enable this option.	false	boolean
allowReplyManagerQuickStop (consumer)	Whether the DefaultMessageListenerContainer used in the reply managers for request-reply messaging allow the DefaultMessageListenerContainer#runningAllowed() flag to quick stop in case JmsConfiguration#isAcceptMessagesWhileStopping() is enabled, and org.apache.camel.CamelContext is currently being stopped. This quick stop ability is enabled by default in the regular JMS consumers but to enable for reply managers you must enable this flag.	false	boolean

Name	Description	Default	Type
consumerType (consumer)	The consumer type to use, which can be one of: Simple, Default, or Custom. The consumer type determines which Spring JMS listener to use. Default will use <code>org.springframework.jms.listener.DefaultMessageListenerContainer</code> , Simple will use <code>org.springframework.jms.listener.SimpleMessageListenerContainer</code> . When Custom is specified, the <code>MessageListenerContainerFactory</code> defined by the <code>messageListenerContainerFactory</code> option will determine what <code>org.springframework.jms.listener.AbstractMessageListenerContainer</code> to use.	Default	ConsumerType
defaultTaskExecutorType (consumer)	Specifies what default <code>TaskExecutor</code> type to use in the <code>DefaultMessageListenerContainer</code> , for both consumer endpoints and the <code>ReplyTo</code> consumer of producer endpoints. Possible values: <code>SimpleAsync</code> (uses Spring's <code>SimpleAsyncTaskExecutor</code>) or <code>ThreadPool</code> (uses Spring's <code>ThreadPoolTaskExecutor</code> with optimal values - cached threadpool-like). If not set, it defaults to the previous behaviour, which uses a cached thread pool for consumer endpoints and <code>SimpleAsync</code> for reply consumers. The use of <code>ThreadPool</code> is recommended to reduce thread trash in elastic configurations with dynamically increasing and decreasing concurrent consumers.		DefaultTaskExecutorType
eagerLoadingOfProperties (consumer)	Enables eager loading of JMS properties and payload as soon as a message is loaded which generally is inefficient as the JMS properties may not be required but sometimes can catch early any issues with the underlying JMS provider and the use of JMS properties	false	boolean
exceptionHandler (consumer)	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at <code>WARN</code> or <code>ERROR</code> level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
exposeListenerSession (consumer)	Specifies whether the listener session should be exposed when consuming messages.	false	boolean

Name	Description	Default	Type
replyToSameDestination Allowed (consumer)	Whether a JMS consumer is allowed to send a reply message to the same destination that the consumer is using to consume from. This prevents an endless loop by consuming and sending back the same message to itself.	false	boolean
taskExecutor (consumer)	Allows you to specify a custom task executor for consuming messages.		TaskExecutor
deliveryDelay (producer)	Sets delivery delay to use for send calls for JMS. This option requires JMS 2.0 compliant broker.	-1	long
deliveryMode (producer)	Specifies the delivery mode to be used. Possible values are those defined by <code>javax.jms.DeliveryMode</code> . <code>NON_PERSISTENT = 1</code> and <code>PERSISTENT = 2</code> .		Integer
deliveryPersistent (producer)	Specifies whether persistent delivery is used by default.	true	boolean
explicitQosEnabled (producer)	Set if the <code>deliveryMode</code> , <code>priority</code> or <code>timeToLive</code> qualities of service should be used when sending messages. This option is based on Spring's <code>JmsTemplate</code> . The <code>deliveryMode</code> , <code>priority</code> and <code>timeToLive</code> options are applied to the current endpoint. This contrasts with the <code>preserveMessageQos</code> option, which operates at message granularity, reading QoS properties exclusively from the Camel In message headers.	false	Boolean
formatDateHeadersToIso8601 (producer)	Sets whether date headers should be formatted according to the ISO 8601 standard.	false	boolean
preserveMessageQos (producer)	Set to true, if you want to send message using the QoS settings specified on the message, instead of the QoS settings on the JMS endpoint. The following three headers are considered <code>JMSPriority</code> , <code>JMSDeliveryMode</code> , and <code>JMSExpiration</code> . You can provide all or only some of them. If not provided, Camel will fall back to use the values from the endpoint instead. So, when using this option, the headers override the values from the endpoint. The <code>explicitQosEnabled</code> option, by contrast, will only use options set on the endpoint, and not values from the message header.	false	boolean

Name	Description	Default	Type
priority (producer)	Values greater than 1 specify the message priority when sending (where 0 is the lowest priority and 9 is the highest). The <code>explicitQosEnabled</code> option must also be enabled in order for this option to have any effect.	4	int
replyToConcurrentConsumers (producer)	Specifies the default number of concurrent consumers when doing request/reply over JMS. See also the <code>maxMessagesPerTask</code> option to control dynamic scaling up/down of threads.	1	int
replyToMaxConcurrentConsumers (producer)	Specifies the maximum number of concurrent consumers when using request/reply over JMS. See also the <code>maxMessagesPerTask</code> option to control dynamic scaling up/down of threads.		int
replyToOnTimeoutMaxConcurrentConsumers (producer)	Specifies the maximum number of concurrent consumers for continue routing when timeout occurred when using request/reply over JMS.	1	int
replyToOverride (producer)	Provides an explicit <code>ReplyTo</code> destination in the JMS message, which overrides the setting of <code>replyTo</code> . It is useful if you want to forward the message to a remote Queue and receive the reply message from the <code>ReplyTo</code> destination.		String
replyToType (producer)	Allows for explicitly specifying which kind of strategy to use for <code>replyTo</code> queues when doing request/reply over JMS. Possible values are: <code>Temporary</code> , <code>Shared</code> , or <code>Exclusive</code> . By default Camel will use temporary queues. However if <code>replyTo</code> has been configured, then <code>Shared</code> is used by default. This option allows you to use exclusive queues instead of shared ones. See Camel JMS documentation for more details, and especially the notes about the implications if running in a clustered environment, and the fact that <code>Shared</code> reply queues has lower performance than its alternatives <code>Temporary</code> and <code>Exclusive</code> .		<code>ReplyToType</code>
requestTimeout (producer)	The timeout for waiting for a reply when using the InOut Exchange Pattern (in milliseconds). The default is 20 seconds. You can include the header <code>CamelJmsRequestTimeout</code> to override this endpoint configured timeout value, and thus have per message individual timeout values. See also the <code>requestTimeoutCheckerInterval</code> option.	20000	long

Name	Description	Default	Type
timeToLive (producer)	When sending messages, specifies the time-to-live of the message (in milliseconds).	-1	long
allowAdditionalHeaders (producer)	This option is used to allow additional headers which may have values that are invalid according to JMS specification. For example some message systems such as WMQ do this with header names using prefix JMS_IBM_MQMD_ containing values with byte array or other invalid types. You can specify multiple header names separated by comma, and use as suffix for wildcard matching.		String
allowNullBody (producer)	Whether to allow sending messages with no body. If this option is false and the message body is null, then an JMSEException is thrown.	true	boolean
alwaysCopyMessage (producer)	If true, Camel will always make a JMS message copy of the message when it is passed to the producer for sending. Copying the message is needed in some situations, such as when a <code>replyToDestinationSelectorName</code> is set (incidentally, Camel will set the <code>alwaysCopyMessage</code> option to true, if a <code>replyToDestinationSelectorName</code> is set)	false	boolean
correlationProperty (producer)	Use this JMS property to correlate messages in InOut exchange pattern (request-reply) instead of JMSCorrelationID property. This allows you to exchange messages with systems that do not correlate messages using JMSCorrelationID JMS property. If used JMSCorrelationID will not be used or set by Camel. The value of here named property will be generated if not supplied in the header of the message under the same name.		String
disableTimeToLive (producer)	Use this option to force disabling time to live. For example when you do request/reply over JMS, then Camel will by default use the <code>requestTimeout</code> value as time to live on the message being sent. The problem is that the sender and receiver systems have to have their clocks synchronized, so they are in sync. This is not always so easy to archive. So you can use <code>disableTimeToLive=true</code> to not set a time to live value on the sent message. Then the message will not expire on the receiver system. See below in section About time to live for more details.	false	boolean

Name	Description	Default	Type
forceSendOriginalMessage (producer)	When using <code>mapJmsMessage=false</code> Camel will create a new JMS message to send to a new JMS destination if you touch the headers (get or set) during the route. Set this option to true to force Camel to send the original JMS message that was received.	false	boolean
includeSentJMSMessageID (producer)	Only applicable when sending to JMS destination using <code>InOnly</code> (eg fire and forget). Enabling this option will enrich the Camel Exchange with the actual <code>JMSMessageID</code> that was used by the JMS client when the message was sent to the JMS destination.	false	boolean
replyToCacheLevelName (producer)	Sets the cache level by name for the reply consumer when doing request/reply over JMS. This option only applies when using fixed reply queues (not temporary). Camel will by default use: <code>CACHE_CONSUMER</code> for exclusive or shared w/ <code>replyToSelectorName</code> . And <code>CACHE_SESSION</code> for shared without <code>replyToSelectorName</code> . Some JMS brokers such as IBM WebSphere may require to set the <code>replyToCacheLevelName=CACHE_NONE</code> to work. Note: If using temporary queues then <code>CACHE_NONE</code> is not allowed, and you must use a higher value such as <code>CACHE_CONSUMER</code> or <code>CACHE_SESSION</code> .		String
replyToDestinationSelector Name (producer)	Sets the JMS Selector using the fixed name to be used so you can filter out your own replies from the others when using a shared queue (that is, if you are not using a temporary reply queue).		String
streamMessageTypeEnabled (producer)	Sets whether <code>StreamMessage</code> type is enabled or not. Message payloads of streaming kind such as files, <code>InputStream</code> , etc will either be sent as <code>BytesMessage</code> or <code>StreamMessage</code> . This option controls which kind will be used. By default <code>BytesMessage</code> is used which enforces the entire message payload to be read into memory. By enabling this option the message payload is read into memory in chunks and each chunk is then written to the <code>StreamMessage</code> until no more data.	false	boolean
allowSerializedHeaders (advanced)	Controls whether or not to include serialized headers. Applies only when <code>isTransferExchange()</code> is true. This requires that the objects are serializable. Camel will exclude any non-serializable objects and log it at <code>WARN</code> level.	false	boolean

Name	Description	Default	Type
asyncStartListener (advanced)	Whether to startup the JmsConsumer message listener asynchronously, when starting a route. For example if a JmsConsumer cannot get a connection to a remote JMS broker, then it may block while retrying and/or failover. This will cause Camel to block while starting routes. By setting this option to true, you will let routes startup, while the JmsConsumer connects to the JMS broker using a dedicated thread in asynchronous mode. If this option is used, then beware that if the connection could not be established, then an exception is logged at WARN level, and the consumer will not be able to receive messages; You can then restart the route to retry.	false	boolean
asyncStopListener (advanced)	Whether to stop the JmsConsumer message listener asynchronously, when stopping a route.	false	boolean
destinationResolver (advanced)	A pluggable org.springframework.jms.support.destination.DestinationResolver that allows you to use your own resolver (for example, to lookup the real destination in a JNDI registry).		DestinationResolver
errorHandler (advanced)	Specifies a org.springframework.util.ErrorHandler to be invoked in case of any uncaught exceptions thrown while processing a Message. By default these exceptions will be logged at the WARN level, if no errorHandler has been configured. You can configure logging level and whether stack traces should be logged using errorHandlerLogLevel and errorHandlerLogStackTrace options. This makes it much easier to configure, than having to code a custom errorHandler.		ErrorHandler
exceptionListener (advanced)	Specifies the JMS Exception Listener that is to be notified of any underlying JMS exceptions.		ExceptionListener
headerFilterStrategy (advanced)	To use a custom HeaderFilterStrategy to filter header to and from Camel message.		HeaderFilterStrategy
idleConsumerLimit (advanced)	Specify the limit for the number of consumers that are allowed to be idle at any given time.	1	int

Name	Description	Default	Type
idleTaskExecutionLimit (advanced)	Specifies the limit for idle executions of a receive task, not having received any message within its execution. If this limit is reached, the task will shut down and leave receiving to other executing tasks (in the case of dynamic scheduling; see the <code>maxConcurrentConsumers</code> setting). There is additional doc available from Spring.	1	int
includeAllJMSXProperties (advanced)	Whether to include all JMSXxxx properties when mapping from JMS to Camel Message. Setting this to true will include properties such as JMSXAppID, and JMSXUserID etc. Note: If you are using a custom <code>headerFilterStrategy</code> then this option does not apply.	false	boolean
jmsKeyFormatStrategy (advanced)	Pluggable strategy for encoding and decoding JMS keys so they can be compliant with the JMS specification. Camel provides two implementations out of the box: default and passthrough. The default strategy will safely marshal dots and hyphens (. and -). The passthrough strategy leaves the key as is. Can be used for JMS brokers which do not care whether JMS header keys contain illegal characters. You can provide your own implementation of the <code>org.apache.camel.component.jms.JmsKeyFormatStrategy</code> and refer to it using the # notation.		String
mapJmsMessage (advanced)	Specifies whether Camel should auto map the received JMS message to a suited payload type, such as <code>javax.jms.TextMessage</code> to a String etc.	true	boolean
maxMessagesPerTask (advanced)	The number of messages per task. -1 is unlimited. If you use a range for concurrent consumers (eg min max), then this option can be used to set a value to eg 100 to control how fast the consumers will shrink when less work is required.	-1	int
messageConverter (advanced)	To use a custom Spring <code>org.springframework.jms.support.converter.MessageConverter</code> so you can be in control how to map to/from a <code>javax.jms.Message</code> .		MessageConverter
messageCreatedStrategy (advanced)	To use the given <code>MessageCreatedStrategy</code> which are invoked when Camel creates new instances of <code>javax.jms.Message</code> objects when Camel is sending a JMS message.		MessageCreatedStrategy

Name	Description	Default	Type
messageIdEnabled (advanced)	When sending, specifies whether message IDs should be added. This is just an hint to the JMS Broker. If the JMS provider accepts this hint, these messages must have the message ID set to null; if the provider ignores the hint, the message ID must be set to its normal unique value	true	boolean
messageListenerContainerFactory (advanced)	Registry ID of the MessageListenerContainerFactory used to determine what org.springframework.jms.listener.AbstractMessageListenerContainer to use to consume messages. Setting this will automatically set consumerType to Custom.		MessageListenerContainerFactory
messageTimestampEnabled (advanced)	Specifies whether timestamps should be enabled by default on sending messages. This is just an hint to the JMS Broker. If the JMS provider accepts this hint, these messages must have the timestamp set to zero; if the provider ignores the hint, the timestamp must be set to its normal value	true	boolean
pubSubNoLocal (advanced)	Specifies whether to inhibit the delivery of messages published by its own connection.	false	boolean
receiveTimeout (advanced)	The timeout for receiving messages (in milliseconds).	1000	long
recoveryInterval (advanced)	Specifies the interval between recovery attempts, i.e. when a connection is being refreshed, in milliseconds. The default is 5000 ms, that is, 5 seconds.	5000	long
requestTimeoutCheckerInterval (advanced)	Configures how often Camel should check for timed out Exchanges when doing request/reply over JMS. By default Camel checks once per second. But if you must react faster when a timeout occurs, then you can lower this interval, to check more frequently. The timeout is determined by the option requestTimeout.	1000	long
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

Name	Description	Default	Type
transferException (advanced)	If enabled and you are using Request Reply messaging (InOut) and an Exchange failed on the consumer side, then the caused Exception will be send back in response as a <code>javax.jms.ObjectMessage</code> . If the client is Camel, the returned Exception is rethrown. This allows you to use Camel JMS as a bridge in your routing - for example, using persistent queues to enable robust routing. Notice that if you also have <code>transferExchange</code> enabled, this option takes precedence. The caught exception is required to be serializable. The original Exception on the consumer side can be wrapped in an outer exception such as <code>org.apache.camel.RuntimeCamelException</code> when returned to the producer.	false	boolean
transferExchange (advanced)	You can transfer the exchange over the wire instead of just the body and headers. The following fields are transferred: In body, Out body, Fault body, In headers, Out headers, Fault headers, exchange properties, exchange exception. This requires that the objects are serializable. Camel will exclude any non-serializable objects and log it at WARN level. You must enable this option on both the producer and consumer side, so Camel knows the payloads is an Exchange and not a regular payload.	false	boolean
transferFault (advanced)	If enabled and you are using Request Reply messaging (InOut) and an Exchange failed with a SOAP fault (not exception) on the consumer side, then the fault flag on <code>org.apache.camel.Message#isFault()</code> will be send back in the response as a JMS header with the key <code>JmsConstants#JMS_TRANSFER_FAULT</code> . If the client is Camel, the returned fault flag will be set on the <code>org.apache.camel.Message#setFault(boolean)</code> . You may want to enable this when using Camel components that support faults such as SOAP based such as cxf or spring-ws.	false	boolean
useMessageIDAs Correlation ID (advanced)	Specifies whether <code>JMSMessageID</code> should always be used as <code>JMSCorrelationID</code> for InOut messages.	false	boolean
waitForProvision Correlation ToBeUpdatedCounter (advanced)	Number of times to wait for provisional correlation id to be updated to the actual correlation id when doing request/reply over JMS and when the option <code>useMessageIDAsCorrelationID</code> is enabled.	50	int

Name	Description	Default	Type
waitForProvisionCorrelationToBeUpdatedThreadSleepingTime (advanced)	Interval in millis to sleep each time while waiting for provisional correlation id to be updated.	100	long
errorHandlerLoggingLevel (logging)	Allows to configure the default errorHandler logging level for logging uncaught exceptions.	WARN	LogLevel
errorHandlerLogStackTrace (logging)	Allows to control whether stacktraces should be logged or not, by the default errorHandler.	true	boolean
password (security)	Password to use with the ConnectionFactory. You can also configure username/password directly on the ConnectionFactory.		String
username (security)	Username to use with the ConnectionFactory. You can also configure username/password directly on the ConnectionFactory.		String
transacted (transaction)	Specifies whether to use transacted mode	false	boolean
lazyCreateTransactionManager (transaction)	If true, Camel will create a JmsTransactionManager, if there is no transactionManager injected when option transacted=true.	true	boolean
transactionManager (transaction)	The Spring transaction manager to use.		PlatformTransactionManager
transactionName (transaction)	The name of the transaction to use.		String
transactionTimeout (transaction)	The timeout value of the transaction (in seconds), if using transacted mode.	-1	int

178.5. SPRING BOOT AUTO-CONFIGURATION

The component supports 172 options, which are listed below.

Name	Description	Default	Type
camel.component.jms.accept-messages-while-stopping	Specifies whether the consumer accept messages while it is stopping. You may consider enabling this option, if you start and stop JMS routes at runtime, while there are still messages enqueued on the queue. If this option is false, and you stop the JMS route, then messages may be rejected, and the JMS broker would have to attempt redeliveries, which yet again may be rejected, and eventually the message may be moved at a dead letter queue on the JMS broker. To avoid this its recommended to enable this option.	false	Boolean
camel.component.jms.acknowledgment-mode	The JMS acknowledgement mode defined as an Integer. Allows you to set vendor-specific extensions to the acknowledgment mode. For the regular modes, it is preferable to use the <code>acknowledgmentModeName</code> instead.		Integer
camel.component.jms.acknowledgment-mode-name	The JMS acknowledgement name, which is one of: <code>SESSION_TRANSACTED</code> , <code>CLIENT_ACKNOWLEDGE</code> , <code>AUTO_ACKNOWLEDGE</code> , <code>DUPS_OK_ACKNOWLEDGE</code>	AUTO_ACKNOWLEDGE	String
camel.component.jms.allow-additional-headers	This option is used to allow additional headers which may have values that are invalid according to JMS specification. For example some message systems such as WMQ do this with header names using prefix <code>JMS_IBM_MQMD_</code> containing values with byte array or other invalid types. You can specify multiple header names separated by comma, and use as suffix for wildcard matching.		String
camel.component.jms.allow-null-body	Whether to allow sending messages with no body. If this option is false and the message body is null, then an <code>JMSEException</code> is thrown.	true	Boolean
camel.component.jms.allow-reply-manager-quick-stop	Whether the <code>DefaultMessageListenerContainer</code> used in the reply managers for request-reply messaging allow the <code>DefaultMessageListenerContainer.runningAllowed</code> flag to quick stop in case <code>JmsConfiguration#isAcceptMessagesWhileStopping</code> is enabled, and <code>org.apache.camel.CamelContext</code> is currently being stopped. This quick stop ability is enabled by default in the regular JMS consumers but to enable for reply managers you must enable this flag.	false	Boolean

Name	Description	Default	Type
camel.component.jms.always-copy-message	If true, Camel will always make a JMS message copy of the message when it is passed to the producer for sending. Copying the message is needed in some situations, such as when a <code>replyToDestinationSelectorName</code> is set (incidentally, Camel will set the <code>alwaysCopyMessage</code> option to true, if a <code>replyToDestinationSelectorName</code> is set)	false	Boolean
camel.component.jms.async-consumer	Whether the <code>JmsConsumer</code> processes the Exchange asynchronously. If enabled then the <code>JmsConsumer</code> may pickup the next message from the JMS queue, while the previous message is being processed asynchronously (by the Asynchronous Routing Engine). This means that messages may be processed not 100% strictly in order. If disabled (as default) then the Exchange is fully processed before the <code>JmsConsumer</code> will pickup the next message from the JMS queue. Note if <code>transacted</code> has been enabled, then <code>asyncConsumer=true</code> does not run asynchronously, as transaction must be executed synchronously (Camel 3.0 may support async transactions).	false	Boolean
camel.component.jms.async-start-listener	Whether to startup the <code>JmsConsumer</code> message listener asynchronously, when starting a route. For example if a <code>JmsConsumer</code> cannot get a connection to a remote JMS broker, then it may block while retrying and/or failover. This will cause Camel to block while starting routes. By setting this option to true, you will let routes startup, while the <code>JmsConsumer</code> connects to the JMS broker using a dedicated thread in asynchronous mode. If this option is used, then beware that if the connection could not be established, then an exception is logged at WARN level, and the consumer will not be able to receive messages; You can then restart the route to retry.	false	Boolean
camel.component.jms.async-stop-listener	Whether to stop the <code>JmsConsumer</code> message listener asynchronously, when stopping a route.	false	Boolean
camel.component.jms.auto-startup	Specifies whether the consumer container should auto-startup.	true	Boolean
camel.component.jms.cache-level	Sets the cache level by ID for the underlying JMS resources. See <code>cacheLevelName</code> option for more details.		Integer

Name	Description	Default	Type
camel.component.jms.cache-level-name	Sets the cache level by name for the underlying JMS resources. Possible values are: <code>CACHE_AUTO</code> , <code>CACHE_CONNECTION</code> , <code>CACHE_CONSUMER</code> , <code>CACHE_NONE</code> , and <code>CACHE_SESSION</code> . The default setting is <code>CACHE_AUTO</code> . See the Spring documentation and Transactions Cache Levels for more information.	<code>CACHE_AUTO</code>	String
camel.component.jms.client-id	Sets the JMS client ID to use. Note that this value, if specified, must be unique and can only be used by a single JMS connection instance. It is typically only required for durable topic subscriptions. If using Apache ActiveMQ you may prefer to use Virtual Topics instead.		String
camel.component.jms.concurrent-consumers	Specifies the default number of concurrent consumers when consuming from JMS (not for request/reply over JMS). See also the <code>maxMessagesPerTask</code> option to control dynamic scaling up/down of threads. When doing request/reply over JMS then the option <code>replyToConcurrentConsumers</code> is used to control number of concurrent consumers on the reply message listener.	1	Integer
camel.component.jms.configuration.accept-messages-while-stopping	Specifies whether the consumer accept messages while it is stopping. You may consider enabling this option, if you start and stop JMS routes at runtime, while there are still messages enqueued on the queue. If this option is false, and you stop the JMS route, then messages may be rejected, and the JMS broker would have to attempt redeliveries, which yet again may be rejected, and eventually the message may be moved at a dead letter queue on the JMS broker. To avoid this its recommended to enable this option.	false	Boolean
camel.component.jms.configuration.acknowledgment-mode	The JMS acknowledgement mode defined as an Integer. Allows you to set vendor-specific extensions to the acknowledgment mode. For the regular modes, it is preferable to use the <code>acknowledgmentModeName</code> instead.		Integer
camel.component.jms.configuration.acknowledgment-mode-name	The JMS acknowledgement name, which is one of: <code>SESSION_TRANSACTED</code> , <code>CLIENT_ACKNOWLEDGE</code> , <code>AUTO_ACKNOWLEDGE</code> , <code>DUPS_OK_ACKNOWLEDGE</code>	<code>AUTO_ACKNOWLEDGE</code>	String

Name	Description	Default	Type
<code>camel.component.jms.configuration.allow-additional-headers</code>	This option is used to allow additional headers which may have values that are invalid according to JMS specification. For example some message systems such as WMQ do this with header names using prefix <code>JMS_IBM_MQMD_</code> containing values with byte array or other invalid types. You can specify multiple header names separated by comma, and use as suffix for wildcard matching.		String
<code>camel.component.jms.configuration.allow-null-body</code>	Whether to allow sending messages with no body. If this option is false and the message body is null, then an <code>JMSEException</code> is thrown.	true	Boolean
<code>camel.component.jms.configuration.allow-reply-manager-quick-stop</code>	Whether the <code>DefaultMessageListenerContainer</code> used in the reply managers for request-reply messaging allow the <code>DefaultMessageListenerContainer#runningAllowed()</code> flag to quick stop in case <code>JmsConfiguration#isAcceptMessagesWhileStopping()</code> is enabled, and <code>org.apache.camel.CamelContext</code> is currently being stopped. This quick stop ability is enabled by default in the regular JMS consumers but to enable for reply managers you must enable this flag.	false	Boolean
<code>camel.component.jms.configuration.allow-serialized-headers</code>	Controls whether or not to include serialized headers. Applies only when <code>isTransferExchange()</code> is true. This requires that the objects are serializable. Camel will exclude any non-serializable objects and log it at WARN level.	false	Boolean
<code>camel.component.jms.configuration.always-copy-message</code>	If true, Camel will always make a JMS message copy of the message when it is passed to the producer for sending. Copying the message is needed in some situations, such as when a <code>replyToDestinationSelectorName</code> is set (incidentally, Camel will set the <code>alwaysCopyMessage</code> option to true, if a <code>replyToDestinationSelectorName</code> is set)	false	Boolean

Name	Description	Default	Type
camel.component.jms.configuration.async-consumer	Whether the <code>JmsConsumer</code> processes the Exchange asynchronously. If enabled then the <code>JmsConsumer</code> may pickup the next message from the JMS queue, while the previous message is being processed asynchronously (by the Asynchronous Routing Engine). This means that messages may be processed not 100% strictly in order. If disabled (as default) then the Exchange is fully processed before the <code>JmsConsumer</code> will pickup the next message from the JMS queue. Note if <code>transacted</code> has been enabled, then <code>asyncConsumer=true</code> does not run asynchronously, as transaction must be executed synchronously (Camel 3.0 may support async transactions).	false	Boolean
camel.component.jms.configuration.async-start-listener	Whether to startup the <code>JmsConsumer</code> message listener asynchronously, when starting a route. For example if a <code>JmsConsumer</code> cannot get a connection to a remote JMS broker, then it may block while retrying and/or failover. This will cause Camel to block while starting routes. By setting this option to true, you will let routes startup, while the <code>JmsConsumer</code> connects to the JMS broker using a dedicated thread in asynchronous mode. If this option is used, then beware that if the connection could not be established, then an exception is logged at WARN level, and the consumer will not be able to receive messages; You can then restart the route to retry.	false	Boolean
camel.component.jms.configuration.async-stop-listener	Whether to stop the <code>JmsConsumer</code> message listener asynchronously, when stopping a route.	false	Boolean
camel.component.jms.configuration.auto-startup	Specifies whether the consumer container should auto-startup.	true	Boolean
camel.component.jms.configuration.cache-level	Sets the cache level by ID for the underlying JMS resources. See <code>cacheLevelName</code> option for more details.		Integer

Name	Description	Default	Type
camel.component.jms.configuration.cache-level-name	Sets the cache level by name for the underlying JMS resources. Possible values are: <code>CACHE_AUTO</code> , <code>CACHE_CONNECTION</code> , <code>CACHE_CONSUMER</code> , <code>CACHE_NONE</code> , and <code>CACHE_SESSION</code> . The default setting is <code>CACHE_AUTO</code> . See the Spring documentation and Transactions Cache Levels for more information.	<code>CACHE_AUTO</code>	String
camel.component.jms.configuration.client-id	Sets the JMS client ID to use. Note that this value, if specified, must be unique and can only be used by a single JMS connection instance. It is typically only required for durable topic subscriptions. If using Apache ActiveMQ you may prefer to use Virtual Topics instead.		String
camel.component.jms.configuration.concurrent-consumers	Specifies the default number of concurrent consumers when consuming from JMS (not for request/reply over JMS). See also the <code>maxMessagesPerTask</code> option to control dynamic scaling up/down of threads. When doing request/reply over JMS then the option <code>replyToConcurrentConsumers</code> is used to control number of concurrent consumers on the reply message listener.	1	Integer
camel.component.jms.configuration.connection-factory	Sets the default connection factory to be used if a connection factory is not specified for either <code>setTemplateConnectionFactory(ConnectionFactory)</code> or <code>setListenerConnectionFactory(ConnectionFactory)</code>		ConnectionFactory
camel.component.jms.configuration.consumer-type	The consumer type to use, which can be one of: Simple, Default, or Custom. The consumer type determines which Spring JMS listener to use. Default will use <code>org.springframework.jms.listener.DefaultMessageListenerContainer</code> , Simple will use <code>org.springframework.jms.listener.SimpleMessageListenerContainer</code> . When Custom is specified, the <code>MessageListenerContainerFactory</code> defined by the <code>messageListenerContainerFactory</code> option will determine what <code>org.springframework.jms.listener.AbstractMessageListenerContainer</code> to use.		ConsumerType

Name	Description	Default	Type
camel.component.jms.configuration.correlation-property	Use this JMS property to correlate messages in InOut exchange pattern (request-reply) instead of JMSCorrelationID property. This allows you to exchange messages with systems that do not correlate messages using JMSCorrelationID JMS property. If used JMSCorrelationID will not be used or set by Camel. The value of here named property will be generated if not supplied in the header of the message under the same name.		String
camel.component.jms.configuration.default-task-executor-type	Specifies what default TaskExecutor type to use in the DefaultMessageListenerContainer, for both consumer endpoints and the ReplyTo consumer of producer endpoints. Possible values: SimpleAsync (uses Spring's SimpleAsyncTaskExecutor) or ThreadPool (uses Spring's ThreadPoolTaskExecutor with optimal values - cached threadpool-like). If not set, it defaults to the previous behaviour, which uses a cached thread pool for consumer endpoints and SimpleAsync for reply consumers. The use of ThreadPool is recommended to reduce thread trash in elastic configurations with dynamically increasing and decreasing concurrent consumers.		DefaultTaskExecutor Type
camel.component.jms.configuration.delivery-mode	Specifies the delivery mode to be used. Possible values are those defined by javax.jms.DeliveryMode. NON_PERSISTENT = 1 and PERSISTENT = 2.		Integer
camel.component.jms.configuration.delivery-persistent	Specifies whether persistent delivery is used by default.	true	Boolean
camel.component.jms.configuration.destination-resolver	A pluggable org.springframework.jms.support.destination.DestinationResolver that allows you to use your own resolver (for example, to lookup the real destination in a JNDI registry).		DestinationResolver
camel.component.jms.configuration.disable-reply-to	Specifies whether Camel ignores the JMSReplyTo header in messages. If true, Camel does not send a reply back to the destination specified in the JMSReplyTo header. You can use this option if you want Camel to consume from a route and you do not want Camel to automatically send back a reply message because another component in your code handles the reply message. You can also use this option if you want to use Camel as a proxy between different message brokers and you want to route message from one system to another.	false	Boolean

Name	Description	Default	Type
<code>camel.component.jms.configuration.disable-time-to-live</code>	Use this option to force disabling time to live. For example when you do request/reply over JMS, then Camel will by default use the requestTimeout value as time to live on the message being sent. The problem is that the sender and receiver systems have to have their clocks synchronized, so they are in sync. This is not always so easy to archive. So you can use <code>disableTimeToLive=true</code> to not set a time to live value on the sent message. Then the message will not expire on the receiver system. See below in section About time to live for more details.	false	Boolean
<code>camel.component.jms.configuration.durable-subscription-name</code>	The durable subscriber name for specifying durable topic subscriptions. The <code>clientId</code> option must be configured as well.		String
<code>camel.component.jms.configuration.eager-loading-of-properties</code>	Enables eager loading of JMS properties and payload as soon as a message is loaded which generally is inefficient as the JMS properties may not be required but sometimes can catch early any issues with the underlying JMS provider and the use of JMS properties	false	Boolean
<code>camel.component.jms.configuration.error-handler</code>	Specifies a <code>org.springframework.util.ErrorHandler</code> to be invoked in case of any uncaught exceptions thrown while processing a Message. By default these exceptions will be logged at the WARN level, if no errorHandler has been configured. You can configure logging level and whether stack traces should be logged using <code>errorHandlerLoggingLevel</code> and <code>errorHandlerLogStackTrace</code> options. This makes it much easier to configure, than having to code a custom errorHandler.		ErrorHandler
<code>camel.component.jms.configuration.error-handler-log-stack-trace</code>	Allows to control whether stacktraces should be logged or not, by the default errorHandler.	true	Boolean
<code>camel.component.jms.configuration.error-handler-logging-level</code>	Allows to configure the default errorHandler logging level for logging uncaught exceptions.		LogLevel

Name	Description	Default	Type
<code>camel.component.jms.configuration.exception-listener</code>	Specifies the JMS Exception Listener that is to be notified of any underlying JMS exceptions.		ExceptionListener
<code>camel.component.jms.configuration.expose-listener-session</code>	Specifies whether the listener session should be exposed when consuming messages.	false	Boolean
<code>camel.component.jms.configuration.force-send-original-message</code>	When using <code>mapJmsMessage=false</code> Camel will create a new JMS message to send to a new JMS destination if you touch the headers (get or set) during the route. Set this option to true to force Camel to send the original JMS message that was received.	false	Boolean
<code>camel.component.jms.configuration.format-date-headers-to-iso8601</code>	Sets whether date headers should be formatted according to the ISO 8601 standard.	false	Boolean
<code>camel.component.jms.configuration.idle-consumer-limit</code>	Specify the limit for the number of consumers that are allowed to be idle at any given time.	1	Integer
<code>camel.component.jms.configuration.idle-task-execution-limit</code>	Specifies the limit for idle executions of a receive task, not having received any message within its execution. If this limit is reached, the task will shut down and leave receiving to other executing tasks (in the case of dynamic scheduling; see the <code>maxConcurrentConsumers</code> setting). There is additional doc available from Spring.	1	Integer
<code>camel.component.jms.configuration.include-all-j-m-s-x-properties</code>	Whether to include all JMSXxxx properties when mapping from JMS to Camel Message. Setting this to true will include properties such as JMSXAppID, and JMSXUserID etc. Note: If you are using a custom <code>headerFilterStrategy</code> then this option does not apply.	false	Boolean
<code>camel.component.jms.configuration.include-sent-j-m-s-message-i-d</code>	Only applicable when sending to JMS destination using <code>InOnly</code> (eg fire and forget). Enabling this option will enrich the Camel Exchange with the actual JMSMessageID that was used by the JMS client when the message was sent to the JMS destination.	false	Boolean

Name	Description	Default	Type
<code>camel.component.jms.configuration.jms-key-format-strategy</code>	Pluggable strategy for encoding and decoding JMS keys so they can be compliant with the JMS specification. Camel provides two implementations out of the box: default and passthrough. The default strategy will safely marshal dots and hyphens (. and -). The passthrough strategy leaves the key as is. Can be used for JMS brokers which do not care whether JMS header keys contain illegal characters. You can provide your own implementation of the <code>org.apache.camel.component.jms.JmsKeyFormatStrategy</code> and refer to it using the <code>#</code> notation.		<code>JmsKeyFormatStrategy</code>
<code>camel.component.jms.configuration.jms-message-type</code>	Allows you to force the use of a specific <code>javax.jms.Message</code> implementation for sending JMS messages. Possible values are: Bytes, Map, Object, Stream, Text. By default, Camel would determine which JMS message type to use from the In body type. This option allows you to specify it.		<code>JmsMessageType</code>
<code>camel.component.jms.configuration.jms-operations</code>	Allows you to use your own implementation of the <code>org.springframework.jms.core.JmsOperations</code> interface. Camel uses <code>JmsTemplate</code> as default. Can be used for testing purpose, but not used much as stated in the spring API docs.		<code>JmsOperations</code>
<code>camel.component.jms.configuration.lazy-create-transaction-manager</code>	If true, Camel will create a <code>JmsTransactionManager</code> , if there is no <code>transactionManager</code> injected when option <code>transacted=true</code> .	true	Boolean
<code>camel.component.jms.configuration.listener-connection-factory</code>	Sets the connection factory to be used for consuming messages		<code>ConnectionFactory</code>
<code>camel.component.jms.configuration.map-jms-message</code>	Specifies whether Camel should auto map the received JMS message to a suited payload type, such as <code>javax.jms.TextMessage</code> to a String etc.	true	Boolean

Name	Description	Default	Type
<code>camel.component.jms.configuration.max-concurrent-consumers</code>	Specifies the maximum number of concurrent consumers when consuming from JMS (not for request/reply over JMS). See also the <code>maxMessagesPerTask</code> option to control dynamic scaling up/down of threads. When doing request/reply over JMS then the option <code>replyToMaxConcurrentConsumers</code> is used to control number of concurrent consumers on the reply message listener.		Integer
<code>camel.component.jms.configuration.max-messages-per-task</code>	The number of messages per task. -1 is unlimited. If you use a range for concurrent consumers (eg min max), then this option can be used to set a value to eg 100 to control how fast the consumers will shrink when less work is required.	-1	Integer
<code>camel.component.jms.configuration.message-converter</code>	To use a custom Spring <code>org.springframework.jms.support.converter.MessageConverter</code> so you can be in control how to map to/from a <code>javax.jms.Message</code> .		MessageConverter
<code>camel.component.jms.configuration.message-created-strategy</code>	To use the given <code>MessageCreatedStrategy</code> which are invoked when Camel creates new instances of <code>javax.jms.Message</code> objects when Camel is sending a JMS message.		MessageCreatedStrategy
<code>camel.component.jms.configuration.message-id-enabled</code>	When sending, specifies whether message IDs should be added. This is just an hint to the JMS Broker. If the JMS provider accepts this hint, these messages must have the message ID set to null; if the provider ignores the hint, the message ID must be set to its normal unique value	true	Boolean
<code>camel.component.jms.configuration.message-listener-container-factory</code>	Registry ID of the <code>MessageListenerContainerFactory</code> used to determine what <code>org.springframework.jms.listener.AbstractMessageListenerContainer</code> to use to consume messages. Setting this will automatically set <code>consumerType</code> to Custom.		MessageListenerContainerFactory
<code>camel.component.jms.configuration.message-timestamp-enabled</code>	Specifies whether timestamps should be enabled by default on sending messages. This is just an hint to the JMS Broker. If the JMS provider accepts this hint, these messages must have the timestamp set to zero; if the provider ignores the hint, the timestamp must be set to its normal value	true	Boolean

Name	Description	Default	Type
<code>camel.component.jms.configuration.metadata-jms-operations</code>	Sets the <code>{@link JmsOperations}</code> used to deduce the <code>{@link JmsProviderMetadata}</code> details which if none is customized one is lazily created on demand		<code>JmsOperations</code>
<code>camel.component.jms.configuration.password</code>	Password to use with the <code>ConnectionFactory</code> . You can also configure username/password directly on the <code>ConnectionFactory</code> .		<code>String</code>
<code>camel.component.jms.configuration.preserve-message-qos</code>	Set to true, if you want to send message using the QoS settings specified on the message, instead of the QoS settings on the JMS endpoint. The following three headers are considered <code>JMSPriority</code> , <code>JMSDeliveryMode</code> , and <code>JMSExpiration</code> . You can provide all or only some of them. If not provided, Camel will fall back to use the values from the endpoint instead. So, when using this option, the headers override the values from the endpoint. The <code>explicitQosEnabled</code> option, by contrast, will only use options set on the endpoint, and not values from the message header.	<code>false</code>	<code>Boolean</code>
<code>camel.component.jms.configuration.priority</code>	Values greater than 1 specify the message priority when sending (where 0 is the lowest priority and 9 is the highest). The <code>explicitQosEnabled</code> option must also be enabled in order for this option to have any effect.	<code>4</code>	<code>Integer</code>
<code>camel.component.jms.configuration.provider-metadata</code>	Allows the provider metadata to be explicitly configured. Typically this is not required and Camel will auto-detect the provider metadata from the underlying provider.		<code>JmsProviderMetadata</code>
<code>camel.component.jms.configuration.pub-sub-no-local</code>	Specifies whether to inhibit the delivery of messages published by its own connection.	<code>false</code>	<code>Boolean</code>
<code>camel.component.jms.configuration.receive-timeout</code>	The timeout for receiving messages (in milliseconds).	<code>1000</code>	<code>Long</code>
<code>camel.component.jms.configuration.recovery-interval</code>	Specifies the interval between recovery attempts, i.e. when a connection is being refreshed, in milliseconds. The default is 5000 ms, that is, 5 seconds.	<code>5000</code>	<code>Long</code>

Name	Description	Default	Type
<code>camel.component.jms.configuration.reply-to</code>	Provides an explicit ReplyTo destination, which overrides any incoming value of <code>Message.getJMSReplyTo()</code> .		String
<code>camel.component.jms.configuration.reply-to-cache-level-name</code>	Sets the cache level by name for the reply consumer when doing request/reply over JMS. This option only applies when using fixed reply queues (not temporary). Camel will by default use: <code>CACHE_CONSUMER</code> for exclusive or shared w/ <code>replyToSelectorName</code> . And <code>CACHE_SESSION</code> for shared without <code>replyToSelectorName</code> . Some JMS brokers such as IBM WebSphere may require to set the <code>replyToCacheLevelName=CACHE_NONE</code> to work. Note: If using temporary queues then <code>CACHE_NONE</code> is not allowed, and you must use a higher value such as <code>CACHE_CONSUMER</code> or <code>CACHE_SESSION</code> .		String
<code>camel.component.jms.configuration.reply-to-concurrent-consumers</code>	Specifies the default number of concurrent consumers when doing request/reply over JMS. See also the <code>maxMessagesPerTask</code> option to control dynamic scaling up/down of threads.	1	Integer
<code>camel.component.jms.configuration.reply-to-delivery-persistent</code>	Specifies whether to use persistent delivery by default for replies.	true	Boolean
<code>camel.component.jms.configuration.reply-to-destination-selector-name</code>	Sets the JMS Selector using the fixed name to be used so you can filter out your own replies from the others when using a shared queue (that is, if you are not using a temporary reply queue).		String
<code>camel.component.jms.configuration.reply-to-max-concurrent-consumers</code>	Specifies the maximum number of concurrent consumers when using request/reply over JMS. See also the <code>maxMessagesPerTask</code> option to control dynamic scaling up/down of threads.		Integer
<code>camel.component.jms.configuration.reply-to-on-timeout-max-concurrent-consumers</code>	Specifies the maximum number of concurrent consumers for continue routing when timeout occurred when using request/reply over JMS.	1	Integer

Name	Description	Default	Type
<code>camel.component.jms.configuration.reply-to-override</code>	Provides an explicit ReplyTo destination in the JMS message, which overrides the setting of replyTo. It is useful if you want to forward the message to a remote Queue and receive the reply message from the ReplyTo destination.		String
<code>camel.component.jms.configuration.reply-to-same-destination-allowed</code>	Whether a JMS consumer is allowed to send a reply message to the same destination that the consumer is using to consume from. This prevents an endless loop by consuming and sending back the same message to itself.	false	Boolean
<code>camel.component.jms.configuration.reply-to-type</code>	Allows for explicitly specifying which kind of strategy to use for replyTo queues when doing request/reply over JMS. Possible values are: Temporary, Shared, or Exclusive. By default Camel will use temporary queues. However if replyTo has been configured, then Shared is used by default. This option allows you to use exclusive queues instead of shared ones. See Camel JMS documentation for more details, and especially the notes about the implications if running in a clustered environment, and the fact that Shared reply queues has lower performance than its alternatives Temporary and Exclusive.		ReplyToType
<code>camel.component.jms.configuration.request-timeout</code>	The timeout for waiting for a reply when using the InOut Exchange Pattern (in milliseconds). The default is 20 seconds. You can include the header CamelJmsRequestTimeout to override this endpoint configured timeout value, and thus have per message individual timeout values. See also the requestTimeoutCheckerInterval option.	20000	Long
<code>camel.component.jms.configuration.request-timeout-checker-interval</code>	Configures how often Camel should check for timed out Exchanges when doing request/reply over JMS. By default Camel checks once per second. But if you must react faster when a timeout occurs, then you can lower this interval, to check more frequently. The timeout is determined by the option requestTimeout.	1000	Long
<code>camel.component.jms.configuration.selector</code>	Sets the JMS selector to use		String

Name	Description	Default	Type
camel.component.jms.configuration.stream-message-type-enabled	Sets whether StreamMessage type is enabled or not. Message payloads of streaming kind such as files, InputStream, etc will either be sent as BytesMessage or StreamMessage. This option controls which kind will be used. By default BytesMessage is used which enforces the entire message payload to be read into memory. By enabling this option the message payload is read into memory in chunks and each chunk is then written to the StreamMessage until no more data.	false	Boolean
camel.component.jms.configuration.subscription-durable	Set whether to make the subscription durable. The durable subscription name to be used can be specified through the subscriptionName property. Default is false. Set this to true to register a durable subscription, typically in combination with a subscriptionName value (unless your message listener class name is good enough as subscription name). Only makes sense when listening to a topic (pub-sub domain), therefore this method switches the pubSubDomain flag as well.	false	Boolean
camel.component.jms.configuration.subscription-name	Set the name of a subscription to create. To be applied in case of a topic (pub-sub domain) with a shared or durable subscription. The subscription name needs to be unique within this client's JMS client id. Default is the class name of the specified message listener. Note: Only 1 concurrent consumer (which is the default of this message listener container) is allowed for each subscription, except for a shared subscription (which requires JMS 2.0).		String
camel.component.jms.configuration.subscription-shared	Set whether to make the subscription shared. The shared subscription name to be used can be specified through the subscriptionName property. Default is false. Set this to true to register a shared subscription, typically in combination with a subscriptionName value (unless your message listener class name is good enough as subscription name). Note that shared subscriptions may also be durable, so this flag can (and often will) be combined with subscriptionDurable as well. Only makes sense when listening to a topic (pub-sub domain), therefore this method switches the pubSubDomain flag as well. Requires a JMS 2.0 compatible message broker.	false	Boolean
camel.component.jms.configuration.task-executor	Allows you to specify a custom task executor for consuming messages.		TaskExecutor

Name	Description	Default	Type
<code>camel.component.jms.configuration.template-connection-factory</code>	Sets the connection factory to be used for sending messages via the <code>{@link JmsTemplate}</code> via <code>{@link #createInOnlyTemplate(JmsEndpoint,boolean,String)}</code>		ConnectionFactory
<code>camel.component.jms.configuration.test-connection-on-startup</code>	Specifies whether to test the connection on startup. This ensures that when Camel starts that all the JMS consumers have a valid connection to the JMS broker. If a connection cannot be granted then Camel throws an exception on startup. This ensures that Camel is not started with failed connections. The JMS producers is tested as well.	false	Boolean
<code>camel.component.jms.configuration.time-to-live</code>	When sending messages, specifies the time-to-live of the message (in milliseconds).	-1	Long
<code>camel.component.jms.configuration.transacted</code>	Specifies whether to use transacted mode	false	Boolean
<code>camel.component.jms.configuration.transaction-manager</code>	The Spring transaction manager to use.		PlatformTransactionManager
<code>camel.component.jms.configuration.transaction-name</code>	The name of the transaction to use.		String
<code>camel.component.jms.configuration.transaction-timeout</code>	The timeout value of the transaction (in seconds), if using transacted mode.	-1	Integer

Name	Description	Default	Type
camel.component.jms.configuration.transfer-exception	If enabled and you are using Request Reply messaging (InOut) and an Exchange failed on the consumer side, then the caused Exception will be send back in response as a javax.jms.ObjectMessage. If the client is Camel, the returned Exception is rethrown. This allows you to use Camel JMS as a bridge in your routing - for example, using persistent queues to enable robust routing. Notice that if you also have transferExchange enabled, this option takes precedence. The caught exception is required to be serializable. The original Exception on the consumer side can be wrapped in an outer exception such as org.apache.camel.RuntimeCamelException when returned to the producer.	false	Boolean
camel.component.jms.configuration.transfer-exchange	You can transfer the exchange over the wire instead of just the body and headers. The following fields are transferred: In body, Out body, Fault body, In headers, Out headers, Fault headers, exchange properties, exchange exception. This requires that the objects are serializable. Camel will exclude any non-serializable objects and log it at WARN level. You must enable this option on both the producer and consumer side, so Camel knows the payloads is an Exchange and not a regular payload.	false	Boolean
camel.component.jms.configuration.transfer-fault	If enabled and you are using Request Reply messaging (InOut) and an Exchange failed with a SOAP fault (not exception) on the consumer side, then the fault flag on org.apache.camel.Message#isFault() will be send back in the response as a JMS header with the key JmsConstants#JMS_TRANSFER_FAULT. If the client is Camel, the returned fault flag will be set on the org.apache.camel.Message#setFault(boolean). You may want to enable this when using Camel components that support faults such as SOAP based such as cxf or spring-ws.	false	Boolean
camel.component.jms.configuration.use-message-id-as-correlation-id	Specifies whether JMSMessageID should always be used as JMSCorrelationID for InOut messages.	false	Boolean
camel.component.jms.configuration.username	Username to use with the ConnectionFactory. You can also configure username/password directly on the ConnectionFactory.		String

Name	Description	Default	Type
<code>camel.component.jms.configuration.wait-for-provision-correlation-to-be-updated-counter</code>	Number of times to wait for provisional correlation id to be updated to the actual correlation id when doing request/reply over JMS and when the option <code>useMessageIDAsCorrelationID</code> is enabled.	50	Integer
<code>camel.component.jms.configuration.wait-for-provision-correlation-to-be-updated-thread-sleeping-time</code>	Interval in millis to sleep each time while waiting for provisional correlation id to be updated.	100	Long
<code>camel.component.jms.connection-factory</code>	The connection factory to be use. A connection factory must be configured either on the component or endpoint. The option is a <code>javax.jms.ConnectionFactory</code> type.		String
<code>camel.component.jms.correlation-property</code>	Use this JMS property to correlate messages in InOut exchange pattern (request-reply) instead of <code>JMSCorrelationID</code> property. This allows you to exchange messages with systems that do not correlate messages using <code>JMSCorrelationID</code> JMS property. If used <code>JMSCorrelationID</code> will not be used or set by Camel. The value of here named property will be generated if not supplied in the header of the message under the same name.		String
<code>camel.component.jms.default-task-executor-type</code>	Specifies what default <code>TaskExecutor</code> type to use in the <code>DefaultMessageListenerContainer</code> , for both consumer endpoints and the <code>ReplyTo</code> consumer of producer endpoints. Possible values: <code>SimpleAsync</code> (uses Spring's <code>SimpleAsyncTaskExecutor</code>) or <code>ThreadPool</code> (uses Spring's <code>ThreadPoolTaskExecutor</code> with optimal values - cached threadpool-like). If not set, it defaults to the previous behaviour, which uses a cached thread pool for consumer endpoints and <code>SimpleAsync</code> for reply consumers. The use of <code>ThreadPool</code> is recommended to reduce thread trash in elastic configurations with dynamically increasing and decreasing concurrent consumers.		<code>DefaultTaskExecutor</code> Type

Name	Description	Default	Type
camel.component.jms.delivery-mode	Specifies the delivery mode to be used. Possible values are those defined by <code>javax.jms.DeliveryMode</code> . <code>NON_PERSISTENT</code> = 1 and <code>PERSISTENT</code> = 2.		Integer
camel.component.jms.delivery-persistent	Specifies whether persistent delivery is used by default.	true	Boolean
camel.component.jms.destination-resolver	A pluggable <code>org.springframework.jms.support.destination.DestinationResolver</code> that allows you to use your own resolver (for example, to lookup the real destination in a JNDI registry). The option is a <code>org.springframework.jms.support.destination.DestinationResolver</code> type.		String
camel.component.jms.durable-subscription-name	The durable subscriber name for specifying durable topic subscriptions. The <code>clientId</code> option must be configured as well.		String
camel.component.jms.eager-loading-of-properties	Enables eager loading of JMS properties as soon as a message is loaded which generally is inefficient as the JMS properties may not be required but sometimes can catch early any issues with the underlying JMS provider and the use of JMS properties	false	Boolean
camel.component.jms.enabled	Enable jms component	true	Boolean
camel.component.jms.error-handler	Specifies a <code>org.springframework.util.ErrorHandler</code> to be invoked in case of any uncaught exceptions thrown while processing a Message. By default these exceptions will be logged at the WARN level, if no errorHandler has been configured. You can configure logging level and whether stack traces should be logged using <code>errorHandlerLoggingLevel</code> and <code>errorHandlerLogStackTrace</code> options. This makes it much easier to configure, than having to code a custom errorHandler. The option is a <code>org.springframework.util.ErrorHandler</code> type.		String
camel.component.jms.error-handler-log-stack-trace	Allows to control whether stacktraces should be logged or not, by the default errorHandler.	true	Boolean

Name	Description	Default	Type
camel.component.jms.error-handler-logging-level	Allows to configure the default errorHandler logging level for logging uncaught exceptions.		LogLevel
camel.component.jms.exception-listener	Specifies the JMS Exception Listener that is to be notified of any underlying JMS exceptions. The option is a javax.jms.ExceptionListener type.		String
camel.component.jms.explicit-qos-enabled	Set if the deliveryMode, priority or timeToLive qualities of service should be used when sending messages. This option is based on Spring's JmsTemplate. The deliveryMode, priority and timeToLive options are applied to the current endpoint. This contrasts with the preserveMessageQos option, which operates at message granularity, reading QoS properties exclusively from the Camel In message headers.	false	Boolean
camel.component.jms.expose-listener-session	Specifies whether the listener session should be exposed when consuming messages.	false	Boolean
camel.component.jms.force-send-original-message	When using mapJmsMessage=false Camel will create a new JMS message to send to a new JMS destination if you touch the headers (get or set) during the route. Set this option to true to force Camel to send the original JMS message that was received.	false	Boolean
camel.component.jms.format-date-headers-to-iso8601	Sets whether date headers should be formatted according to the ISO 8601 standard.	false	Boolean
camel.component.jms.header-filter-strategy	To use a custom org.apache.camel.spi.HeaderFilterStrategy to filter header to and from Camel message. The option is a org.apache.camel.spi.HeaderFilterStrategy type.		String
camel.component.jms.idle-consumer-limit	Specify the limit for the number of consumers that are allowed to be idle at any given time.	1	Integer

Name	Description	Default	Type
camel.component.jms.idle-task-execution-limit	Specifies the limit for idle executions of a receive task, not having received any message within its execution. If this limit is reached, the task will shut down and leave receiving to other executing tasks (in the case of dynamic scheduling; see the <code>maxConcurrentConsumers</code> setting). There is additional doc available from Spring.	1	Integer
camel.component.jms.include-all-jms-x-properties	Whether to include all JMSxxx properties when mapping from JMS to Camel Message. Setting this to true will include properties such as JMSXAppID, and JMSXUserID etc. Note: If you are using a custom <code>headerFilterStrategy</code> then this option does not apply.	false	Boolean
camel.component.jms.include-sent-jms-message-id	Only applicable when sending to JMS destination using <code>InOnly</code> (eg fire and forget). Enabling this option will enrich the Camel Exchange with the actual JMSMessageID that was used by the JMS client when the message was sent to the JMS destination.	false	Boolean
camel.component.jms.jms-key-format-strategy	Pluggable strategy for encoding and decoding JMS keys so they can be compliant with the JMS specification. Camel provides two implementations out of the box: <code>default</code> and <code>passthrough</code> . The default strategy will safely marshal dots and hyphens (<code>.</code> and <code>-</code>). The <code>passthrough</code> strategy leaves the key as is. Can be used for JMS brokers which do not care whether JMS header keys contain illegal characters. You can provide your own implementation of the <code>org.apache.camel.component.jms.JmsKeyFormatStrategy</code> and refer to it using the <code>#</code> notation. The option is a <code>org.apache.camel.component.jms.JmsKeyFormatStrategy</code> type.		String
camel.component.jms.jms-operations	Allows you to use your own implementation of the <code>org.springframework.jms.core.JmsOperations</code> interface. Camel uses <code>JmsTemplate</code> as default. Can be used for testing purpose, but not used much as stated in the spring API docs. The option is a <code>org.springframework.jms.core.JmsOperations</code> type.		String
camel.component.jms.lazy-create-transaction-manager	If true, Camel will create a <code>JmsTransactionManager</code> , if there is no <code>transactionManager</code> injected when option <code>transacted=true</code> .	true	Boolean

Name	Description	Default	Type
<code>camel.component.jms.map-jms-message</code>	Specifies whether Camel should auto map the received JMS message to a suited payload type, such as <code>javax.jms.TextMessage</code> to a <code>String</code> etc. See section about how mapping works below for more details.	<code>true</code>	Boolean
<code>camel.component.jms.max-concurrent-consumers</code>	Specifies the maximum number of concurrent consumers when consuming from JMS (not for request/reply over JMS). See also the <code>maxMessagesPerTask</code> option to control dynamic scaling up/down of threads. When doing request/reply over JMS then the option <code>replyToMaxConcurrentConsumers</code> is used to control number of concurrent consumers on the reply message listener.		Integer
<code>camel.component.jms.max-messages-per-task</code>	The number of messages per task. -1 is unlimited. If you use a range for concurrent consumers (eg min max), then this option can be used to set a value to eg 100 to control how fast the consumers will shrink when less work is required.	<code>-1</code>	Integer
<code>camel.component.jms.message-converter</code>	To use a custom Spring <code>org.springframework.jms.support.converter.MessageConverter</code> so you can be in control how to map to/from a <code>javax.jms.Message</code> . The option is a <code>org.springframework.jms.support.converter.MessageConverter</code> type.		String
<code>camel.component.jms.message-created-strategy</code>	To use the given <code>MessageCreatedStrategy</code> which are invoked when Camel creates new instances of <code>javax.jms.Message</code> objects when Camel is sending a JMS message. The option is a <code>org.apache.camel.component.jms.MessageCreatedStrategy</code> type.		String
<code>camel.component.jms.message-id-enabled</code>	When sending, specifies whether message IDs should be added. This is just an hint to the JMS Broker. If the JMS provider accepts this hint, these messages must have the message ID set to null; if the provider ignores the hint, the message ID must be set to its normal unique value	<code>true</code>	Boolean
<code>camel.component.jms.message-timestamp-enabled</code>	Specifies whether timestamps should be enabled by default on sending messages.	<code>true</code>	Boolean

Name	Description	Default	Type
<code>camel.component.jms.password</code>	Password to use with the ConnectionFactory. You can also configure username/password directly on the ConnectionFactory.		String
<code>camel.component.jms.preserve-message-qos</code>	Set to true, if you want to send message using the QoS settings specified on the message, instead of the QoS settings on the JMS endpoint. The following three headers are considered JMSPriority, JMSDeliveryMode, and JMSExpiration. You can provide all or only some of them. If not provided, Camel will fall back to use the values from the endpoint instead. So, when using this option, the headers override the values from the endpoint. The explicitQosEnabled option, by contrast, will only use options set on the endpoint, and not values from the message header.	false	Boolean
<code>camel.component.jms.priority</code>	Values greater than 1 specify the message priority when sending (where 0 is the lowest priority and 9 is the highest). The explicitQosEnabled option must also be enabled in order for this option to have any effect.	4	Integer
<code>camel.component.jms.pub-sub-no-local</code>	Specifies whether to inhibit the delivery of messages published by its own connection.	false	Boolean
<code>camel.component.jms.queue-browse-strategy</code>	To use a custom QueueBrowseStrategy when browsing queues. The option is a <code>org.apache.camel.component.jms.QueueBrowseStrategy</code> type.		String
<code>camel.component.jms.receive-timeout</code>	The timeout for receiving messages (in milliseconds).	1000	Long
<code>camel.component.jms.recovery-interval</code>	Specifies the interval between recovery attempts, i.e. when a connection is being refreshed, in milliseconds. The default is 5000 ms, that is, 5 seconds.	5000	Long
<code>camel.component.jms.reply-on-timeout-to-max-concurrent-consumers</code>	Specifies the maximum number of concurrent consumers for continue routing when timeout occurred when using request/reply over JMS.	1	Integer

Name	Description	Default	Type
camel.component.jms.reply-to-cache-level-name	Sets the cache level by name for the reply consumer when doing request/reply over JMS. This option only applies when using fixed reply queues (not temporary). Camel will by default use: CACHE_CONSUMER for exclusive or shared w/ replyToSelectorName. And CACHE_SESSION for shared without replyToSelectorName. Some JMS brokers such as IBM WebSphere may require to set the replyToCacheLevelName=CACHE_NONE to work. Note: If using temporary queues then CACHE_NONE is not allowed, and you must use a higher value such as CACHE_CONSUMER or CACHE_SESSION.		String
camel.component.jms.reply-to-concurrent-consumers	Specifies the default number of concurrent consumers when doing request/reply over JMS. See also the maxMessagesPerTask option to control dynamic scaling up/down of threads.	1	Integer
camel.component.jms.reply-to-max-concurrent-consumers	Specifies the maximum number of concurrent consumers when using request/reply over JMS. See also the maxMessagesPerTask option to control dynamic scaling up/down of threads.		Integer
camel.component.jms.reply-to-type	Allows for explicitly specifying which kind of strategy to use for replyTo queues when doing request/reply over JMS. Possible values are: Temporary, Shared, or Exclusive. By default Camel will use temporary queues. However if replyTo has been configured, then Shared is used by default. This option allows you to use exclusive queues instead of shared ones. See Camel JMS documentation for more details, and especially the notes about the implications if running in a clustered environment, and the fact that Shared reply queues has lower performance than its alternatives Temporary and Exclusive.		ReplyToType
camel.component.jms.request-timeout	The timeout for waiting for a reply when using the InOut Exchange Pattern (in milliseconds). The default is 20 seconds. You can include the header CamelJmsRequestTimeout to override this endpoint configured timeout value, and thus have per message individual timeout values. See also the requestTimeoutCheckerInterval option.	20000	Long

Name	Description	Default	Type
camel.component.jms.request-timeout-checker-interval	Configures how often Camel should check for timed out Exchanges when doing request/reply over JMS. By default Camel checks once per second. But if you must react faster when a timeout occurs, then you can lower this interval, to check more frequently. The timeout is determined by the option requestTimeout.	1000	Long
camel.component.jms.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
camel.component.jms.stream-message-type-enabled	Sets whether StreamMessage type is enabled or not. Message payloads of streaming kind such as files, InputStream, etc will either be sent as BytesMessage or StreamMessage. This option controls which kind will be used. By default BytesMessage is used which enforces the entire message payload to be read into memory. By enabling this option the message payload is read into memory in chunks and each chunk is then written to the StreamMessage until no more data.	false	Boolean
camel.component.jms.subscription-durable	Set whether to make the subscription durable. The durable subscription name to be used can be specified through the subscriptionName property. Default is false. Set this to true to register a durable subscription, typically in combination with a subscriptionName value (unless your message listener class name is good enough as subscription name). Only makes sense when listening to a topic (pub-sub domain), therefore this method switches the pubSubDomain flag as well.	false	Boolean
camel.component.jms.subscription-name	Set the name of a subscription to create. To be applied in case of a topic (pub-sub domain) with a shared or durable subscription. The subscription name needs to be unique within this client's JMS client id. Default is the class name of the specified message listener. Note: Only 1 concurrent consumer (which is the default of this message listener container) is allowed for each subscription, except for a shared subscription (which requires JMS 2.0).		String

Name	Description	Default	Type
<code>camel.component.jms.subscription-shared</code>	Set whether to make the subscription shared. The shared subscription name to be used can be specified through the <code>subscriptionName</code> property. Default is false. Set this to true to register a shared subscription, typically in combination with a <code>subscriptionName</code> value (unless your message listener class name is good enough as subscription name). Note that shared subscriptions may also be durable, so this flag can (and often will) be combined with <code>subscriptionDurable</code> as well. Only makes sense when listening to a topic (pub-sub domain), therefore this method switches the <code>pubSubDomain</code> flag as well. Requires a JMS 2.0 compatible message broker.	false	Boolean
<code>camel.component.jms.task-executor</code>	Allows you to specify a custom task executor for consuming messages. The option is a <code>org.springframework.core.task.TaskExecutor</code> type.		String
<code>camel.component.jms.test-connection-on-startup</code>	Specifies whether to test the connection on startup. This ensures that when Camel starts that all the JMS consumers have a valid connection to the JMS broker. If a connection cannot be granted then Camel throws an exception on startup. This ensures that Camel is not started with failed connections. The JMS producers is tested as well.	false	Boolean
<code>camel.component.jms.time-to-live</code>	When sending messages, specifies the time-to-live of the message (in milliseconds).	-1	Long
<code>camel.component.jms.transacted</code>	Specifies whether to use transacted mode	false	Boolean
<code>camel.component.jms.transaction-manager</code>	The Spring transaction manager to use. The option is a <code>org.springframework.transaction.PlatformTransactionManager</code> type.		String
<code>camel.component.jms.transaction-name</code>	The name of the transaction to use.		String
<code>camel.component.jms.transaction-timeout</code>	The timeout value of the transaction (in seconds), if using transacted mode.	-1	Integer

Name	Description	Default	Type
camel.component.jms.transfer-exception	If enabled and you are using Request Reply messaging (InOut) and an Exchange failed on the consumer side, then the caused Exception will be send back in response as a javax.jms.ObjectMessage. If the client is Camel, the returned Exception is rethrown. This allows you to use Camel JMS as a bridge in your routing - for example, using persistent queues to enable robust routing. Notice that if you also have transferExchange enabled, this option takes precedence. The caught exception is required to be serializable. The original Exception on the consumer side can be wrapped in an outer exception such as org.apache.camel.RuntimeCamelException when returned to the producer.	false	Boolean
camel.component.jms.transfer-exchange	You can transfer the exchange over the wire instead of just the body and headers. The following fields are transferred: In body, Out body, Fault body, In headers, Out headers, Fault headers, exchange properties, exchange exception. This requires that the objects are serializable. Camel will exclude any non-serializable objects and log it at WARN level. You must enable this option on both the producer and consumer side, so Camel knows the payloads is an Exchange and not a regular payload.	false	Boolean
camel.component.jms.transfer-fault	If enabled and you are using Request Reply messaging (InOut) and an Exchange failed with a SOAP fault (not exception) on the consumer side, then the fault flag on org.apache.camel.Message#isFault() will be send back in the response as a JMS header with the key JmsConstants#JMS_TRANSFER_FAULT. If the client is Camel, the returned fault flag will be set on the org.apache.camel.Message#setFault(boolean). You may want to enable this when using Camel components that support faults such as SOAP based such as cxf or spring-ws.	false	Boolean
camel.component.jms.use-message-i-d-as-correlation-i-d	Specifies whether JMSPeopleID should always be used as JMSCorrelationID for InOut messages.	false	Boolean
camel.component.jms.username	Username to use with the ConnectionFactory. You can also configure username/password directly on the ConnectionFactory.		String

Name	Description	Default	Type
<code>camel.component.jms.wait-for-provision-correlation-to-be-updated-counter</code>	Number of times to wait for provisional correlation id to be updated to the actual correlation id when doing request/reply over JMS and when the option <code>useMessageIDAsCorrelationID</code> is enabled.	50	Integer
<code>camel.component.jms.wait-for-provision-correlation-to-be-updated-thread-sleeping-time</code>	Interval in millis to sleep each time while waiting for provisional correlation id to be updated.	100	Long
<code>camel.component.jms.configuration.transacted-in-out</code>			Boolean

178.6. SAMPLES

JMS is used in many examples for other components as well. But we provide a few samples below to get started.

178.6.1. Receiving from JMS

In the following sample we configure a route that receives JMS messages and routes the message to a POJO:

```
from("jms:queue:foo").
  to("bean:myBusinessLogic");
```

You can of course use any of the EIP patterns so the route can be context based. For example, here's how to filter an order topic for the big spenders:

```
from("jms:topic:OrdersTopic").
  filter().method("myBean", "isGoldCustomer").
  to("jms:queue:BigSpendersQueue");
```

178.6.2. Sending to JMS

In the sample below we poll a file folder and send the file content to a JMS topic. As we want the content of the file as a **TextMessage** instead of a **BytesMessage**, we need to convert the body to a **String**:

```
from("file://orders").
  convertBodyTo(String.class).
  to("jms:topic:OrdersTopic");
```

178.6.3. Using Annotations

Camel also has annotations so you can use [POJO Consuming](#) and POJO Producing.

178.6.4. Spring DSL sample

The preceding examples use the Java DSL. Camel also supports Spring XML DSL. Here is the big spender sample using Spring DSL:

```
<route>
  <from uri="jms:topic:OrdersTopic"/>
  <filter>
    <method bean="myBean" method="isGoldCustomer"/>
    <to uri="jms:queue:BigSpendersQueue"/>
  </filter>
</route>
```

178.6.5. Other samples

JMS appears in many of the examples for other components and EIP patterns, as well in this Camel documentation. So feel free to browse the documentation.

178.6.6. Using JMS as a Dead Letter Queue storing Exchange

Normally, when using [JMS](#) as the transport, it only transfers the body and headers as the payload. If you want to use [JMS](#) with a [Dead Letter Channel](#), using a JMS queue as the Dead Letter Queue, then normally the caused Exception is not stored in the JMS message. You can, however, use the **transferExchange** option on the JMS dead letter queue to instruct Camel to store the entire Exchange in the queue as a **javax.jms.ObjectMessage** that holds a **org.apache.camel.impl.DefaultExchangeHolder**. This allows you to consume from the Dead Letter Queue and retrieve the caused exception from the Exchange property with the key **Exchange.EXCEPTION_CAUGHT**. The demo below illustrates this:

```
// setup error handler to use JMS as queue and store the entire Exchange
errorHandler(deadLetterChannel("jms:queue:dead?transferExchange=true"));
```

Then you can consume from the JMS queue and analyze the problem:

```
from("jms:queue:dead").to("bean:myErrorAnalyzer");

// and in our bean
String body = exchange.getIn().getBody();
Exception cause = exchange.getProperty(Exchange.EXCEPTION_CAUGHT, Exception.class);
// the cause message is
String problem = cause.getMessage();
```

178.6.7. Using JMS as a Dead Letter Channel storing error only

You can use JMS to store the cause error message or to store a custom body, which you can initialize yourself. The following example uses the Message Translator EIP to do a transformation on the failed exchange before it is moved to the [JMS](#) dead letter queue:

```
// we sent it to a seda dead queue first
errorHandler(deadLetterChannel("seda:dead"));

// and on the seda dead queue we can do the custom transformation before its sent to the JMS queue
from("seda:dead").transform(exceptionMessage()).to("jms:queue:dead");
```

Here we only store the original cause error message in the transform. You can, however, use any Expression to send whatever you like. For example, you can invoke a method on a Bean or use a custom processor.

178.7. MESSAGE MAPPING BETWEEN JMS AND CAMEL

Camel automatically maps messages between `javax.jms.Message` and `org.apache.camel.Message`.

When sending a JMS message, Camel converts the message body to the following JMS message types:

Body Type	JMS Message	Comment
String	javax.jms.TextMessage	
org.w3c.dom.Node	javax.jms.TextMessage	The DOM will be converted to String .
Map	javax.jms.MapMessage	
java.io.Serializable	javax.jms.ObjectMessage	
byte[]	javax.jms.BytesMessage	

Body Type	JMS Message	Comment
<code>java.io.File</code>	<code>javax.jms.BytesMessage</code>	
<code>java.io.Reader</code>	<code>javax.jms.BytesMessage</code>	
<code>java.io.InputStream</code>	<code>javax.jms.BytesMessage</code>	
<code>java.nio.ByteBuffer</code>	<code>javax.jms.BytesMessage</code>	

When receiving a JMS message, Camel converts the JMS message to the following body type:

JMS Message	Body Type
<code>javax.jms.TextMessage</code>	<code>String</code>
<code>javax.jms.BytesMessage</code>	<code>byte[]</code>
<code>javax.jms.MapMessage</code>	<code>Map<String, Object></code>
<code>javax.jms.ObjectMessage</code>	<code>Object</code>

178.7.1. Disabling auto-mapping of JMS messages

You can use the `mapJmsMessage` option to disable the auto-mapping above. If disabled, Camel will not try to map the received JMS message, but instead uses it directly as the payload. This allows you to avoid the overhead of mapping and let Camel just pass through the JMS message. For instance, it even allows you to route `javax.jms.ObjectMessage` JMS messages with classes you do **not** have on the classpath.

178.7.2. Using a custom MessageConverter

You can use the `messageConverter` option to do the mapping yourself in a Spring `org.springframework.jms.support.converter.MessageConverter` class.

For example, in the route below we use a custom message converter when sending a message to the JMS order queue:

```
from("file://inbox/order").to("jms:queue:order?messageConverter=#myMessageConverter");
```

You can also use a custom message converter when consuming from a JMS destination.

178.7.3. Controlling the mapping strategy selected

You can use the `jmsMessageType` option on the endpoint URL to force a specific message type for all messages.

In the route below, we poll files from a folder and send them as `javax.jms.TextMessage` as we have forced the JMS producer endpoint to use text messages:

```
from("file://inbox/order").to("jms:queue:order?jmsMessageType=Text");
```

You can also specify the message type to use for each message by setting the header with the key `CamelJmsMessageType`. For example:

```
from("file://inbox/order").setHeader("CamelJmsMessageType",
    JmsMessageType.Text).to("jms:queue:order");
```

The possible values are defined in the `enum` class, `org.apache.camel.jms.JmsMessageType`.

178.8. MESSAGE FORMAT WHEN SENDING

The exchange that is sent over the JMS wire must conform to the [JMS Message spec](#).

For the `exchange.in.header` the following rules apply for the header `keys`:

- Keys starting with **JMS** or **JMSX** are reserved.
- `exchange.in.headers` keys must be literals and all be valid Java identifiers (do not use dots in the key name).
- Camel replaces dots & hyphens and the reverse when consuming JMS messages:
 - `.` is replaced by **DOT** and the reverse replacement when Camel consumes the message.
 - `-` is replaced by **HYPHEN** and the reverse replacement when Camel consumes the message.
- See also the option `jmsKeyFormatStrategy`, which allows use of your own custom strategy for formatting keys.

For the `exchange.in.header`, the following rules apply for the header `values`:

- The values must be primitives or their counter objects (such as **Integer**, **Long**, **Character**). The types, **String**, **CharSequence**, **Date**, **BigDecimal** and **BigInteger** are all converted to their `toString()` representation. All other types are dropped.

Camel will log with category `org.apache.camel.component.jms.JmsBinding` at **DEBUG** level if it drops a given header value. For example:

```
2008-07-09 06:43:04,046 [main      ] DEBUG JmsBinding
- Ignoring non primitive header: order of class:
org.apache.camel.component.jms.issues.DummyOrder with value: DummyOrder{orderId=333,
```

```
itemId=4444, quantity=2}
```

178.9. MESSAGE FORMAT WHEN RECEIVING

Camel adds the following properties to the **Exchange** when it receives a message:

Property	Type	Description
org.apache.camel.jms.replyDestination	javax.jms.Destination	The reply destination.

Camel adds the following JMS properties to the In message headers when it receives a JMS message:

Header	Type	Description
JMSCorrelationID	String	The JMS correlation ID.
JMSDeliveryMode	int	The JMS delivery mode.
JMSDestination	javax.jms.Destination	The JMS destination.
JMSExpiration	long	The JMS expiration.
JMSMessageID	String	The JMS unique message ID.
JMSPriority	int	The JMS priority (with 0 as the lowest priority and 9 as the highest).
JMSRedelivered	boolean	Is the JMS message redelivered.

Header	Type	Description
JMSReplyTo	javax.jms.Destination	The JMS reply-to destination.
JMSTimestamp	long	The JMS timestamp.
JMSType	String	The JMS type.
JMSXGroupID	String	The JMS group ID.

As all the above information is standard JMS you can check the [JMS documentation](#) for further details.

178.10. ABOUT USING CAMEL TO SEND AND RECEIVE MESSAGES AND JMSREPLYTO

The JMS component is complex and you have to pay close attention to how it works in some cases. So this is a short summary of some of the areas/pitfalls to look for.

When Camel sends a message using its **JMSProducer**, it checks the following conditions:

- The message exchange pattern,
- Whether a **JMSReplyTo** was set in the endpoint or in the message headers,
- Whether any of the following options have been set on the JMS endpoint: **disableReplyTo**, **preserveMessageQos**, **explicitQosEnabled**.

All this can be a tad complex to understand and configure to support your use case.

178.10.1. JmsProducer

The **JmsProducer** behaves as follows, depending on configuration:

Exchange Pattern	Other options	Description
<i>InOut</i>	-	Camel will expect a reply, set a temporary JMSReplyTo , and after sending the message, it will start to listen for the reply message on the temporary queue.

Exchange Pattern	Other options	Description
<i>InOut</i>	JMSReplyTo is set	Camel will expect a reply and, after sending the message, it will start to listen for the reply message on the specified JMSReplyTo queue.
<i>InOnly</i>	-	Camel will send the message and not expect a reply.
<i>InOnly</i>	JMSReplyTo is set	By default, Camel discards the JMSReplyTo destination and clears the JMSReplyTo header before sending the message. Camel then sends the message and does not expect a reply. Camel logs this in the log at WARN level (changed to DEBUG level from Camel 2.6 onwards. You can use preserveMessageQuo=true to instruct Camel to keep the JMSReplyTo . In all situations the JmsProducer does not expect any reply and thus continue after sending the message.

178.10.2. JmsConsumer

The **JmsConsumer** behaves as follows, depending on configuration:

Exchange Pattern	Other options	Description
<i>InOut</i>	-	Camel will send the reply back to the JMSReplyTo queue.
<i>InOnly</i>	-	Camel will not send a reply back, as the pattern is <i>InOnly</i> .
-	disableReplyTo=true	This option suppresses replies.

So pay attention to the message exchange pattern set on your exchanges.

If you send a message to a JMS destination in the middle of your route you can specify the exchange pattern to use, see more at Request Reply.

This is useful if you want to send an **InOnly** message to a JMS topic:

```
from("activemq:queue:in")
  .to("bean:validateOrder")
  .to(ExchangePattern.InOnly, "activemq:topic:order")
  .to("bean:handleOrder");
```

178.11. REUSE ENDPOINT AND SEND TO DIFFERENT DESTINATIONS COMPUTED AT RUNTIME

If you need to send messages to a lot of different JMS destinations, it makes sense to reuse a JMS endpoint and specify the real destination in a message header. This allows Camel to reuse the same endpoint, but send to different destinations. This greatly reduces the number of endpoints created and economizes on memory and thread resources.

You can specify the destination in the following headers:

Header	Type	Description
CamelJmsDestination	javax.jms.Destination	A destination object.
CamelJmsDestinationName	String	The destination name.

For example, the following route shows how you can compute a destination at run time and use it to override the destination appearing in the JMS URL:

```
from("file://inbox")
  .to("bean:computeDestination")
  .to("activemq:queue:dummy");
```

The queue name, **dummy**, is just a placeholder. It must be provided as part of the JMS endpoint URL, but it will be ignored in this example.

In the **computeDestination** bean, specify the real destination by setting the **CamelJmsDestinationName** header as follows:

```
public void setJmsHeader(Exchange exchange) {
    String id = ....
    exchange.getIn().setHeader("CamelJmsDestinationName", "order:" + id);
}
```

Then Camel will read this header and use it as the destination instead of the one configured on the endpoint. So, in this example Camel sends the message to **activemq:queue:order:2**, assuming the **id** value was 2.

If both the **CamelJmsDestination** and the **CamelJmsDestinationName** headers are set, **CamelJmsDestination** takes priority. Keep in mind that the JMS producer removes both **CamelJmsDestination** and **CamelJmsDestinationName** headers from the exchange and do not propagate them to the created JMS message in order to avoid the accidental loops in the routes (in scenarios when the message will be forwarded to the another JMS endpoint).

178.12. CONFIGURING DIFFERENT JMS PROVIDERS

You can configure your JMS provider in Spring XML as follows:

Basically, you can configure as many JMS component instances as you wish and give them a **unique name using the id attribute**. The preceding example configures an **activemq** component. You could do the same to configure MQSeries, TibCo, BEA, Sonic and so on.

Once you have a named JMS component, you can then refer to endpoints within that component using URIs. For example for the component name, **activemq**, you can then refer to destinations using the URI format, **activemq:[queue:|topic:]destinationName**. You can use the same approach for all other JMS providers.

This works by the SpringCamelContext lazily fetching components from the spring context for the scheme name you use for Endpoint URIs and having the Component resolve the endpoint URIs.

178.12.1. Using JNDI to find the ConnectionFactory

If you are using a J2EE container, you might need to look up JNDI to find the JMS **ConnectionFactory** rather than use the usual **<bean>** mechanism in Spring. You can do this using Spring's factory bean or the new Spring XML namespace. For example:

```
<bean id="weblogic" class="org.apache.camel.component.jms.JmsComponent">
  <property name="connectionFactory" ref="myConnectionFactory"/>
</bean>

<jee:jndi-lookup id="myConnectionFactory" jndi-name="jms/connectionFactory"/>
```

See [The jee schema](#) in the Spring reference documentation for more details about JNDI lookup.

178.13. CONCURRENT CONSUMING

A common requirement with JMS is to consume messages concurrently in multiple threads in order to make an application more responsive. You can set the **concurrentConsumers** option to specify the number of threads servicing the JMS endpoint, as follows:

```
from("jms:SomeQueue?concurrentConsumers=20").
  bean(MyClass.class);
```

You can configure this option in one of the following ways:

- On the **JmsComponent**,
- On the endpoint URI or,
- By invoking **setConcurrentConsumers()** directly on the **JmsEndpoint**.

178.13.1. Concurrent Consuming with async consumer

Notice that each concurrent consumer will only pickup the next available message from the JMS broker, when the current message has been fully processed. You can set the option **asyncConsumer=true** to let the consumer pickup the next message from the JMS queue, while the previous message is being processed asynchronously (by the Asynchronous Routing Engine). See more details in the table on top of the page about the **asyncConsumer** option.

```
from("jms:SomeQueue?concurrentConsumers=20&asyncConsumer=true").
  bean(MyClass.class);
```

178.14. REQUEST-REPLY OVER JMS

Camel supports Request Reply over JMS. In essence the MEP of the Exchange should be **InOut** when you send a message to a JMS queue.

Camel offers a number of options to configure request/reply over JMS that influence performance and clustered environments. The table below summarizes the options.

Option	Performance	Cluster	Description
Temporary	Fast	Yes	A temporary queue is used as reply queue, and automatic created by Camel. To use this do not specify a replyTo queue name. And you can optionally configure replyToType=Temporary to make it stand out that temporary queues are in use.
Shared	Slow	Yes	A shared persistent queue is used as reply queue. The queue must be created beforehand, although some brokers can create them on the fly such as Apache ActiveMQ. To use this you must specify the replyTo queue name. And you can optionally configure replyToType=Shared to make it stand out that shared queues are in use. A shared queue can be used in a clustered environment with multiple nodes running this Camel application at the same time. All using the same shared reply queue. This is possible because JMS Message selectors are used to correlate expected reply messages; this impacts performance though. JMS Message selectors is slower, and therefore not as fast as Temporary or Exclusive queues. See further below how to tweak this for better performance.
Exclusive	Fast	No (*Yes)	An exclusive persistent queue is used as reply queue. The queue must be created beforehand, although some brokers can create them on the fly such as Apache ActiveMQ. To use this you must specify the replyTo queue name. And you must configure replyToType=Exclusive to instruct Camel to use exclusive queues, as Shared is used by default, if a replyTo queue name was configured. When using exclusive reply queues, then JMS Message selectors are not in use, and therefore other applications must not use this queue as well. An exclusive queue cannot be used in a clustered environment with multiple nodes running this Camel application at the same time; as we do not have control if the reply queue comes back to the same node that sent the request message; that is why shared queues use JMS Message selectors to make sure of this. Though if you configure each Exclusive reply queue with an unique name per node, then you can run this in a clustered environment. As then the reply message will be sent back to that queue for the given node, that awaits the reply message.
concurrentConsumers	Fast	Yes	Camel 2.10.3: Allows to process reply messages concurrently using concurrent message listeners in use. You can specify a range using the concurrentConsumers and maxConcurrentConsumers options. Notice: That using Shared reply queues may not work as well with concurrent listeners, so use this option with care.

Option	Performance	Cluster	Description
maxConcurrentConsumers	Fast	Yes	Camel 2.10.3: Allows to process reply messages concurrently using concurrent message listeners in use. You can specify a range using the concurrentConsumers and maxConcurrentConsumers options. Notice: That using Shared reply queues may not work as well with concurrent listeners, so use this option with care.

The **JmsProducer** detects the **InOut** and provides a **JMSReplyTo** header with the reply destination to be used. By default Camel uses a temporary queue, but you can use the **replyTo** option on the endpoint to specify a fixed reply queue (see more below about fixed reply queue).

Camel will automatic setup a consumer which listen on the reply queue, so you should **not** do anything. This consumer is a Spring **DefaultMessageListenerContainer** which listen for replies. However it's fixed to 1 concurrent consumer.

That means replies will be processed in sequence as there are only 1 thread to process the replies. If you want to process replies faster, then we need to use concurrency. But **not** using the **concurrentConsumer** option. We should use the **threads** from the Camel DSL instead, as shown in the route below:

Instead of using threads, then use `concurrentConsumers` option if using Camel 2.10.3 or better. See further below.

```
from(xxx)
.inOut().to("activemq:queue:foo")
.threads(5)
.to(yyy)
.to(zzz);
```

In this route we instruct Camel to route replies asynchronously using a thread pool with 5 threads.

From **Camel 2.10.3** onwards you can now configure the listener to use concurrent threads using the **concurrentConsumers** and **maxConcurrentConsumers** options. This allows you to easier configure this in Camel as shown below:

```
from(xxx)
.inOut().to("activemq:queue:foo?concurrentConsumers=5")
.to(yyy)
.to(zzz);
```

178.14.1. Request-reply over JMS and using a shared fixed reply queue

If you use a fixed reply queue when doing Request Reply over JMS as shown in the example below, then pay attention.

```
from(xxx)
.inOut().to("activemq:queue:foo?replyTo=bar")
.to(yyy)
```

In this example the fixed reply queue named "bar" is used. By default Camel assumes the queue is shared when using fixed reply queues, and therefore it uses a **JMSSelector** to only pickup the expected

reply messages (eg based on the **JMSCorrelationID**). See next section for exclusive fixed reply queues. That means its not as fast as temporary queues. You can speedup how often Camel will pull for reply messages using the **receiveTimeout** option. By default its 1000 millis. So to make it faster you can set it to 250 millis to pull 4 times per second as shown:

```
from(xxx)
.inOut().to("activemq:queue:foo?replyTo=bar&receiveTimeout=250")
.to(yyy)
```

Notice this will cause the Camel to send pull requests to the message broker more frequent, and thus require more network traffic.

It is generally recommended to use temporary queues if possible.

178.14.2. Request-reply over JMS and using an exclusive fixed reply queue

Available as of Camel 2.9

In the previous example, Camel would anticipate the fixed reply queue named "bar" was shared, and thus it uses a **JMSSelector** to only consume reply messages which it expects. However there is a drawback doing this as JMS selectors is slower. Also the consumer on the reply queue is slower to update with new JMS selector ids. In fact it only updates when the **receiveTimeout** option times out, which by default is 1 second. So in theory the reply messages could take up till about 1 sec to be detected. On the other hand if the fixed reply queue is exclusive to the Camel reply consumer, then we can avoid using the JMS selectors, and thus be more performant. In fact as fast as using temporary queues. So in **Camel 2.9** onwards we introduced the **ReplyToType** option which you can configure to **Exclusive** to tell Camel that the reply queue is exclusive as shown in the example below:

```
from(xxx)
.inOut().to("activemq:queue:foo?replyTo=bar&replyToType=Exclusive")
.to(yyy)
```

Mind that the queue must be exclusive to each and every endpoint. So if you have two routes, then they each need an unique reply queue as shown in the next example:

```
from(xxx)
.inOut().to("activemq:queue:foo?replyTo=bar&replyToType=Exclusive")
.to(yyy)

from(aaa)
.inOut().to("activemq:queue:order?replyTo=order.reply&replyToType=Exclusive")
.to(bbb)
```

The same applies if you run in a clustered environment. Then each node in the cluster must use an unique reply queue name. As otherwise each node in the cluster may pickup messages which was intended as a reply on another node. For clustered environments its recommended to use shared reply queues instead.

178.15. SYNCHRONIZING CLOCKS BETWEEN SENDERS AND RECEIVERS

When doing messaging between systems, its desirable that the systems have synchronized clocks. For example when sending a **JMS** message, then you can set a time to live value on the message. Then the receiver can inspect this value, and determine if the message is already expired, and thus drop the

message instead of consume and process it. However this requires that both sender and receiver have synchronized clocks. If you are using [ActiveMQ](#) then you can use the [timestamp plugin](#) to synchronize clocks.

178.16. ABOUT TIME TO LIVE

Read first above about synchronized clocks.

When you do request/reply (InOut) over [JMS](#) with Camel then Camel uses a timeout on the sender side, which is default 20 seconds from the **requestTimeout** option. You can control this by setting a higher/lower value. However the time to live value is still set on the [JMS](#) message being send. So that requires the clocks to be synchronized between the systems. If they are not, then you may want to disable the time to live value being set. This is now possible using the **disableTimeToLive** option from **Camel 2.8** onwards. So if you set this option to **disableTimeToLive=true**, then Camel does **not** set any time to live value when sending [JMS](#) messages. **But** the request timeout is still active. So for example if you do request/reply over [JMS](#) and have disabled time to live, then Camel will still use a timeout by 20 seconds (the **requestTimeout** option). That option can of course also be configured. So the two options **requestTimeout** and **disableTimeToLive** gives you fine grained control when doing request/reply.

From **Camel 2.13/2.12.3** onwards you can provide a header in the message to override and use as the request timeout value instead of the endpoint configured value. For example:

```
from("direct:someWhere")
  .to("jms:queue:foo?replyTo=bar&requestTimeout=30s")
  .to("bean:processReply");
```

In the route above we have a endpoint configured **requestTimeout** of 30 seconds. So Camel will wait up till 30 seconds for that reply message to come back on the bar queue. If no reply message is received then a **org.apache.camel.ExchangeTimedOutException** is set on the Exchange and Camel continues routing the message, which would then fail due the exception, and Camel's error handler reacts.

If you want to use a per message timeout value, you can set the header with key **org.apache.camel.component.jms.JmsConstants#JMS_REQUEST_TIMEOUT** which has constant value **"CamelJmsRequestTimeout"** with a timeout value as long type.

For example we can use a bean to compute the timeout value per individual message, such as calling the **"whatIsTheTimeout"** method on the service bean as shown below:

```
from("direct:someWhere")
  .setHeader("CamelJmsRequestTimeout", method(ServiceBean.class, "whatIsTheTimeout"))
  .to("jms:queue:foo?replyTo=bar&requestTimeout=30s")
  .to("bean:processReply");
```

When you do fire and forget (InOut) over [JMS](#) with Camel then Camel by default does **not** set any time to live value on the message. You can configure a value by using the **timeToLive** option. For example to indicate a 5 sec., you set **timeToLive=5000**. The option **disableTimeToLive** can be used to force disabling the time to live, also for InOnly messaging. The **requestTimeout** option is not being used for InOnly messaging.

178.17. ENABLING TRANSACTED CONSUMPTION

A common requirement is to consume from a queue in a transaction and then process the message using the Camel route. To do this, just ensure that you set the following properties on the component/endpoint:

- **transacted** = true
- **transactionManager** = a *Transaction Manager* - typically the **JmsTransactionManager**

See the Transactional Client EIP pattern for further details.

Transactions and [Request Reply] over JMS

When using Request Reply over JMS you cannot use a single transaction; JMS will not send any messages until a commit is performed, so the server side won't receive anything at all until the transaction commits. Therefore to use [Request Reply](#) you must commit a transaction after sending the request and then use a separate transaction for receiving the response.

To address this issue the JMS component uses different properties to specify transaction use for oneway messaging and request reply messaging:

The **transacted** property applies **only** to the InOnly message Exchange Pattern (MEP).

The **transactedInOut** property applies to the InOut(Request Reply) message Exchange Pattern (MEP).

If you want to use transactions for [Request Reply](#) (InOut MEP), you **must** set **transactedInOut=true**.

Available as of Camel 2.10

You can leverage the [DMLC transacted session API](#) using the following properties on component/endpoint:

- **transacted** = true
- **lazyCreateTransactionManager** = false

The benefit of doing so is that the cacheLevel setting will be honored when using local transactions without a configured TransactionManager. When a TransactionManager is configured, no caching happens at DMLC level and it is necessary to rely on a pooled connection factory. For more details about this kind of setup, see [here](#) and [here](#).

178.18. USING JMSREPLYTO FOR LATE REPLIES

When using Camel as a JMS listener, it sets an Exchange property with the value of the ReplyTo **javax.jms.Destination** object, having the key **ReplyTo**. You can obtain this **Destination** as follows:

```
Destination replyDestination =
exchange.getIn().getHeader(JmsConstants.JMS_REPLY_DESTINATION, Destination.class);
```

And then later use it to send a reply using regular JMS or Camel.

```
// we need to pass in the JMS component, and in this sample we use ActiveMQ
JmsEndpoint endpoint = JmsEndpoint.newInstance(replyDestination, activeMQComponent);
// now we have the endpoint we can use regular Camel API to send a message to it
template.sendBody(endpoint, "Here is the late reply.");
```

A different solution to sending a reply is to provide the **replyDestination** object in the same Exchange property when sending. Camel will then pick up this property and use it for the real destination. The endpoint URI must include a dummy destination, however. For example:

```
// we pretend to send it to some non existing dummy queue
template.send("activemq:queue:dummy, new Processor() {
    public void process(Exchange exchange) throws Exception {
        // and here we override the destination with the ReplyTo destination object so the message is sent
        // to there instead of dummy
        exchange.getIn().setHeader(JmsConstants.JMS_DESTINATION, replyDestination);
        exchange.getIn().setBody("Here is the late reply.");
    }
}
```

178.19. USING A REQUEST TIMEOUT

In the sample below we send a Request Reply style message Exchange (we use the **requestBody** method = **InOut**) to the slow queue for further processing in Camel and we wait for a return reply:

178.20. SAMPLES

JMS is used in many examples for other components as well. But we provide a few samples below to get started.

178.20.1. Receiving from JMS

In the following sample we configure a route that receives JMS messages and routes the message to a POJO:

```
from("jms:queue:foo").
    to("bean:myBusinessLogic");
```

You can of course use any of the EIP patterns so the route can be context based. For example, here's how to filter an order topic for the big spenders:

```
from("jms:topic:OrdersTopic").
    filter().method("myBean", "isGoldCustomer").
    to("jms:queue:BigSpendersQueue");
```

178.20.2. Sending to JMS

In the sample below we poll a file folder and send the file content to a JMS topic. As we want the content of the file as a **TextMessage** instead of a **BytesMessage**, we need to convert the body to a **String**:

```
from("file://orders").
    convertBodyTo(String.class).
    to("jms:topic:OrdersTopic");
```

178.20.3. Using Annotations

Camel also has annotations so you can use [POJO Consuming](#) and POJO Producing.

178.20.4. Spring DSL sample

The preceding examples use the Java DSL. Camel also supports Spring XML DSL. Here is the big spender sample using Spring DSL:

```
<route>
  <from uri="jms:topic:OrdersTopic"/>
  <filter>
    <method bean="myBean" method="isGoldCustomer"/>
    <to uri="jms:queue:BigSpendersQueue"/>
  </filter>
</route>
```

178.20.5. Other samples

JMS appears in many of the examples for other components and EIP patterns, as well in this Camel documentation. So feel free to browse the documentation. If you have time, check out the this tutorial that uses JMS but focuses on how well Spring Remoting and Camel works together Tutorial-JmsRemoting.

178.20.6. Using JMS as a Dead Letter Queue storing Exchange

Normally, when using [JMS](#) as the transport, it only transfers the body and headers as the payload. If you want to use [JMS](#) with a [Dead Letter Channel](#), using a JMS queue as the Dead Letter Queue, then normally the caused Exception is not stored in the JMS message. You can, however, use the **transferExchange** option on the JMS dead letter queue to instruct Camel to store the entire Exchange in the queue as a **javax.jms.ObjectMessage** that holds a **org.apache.camel.impl.DefaultExchangeHolder**. This allows you to consume from the Dead Letter Queue and retrieve the caused exception from the Exchange property with the key **Exchange.EXCEPTION_CAUGHT**. The demo below illustrates this:

```
// setup error handler to use JMS as queue and store the entire Exchange
errorHandler(deadLetterChannel("jms:queue:dead?transferExchange=true"));
```

Then you can consume from the JMS queue and analyze the problem:

```
from("jms:queue:dead").to("bean:myErrorAnalyzer");

// and in our bean
String body = exchange.getIn().getBody();
Exception cause = exchange.getProperty(Exchange.EXCEPTION_CAUGHT, Exception.class);
// the cause message is
String problem = cause.getMessage();
```

178.20.7. Using JMS as a Dead Letter Channel storing error only

You can use JMS to store the cause error message or to store a custom body, which you can initialize yourself. The following example uses the Message Translator EIP to do a transformation on the failed exchange before it is moved to the [JMS](#) dead letter queue:

```
// we sent it to a seda dead queue first
errorHandler(deadLetterChannel("seda:dead"));

// and on the seda dead queue we can do the custom transformation before its sent to the JMS queue
from("seda:dead").transform(exceptionMessage()).to("jms:queue:dead");
```

Here we only store the original cause error message in the transform. You can, however, use any Expression to send whatever you like. For example, you can invoke a method on a Bean or use a custom processor.

178.21. SENDING AN INONLY MESSAGE AND KEEPING THE JMSREPLYTO HEADER

When sending to a [JMS](#) destination using `camel-jms` the producer will use the MEP to detect if its *InOnly* or *InOut* messaging. However there can be times where you want to send an *InOnly* message but keeping the **JMSReplyTo** header. To do so you have to instruct Camel to keep it, otherwise the **JMSReplyTo** header will be dropped.

For example to send an *InOnly* message to the foo queue, but with a **JMSReplyTo** with bar queue you can do as follows:

```
template.send("activemq:queue:foo?preserveMessageQos=true", new Processor() {
    public void process(Exchange exchange) throws Exception {
        exchange.getIn().setBody("World");
        exchange.getIn().setHeader("JMSReplyTo", "bar");
    }
});
```

Notice we use `preserveMessageQos=true` to instruct Camel to keep the **JMSReplyTo** header.

178.22. SETTING JMS PROVIDER OPTIONS ON THE DESTINATION

Some JMS providers, like IBM's WebSphere MQ need options to be set on the JMS destination. For example, you may need to specify the **targetClient** option. Since **targetClient** is a WebSphere MQ option and not a Camel URI option, you need to set that on the JMS destination name like so:

```
// ...
.setHeader("CamelJmsDestinationName", constant("queue:///MY_QUEUE?targetClient=1"))
.to("wmq:queue:MY_QUEUE?useMessageIDAsCorrelationID=true");
```

Some versions of WMQ won't accept this option on the destination name and you will get an exception like:

```
com.ibm.msg.client.jms.DetailedJMSEException: JMSSC0005: The specified
value 'MY_QUEUE?targetClient=1' is not allowed for
'XMSC_DESTINATION_NAME'
```

A workaround is to use a custom DestinationResolver:

```
JmsComponent wmq = new JmsComponent(connectionFactory);

wmq.setDestinationResolver(new DestinationResolver() {
    public Destination resolveDestinationName(Session session, String destinationName, boolean
pubSubDomain) throws JMSEException {
        MQQueueSession wmqSession = (MQQueueSession) session;
        return wmqSession.createQueue("queue:///" + destinationName + "?targetClient=1");
    }
});
```

CHAPTER 179. JMX COMPONENT

179.1. CAMEL JMX

Apache Camel has extensive support for JMX to allow you to monitor and control the Camel managed objects with a JMX client.

Camel also provides a [JMX](#) component that allows you to subscribe to MBean notifications. This page is about how to manage and monitor Camel using JMX.

179.2. OPTIONS

The JMX component has no options.

The JMX endpoint is configured using URI syntax:

```
jmx:serverURL
```

with the following path and query parameters:

179.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
serverURL	Server url comes from the remaining endpoint. Use platform to connect to local JVM.		String

179.2.2. Query Parameters (30 parameters):

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
format (consumer)	Format for the message body. Either xml or raw. If xml, the notification is serialized to xml. If raw, then the raw java object is set as the body.	xml	String
granularityPeriod (consumer)	The frequency to poll the bean to check the monitor (monitor types only).	10000	long

Name	Description	Default	Type
monitorType (consumer)	The type of monitor to create. One of string, gauge, counter (monitor types only).		String
objectDomain (consumer)	Required The domain for the mbean you're connecting to		String
objectName (consumer)	The name key for the mbean you're connecting to. This value is mutually exclusive with the object properties that get passed.		String
observedAttribute (consumer)	The attribute to observe for the monitor bean or consumer.		String
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
executorService (advanced)	To use a custom shared thread pool for the consumers. By default each consume has their own thread-pool to process and route notifications.		ExecutorService
handback (advanced)	Value to handback to the listener when a notification is received. This value will be put in the message header with the key jmx.handback		Object
notificationFilter (advanced)	Reference to a bean that implements the NotificationFilter.		NotificationFilter
objectProperties (advanced)	Properties for the object name. These values will be used if the objectName param is not set		Map
reconnectDelay (advanced)	The number of seconds to wait before attempting to retry establishment of the initial connection or attempt to reconnect a lost connection	10	int
reconnectOnConnection Failure (advanced)	If true the consumer will attempt to reconnect to the JMX server when any connection failure occurs. The consumer will attempt to re-establish the JMX connection every 'x' seconds until the connection is made-- where 'x' is the configured reconnectDelay	false	boolean

Name	Description	Default	Type
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
testConnectionOnStartup (advanced)	If true the consumer will throw an exception if unable to establish the JMX connection upon startup. If false, the consumer will attempt to establish the JMX connection every 'x' seconds until the connection is made – where 'x' is the configured <code>reconnectionDelay</code>	true	boolean
notifyDiffer (string)	If true, will fire a notification when the string attribute differs from the string to compare (string monitor or consumer). By default the consumer will notify match if observed attribute and string to compare has been configured.	false	boolean
notifyMatch (string)	If true, will fire a notification when the string attribute matches the string to compare (string monitor or consumer). By default the consumer will notify match if observed attribute and string to compare has been configured.	false	boolean
stringToCompare (string)	Value for attribute to compare (string monitor or consumer). By default the consumer will notify match if observed attribute and string to compare has been configured.		String
initThreshold (counter)	Initial threshold for the monitor. The value must exceed this before notifications are fired (counter monitor only).		int
modulus (counter)	The value at which the counter is reset to zero (counter monitor only).		int
offset (counter)	The amount to increment the threshold after it's been exceeded (counter monitor only).		int
differenceMode (gauge)	If true, then the value reported in the notification is the difference from the threshold as opposed to the value itself (counter and gauge monitor only).	false	boolean
notifyHigh (gauge)	If true, the gauge will fire a notification when the high threshold is exceeded (gauge monitor only).	false	boolean
notifyLow (gauge)	If true, the gauge will fire a notification when the low threshold is exceeded (gauge monitor only).	false	boolean

Name	Description	Default	Type
thresholdHigh (gauge)	Value for the gauge's high threshold (gauge monitor only).		Double
thresholdLow (gauge)	Value for the gauge's low threshold (gauge monitor only).		Double
password (security)	Credentials for making a remote connection		String
user (security)	Credentials for making a remote connection		String

179.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.component.jmx.enabled	Enable jmx component	true	Boolean
camel.component.jmx.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

179.4. ACTIVATING JMX IN CAMEL

NOTE

Spring JAR dependency, required for Camel 2.8 or older

spring-context.jar, **spring-aop.jar**, **spring-beans.jar**, and **spring-core.jar** are needed on the classpath by Camel to be able to use JMX instrumentation. If these .jars are not on the classpath, Camel will fallback to non JMX mode. This situation is logged at **WARN** level using logger name **org.apache.camel.impl.DefaultCamelContext**.

From **Camel 2.9** onwards, the Spring JARs are **no** longer required to run Camel in JMX mode.

179.4.1. Using JMX to manage Apache Camel

By default, JMX instrumentation agent is enabled in Camel, which means that Camel runtime creates and registers MBean management objects with a **MBeanServer** instance in the VM. This allows Camel users to instantly obtain insights into how Camel routes perform down to the individual processor level.

The supported types of management objects are [endpoint](#), [route](#), [service](#), and [processor](#). Some of these management objects also expose lifecycle operations in addition to performance counter attributes.

The [DefaultManagementNamingStrategy](#) is the default naming strategy which builds object names used for MBean registration. By default, **org.apache.camel** is the domain name for all object names created by [CamelNamingStrategy](#). The domain name of the MBean object can be configured by Java VM system property:

```
-Dorg.apache.camel.jmx.mbeanObjectNameDomainName=your.domain.name
```

Or, by adding a **jmxAgent** element inside the camelContext element in Spring configuration:

```
<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
  <jmxAgent id="agent" mbeanObjectNameDomainName="your.domain.name"/>
  ...
</camelContext>
```

Spring configuration always takes precedence over system properties when they both present. It is true for all JMX related configurations.

179.4.2. Disabling JMX instrumentation agent in Camel

You can disable JMX instrumentation agent by setting the Java VM system property as follow:

```
-Dorg.apache.camel.jmx.disabled=true
```

The property value is treated as **boolean**.

Or, by adding a **jmxAgent** element inside the **camelContext** element in Spring configuration:

```
<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
  <jmxAgent id="agent" disabled="true"/>
  ...
</camelContext>
```

Or in **Camel 2.1** its a bit easier (not having to use JVM system property) if using pure Java as you can disable it as follows:

```
CamelContext camel = new DefaultCamelContext();
camel.disableJMX();
```

179.4.3. Locating a MBeanServer in the Java VM

Each CamelContext can have an instance of [InstrumentationAgent](#) wrapped inside the [InstrumentationLifecycleStrategy](#). The InstrumentationAgent is the object that interfaces with a [MBeanServer](#) to register / unregister Camel MBeans. Multiple CamelContexts / InstrumentationAgents can / should share a [MBeanServer](#). By default, Camel runtime picks the first [MBeanServer](#) returned by [MBeanServerFactory.findMBeanServer method](#) that matches the default domain name of **org.apache.camel**.

You may want to change the default domain name to match the **MBeanServer** instance that you are already using in your application. Especially, if your **MBeanServer** is attached to a JMX connector server, you will not need to create a connector server in Camel.

You can configure the matching default domain name via system property.

```
-Dorg.apache.camel.jmx.mbeanServerDefaultDomain=<your.domain.name>
```

Or, by adding a **jmxAgent** element inside the camelContext element in Spring configuration:

```
<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
  <jmxAgent id="agent" mbeanServerDefaultDomain="your.domain.name"/>
  ...
</camelContext>
```

If no matching **MBeanServer** can be found, a new one is created and the new **MBeanServer**'s default domain name is set according to the default and configuration as mentioned above.

It is also possible to use the **PlatformMBeanServer** when it is desirable to manage JVM MBeans by setting the system property. The **MBeanServer** default domain name configuration is ignored as it is not applicable.

CAUTION

Starting in next release (1.5), the default value of **usePlatformMBeanServer** will be changed to **true**. You can set the property to **false** to disable using platform **MBeanServer**.

```
-Dorg.apache.camel.jmx.usePlatformMBeanServer=True
```

Or, by adding a **jmxAgent** element inside the **camelContext** element in Spring configuration:

```
<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
  <jmxAgent id="agent" usePlatformMBeanServer="true"/>
  ...
</camelContext>
```

179.4.4. The System Properties for Camel JMX support

Property Name	value	Description
org.apache.camel.jmx	true or false	if is true , it will enable jmx feature in Camel

See more system properties in this section below: *jmxAgent Properties Reference*.

179.4.5. How to use authentication with JMX

JMX in the JDK have features for authentication and also for using secure connections over SSL. You have to refer to the SUN documentation how to use this:

- <http://java.sun.com/j2se/1.5.0/docs/guide/management/agent.html>

- <http://java.sun.com/javase/6/docs/technotes/guides/management/agent.html>

179.4.6. JMX inside an Application Server

179.4.6.1. Tomcat 6

See [this page](#) for details about enabling JMX in Tomcat.

In short, modify your catalina.sh (or catalina.bat in Windows) file to set the following options...

```
set CATALINA_OPTS=-Dcom.sun.management.jmxremote \
-Dcom.sun.management.jmxremote.port=1099 \
-Dcom.sun.management.jmxremote.ssl=false \
-Dcom.sun.management.jmxremote.authenticate=false
```

179.4.6.2. JBoss AS 4

By default JBoss creates its own **MBeanServer**. To allow Camel to expose to the same server follow these steps:

1. Tell Camel to use the Platform **MBeanServer** (This defaults to true in Camel 1.5)

```
<camel:camelContext id="camelContext">
  <camel:jmxAgent id="jmxAgent" mbeanObjectName="org.yourname"
  usePlatformMBeanServer="true" />
</camel:camelContext>
```

1. Alter your JBoss instance to use the Platform **MBeanServer**.
Add the following property to your **JAVA_OPTS** by editing **run.sh** or **run.conf** -
Djboss.platform.mbeanserver. See <http://wiki.jboss.org/wiki/JBossMBeansInJConsole>

179.4.6.3. WebSphere

Alter the **mbeanServerDefaultDomain** to be **WebSphere**:

```
<camel:jmxAgent id="agent" createConnector="true" mbeanObjectName="org.yourname"
usePlatformMBeanServer="false" mbeanServerDefaultDomain="WebSphere"/>
```

179.4.6.4. Oracle OC4j

The Oracle OC4J J2EE application server will not allow Camel to access the platform **MBeanServer**. You can identify this in the log as Camel will log a **WARNING**.

```
xxx xx, xxxx xx:xx:xx xx org.apache.camel.management.InstrumentationLifecycleStrategy
onContextStart
WARNING: Could not register CamelContext MBean
java.lang.SecurityException: Unauthorized access from application: xx to MBean:
java.lang:type=ClassLoading
  at
oracle.oc4j.admin.jmx.shared.UserMBeanServer.checkRegisterAccess(UserMBeanServer.java:873)
```

To resolve this you should disable the JMX agent in Camel, see section *Disabling JMX instrumentation agent in Camel*.

179.4.7. Advanced JMX Configuration

The Spring configuration file allows you to configure how Camel is exposed to JMX for management. In some cases, you could specify more information here, like the connector's port or the path name.

179.4.8. Example:

```
<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
  <jmxAgent id="agent" createConnector="true" registryPort="2000"
  mbeanServerDefaultDomain="org.apache.camel.test"/>
  <route>
    <from uri="seda:start"/>
    <to uri="mock:result"/>
  </route>
</camelContext>
```

If you wish to change the Java 5 JMX settings you can use various [JMX system properties](#)

For example you can enable remote JMX connections to the Sun JMX connector, via setting the following environment variable (using **set** or **export** depending on your platform). These settings only configure the Sun JMX connector within Java 1.5+, not the JMX connector that Camel creates by default.

```
SUNJMX=-Dcom.sun.management.jmxremote=true -Dcom.sun.management.jmxremote.port=1616 \
-Dcom.sun.management.jmxremote.authenticate=false -Dcom.sun.management.jmxremote.ssl=false
```

(The SUNJMX environment variable is simple used by the startup script for Camel, as additional startup parameters for the JVM. If you start Camel directly, you'll have to pass these parameters yourself.)

179.4.9. jmxAgent Properties Reference

Spring property	System property	Default Value	Description
id			The JMX agent name, and it is not optional
usePlatformMBeanServer	org.apache.camel.jmx.usePlatformMBeanServer	false, true - Release 1.5 or later	If true , it will use the MBeanServer from the JVM
mbeanServerDefaultDomain	org.apache.camel.jmx.mbeanServerDefaultDomain	org.apache.camel	The default JMX domain of the MBeanServer
mbeanObjectDomainName	org.apache.camel.jmx.mbeanObjectDomainName	org.apache.camel	The JMX domain that all object names will use

Spring property	System property	Default Value	Description
createConnector	org.apache.camel.jmx.createRmiConnector	false	If we should create a JMX connector (to allow remote management) for the MBeanServer
registryPort	org.apache.camel.jmx.rmiConnector.registryPort	1099	The port that the JMX RMI registry will use
connectorPort	org.apache.camel.jmx.rmiConnector.connectorPort	-1 (dynamic)	The port that the JMX RMI server will use
serviceUriPath	org.apache.camel.jmx.serviceUriPath	/jmxrmi/camel	The path that JMX connector will be registered under
onlyRegisterProcessorWithCustomId	org.apache.camel.jmx.onlyRegisterProcessorWithCustomId	false	Camel 2.0: If this option is enabled then only processors with a custom id set will be registered. This allows you to filter out unwanted processors in the JMX console.
statisticsLevel		All / Default	Camel 2.1: Configures the level for whether performance statistics is enabled for the MBean. See section <i>Configuring level of granularity for performance statistics</i> for more details. From Camel 2.16 onwards the All option is renamed to Default, and a new Extended option has been introduced which allows gathered additional runtime JMX metrics.

Spring property	System property	Default Value	Description
includeHostName	org.apache.camel.jmx.includeHostName		Camel 2.13: Whether to include the hostname in the MBean naming. From Camel 2.13 onwards this is default false , where as in older releases its default true . You can use this option to restore old behavior if really needed.
useHostIPAddress	org.apache.camel.jmx.useHostIPAddress	false	Camel 2.16: Whether to use hostname or IP Address in the service url when creating the remote connector. By default the hostname will be used.
loadStatisticsEnabled	org.apache.camel.jmx.loadStatisticsEnabled	false	Camel 2.16: Whether load statistics is enabled (gathers load statistics using a background thread per CamelContext).
endpointRuntimeStatisticsEnabled	org.apache.camel.jmx.endpointRuntimeStatisticsEnabled	true	Camel 2.16: Whether endpoint runtime statistics is enabled (gathers runtime usage of each incoming and outgoing endpoints).

179.4.10. Configuring whether to register MBeans always, for new routes or just by default

Available as of Camel 2.7

Camel now offers 2 settings to control whether or not to register mbeans

Option	Default	Description
registerAlways	false	If enabled then MBeans is always registered.

Option	Default	Description
registerNewRoutes	true	If enabled then adding new routes after CamelContext has been started will also register MBeans from that given route.

By default Camel registers MBeans for all the routes configured when its starting. The **registerNewRoutes** option control if MBeans should also be registered if you add new routes thereafter. You can disable this, if you for example add and remove temporary routes where management is not needed.

Be a bit caution to use the **registerAlways** option when using dynamic EIP patterns such as the Recipient List having unique endpoints. If so then each unique endpoint and its associated services/producers would also be registered. This could potential lead to system degraation due the rising number of mbeans in the registry. A MBean is not a light-weight object and thus consumes memory.

179.5. MONITORING CAMEL USING JMX

179.5.1. Using JConsole to monitor Camel

The **CamelContext** should appear in the list of local connections, if you are running JConsole on the same host as Camel.

To connect to a remote Camel instance, or if the local process does not show up, use Remote Process option, and enter an URL. Here is an example localhost

URL:service:jmx:rmi:///jndi/rmi://localhost:1099/jmxrmi/camel.

Using the Apache Camel with JConsole:

The screenshot shows the J2SE 5.0 Monitoring & Management Console. The title bar indicates the service is 'jmx:rmi:///jndi/rmi://localhost:1099/jmxrmi/camel'. The 'MBeans' tab is active, showing a tree view on the left and a table of attributes on the right.

MBeans Tree:

- JMImplementation
 - com.sun.management
 - java.lang
 - java.util.logging
 - org.apache.camel
 - pebble/camel
 - consumers
 - FileConsumer(0x5dd78d57)
 - FileConsumer(0x783eef33)
 - JmsConsumer(0x30ea0dfc)
 - context
 - endpoints
 - "file://target/test?id=0xa0f754a"
 - "file:src/data?id=0x1984e9d2"
 - "jms:test.MyQueue?id=0x68c2e1"
 - "spring-event:default?id=0x20a"
 - processors
 - bean1
 - to1
 - to2
 - routes
 - "node1"
 - "node2"
 - "node3"

Attributes Table:

Name	Value
Description	EventDrivenConsumerRoute[Endpoint[file:src/data?no...
EndpointUri	file:src/data?noop=true
FirstExchangeCompletionTime	Wed Oct 22 16:00:07 EDT 2008
FirstExchangeFailureTime	
LastExchangeCompletionTime	Wed Oct 22 16:00:07 EDT 2008
LastExchangeFailureTime	
MaxProcessingTimeMillis	95.712
MeanProcessingTimeMillis	55.07
MinProcessingTimeMillis	14.428
NumCompleted	2
NumExchanges	2
NumFailed	0
TotalProcessingTimeMillis	110.14

179.5.2. Which endpoints are registered

In **Camel 2.1** onwards **only singleton** endpoints are registered as the overhead for non singleton will be substantial in cases where thousands or millions of endpoints are used. This can happen when using a Recipient List EIP or from a **ProducerTemplate** that sends a lot of messages.

179.5.3. Which processors are registered

See this FAQ.

179.5.4. How to use the JMX NotificationListener to listen the camel events?

The Camel notification events give a coarse grained overview what is happening. You can see lifecycle event from context and endpoints and you can see exchanges being received by and sent to endpoints.

From **Camel 2.4** you can use a custom JMX NotificationListener to listen the camel events.

First you need to set up a **JmxNotificationEventNotifier** before you start the CamelContext:

```
// Set up the JmxNotificationEventNotifier
notifier = new JmxNotificationEventNotifier();
notifier.setSource("MyCamel");
notifier.setIgnoreCamelContextEvents(true);
notifier.setIgnoreRouteEvents(true);
notifier.setIgnoreServiceEvents(true);
```

```
CamelContext context = new DefaultCamelContext(createRegistry());
context.getManagementStrategy().addEventNotifier(notifier);
```

Second you can register your listener for listening the event:

```
// register the NotificationListener
ObjectName on = ObjectName.getInstance("org.apache.camel:context=camel-
1,type=eventnotifiers,name=JmxEventNotifier");
MyNotificationListener listener = new MyNotificationListener();
context.getManagementStrategy().getManagementAgent().getMBeanServer().addNotificationListener(o
n,
    listener,
    new NotificationFilter() {
        private static final long serialVersionUID = 1L;

        public boolean isNotificationEnabled(Notification notification) {
            return notification.getSource().equals("MyCamel");
        }
    }, null);
```

179.5.5. Using the Tracer MBean to get fine grained tracing

Additionally to the coarse grained notifications above **Camel 2.9.0** support JMX Notification for fine grained trace events.

These can be found in the Tracer MBean. To activate fine grained tracing you first need to activate tracing on the context or on a route.

This can either be done when configuring the context or on the context / route MBeans.

As a second step you have to set the **jmxTraceNotifications** attribute to **true** on the tracer. This can again be done when configuring the context or at runtime on the tracer MBean.

Now you can register for TraceEvent Notifications on the Tracer MBean using JConsole. There will be one Notification for every step on the route with all exchange and message details:

The screenshot shows the Java Monitoring & Management Console (JM) interface. The left sidebar displays a tree view of the application structure, including packages like `org.apache.camel` and `sopwin58/camel-1`. The main window shows a 'Notification buffer' table with columns: TimeStamp, Type, UserData, Message, Event, and Source. A detailed view of a notification is expanded, showing the following details:

- Timestamp: 10:26:2...
- Type: TraceNotifica...
- UserData: Headers={myheader=Test 10, breadorum...
- Body: Test 10
- ExchangeId: ID-sopwin58-51211-1317975...
- EndpointURI: transform[Simple: \${in.l...
- Properties: {CamelCreatedTimestamp=Fr...

At the bottom of the notification buffer, there are buttons for 'Subscribe', 'Unsubscribe', and 'Clear'.

179.6. USING JMX FOR YOUR OWN CAMEL CODE

179.6.1. Registering your own Managed Endpoints

Available as of Camel 2.0

You can decorate your own endpoints with Spring managed annotations `@ManagedResource` to allow to register them in the Camel `MBeanServer` and thus access your custom MBeans using JMX.

NOTE

In **Camel 2.1** we have changed this to apply other than just endpoints but then you need to implement the interface `org.apache.camel.spi.ManagementAware` as well. More about this later.

For example we have the following custom endpoint where we define some options to be managed:

```
@ManagedResource(description = "Our custom managed endpoint")
public class CustomEndpoint extends MockEndpoint implements
ManagementAware<CustomEndpoint> {

    public CustomEndpoint(final String endpointUri, final Component component) {
        super(endpointUri, component);
    }

    public Object getManagedObject(CustomEndpoint object) {
        return this;
    }

    public boolean isSingleton() {
        return true;
    }
}
```

```

protected String createEndpointUri() {
    return "custom";
}

@ManagedAttribute
public String getFoo() {
    return "bar";
}

@ManagedAttribute
public String getEndpointUri() {
    return super.getEndpointUri();
}
}

```

Notice from **Camel 2.9** onwards its encouraged to use the **@ManagedResource**, **@ManagedAttribute**, and **@ManagedOperation** from the **org.apache.camel.api.management** package. This allows your custom code to not depend on Spring JARs.

179.6.2. Programming your own Managed Services

Available as of Camel 2.1

Camel now offers to use your own MBeans when registering services for management. What that means is for example you can develop a custom Camel component and have it expose MBeans for endpoints, consumers and producers etc. All you need to do is to implement the interface **org.apache.camel.spi.ManagementAware** and return the managed object Camel should use.

Now before you think oh boys the JMX API is really painful and terrible, then yeah you are right. Lucky for us Spring though too and they created a range of annotations you can use to export management on an existing bean. That means that you often use that and just return **this** in the **getManagedObject** from the **ManagementAware** interface. For an example see the code example above with the **CustomEndpoint**.

Now in **Camel 2.1** you can do this for all the objects that Camel registers for management which are quite a bunch, but not all.

For services which do not implement this **ManagementAware** interface then Camel will fallback to using default wrappers as defined in the table below:

Type	MBean wrapper
CamelContext	ManagedCamelContext
Component	ManagedComponent
Endpoint	ManagedEndpoint
Consumer	ManagedConsumer
Producer	ManagedProducer

Type	MBean wrapper
Route	ManagedRoute
Processor	ManagedProcessor
Tracer	ManagedTracer
Service	ManagedService

In addition to that there are some extended wrappers for specialized types such as:

Type	MBean wrapper
ScheduledPollConsumer	ManagedScheduledPollConsumer
BrowsableEndpoint	ManagedBrowseableEndpoint
Throttler	ManagedThrottler
Delayer	ManagedDelayer
SendProcessor	ManagedSendProcessor

And in the future we will add additional wrappers for more EIP patterns.

179.6.3. ManagementNamingStrategy

Available as of Camel 2.1

Camel provides a pluggable API for naming strategy by **org.apache.camel.spi.ManagementNamingStrategy**. A default implementation is used to compute the MBean names that all MBeans are registered with.

179.6.4. Management naming pattern

Available as of Camel 2.10

From **Camel 2.10** onwards we made it easier to configure a naming pattern for the MBeans. The pattern is used as part of the **ObjectName** as they key after the domain name.

By default Camel will use MBean names for the **ManagedCamelContextMBean** as follows:

```
org.apache.camel:context=localhost/camel-1,type=context,name=camel-1
```

And from **Camel 2.13** onwards the hostname is not included in the MBean names, so the above example would be as follows:

```
org.apache.camel:context=camel-1,type=context,name=camel-1
```

If you configure a name on the **CamelContext** then that name is part of the **ObjectName** as well. For example if we have

```
<camelContext id="myCamel" ...>
```

Then the MBean names will be as follows:

```
org.apache.camel:context=localhost/myCamel,type=context,name=myCamel
```

Now if there is a naming clash in the JVM, such as there already exists a MBean with that given name above, then Camel will by default try to auto correct this by finding a new free name in the **JMXMBeanServer** by using a counter. As shown below the counter is now appended, so we have **myCamel-1** as part of the **ObjectName**:

```
org.apache.camel:context=localhost/myCamel-1,type=context,name=myCamel
```

This is possible because Camel uses a naming pattern by default that supports the following tokens:

- **camelId** = the CamelContext id (eg the name)
- **name** - same as **camelId**
- **counter** - an incrementing counter * **bundleId** - the OSGi bundle id (only for OSGi environments)
- **symbolicName** - the OSGi symbolic name (only for OSGi environments)
- **version** - the OSGi bundle version (only for OSGi environments)

The default naming pattern is differentiated between OSGi and non-OSGi as follows:

- non OSGi: **name**
- OSGi: **bundleId-name**
- OSGi **Camel 2.13**: **symbolicName**

However if there is a naming clash in the **JMXMBeanServer** then Camel will automatic fallback and use the **counter** in the pattern to remedy this. And thus the following patterns will then be used:

- non OSGi: **name-counter**
- OSGi: **bundleId-name-counter**
- OSGi **Camel 2.13**: **symbolicName-counter**

If you set an explicit naming pattern, then that pattern is always used, and the default patterns above is **not** used.

This allows us to have full control, very easily, of the naming for both the **CamelContext** id in the Registry as well the JMX MBeans in the **JMXMBeanRegistry**.

From **Camel 2.15** onwards you can configure the default management name pattern using a JVM system property, to configure this globally for the JVM. Notice that you can override this pattern by configure it explicit, as shown in the examples further below.

Set a JVM system property to use a default management name pattern that prefixes the name with cool.

```
System.setProperty(JmxSystemPropertyKeys.MANAGEMENT_NAME_PATTERN, "cool-#name#");
```

So if we want to explicit name both the **CamelContext** and to use fixed MBean names, that do not change (eg has no counters), then we can use the new **managementNamePattern** attribute:

```
<camelContext id="myCamel" managementNamePattern="#name#">
```

Then the MBean names will always be as follows:

```
org.apache.camel:context=localhost/myCamel,type=context,name=myCamel
```

In Java, you can configure the **managementNamePattern** as follows:

```
context.getManagementNameStrategy().setNamePattern("#name#");
```

You can also use a different name in the **managementNamePattern** than the id, so for example we can do:

```
<camelContext id="myCamel" managementNamePattern="coolCamel">
```

You may want to do this in OSGi environments in case you do not want the OSGi bundle id as part of the MBean names. As the OSGi bundle id can change if you restart the server, or uninstall and install the same application. You can then do as follows to not use the OSGi bundle id as part of the name:

```
<camelContext id="myCamel" managementNamePattern="#name#">
```

Note this requires that **myCamel** is unique in the entire JVM. If you install a 2nd Camel application that has the same **CamelContext** id and **managementNamePattern** then Camel will fail upon starting, and report a MBean already exists exception.

179.6.5. ManagementStrategy

Available as of Camel 2.1

Camel now provides a totally pluggable management strategy that allows you to be 100% in control of management. It is a rich interface with many methods for management. Not only for adding and removing managed objects from the **MBeanServer**, but also event notification is provided as well using the **org.apache.camel.spi.EventNotifier** API. What it does, for example, is make it easier to provide an adapter for other management products. In addition, it also allows you to provide more details and features that are provided out of the box at Apache.

179.6.6. Configuring level of granularity for performance statistics

Available as of Camel 2.1

You can now set a pre set level whether performance statistics is enabled or not when Camel start ups. The levels are

- **Extended** - As default but with additional statistics gathered during runtime such as fine grained level of usage of endpoints and more. This options requires Camel 2.16

- **All / Default** - Camel will enable statistics for both routes and processors (fine grained). From **Camel 2.16** onwards the All option was renamed to Default.
- **RoutesOnly** - Camel will only enable statistics for routes (coarse grained)
- **Off** - Camel will not enable statistics for any.

From **Camel 2.9** onwards the performance statistics also include average load statistics per CamelContext and Route MBeans. The statistics is average load based on the number of in-flight exchanges, on a per 1, 5, and 15 minute rate. This is similar to load statistics on Unix systems. **Camel 2.11** onwards allows you to explicit disable load performance statistics by setting **loadStatisticsEnabled=false** on the `<jmxAgent>`. Note that it will be off if the statics level is configured to off as well. From **Camel 2.13** onwards the load performance statistics is by default disabled. You can enable this by setting **loadStatisticsEnabled=true** on the `<jmxAgent>`.

At runtime you can always use the management console (such as JConsole) to change on a given route or processor whether its statistics are enabled or not.

NOTE

What does statistics enabled mean?

Statistics enabled means that Camel will do fine grained performance statistics for that particular MBean. The statistics you can see are many, such as: number of exchanges completed/failed, last/total/mina/max/mean processing time, first/last failed time, etc.

Using Java DSL you set this level by:

```
// only enable routes when Camel starts
context.getManagementStrategy().setStatisticsLevel(ManagementStatisticsLevel.RoutesOnly);
```

And from Spring DSL you do:

```
<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
  <jmxAgent id="agent" statisticsLevel="RoutesOnly"/>
  ...
</camelContext>
```

179.7. HIDING SENSITIVE INFORMATION

Available as of Camel 2.12

By default, Camel enlists MBeans in JMX such as endpoints configured using URIs. In this configuration, there may be sensitive information such as passwords.

This information can be hidden by enabling the **mask** option as shown below:

Using Java DSL you turn this on by:

```
// only enable routes when Camel starts
context.getManagementStrategy().getManagementAgent().setMask(true);
```

And from Spring DSL you do:

```
<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
  <jmxAgent id="agent" mask="true"/>
  ...
</camelContext>
```

This will mask URIs having options such as password and passphrase, and use **xxxxxx** as the replacement value.

179.7.1. Declaring which JMX attributes and operations to mask

On the **org.apache.camel.api.management.ManagedAttribute** and **org.apache.camel.api.management.ManagedOperation**, the attribute **mask** can be set to **true** to indicate that the result of this JMX attribute/operation should be masked (if enabled on JMX agent, see above).

For example, on the default managed endpoints from camel-core **org.apache.camel.api.management.mbean.ManagedEndpointMBean**, we have declared that the **EndpointUri** JMX attribute is masked:

```
@ManagedAttribute(description = "Endpoint URI", mask = true)
String getEndpointUri();
```

CHAPTER 180. JOLT COMPONENT

Available as of Camel version 2.16

The **jolt**: component allows you to process a JSON messages using an **JOLT** specification. This can be ideal when doing JSON to JSON transformation.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-jolt</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

180.1. URI FORMAT

```
jolt:specName[?options]
```

Where **specName** is the classpath-local URI of the specification to invoke; or the complete URL of the remote specification (eg: <file://folder/myfile.json>).

You can append query options to the URI in the following format, **?option=value&option=value&...**

180.2. OPTIONS

The JOLT component supports 4 options, which are listed below.

Name	Description	Default	Type
allowContextMapAll (producer)	Sets whether the context map should allow access to all details. By default only the message body and headers can be accessed. This option can be enabled for full access to the current Exchange and CamelContext. Doing so imposes a potential security risk as this opens access to the full power of CamelContext API.	false	boolean
allowTemplateFromHeader (producer)	Whether to allow to use resource template from header or not (default false). Enabling this option has security ramifications. For example, if the header contains untrusted or user derived content, this can ultimately impact on the confidentiality and integrity of your end application, so use this option with caution.	false	boolean

Name	Description	Default	Type
transform (advanced)	Explicitly sets the Transform to use. If not set a Transform specified by the transformDsl will be created		Transform
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The JOLT endpoint is configured using URI syntax:

```
jolt:resourceUri
```

with the following path and query parameters:

180.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
resourceUri	Required Path to the resource. You can prefix with: classpath, file, http, ref, or bean. classpath, file and http loads the resource using these protocols (classpath is default). ref will lookup the resource in the registry. bean will call a method on a bean to be used as the resource. For bean you can specify the method name after dot, eg bean:myBean.myMethod.		String

180.2.2. Query Parameters (7 parameters):

Name	Description	Default	Type
allowContextMapAll (producer)	Sets whether the context map should allow access to all details. By default only the message body and headers can be accessed. This option can be enabled for full access to the current Exchange and CamelContext. Doing so imposes a potential security risk as this opens access to the full power of CamelContext API.	false	boolean

Name	Description	Default	Type
allowTemplateFromHeader (producer)	Whether to allow to use resource template from header or not (default false). Enabling this option has security ramifications. For example, if the header contains untrusted or user derived content, this can ultimately impact on the confidentiality and integrity of your end application, so use this option with caution.	false	boolean
contentCache (producer)	Sets whether to use resource content cache or not	false	boolean
inputType (producer)	Specifies if the input is hydrated JSON or a JSON String.	Hydrated	JoltInputOutputType
outputType (producer)	Specifies if the output should be hydrated JSON or a JSON String.	Hydrated	JoltInputOutputType
transformDsl (producer)	Specifies the Transform DSL of the endpoint resource. If none is specified Chainr will be used.	Chainr	JoltTransformType
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

180.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 3 options, which are listed below.

Name	Description	Default	Type
camel.component.jolt.enabled	Enable jolt component	true	Boolean
camel.component.jolt.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
camel.component.jolt.transform	Explicitly sets the Transform to use. If not set a Transform specified by the transformDsl will be created. The option is a <code>com.bazaarvoice.jolt.Transform</code> type.		String

180.4. SAMPLES

For example you could use something like

```
from("activemq:My.Queue").  
to("jolt:com/acme/MyResponse.json");
```

And a file based resource:

```
from("activemq:My.Queue").  
to("jolt:file://myfolder/MyResponse.json?contentCache=true").  
to("activemq:Another.Queue");
```

You can also specify what specification the component should use dynamically via a header, so for example:

```
from("direct:in").  
setHeader("CamelJoltResourceUri").constant("path/to/my/spec.json").  
to("jolt:dummy?allowTemplateFromHeader=true");
```

WARNING

Enabling the **allowTemplateFromHeader** option has security ramifications. For example, if the header contains untrusted or user derived content, this can ultimately impact on the confidentiality and integrity of your end application, so use this option with caution.

- [Endpoint](#)
- [Getting Started](#)

CHAPTER 181. JPA COMPONENT

Available as of Camel version 1.0

The **jpa** component enables you to store and retrieve Java objects from persistent storage using EJB 3's Java Persistence Architecture (JPA), which is a standard interface layer that wraps Object/Relational Mapping (ORM) products such as OpenJPA, Hibernate, TopLink, and so on.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-jpa</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

181.1. SENDING TO THE ENDPOINT

You can store a Java entity bean in a database by sending it to a JPA producer endpoint. The body of the *In* message is assumed to be an entity bean (that is, a POJO with an `@Entity` annotation on it) or a collection or array of entity beans.

If the body is a List of entities, make sure to use **entityType=java.util.ArrayList** as a configuration passed to the producer endpoint.

If the body does not contain one of the previous listed types, put a Message Translator in front of the endpoint to perform the necessary conversion first.

From **Camel 2.19** onwards you can use **query**, **namedQuery** or **nativeQuery** for the producer as well. Also in the value of the **parameters**, you can use Simple expression which allows you to retrieve parameter values from Message body, header and etc. Those query can be used for retrieving a set of data with using **SELECT** JPQL/SQL statement as well as executing bulk update/delete with using **UPDATE/DELETE** JPQL/SQL statement. Please note that you need to specify **useExecuteUpdate** to **true** if you execute **UPDATE/DELETE** with **namedQuery** as camel don't look into the named query unlike **query** and **nativeQuery**.

181.2. CONSUMING FROM THE ENDPOINT

Consuming messages from a JPA consumer endpoint removes (or updates) entity beans in the database. This allows you to use a database table as a logical queue: consumers take messages from the queue and then delete/update them to logically remove them from the queue.

If you do not wish to delete the entity bean when it has been processed (and when routing is done), you can specify **consumeDelete=false** on the URI. This will result in the entity being processed each poll.

If you would rather perform some update on the entity to mark it as processed (such as to exclude it from a future query) then you can annotate a method with `@Consumed` which will be invoked on your entity bean when the entity bean when it has been processed (and when routing is done).

From **Camel 2.13** onwards you can use `@PreConsumed` which will be invoked on your entity bean before it has been processed (before routing).

If you are consuming a lot (100K+) of rows and experience OutOfMemory problems you should set the `maximumResults` to sensible value.

181.3. URI FORMAT

```
jpa:entityClassName[?options]
```

For sending to the endpoint, the *entityClassName* is optional. If specified, it helps the [Type Converter](#) to ensure the body is of the correct type.

For consuming, the *entityClassName* is mandatory.

You can append query options to the URI in the following format, **?option=value&option=value&...**

181.4. OPTIONS

The JPA component supports 5 options, which are listed below.

Name	Description	Default	Type
entityManagerFactory (common)	To use the EntityManagerFactory. This is strongly recommended to configure.		EntityManagerFactory
transactionManager (common)	To use the PlatformTransactionManager for managing transactions.		PlatformTransactionManager
joinTransaction (common)	The camel-jpa component will join transaction by default. You can use this option to turn this off, for example if you use LOCAL_RESOURCE and join transaction doesn't work with your JPA provider. This option can also be set globally on the JpaComponent, instead of having to set it on all endpoints.	true	boolean
sharedEntityManager (common)	Whether to use Spring's SharedEntityManager for the consumer/producer. Note in most cases joinTransaction should be set to false as this is not an EXTENDED EntityManager.	false	boolean
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The JPA endpoint is configured using URI syntax:

```
jpa:entityType
```

with the following path and query parameters:

181.4.1. Path Parameters (1 parameters):

Name	Description	Default	Type
entityType	Required The JPA annotated class to use as entity.		Class

181.4.2. Query Parameters (42 parameters):

Name	Description	Default	Type
joinTransaction (common)	The camel-jpa component will join transaction by default. You can use this option to turn this off, for example if you use LOCAL_RESOURCE and join transaction doesn't work with your JPA provider. This option can also be set globally on the JpaComponent, instead of having to set it on all endpoints.	true	boolean
maximumResults (common)	Set the maximum number of results to retrieve on the Query.	-1	int
namedQuery (common)	To use a named query.		String
nativeQuery (common)	To use a custom native query. You may want to use the option resultClass also when using native queries.		String
parameters (common)	This key/value mapping is used for building the query parameters. It is expected to be of the generic type java.util.Map where the keys are the named parameters of a given JPA query and the values are their corresponding effective values you want to select for. When it's used for producer, Simple expression can be used as a parameter value. It allows you to retrieve parameter values from the message body, header and etc.		Map
persistenceUnit (common)	Required The JPA persistence unit used by default.	camel	String
query (common)	To use a custom query.		String
resultClass (common)	Defines the type of the returned payload (we will call entityManager.createNativeQuery(nativeQuery, resultClass) instead of entityManager.createNativeQuery(nativeQuery)). Without this option, we will return an object array. Only has an affect when using in conjunction with native query when consuming data.		Class

Name	Description	Default	Type
sharedEntityManager (common)	Whether to use Spring's SharedEntityManager for the consumer/producer. Note in most cases joinTransaction should be set to false as this is not an EXTENDED EntityManager.	false	boolean
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
consumeDelete (consumer)	If true, the entity is deleted after it is consumed; if false, the entity is not deleted.	true	boolean
consumeLockEntity (consumer)	Specifies whether or not to set an exclusive lock on each entity bean while processing the results from polling.	true	boolean
deleteHandler (consumer)	To use a custom DeleteHandler to delete the row after the consumer is done processing the exchange		DeleteHandler
lockModeType (consumer)	To configure the lock mode on the consumer.	PESSIMISTIC_WRITE	LockModeType
maxMessagesPerPoll (consumer)	An integer value to define the maximum number of messages to gather per poll. By default, no maximum is set. Can be used to avoid polling many thousands of messages when starting up the server. Set a value of 0 or negative to disable.		int
preDeleteHandler (consumer)	To use a custom Pre-DeleteHandler to delete the row after the consumer has read the entity.		DeleteHandler
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean
skipLockedEntity (consumer)	To configure whether to use NOWAIT on lock and silently skip the entity.	false	boolean

Name	Description	Default	Type
transacted (consumer)	Whether to run the consumer in transacted mode, by which all messages will either commit or rollback, when the entire batch has been processed. The default behavior (false) is to commit all the previously successfully processed messages, and only rollback the last failed message.	false	boolean
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
pollStrategy (consumer)	A pluggable org.apache.camel.PollingConsumerPollingStrategy allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		PollingConsumerPollStrategy
flushOnSend (producer)	Flushes the EntityManager after the entity bean has been persisted.	true	boolean
remove (producer)	Indicates to use entityManager.remove(entity).	false	boolean
useExecuteUpdate (producer)	To configure whether to use executeUpdate() when producer executes a query. When you use INSERT, UPDATE or DELETE statement as a named query, you need to specify this option to 'true'.		Boolean
usePassedInEntityManager (producer)	If set to true, then Camel will use the EntityManager from the header JpaConstants.ENTITY_MANAGER instead of the configured entity manager on the component/endpoint. This allows end users to control which entity manager will be in use.	false	boolean
usePersist (producer)	Indicates to use entityManager.persist(entity) instead of entityManager.merge(entity). Note: entityManager.persist(entity) doesn't work for detached entities (where the EntityManager has to execute an UPDATE instead of an INSERT query)!	false	boolean

Name	Description	Default	Type
entityManagerProperties (advanced)	Additional properties for the entity manager to use.		Map
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.		int
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.		int
delay (scheduler)	Milliseconds before the next poll. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	500	long
greedy (scheduler)	If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	1000	long
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that.	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz2 component	none	ScheduledPollConsumer Scheduler

Name	Description	Default	Type
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz2, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for initialDelay and delay options.	MILLIS ECON DS	TimeUnit
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.	true	boolean

181.5. SPRING BOOT AUTO-CONFIGURATION

The component supports 6 options, which are listed below.

Name	Description	Default	Type
camel.component.jpa.enabled	Enable jpa component	true	Boolean
camel.component.jpa.entity-manager-factory	To use the EntityManagerFactory. This is strongly recommended to configure. The option is a javax.persistence.EntityManagerFactory type.		String
camel.component.jpa.join-transaction	The camel-jpa component will join transaction by default. You can use this option to turn this off, for example if you use LOCAL_RESOURCE and join transaction doesn't work with your JPA provider. This option can also be set globally on the JpaComponent, instead of having to set it on all endpoints.	true	Boolean
camel.component.jpa.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
camel.component.jpa.shared-entity-manager	Whether to use Spring's SharedEntityManager for the consumer/producer. Note in most cases joinTransaction should be set to false as this is not an EXTENDED EntityManager.	false	Boolean

Name	Description	Default	Type
<code>camel.component.jpa.transaction-manager</code>	To use the PlatformTransactionManager for managing transactions. The option is a <code>org.springframework.transaction.PlatformTransactionManager</code> type.		String

181.6. MESSAGE HEADERS

Camel adds the following message headers to the exchange:

Header	Type	Description
Camel JpaTemplate	JpaTemplate	Not supported anymore since Camel 2.12: The JpaTemplate object that is used to access the entity bean. You need this object in some situations, for instance in a type converter or when you are doing some custom processing. See CAMEL-5932 for the reason why the support for this header has been dropped.
Camel EntityManager	EntityManager	Camel 2.12: JPA consumer / Camel 2.12.2: JPA producer: The JPA EntityManager object being used by JpaConsumer or JpaProducer .
Camel JpaParameters	Map<String, Object>	Camel 2.23: JPA producer: Alternative way for passing query parameters as an Exchange header.

181.7. CONFIGURING ENTITYMANAGERFACTORY

Its strongly advised to configure the JPA component to use a specific **EntityManagerFactory** instance. If failed to do so each **JpaEndpoint** will auto create their own instance of **EntityManagerFactory** which most often is not what you want.

For example, you can instantiate a JPA component that references the **myEMFactory** entity manager factory, as follows:

```
<bean id="jpa" class="org.apache.camel.component.jpa.JpaComponent">
  <property name="entityManagerFactory" ref="myEMFactory"/>
</bean>
```

In **Camel 2.3** the **JpaComponent** will auto lookup the **EntityManagerFactory** from the Registry which means you do not need to configure this on the **JpaComponent** as shown above. You only need to do so if there is ambiguity, in which case Camel will log a WARN.

181.8. CONFIGURING TRANSACTIONMANAGER

Since **Camel 2.3** the **JpaComponent** will auto lookup the **TransactionManager** from the Registry. If Camel won't find any **TransactionManager** instance registered, it will also look up for the **TransactionTemplate** and try to extract **TransactionManager** from it.

If none **TransactionTemplate** is available in the registry, **JpaEndpoint** will auto create their own instance of **TransactionManager** which most often is not what you want.

If more than single instance of the **TransactionManager** is found, Camel will log a WARN. In such cases you might want to instantiate and explicitly configure a JPA component that references the **myTransactionManager** transaction manager, as follows:

```
<bean id="jpa" class="org.apache.camel.component.jpa.JpaComponent">
  <property name="entityManagerFactory" ref="myEMFactory"/>
  <property name="transactionManager" ref="myTransactionManager"/>
</bean>
```

181.9. USING A CONSUMER WITH A NAMED QUERY

For consuming only selected entities, you can use the **consumer.namedQuery** URI query option. First, you have to define the named query in the JPA Entity class:

```
@Entity
@NamedQuery(name = "step1", query = "select x from MultiSteps x where x.step = 1")
public class MultiSteps {
  ...
}
```

After that you can define a consumer uri like this one:

```
from("jpa://org.apache.camel.examples.MultiSteps?consumer.namedQuery=step1")
.to("bean:myBusinessLogic");
```

181.10. USING A CONSUMER WITH A QUERY

For consuming only selected entities, you can use the **consumer.query** URI query option. You only have to define the query option:

```
from("jpa://org.apache.camel.examples.MultiSteps?consumer.query=select o from
org.apache.camel.examples.MultiSteps o where o.step = 1")
.to("bean:myBusinessLogic");
```

181.11. USING A CONSUMER WITH A NATIVE QUERY

For consuming only selected entities, you can use the **consumer.nativeQuery** URI query option. You only have to define the native query option:

```
from("jpa://org.apache.camel.examples.MultiSteps?consumer.nativeQuery=select * from MultiSteps
where step = 1")
.to("bean:myBusinessLogic");
```

If you use the native query option, you will receive an object array in the message body.

181.12. USING A PRODUCER WITH A NAMED QUERY

For retrieving selected entities or execute bulk update/delete, you can use the **namedQuery** URI query option. First, you have to define the named query in the JPA Entity class:

```
@Entity
@NamedQuery(name = "step1", query = "select x from MultiSteps x where x.step = 1")
public class MultiSteps {
    ...
}
```

After that you can define a producer uri like this one:

```
from("direct:namedQuery")
.to("jpa://org.apache.camel.examples.MultiSteps?namedQuery=step1");
```

Note that you need to specify **useExecuteUpdate** option to **true** to execute **UPDATE/DELETE** statement as a named query.

181.13. USING A PRODUCER WITH A QUERY

For retrieving selected entities or execute bulk update/delete, you can use the **query** URI query option. You only have to define the query option:

```
from("direct:query")
.to("jpa://org.apache.camel.examples.MultiSteps?query=select o from
org.apache.camel.examples.MultiSteps o where o.step = 1");
```

181.14. USING A PRODUCER WITH A NATIVE QUERY

For retrieving selected entities or execute bulk update/delete, you can use the **nativeQuery** URI query option. You only have to define the native query option:

```
from("direct:nativeQuery")
.to("jpa://org.apache.camel.examples.MultiSteps?
resultClass=org.apache.camel.examples.MultiSteps&nativeQuery=select * from MultiSteps where
step = 1");
```

If you use the native query option without specifying **resultClass**, you will receive an object array in the message body.

181.15. EXAMPLE

See [Tracer Example](#) for an example using [JPA](#) to store traced messages into a database.

181.16. USING THE JPA-BASED IDEMPOTENT REPOSITORY

The Idempotent Consumer from the [EIP patterns](#) is used to filter out duplicate messages. A JPA-based idempotent repository is provided.

To use the JPA based idempotent repository.

Procedure

1. Set up a **persistence-unit** in the persistence.xml file:
2. Set up a **org.springframework.orm.jpa.JpaTemplate** which is used by the **org.apache.camel.processor.idempotent.jpa.JpaMessageIdRepository**:
3. Configure the error formatting macro: snippet: java.lang.IndexOutOfBoundsException: Index: 20, Size: 20
4. Configure the idempotent repository:
org.apache.camel.processor.idempotent.jpa.JpaMessageIdRepository:
5. Create the JPA idempotent repository in the Spring XML file:

```
<camelContext xmlns="http://camel.apache.org/schema/spring">
  <route id="JpaMessageIdRepositoryTest">
    <from uri="direct:start" />
    <idempotentConsumer messageIdRepositoryRef="jpaStore">
      <header>messageId</header>
      <to uri="mock:result" />
    </idempotentConsumer>
  </route>
</camelContext>
```

When running this Camel component tests inside your IDE

If you run the [tests of this component](#) directly inside your IDE, and not through Maven, then you could see exceptions like these:

```
org.springframework.transaction.CannotCreateTransactionException: Could not open JPA
EntityManager for transaction; nested exception is
<openjpa-2.2.1-r422266:1396819 nonfatal user error>
org.apache.openjpa.persistence.ArgumentException: This configuration disallows runtime
optimization,
but the following listed types were not enhanced at build time or at class load time with a javaagent:
"org.apache.camel.examples.SendEmail".
    at
org.springframework.orm.jpa.JpaTransactionManager.doBegin(JpaTransactionManager.java:427)
    at
org.springframework.transaction.support.AbstractPlatformTransactionManager.getTransaction(AbstractPlatformTransactionManager.java:371)
    at
org.springframework.transaction.support.TransactionTemplate.execute(TransactionTemplate.java:127)
    at org.apache.camel.processor.jpa.JpaRouteTest.cleanupRepository(JpaRouteTest.java:96)
    at org.apache.camel.processor.jpa.JpaRouteTest.createCamelContext(JpaRouteTest.java:67)
    at org.apache.camel.test.junit4.CamelTestSupport.doSetUp(CamelTestSupport.java:238)
    at org.apache.camel.test.junit4.CamelTestSupport.setUp(CamelTestSupport.java:208)
```

The problem here is that the source has been compiled or recompiled through your IDE and not through Maven, which would [enhance the byte-code at build time](#). To overcome this you need to enable [dynamic byte-code enhancement of OpenJPA](#). For example, assuming the current OpenJPA version being used in Camel is 2.2.1, to run the tests inside your IDE you would need to pass the following argument to the JVM:

`-javaagent:<path_to_your_local_m2_cache>/org/apache/openjpa/openjpa/2.2.1/openjpa-2.2.1.jar`

CHAPTER 182. JSON FASTJSON DATAFORMAT

Available as of Camel version 2.20

Fastjson is a Data Format which uses the [Fastjson Library](#)

```
from("activemq:My.Queue").
  marshal().json(JsonLibrary.Fastjson).
  to("mqseries:Another.Queue");
```

182.1. FASTJSON OPTIONS

The JSon Fastjson dataformat supports 19 options, which are listed below.

Name	Default	Java Type	Description
objectMapper		String	Lookup and use the existing ObjectMapper with the given id when using Jackson.
useDefaultObject Mapper	true	Boole an	Whether to lookup and use default Jackson ObjectMapper from the registry.
prettyPrint	false	Boole an	To enable pretty printing output nicely formatted. Is by default false.
library	XStrea m	JsonL ibrary	Which json library to use.
unmarshalTypeNa me		String	Class name of the java type to use when unarmshalling
jsonView		Class	When marshalling a POJO to JSON you might want to exclude certain fields from the JSON output. With Jackson you can use JSON views to accomplish this. This option is to refer to the class which has JsonView annotations
include		String	If you want to marshal a pojo to JSON, and the pojo has some fields with null values. And you want to skip these null values, you can set this option to NON_NULL
allowJmsType	false	Boole an	Used for JMS users to allow the JMSType header from the JMS spec to specify a FQN classname to use to unmarshal to.
collectionTypeNa me		String	Refers to a custom collection type to lookup in the registry to use. This option should rarely be used, but allows to use different collection types than java.util.Collection based as default.
useList	false	Boole an	To unarmshal to a List of Map or a List of Pojo.

Name	Default	Java Type	Description
<code>enableJaxbAnnotationModule</code>	false	Boolean	Whether to enable the JAXB annotations module when using Jackson. When enabled then JAXB annotations can be used by Jackson.
<code>moduleClassNames</code>		String	To use custom Jackson modules <code>com.fasterxml.jackson.databind.Module</code> specified as a String with FQN class names. Multiple classes can be separated by comma.
<code>moduleRefs</code>		String	To use custom Jackson modules referred from the Camel registry. Multiple modules can be separated by comma.
<code>enableFeatures</code>		String	Set of features to enable on the Jackson <code>com.fasterxml.jackson.databind.ObjectMapper</code> . The features should be a name that matches a enum from <code>com.fasterxml.jackson.databind.SerializationFeature</code> , <code>com.fasterxml.jackson.databind.DeserializationFeature</code> , or <code>com.fasterxml.jackson.databind.MapperFeature</code> Multiple features can be separated by comma
<code>disableFeatures</code>		String	Set of features to disable on the Jackson <code>com.fasterxml.jackson.databind.ObjectMapper</code> . The features should be a name that matches a enum from <code>com.fasterxml.jackson.databind.SerializationFeature</code> , <code>com.fasterxml.jackson.databind.DeserializationFeature</code> , or <code>com.fasterxml.jackson.databind.MapperFeature</code> Multiple features can be separated by comma
<code>permissions</code>		String	Adds permissions that controls which Java packages and classes XStream is allowed to use during unmarshal from xml/json to Java beans. A permission must be configured either here or globally using a JVM system property. The permission can be specified in a syntax where a plus sign is allow, and minus sign is deny. Wildcards is supported by using <code>.</code> as prefix. For example to allow <code>com.foo</code> and all subpackages then specify <code>com.foo..</code> Multiple permissions can be configured separated by comma, such as <code>com.foo.,-com.foo.bar.MySecretBean</code> . The following default permission is always included: <code>-java.lang.,java.util.</code> unless its overridden by specifying a JVM system property with they key <code>org.apache.camel.xstream.permissions</code> .
<code>allowUnmarshalType</code>	false	Boolean	If enabled then Jackson is allowed to attempt to use the <code>CamelJacksonUnmarshalType</code> header during the unmarshalling. This should only be enabled when desired to be used.
<code>timezone</code>		String	If set then Jackson will use the Timezone when marshalling/unmarshalling. This option will have no effect on the others Json DataFormat, like gson, fastjson and xstream.

Name	Default	Java Type	Description
<code>contentTypeHeader</code>	false	Boolean	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example <code>application/xml</code> for data formats marshalling to XML, or <code>application/json</code> for data formats marshalling to JSON etc.

182.2. SPRING BOOT AUTO-CONFIGURATION

The component supports 20 options, which are listed below.

Name	Description	Default	Type
<code>camel.dataformat.json-fastjson.allow-jms-type</code>	Used for JMS users to allow the <code>JMSType</code> header from the JMS spec to specify a FQN classname to use to unmarshal to.	false	Boolean
<code>camel.dataformat.json-fastjson.allow-unmarshall-type</code>	If enabled then Jackson is allowed to attempt to use the <code>CamelJacksonUnmarshalType</code> header during the unmarshalling. This should only be enabled when desired to be used.	false	Boolean
<code>camel.dataformat.json-fastjson.collection-type-name</code>	Refers to a custom collection type to lookup in the registry to use. This option should rarely be used, but allows to use different collection types than <code>java.util.Collection</code> based as default.		String
<code>camel.dataformat.json-fastjson.content-type-header</code>	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example <code>application/xml</code> for data formats marshalling to XML, or <code>application/json</code> for data formats marshalling to JSON etc.	false	Boolean
<code>camel.dataformat.json-fastjson.disable-features</code>	Set of features to disable on the Jackson <code>com.fasterxml.jackson.databind.ObjectMapper</code> . The features should be a name that matches an enum from <code>com.fasterxml.jackson.databind.SerializationFeature</code> , <code>com.fasterxml.jackson.databind.DeserializationFeature</code> , or <code>com.fasterxml.jackson.databind.MapperFeature</code> . Multiple features can be separated by comma.		String

Name	Description	Default	Type
<code>camel.dataformat.json-fastjson.enable-features</code>	Set of features to enable on the Jackson <code>com.fasterxml.jackson.databind.ObjectMapper</code> . The features should be a name that matches a enum from <code>com.fasterxml.jackson.databind.SerializationFeature</code> , <code>com.fasterxml.jackson.databind.DeserializationFeature</code> , or <code>com.fasterxml.jackson.databind.MapperFeature</code> . Multiple features can be separated by comma		String
<code>camel.dataformat.json-fastjson.enable-jaxb-annotation-module</code>	Whether to enable the JAXB annotations module when using jackson. When enabled then JAXB annotations can be used by Jackson.	false	Boolean
<code>camel.dataformat.json-fastjson.enabled</code>	Whether to enable auto configuration of the json-fastjson data format. This is enabled by default.		Boolean
<code>camel.dataformat.json-fastjson.include</code>	If you want to marshal a pojo to JSON, and the pojo has some fields with null values. And you want to skip these null values, you can set this option to <code>NON_NULL</code>		String
<code>camel.dataformat.json-fastjson.json-view</code>	When marshalling a POJO to JSON you might want to exclude certain fields from the JSON output. With Jackson you can use JSON views to accomplish this. This option is to refer to the class which has <code>JsonView</code> annotations		Class
<code>camel.dataformat.json-fastjson.library</code>	Which json library to use.		JsonLibrary
<code>camel.dataformat.json-fastjson.module-class-names</code>	To use custom Jackson modules <code>com.fasterxml.jackson.databind.Module</code> specified as a String with FQN class names. Multiple classes can be separated by comma.		String
<code>camel.dataformat.json-fastjson.module-refs</code>	To use custom Jackson modules referred from the Camel registry. Multiple modules can be separated by comma.		String
<code>camel.dataformat.json-fastjson.object-mapper</code>	Lookup and use the existing <code>ObjectMapper</code> with the given id when using Jackson.		String

Name	Description	Default	Type
<code>camel.dataformat.json-fastjson.permissions</code>	Adds permissions that controls which Java packages and classes XStream is allowed to use during unmarshal from xml/json to Java beans. A permission must be configured either here or globally using a JVM system property. The permission can be specified in a syntax where a plus sign is allow, and minus sign is deny. Wildcards is supported by using . as prefix. For example to allow com.foo and all subpackages then specify com.foo.. Multiple permissions can be configured separated by comma, such as com.foo.,-com.foo.bar.MySecretBean. The following default permission is always included: - ,java.lang,java.util. unless its overridden by specifying a JVM system property with they key org.apache.camel.xstream.permissions.		String
<code>camel.dataformat.json-fastjson.pretty-print</code>	To enable pretty printing output nicely formatted. Is by default false.	false	Boolean
<code>camel.dataformat.json-fastjson.timezone</code>	If set then Jackson will use the Timezone when marshalling/unmarshalling. This option will have no effect on the others Json DataFormat, like gson, fastjson and xstream.		String
<code>camel.dataformat.json-fastjson.unmarshal-type-name</code>	Class name of the java type to use when unarmshalling		String
<code>camel.dataformat.json-fastjson.use-default-object-mapper</code>	Whether to lookup and use default Jackson ObjectMapper from the registry.	true	Boolean
<code>camel.dataformat.json-fastjson.use-list</code>	To unarmshal to a List of Map or a List of Pojo.	false	Boolean

182.3. DEPENDENCIES

To use Fastjson in your camel routes you need to add the dependency on **camel-fastjson** which implements this data format.

If you use maven you could just add the following to your pom.xml, substituting the version number for the latest & greatest release (see the download page for the latest versions).

```
<dependency>  
  <groupId>org.apache.camel</groupId>  
  <artifactId>camel-fastjson</artifactId>  
  <version>x.x.x</version>  
  <!-- use the same version as your Camel core version -->  
</dependency>
```

CHAPTER 183. JSON GSON DATAFORMAT

Available as of Camel version 2.10

Gson is a Data Format which uses the [Gson Library](#)

```
from("activemq:My.Queue").
  marshal().json(JsonLibrary.Gson).
  to("mqseries:Another.Queue");
```

183.1. GSON OPTIONS

The JSon GSon dataformat supports 19 options, which are listed below.

Name	Default	Java Type	Description
objectMapper		String	Lookup and use the existing ObjectMapper with the given id when using Jackson.
useDefaultObject Mapper	true	Boole an	Whether to lookup and use default Jackson ObjectMapper from the registry.
prettyPrint	false	Boole an	To enable pretty printing output nicely formatted. Is by default false.
library	XStrea m	JsonL ibrary	Which json library to use.
unmarshalTypeNa me		String	Class name of the java type to use when unarmshalling
jsonView		Class	When marshalling a POJO to JSON you might want to exclude certain fields from the JSON output. With Jackson you can use JSON views to accomplish this. This option is to refer to the class which has JsonView annotations
include		String	If you want to marshal a pojo to JSON, and the pojo has some fields with null values. And you want to skip these null values, you can set this option to NON_NULL
allowJmsType	false	Boole an	Used for JMS users to allow the JMSType header from the JMS spec to specify a FQN classname to use to unmarshal to.
collectionTypeNa me		String	Refers to a custom collection type to lookup in the registry to use. This option should rarely be used, but allows to use different collection types than java.util.Collection based as default.
useList	false	Boole an	To unarmshal to a List of Map or a List of Pojo.

Name	Default	Java Type	Description
<code>enableJaxbAnnotationModule</code>	false	Boolean	Whether to enable the JAXB annotations module when using Jackson. When enabled then JAXB annotations can be used by Jackson.
<code>moduleClassNames</code>		String	To use custom Jackson modules <code>com.fasterxml.jackson.databind.Module</code> specified as a String with FQN class names. Multiple classes can be separated by comma.
<code>moduleRefs</code>		String	To use custom Jackson modules referred from the Camel registry. Multiple modules can be separated by comma.
<code>enableFeatures</code>		String	Set of features to enable on the Jackson <code>com.fasterxml.jackson.databind.ObjectMapper</code> . The features should be a name that matches a enum from <code>com.fasterxml.jackson.databind.SerializationFeature</code> , <code>com.fasterxml.jackson.databind.DeserializationFeature</code> , or <code>com.fasterxml.jackson.databind.MapperFeature</code> Multiple features can be separated by comma
<code>disableFeatures</code>		String	Set of features to disable on the Jackson <code>com.fasterxml.jackson.databind.ObjectMapper</code> . The features should be a name that matches a enum from <code>com.fasterxml.jackson.databind.SerializationFeature</code> , <code>com.fasterxml.jackson.databind.DeserializationFeature</code> , or <code>com.fasterxml.jackson.databind.MapperFeature</code> Multiple features can be separated by comma
<code>permissions</code>		String	Adds permissions that controls which Java packages and classes XStream is allowed to use during unmarshal from xml/json to Java beans. A permission must be configured either here or globally using a JVM system property. The permission can be specified in a syntax where a plus sign is allow, and minus sign is deny. Wildcards is supported by using <code>.</code> as prefix. For example to allow <code>com.foo</code> and all subpackages then specify <code>com.foo..</code> Multiple permissions can be configured separated by comma, such as <code>com.foo.,-com.foo.bar.MySecretBean</code> . The following default permission is always included: <code>-java.lang.,java.util.</code> unless its overridden by specifying a JVM system property with they key <code>org.apache.camel.xstream.permissions</code> .
<code>allowUnmarshalType</code>	false	Boolean	If enabled then Jackson is allowed to attempt to use the <code>CamelJacksonUnmarshalType</code> header during the unmarshalling. This should only be enabled when desired to be used.
<code>timezone</code>		String	If set then Jackson will use the Timezone when marshalling/unmarshalling. This option will have no effect on the others Json DataFormat, like gson, fastjson and xstream.

Name	Default	Java Type	Description
<code>contentTypeHeader</code>	false	Boolean	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example <code>application/xml</code> for data formats marshalling to XML, or <code>application/json</code> for data formats marshalling to JSon etc.

183.2. SPRING BOOT AUTO-CONFIGURATION

The component supports 20 options, which are listed below.

Name	Description	Default	Type
<code>camel.dataformat.json-gson.allow-jms-type</code>	Used for JMS users to allow the <code>JMSType</code> header from the JMS spec to specify a FQN classname to use to unmarshal to.	false	Boolean
<code>camel.dataformat.json-gson.allow-unmarshall-type</code>	If enabled then Jackson is allowed to attempt to use the <code>CamelJacksonUnmarshalType</code> header during the unmarshalling. This should only be enabled when desired to be used.	false	Boolean
<code>camel.dataformat.json-gson.collection-type-name</code>	Refers to a custom collection type to lookup in the registry to use. This option should rarely be used, but allows to use different collection types than <code>java.util.Collection</code> based as default.		String
<code>camel.dataformat.json-gson.content-type-header</code>	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example <code>application/xml</code> for data formats marshalling to XML, or <code>application/json</code> for data formats marshalling to JSon etc.	false	Boolean
<code>camel.dataformat.json-gson.disable-features</code>	Set of features to disable on the Jackson <code>com.fasterxml.jackson.databind.ObjectMapper</code> . The features should be a name that matches a enum from <code>com.fasterxml.jackson.databind.SerializationFeature</code> , <code>com.fasterxml.jackson.databind.DeserializationFeature</code> , or <code>com.fasterxml.jackson.databind.MapperFeature</code> . Multiple features can be separated by comma		String

Name	Description	Default	Type
<code>camel.dataformat.json-gson.enable-features</code>	Set of features to enable on the Jackson <code>com.fasterxml.jackson.databind.ObjectMapper</code> . The features should be a name that matches a enum from <code>com.fasterxml.jackson.databind.SerializationFeature</code> , <code>com.fasterxml.jackson.databind.DeserializationFeature</code> , or <code>com.fasterxml.jackson.databind.MapperFeature</code> . Multiple features can be separated by comma		String
<code>camel.dataformat.json-gson.enable-jaxb-annotation-module</code>	Whether to enable the JAXB annotations module when using jackson. When enabled then JAXB annotations can be used by Jackson.	false	Boolean
<code>camel.dataformat.json-gson.enabled</code>	Enable json-gson dataformat	true	Boolean
<code>camel.dataformat.json-gson.include</code>	If you want to marshal a pojo to JSON, and the pojo has some fields with null values. And you want to skip these null values, you can set this option to <code>NON_NULL</code>		String
<code>camel.dataformat.json-gson.json-view</code>	When marshalling a POJO to JSON you might want to exclude certain fields from the JSON output. With Jackson you can use JSON views to accomplish this. This option is to refer to the class which has <code>JsonView</code> annotations		Class
<code>camel.dataformat.json-gson.library</code>	Which json library to use.		JsonLibrary
<code>camel.dataformat.json-gson.module-class-names</code>	To use custom Jackson modules <code>com.fasterxml.jackson.databind.Module</code> specified as a String with FQN class names. Multiple classes can be separated by comma.		String
<code>camel.dataformat.json-gson.module-refs</code>	To use custom Jackson modules referred from the Camel registry. Multiple modules can be separated by comma.		String
<code>camel.dataformat.json-gson.object-mapper</code>	Lookup and use the existing <code>ObjectMapper</code> with the given id when using Jackson.		String

Name	Description	Default	Type
<code>camel.dataformat.json-gson.permissions</code>	Adds permissions that controls which Java packages and classes XStream is allowed to use during unmarshal from xml/json to Java beans. A permission must be configured either here or globally using a JVM system property. The permission can be specified in a syntax where a plus sign is allow, and minus sign is deny. Wildcards is supported by using . as prefix. For example to allow com.foo and all subpackages then specify com.foo.. Multiple permissions can be configured separated by comma, such as com.foo.,-com.foo.bar.MySecretBean. The following default permission is always included: - ,java.lang,java.util. unless its overridden by specifying a JVM system property with they key org.apache.camel.xstream.permissions.		String
<code>camel.dataformat.json-gson.pretty-print</code>	To enable pretty printing output nicely formatted. Is by default false.	false	Boolean
<code>camel.dataformat.json-gson.timezone</code>	If set then Jackson will use the Timezone when marshalling/unmarshalling. This option will have no effect on the others Json DataFormat, like gson, fastjson and xstream.		String
<code>camel.dataformat.json-gson.unmarshal-type-name</code>	Class name of the java type to use when unarmshalling		String
<code>camel.dataformat.json-gson.use-default-object-mapper</code>	Whether to lookup and use default Jackson ObjectMapper from the registry.	true	Boolean
<code>camel.dataformat.json-gson.use-list</code>	To unarmshal to a List of Map or a List of Pojo.	false	Boolean

183.3. DEPENDENCIES

To use Gson in your camel routes you need to add the dependency on **camel-gson** which implements this data format.

If you use maven you could just add the following to your pom.xml, substituting the version number for the latest & greatest release (see the download page for the latest versions).

```
<dependency>  
  <groupId>org.apache.camel</groupId>  
  <artifactId>camel-gson</artifactId>  
  <version>x.x.x</version>  
  <!-- use the same version as your Camel core version -->  
</dependency>
```

CHAPTER 184. JSON JACKSON DATAFORMAT

Available as of Camel version 2.0

Jackson is a Data Format which uses the [Jackson Library](#)

```
from("activemq:My.Queue").
  marshal().json(JsonLibrary.Jackson).
  to("mqseries:Another.Queue");
```

184.1. JACKSON OPTIONS

The JSon Jackson dataformat supports 19 options, which are listed below.

Name	Default	Java Type	Description
objectMapper		String	Lookup and use the existing ObjectMapper with the given id when using Jackson.
useDefaultObjectMapper	true	Boolean	Whether to lookup and use default Jackson ObjectMapper from the registry.
prettyPrint	false	Boolean	To enable pretty printing output nicely formatted. Is by default false.
library	XStream	JsonLibrary	Which json library to use.
unmarshalTypeName		String	Class name of the java type to use when unmarshalling
jsonView		Class	When marshalling a POJO to JSON you might want to exclude certain fields from the JSON output. With Jackson you can use JSON views to accomplish this. This option is to refer to the class which has JsonView annotations
include		String	If you want to marshal a pojo to JSON, and the pojo has some fields with null values. And you want to skip these null values, you can set this option to NON_NULL
allowJmsType	false	Boolean	Used for JMS users to allow the JMSType header from the JMS spec to specify a FQN classname to use to unmarshal to.
collectionTypeName		String	Refers to a custom collection type to lookup in the registry to use. This option should rarely be used, but allows to use different collection types than java.util.Collection based as default.
useList	false	Boolean	To unarmshal to a List of Map or a List of Pojo.

Name	Default	Java Type	Description
<code>enableJaxbAnnotationModule</code>	false	Boolean	Whether to enable the JAXB annotations module when using Jackson. When enabled then JAXB annotations can be used by Jackson.
<code>moduleClassNames</code>		String	To use custom Jackson modules <code>com.fasterxml.jackson.databind.Module</code> specified as a String with FQN class names. Multiple classes can be separated by comma.
<code>moduleRefs</code>		String	To use custom Jackson modules referred from the Camel registry. Multiple modules can be separated by comma.
<code>enableFeatures</code>		String	Set of features to enable on the Jackson <code>com.fasterxml.jackson.databind.ObjectMapper</code> . The features should be a name that matches a enum from <code>com.fasterxml.jackson.databind.SerializationFeature</code> , <code>com.fasterxml.jackson.databind.DeserializationFeature</code> , or <code>com.fasterxml.jackson.databind.MapperFeature</code> Multiple features can be separated by comma
<code>disableFeatures</code>		String	Set of features to disable on the Jackson <code>com.fasterxml.jackson.databind.ObjectMapper</code> . The features should be a name that matches a enum from <code>com.fasterxml.jackson.databind.SerializationFeature</code> , <code>com.fasterxml.jackson.databind.DeserializationFeature</code> , or <code>com.fasterxml.jackson.databind.MapperFeature</code> Multiple features can be separated by comma
<code>permissions</code>		String	Adds permissions that controls which Java packages and classes XStream is allowed to use during unmarshal from xml/json to Java beans. A permission must be configured either here or globally using a JVM system property. The permission can be specified in a syntax where a plus sign is allow, and minus sign is deny. Wildcards is supported by using <code>.</code> as prefix. For example to allow <code>com.foo</code> and all subpackages then specify <code>com.foo..</code> Multiple permissions can be configured separated by comma, such as <code>com.foo.,-com.foo.bar.MySecretBean</code> . The following default permission is always included: <code>-java.lang.,java.util.</code> unless its overridden by specifying a JVM system property with they key <code>org.apache.camel.xstream.permissions</code> .
<code>allowUnmarshalType</code>	false	Boolean	If enabled then Jackson is allowed to attempt to use the <code>CamelJacksonUnmarshalType</code> header during the unmarshalling. This should only be enabled when desired to be used.
<code>timezone</code>		String	If set then Jackson will use the Timezone when marshalling/unmarshalling. This option will have no effect on the others Json DataFormat, like gson, fastjson and xstream.

Name	Default	Java Type	Description
<code>contentTypeHeader</code>	true	Boolean	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example <code>application/xml</code> for data formats marshalling to XML, or <code>application/json</code> for data formats marshalling to JSON etc.

184.2. SPRING BOOT AUTO-CONFIGURATION

The component supports 20 options, which are listed below.

Name	Description	Default	Type
<code>camel.dataformat.json-jackson.allow-jms-type</code>	Used for JMS users to allow the <code>JMSType</code> header from the JMS spec to specify a FQN classname to use to unmarshal to.	false	Boolean
<code>camel.dataformat.json-jackson.allow-unmarshall-type</code>	If enabled then Jackson is allowed to attempt to use the <code>CamelJacksonUnmarshalType</code> header during the unmarshalling. This should only be enabled when desired to be used.	false	Boolean
<code>camel.dataformat.json-jackson.collection-type-name</code>	Refers to a custom collection type to lookup in the registry to use. This option should rarely be used, but allows to use different collection types than <code>java.util.Collection</code> based as default.		String
<code>camel.dataformat.json-jackson.content-type-header</code>	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example <code>application/xml</code> for data formats marshalling to XML, or <code>application/json</code> for data formats marshalling to JSON etc.	false	Boolean
<code>camel.dataformat.json-jackson.disable-features</code>	Set of features to disable on the Jackson <code>com.fasterxml.jackson.databind.ObjectMapper</code> . The features should be a name that matches a enum from <code>com.fasterxml.jackson.databind.SerializationFeature</code> , <code>com.fasterxml.jackson.databind.DeserializationFeature</code> , or <code>com.fasterxml.jackson.databind.MapperFeature</code> . Multiple features can be separated by comma		String

Name	Description	Default	Type
<code>camel.dataformat.json-jackson.enable-features</code>	Set of features to enable on the Jackson <code>com.fasterxml.jackson.databind.ObjectMapper</code> . The features should be a name that matches a enum from <code>com.fasterxml.jackson.databind.SerializationFeature</code> , <code>com.fasterxml.jackson.databind.DeserializationFeature</code> , or <code>com.fasterxml.jackson.databind.MapperFeature</code> . Multiple features can be separated by comma		String
<code>camel.dataformat.json-jackson.enable-jaxb-annotation-module</code>	Whether to enable the JAXB annotations module when using jackson. When enabled then JAXB annotations can be used by Jackson.	false	Boolean
<code>camel.dataformat.json-jackson.enabled</code>	Enable json-jackson dataformat	true	Boolean
<code>camel.dataformat.json-jackson.include</code>	If you want to marshal a pojo to JSON, and the pojo has some fields with null values. And you want to skip these null values, you can set this option to <code>NON_NULL</code>		String
<code>camel.dataformat.json-jackson.json-view</code>	When marshalling a POJO to JSON you might want to exclude certain fields from the JSON output. With Jackson you can use JSON views to accomplish this. This option is to refer to the class which has <code>JsonView</code> annotations		Class
<code>camel.dataformat.json-jackson.library</code>	Which json library to use.		JsonLibrary
<code>camel.dataformat.json-jackson.module-class-names</code>	To use custom Jackson modules <code>com.fasterxml.jackson.databind.Module</code> specified as a String with FQN class names. Multiple classes can be separated by comma.		String
<code>camel.dataformat.json-jackson.module-refs</code>	To use custom Jackson modules referred from the Camel registry. Multiple modules can be separated by comma.		String
<code>camel.dataformat.json-jackson.object-mapper</code>	Lookup and use the existing <code>ObjectMapper</code> with the given id when using Jackson.		String

Name	Description	Default	Type
<code>camel.dataformat.json-jackson.permissions</code>	Adds permissions that controls which Java packages and classes XStream is allowed to use during unmarshal from xml/json to Java beans. A permission must be configured either here or globally using a JVM system property. The permission can be specified in a syntax where a plus sign is allow, and minus sign is deny. Wildcards is supported by using . as prefix. For example to allow com.foo and all subpackages then specify com.foo.. Multiple permissions can be configured separated by comma, such as com.foo.,-com.foo.bar.MySecretBean. The following default permission is always included: - ,java.lang,java.util. unless its overridden by specifying a JVM system property with they key org.apache.camel.xstream.permissions.		String
<code>camel.dataformat.json-jackson.pretty-print</code>	To enable pretty printing output nicely formatted. Is by default false.	false	Boolean
<code>camel.dataformat.json-jackson.timezone</code>	If set then Jackson will use the Timezone when marshalling/unmarshalling. This option will have no effect on the others Json DataFormat, like gson, fastjson and xstream.		String
<code>camel.dataformat.json-jackson.unmarshal-type-name</code>	Class name of the java type to use when unarmshalling		String
<code>camel.dataformat.json-jackson.use-default-object-mapper</code>	Whether to lookup and use default Jackson ObjectMapper from the registry.	true	Boolean
<code>camel.dataformat.json-jackson.use-list</code>	To unarmshal to a List of Map or a List of Pojo.	false	Boolean

184.3. USING CUSTOM OBJECTMAPPER

You can configure **JacksonDataFormat** to use a custom **ObjectMapper** in case you need more control of the mapping configuration.

If you setup a single **ObjectMapper** in the registry, then Camel will automatic lookup and use this **ObjectMapper**. For example if you use Spring Boot, then Spring Boot can provide a default **ObjectMapper** for you if you have Spring MVC enabled. And this would allow Camel to detect that there

is one bean of **ObjectMapper** class type in the Spring Boot bean registry and then use it. When this happens you should set a **INFO** logging from Camel.

184.4. DEPENDENCIES

To use Jackson in your camel routes you need to add the dependency on **camel-jackson** which implements this data format.

If you use maven you could just add the following to your pom.xml, substituting the version number for the latest & greatest release (see the download page for the latest versions).

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-jackson</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

184.5. JACKSON OBJECTMAPPER

184.5.1. What is object mapping?

Jackson provides a mechanism for serializing Java objects, using the **com.fasterxml.jackson.databind.ObjectMapper** class. For example, you can serialize a **MyClass** java object using **ObjectMapper**, as follows:

```
ObjectMapper objectMapper = new ObjectMapper();
MyClass myobject = new MyClass("foo", "bar");
objectMapper.writeValue(new File("myobject.json"), myobject);
```

The object, **myobject**, gets serialized to JSON format and written to the file, **myobject.json** (Jackson also supports conversion to XML and YAML formats).

To deserialize the JSON contents of the file, **myobject.json**, you can invoke the **ObjectMapper** as follows:

```
ObjectMapper objectMapper = new ObjectMapper();
MyClass myobject = objectMapper.readValue(new File("myobject.json"), MyClass.class);
```

Note that the receiver needs to know the type of the class in advance and must specify the type, **MyClass.class**, as the second argument to **readValue()**.

184.5.2. What is polymorphic object mapping?

In some cases, it is impossible for the receiver of a serialized object to know the object's type in advance. For example, this applies to the case of a polymorphic object array. Consider the abstract type, **Shape**, and its subtypes, **Triangle**, **Square** (and so on):

```
package com.example;
...
public abstract class Shape {
}
```

```

public class Triangle extends Shape {
    ...
}

public class Square extends Shape {
    ...
}

public class ListOfShape {
    public List<Shape> shapes;
    ...
}

```

You can instantiate and serialize an array list of shapes (**ListOfShape**) as follows:

```

ObjectMapper objectMapper = new ObjectMapper();

ListOfShape shapeList = new ListOfShape();
shapeList.shapes = new ArrayList<Shape>();
shapeList.shapes.add(new Triangle());
shapeList.shapes.add(new Square());

String serialized = objectMapper.writeValueAsString(shapeList);

```

But there is now a problem on the receiver side. You can tell the receiver to expect a **ListOfShape** object, by specifying this type as the second argument to **readValue()**:

```

MyClass myobject = objectMapper.readValue(serialized, ListOfShape.class);
ObjectMapper objectMapper = new ObjectMapper();

```

However, there is no way that the receiver can know that the first element of the list is **Triangle** and the second element is **Square**. To get around this problem, you need to enable *polymorphic object mapping* as described in the next section.

184.5.3. How to enable polymorphic object mapping

Polymorphic object mapping is a mechanism that makes it possible to serialize and deserialize arrays of abstract classes, by providing additional metadata in the serialized array, which identifies the type of the objects in the array.

IMPORTANT

Polymorphic object mapping poses an inherent security risk, because the mechanism allows the *sender* to choose which class to instantiate, which can form the basis of an attack by the sender. Red Hat's distribution of the FasterXML Jackson library features a whitelist mechanism, which provides an extra level of protection against this threat. You must ensure that you are using Red Hat's distribution of the `jackson-databind` library (provided with Fuse versions 7.7 and later) in order to get this additional layer of protection. For more details, see [Section 184.5.5, "Security risk from polymorphic deserialization"](#).

To make it possible for the receiver to deserialize the objects in an array, it is necessary to provide type metadata in the serialized data. By default, Jackson does not encode any type metadata for serialized objects, so you need to write some additional code to enable this feature.

To enable polymorphic object mapping, perform the following steps (using **ListOfShape** as an example):

1. For each of the classes that can be elements of the list (subclasses of **Shape**), annotate the class with **@JsonTypeInfo**, as follows:

```
@JsonTypeInfo(use=JsonTypeInfo.Id.CLASS, include=JsonTypeInfo.As.PROPERTY)
public class Triangle extends Shape {
    ...
}
```

2. When the **Triangle** class is serialized to JSON format, it has the following format:

```
{"@class":"com.example.Triangle", "property1":"value1", "property2":"value2", ...}
```

3. The receiver must be configured to allow deserialization of the **Triangle**, **Square**, and other shape classes, by adding these classes to the deserialization whitelist. To configure the whitelist, set the **jackson.deserialization.whitelist.packages** system property to a comma-separated list of classes and packages. For example, to allow deserialization of the **Triangle**, **Square** classes, set the system property as follows:

```
-Djackson.deserialization.whitelist.packages=com.example.Triangle,com.example.Square
```

Alternatively, you could set the system property to allow the entire **com.example** package:

```
-Djackson.deserialization.whitelist.packages=com.example
```

NOTE

This whitelist mechanism is available only for Red Hat's distribution of the `jackson-databind` library. The standard `jackson-databind` library uses a blacklist mechanism instead, which needs to be updated every time a potentially dangerous new gadget class is discovered.

184.5.4. Default mapping for polymorphic deserialization

If a given Java class, **com.example.MyClass**, is not whitelisted, it is still possible to serialize instances of the class, but on the receiving side, the instances will be deserialized using a generic, default mapping.

When polymorphic object mapping is enabled in Jackson, there are a few alternative ways of encoding an object:

- With **@JsonTypeInfo(use=JsonTypeInfo.Id.CLASS, include=JsonTypeInfo.As.PROPERTY)**:

```
{"@class":"com.example.MyClass", "property1":"value1", "property2":"value2", ...}
```

In this case, the instance will be deserialized to an **Object** with properties.

- With `@JsonTypeInfo(use=JsonTypeInfo.Id.CLASS, include=JsonTypeInfo.As.WRAPPER_ARRAY)`:

```
["com.example.MyClass", {"property1":"value1", "property2":"value2", ...}]
```

In this case, the instance will be deserialized to a JSON array containing two fields:

- **String** with value `com.example.MyClass`
 - **Object** with two (or more) properties
- With `@JsonTypeInfo(use=JsonTypeInfo.Id.CLASS, include=JsonTypeInfo.As.WRAPPER_OBJECT)`:

```
{"com.example.MyClass":{"property1":"value1", "property2":"value2", ...}}
```

In this case, the instance will be deserialized to a JSON map with a single field, `com.example.MyClass`, and the value as **Object** having two (or more) properties.

184.5.5. Security risk from polymorphic deserialization

Applications that use the FasterXML `jackson-databind` library to instantiate Java objects by deserializing JSON content are potentially vulnerable to a *remote code execution* attack. The vulnerability is not automatic, however, and it can be avoided if you take the appropriate mitigation steps.

At a minimum, the following prerequisites must all be satisfied before an attack becomes possible:

1. You have enabled polymorphic type handling for deserialization of JSON content in **jackson-databind**. There are two alternative ways of enabling polymorphic type handling in Jackson JSON:
 - a. Using a combination of the `@JsonTypeInfo` and `@JsonSubTypes` annotations.
 - b. By calling the `ObjectMapper.enableDefaultTyping()` method. This option is particularly dangerous, as it effectively enables polymorphic typing globally.
2. There are one or more *gadget classes* in your Java classpath. A gadget class is defined as any class that performs a sensitive (potentially exploitable) operation as a side effect of executing a constructor or a setter method (which are the methods that can be called during a deserialization).
3. One or more gadget classes in your Java classpath have not yet been blacklisted by the current version of **jackson-databind**. If you are using the standard distribution of the `jackson-databind` library, the gadget blacklist maintained by the Jackson JSON library is the last line of defence against the remote code execution vulnerability.
4. (*Red Hat distribution of jackson-databind library only*) You explicitly added one of the gadget classes to the deserialization whitelist on the receiver (by setting the `jackson.deserialization.whitelist.packages` system property). As this is something you are unlikely to do, the whitelist mechanism provides effective protection against all gadget classes by default.

CHAPTER 185. JSON JOHNSON DATAFORMAT

Available as of Camel version 2.18

Johnzon is a Data Format which uses the [Johnzon Library](#)

```
from("activemq:My.Queue").
  marshal().json(JsonLibrary.Johnzon).
  to("mqseries:Another.Queue");
```

185.1. JOHNSON OPTIONS

The JSon Johnzon dataformat supports 19 options, which are listed below.

Name	Default	Java Type	Description
<code>objectMapper</code>		String	Lookup and use the existing ObjectMapper with the given id when using Jackson.
<code>useDefaultObjectMapper</code>	true	Boolean	Whether to lookup and use default Jackson ObjectMapper from the registry.
<code>prettyPrint</code>	false	Boolean	To enable pretty printing output nicely formatted. Is by default false.
<code>library</code>	XStream	JsonLibrary	Which json library to use.
<code>unmarshalTypeName</code>		String	Class name of the java type to use when unmarshalling
<code>jsonView</code>		Class	When marshalling a POJO to JSON you might want to exclude certain fields from the JSON output. With Jackson you can use JSON views to accomplish this. This option is to refer to the class which has JsonView annotations
<code>include</code>		String	If you want to marshal a pojo to JSON, and the pojo has some fields with null values. And you want to skip these null values, you can set this option to NON_NULL
<code>allowJmsType</code>	false	Boolean	Used for JMS users to allow the JMSType header from the JMS spec to specify a FQN classname to use to unmarshal to.
<code>collectionTypeName</code>		String	Refers to a custom collection type to lookup in the registry to use. This option should rarely be used, but allows to use different collection types than java.util.Collection based as default.
<code>useList</code>	false	Boolean	To unarmshal to a List of Map or a List of Pojo.

Name	Default	Java Type	Description
<code>enableJaxbAnnotationModule</code>	false	Boolean	Whether to enable the JAXB annotations module when using Jackson. When enabled then JAXB annotations can be used by Jackson.
<code>moduleClassNames</code>		String	To use custom Jackson modules <code>com.fasterxml.jackson.databind.Module</code> specified as a String with FQN class names. Multiple classes can be separated by comma.
<code>moduleRefs</code>		String	To use custom Jackson modules referred from the Camel registry. Multiple modules can be separated by comma.
<code>enableFeatures</code>		String	Set of features to enable on the Jackson <code>com.fasterxml.jackson.databind.ObjectMapper</code> . The features should be a name that matches a enum from <code>com.fasterxml.jackson.databind.SerializationFeature</code> , <code>com.fasterxml.jackson.databind.DeserializationFeature</code> , or <code>com.fasterxml.jackson.databind.MapperFeature</code> Multiple features can be separated by comma
<code>disableFeatures</code>		String	Set of features to disable on the Jackson <code>com.fasterxml.jackson.databind.ObjectMapper</code> . The features should be a name that matches a enum from <code>com.fasterxml.jackson.databind.SerializationFeature</code> , <code>com.fasterxml.jackson.databind.DeserializationFeature</code> , or <code>com.fasterxml.jackson.databind.MapperFeature</code> Multiple features can be separated by comma
<code>permissions</code>		String	Adds permissions that controls which Java packages and classes XStream is allowed to use during unmarshal from xml/json to Java beans. A permission must be configured either here or globally using a JVM system property. The permission can be specified in a syntax where a plus sign is allow, and minus sign is deny. Wildcards is supported by using <code>.</code> as prefix. For example to allow <code>com.foo</code> and all subpackages then specify <code>com.foo..</code> Multiple permissions can be configured separated by comma, such as <code>com.foo.,-com.foo.bar.MySecretBean</code> . The following default permission is always included: <code>-java.lang.,java.util</code> . unless its overridden by specifying a JVM system property with they key <code>org.apache.camel.xstream.permissions</code> .
<code>allowUnmarshalType</code>	false	Boolean	If enabled then Jackson is allowed to attempt to use the <code>CamelJacksonUnmarshalType</code> header during the unmarshalling. This should only be enabled when desired to be used.
<code>timezone</code>		String	If set then Jackson will use the Timezone when marshalling/unmarshalling. This option will have no effect on the others Json DataFormat, like gson, fastjson and xstream.

Name	Default	Java Type	Description
<code>contentTypeHeader</code>	false	Boolean	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example <code>application/xml</code> for data formats marshalling to XML, or <code>application/json</code> for data formats marshalling to JSON etc.

185.2. SPRING BOOT AUTO-CONFIGURATION

The component supports 20 options, which are listed below.

Name	Description	Default	Type
<code>camel.dataformat.json-johnzon.allow-jms-type</code>	Used for JMS users to allow the <code>JMSType</code> header from the JMS spec to specify a FQN classname to use to unmarshal to.	false	Boolean
<code>camel.dataformat.json-johnzon.allow-unmarshall-type</code>	If enabled then Jackson is allowed to attempt to use the <code>CamelJacksonUnmarshalType</code> header during the unmarshalling. This should only be enabled when desired to be used.	false	Boolean
<code>camel.dataformat.json-johnzon.collection-type-name</code>	Refers to a custom collection type to lookup in the registry to use. This option should rarely be used, but allows to use different collection types than <code>java.util.Collection</code> based as default.		String
<code>camel.dataformat.json-johnzon.content-type-header</code>	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example <code>application/xml</code> for data formats marshalling to XML, or <code>application/json</code> for data formats marshalling to JSON etc.	false	Boolean
<code>camel.dataformat.json-johnzon.disable-features</code>	Set of features to disable on the Jackson <code>com.fasterxml.jackson.databind.ObjectMapper</code> . The features should be a name that matches a enum from <code>com.fasterxml.jackson.databind.SerializationFeature</code> , <code>com.fasterxml.jackson.databind.DeserializationFeature</code> , or <code>com.fasterxml.jackson.databind.MapperFeature</code> . Multiple features can be separated by comma		String

Name	Description	Default	Type
<code>camel.dataformat.json-johnzon.enable-features</code>	Set of features to enable on the Jackson <code>com.fasterxml.jackson.databind.ObjectMapper</code> . The features should be a name that matches a enum from <code>com.fasterxml.jackson.databind.SerializationFeature</code> , <code>com.fasterxml.jackson.databind.DeserializationFeature</code> , or <code>com.fasterxml.jackson.databind.MapperFeature</code> . Multiple features can be separated by comma		String
<code>camel.dataformat.json-johnzon.enable-jaxb-annotation-module</code>	Whether to enable the JAXB annotations module when using Jackson. When enabled then JAXB annotations can be used by Jackson.	false	Boolean
<code>camel.dataformat.json-johnzon.enabled</code>	Enable json-johnzon dataformat	true	Boolean
<code>camel.dataformat.json-johnzon.include</code>	If you want to marshal a pojo to JSON, and the pojo has some fields with null values. And you want to skip these null values, you can set this option to <code>NON_NULL</code>		String
<code>camel.dataformat.json-johnzon.json-view</code>	When marshalling a POJO to JSON you might want to exclude certain fields from the JSON output. With Jackson you can use JSON views to accomplish this. This option is to refer to the class which has <code>JsonView</code> annotations		Class
<code>camel.dataformat.json-johnzon.library</code>	Which json library to use.		JsonLibrary
<code>camel.dataformat.json-johnzon.module-class-names</code>	To use custom Jackson modules <code>com.fasterxml.jackson.databind.Module</code> specified as a String with FQN class names. Multiple classes can be separated by comma.		String
<code>camel.dataformat.json-johnzon.module-refs</code>	To use custom Jackson modules referred from the Camel registry. Multiple modules can be separated by comma.		String
<code>camel.dataformat.json-johnzon.object-mapper</code>	Lookup and use the existing <code>ObjectMapper</code> with the given id when using Jackson.		String

Name	Description	Default	Type
<code>camel.dataformat.json-johnzon.permissions</code>	Adds permissions that controls which Java packages and classes XStream is allowed to use during unmarshal from xml/json to Java beans. A permission must be configured either here or globally using a JVM system property. The permission can be specified in a syntax where a plus sign is allow, and minus sign is deny. Wildcards is supported by using . as prefix. For example to allow com.foo and all subpackages then specify com.foo.. Multiple permissions can be configured separated by comma, such as com.foo.,-com.foo.bar.MySecretBean. The following default permission is always included: - ,java.lang,java.util. unless its overridden by specifying a JVM system property with they key org.apache.camel.xstream.permissions.		String
<code>camel.dataformat.json-johnzon.pretty-print</code>	To enable pretty printing output nicely formatted. Is by default false.	false	Boolean
<code>camel.dataformat.json-johnzon.timezone</code>	If set then Jackson will use the Timezone when marshalling/unmarshalling. This option will have no effect on the others Json DataFormat, like gson, fastjson and xstream.		String
<code>camel.dataformat.json-johnzon.unmarshal-type-name</code>	Class name of the java type to use when unarmshalling		String
<code>camel.dataformat.json-johnzon.use-default-object-mapper</code>	Whether to lookup and use default Jackson ObjectMapper from the registry.	true	Boolean
<code>camel.dataformat.json-johnzon.use-list</code>	To unarmshal to a List of Map or a List of Pojo.	false	Boolean

185.3. DEPENDENCIES

To use Johnzon in your camel routes you need to add the dependency on `camel-johnzon` which implements this data format.

If you use maven you could just add the following to your pom.xml, substituting the version number for the latest & greatest release (see the download page for the latest versions).

```
<dependency>  
  <groupId>org.apache.camel</groupId>  
  <artifactId>camel-johnzon</artifactId>  
  <version>x.x.x</version>  
  <!-- use the same version as your Camel core version -->  
</dependency>
```

CHAPTER 186. JSON SCHEMA VALIDATOR COMPONENT

Available as of Camel version 2.20

The JSON Schema Validator component performs bean validation of the message body against JSON Schemas v4 draft using the NetworkNT JSON Schema library (<https://github.com/networknt/json-schema-validator>).

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-json-validator</artifactId>
  <version>x.y.z</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

186.1. URI FORMAT

```
json-validator:resourceUri[?options]
```

Where **resourceUri** is some URL to a local resource on the classpath or a full URL to a remote resource or resource on the file system which contains the JSON Schema to validate against.

186.2. URI OPTIONS

The JSON Schema Validator component has no options.

The JSON Schema Validator endpoint is configured using URI syntax:

```
json-validator:resourceUri
```

with the following path and query parameters:

186.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
resourceUri	Required Path to the resource. You can prefix with: classpath, file, http, ref, or bean. classpath, file and http loads the resource using these protocols (classpath is default). ref will lookup the resource in the registry. bean will call a method on a bean to be used as the resource. For bean you can specify the method name after dot, eg bean:myBean.myMethod.		String

186.2.2. Query Parameters (7 parameters):

Name	Description	Default	Type
contentCache (producer)	Sets whether to use resource content cache or not	false	boolean
failOnNullBody (producer)	Whether to fail if no body exists.	true	boolean
failOnNullHeader (producer)	Whether to fail if no header exists when validating against a header.	true	boolean
headerName (producer)	To validate against a header instead of the message body.		String
errorHandler (advanced)	To use a custom ValidatorErrorHandler. The default error handler captures the errors and throws an exception.		JsonValidatorErrorHandler
schemaLoader (advanced)	To use a custom schema loader allowing for adding custom format validation. The default implementation will create a schema loader with draft v4 support.		JsonSchemaLoader
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

186.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.component.json-validator.enabled	Whether to enable auto configuration of the json-validator component. This is enabled by default.		Boolean
camel.component.json-validator.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

186.4. EXAMPLE

Assumed we have the following JSON Schema

myschema.json

```
{
  "$schema": "http://json-schema.org/draft-04/schema#",
  "definitions": {},
  "id": "my-schema",
  "properties": {
    "id": {
      "default": 1,
      "description": "An explanation about the purpose of this instance.",
      "id": "/properties/id",
      "title": "The id schema",
      "type": "integer"
    },
    "name": {
      "default": "A green door",
      "description": "An explanation about the purpose of this instance.",
      "id": "/properties/name",
      "title": "The name schema",
      "type": "string"
    },
    "price": {
      "default": 12.5,
      "description": "An explanation about the purpose of this instance.",
      "id": "/properties/price",
      "title": "The price schema",
      "type": "number"
    }
  },
  "required": [
    "name",
    "id",
    "price"
  ],
  "type": "object"
}
```

we can validate incoming JSON with the following Camel route, where **myschema.json** is loaded from the classpath.

```
from("direct:start")
  .to("json-validator:myschema.json")
  .to("mock:end")
```

CHAPTER 187. JSON XSTREAM DATAFORMAT

Available as of Camel version 2.0

XStream is a Data Format which uses the [XStream library](#) to marshal and unmarshal Java objects to and from XML.

To use XStream in your camel routes you need to add the a dependency on **camel-xstream** which implements this data format.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-xstream</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

187.1. OPTIONS

The JSon XStream dataformat supports 19 options, which are listed below.

Name	Default	Java Type	Description
objectMapper		String	Lookup and use the existing ObjectMapper with the given id when using Jackson.
useDefaultObjectMapper	true	Boolean	Whether to lookup and use default Jackson ObjectMapper from the registry.
prettyPrint	false	Boolean	To enable pretty printing output nicely formatted. Is by default false.
library	XStream	JsonLibrary	Which json library to use.
unmarshalTypeName		String	Class name of the java type to use when unmarshalling
jsonView		Class	When marshalling a POJO to JSON you might want to exclude certain fields from the JSON output. With Jackson you can use JSON views to accomplish this. This option is to refer to the class which has JsonView annotations
include		String	If you want to marshal a pojo to JSON, and the pojo has some fields with null values. And you want to skip these null values, you can set this option to NON_NULL

Name	Default	Java Type	Description
<code>allowJmsType</code>	false	Boolean	Used for JMS users to allow the JMSType header from the JMS spec to specify a FQN classname to use to unmarshal to.
<code>collectionTypeName</code>		String	Refers to a custom collection type to lookup in the registry to use. This option should rarely be used, but allows to use different collection types than java.util.Collection based as default.
<code>useList</code>	false	Boolean	To unarmshal to a List of Map or a List of Pojo.
<code>enableJaxbAnnotationModule</code>	false	Boolean	Whether to enable the JAXB annotations module when using jackson. When enabled then JAXB annotations can be used by Jackson.
<code>moduleClassNames</code>		String	To use custom Jackson modules com.fasterxml.jackson.databind.Module specified as a String with FQN class names. Multiple classes can be separated by comma.
<code>moduleRefs</code>		String	To use custom Jackson modules referred from the Camel registry. Multiple modules can be separated by comma.
<code>enableFeatures</code>		String	Set of features to enable on the Jackson com.fasterxml.jackson.databind.ObjectMapper. The features should be a name that matches a enum from com.fasterxml.jackson.databind.SerializationFeature, com.fasterxml.jackson.databind.DeserializationFeature, or com.fasterxml.jackson.databind.MapperFeature Multiple features can be separated by comma
<code>disableFeatures</code>		String	Set of features to disable on the Jackson com.fasterxml.jackson.databind.ObjectMapper. The features should be a name that matches a enum from com.fasterxml.jackson.databind.SerializationFeature, com.fasterxml.jackson.databind.DeserializationFeature, or com.fasterxml.jackson.databind.MapperFeature Multiple features can be separated by comma

Name	Default	Java Type	Description
permissions		String	Adds permissions that controls which Java packages and classes XStream is allowed to use during unmarshal from xml/json to Java beans. A permission must be configured either here or globally using a JVM system property. The permission can be specified in a syntax where a plus sign is allow, and minus sign is deny. Wildcards is supported by using . as prefix. For example to allow com.foo and all subpackages then specify com.foo.. Multiple permissions can be configured separated by comma, such as com.foo.,-com.foo.bar.MySecretBean. The following default permission is always included: - ,java.lang.,java.util. unless its overridden by specifying a JVM system property with they key org.apache.camel.xstream.permissions.
allowUnmarshallType	false	Boolean	If enabled then Jackson is allowed to attempt to use the CamelJacksonUnmarshalType header during the unmarshalling. This should only be enabled when desired to be used.
timezone		String	If set then Jackson will use the Timezone when marshalling/unmarshalling. This option will have no effect on the others Json DataFormat, like gson, fastjson and xstream.
contentTypeHeader	false	Boolean	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSon etc.

187.2. USING THE JAVA DSL

```
// lets turn Object messages into XML then send to MQSeries
from("activemq:My.Queue").
    marshal().xstream().
    to("mqseries:Another.Queue");
```

If you would like to configure the **XStream** instance used by the Camel for the message transformation, you can simply pass a reference to that instance on the DSL level.

```
XStream xStream = new XStream();
xStream.aliasField("money", PurchaseOrder.class, "cash");
// new Added setModel option since Camel 2.14
xStream.setModel("NO_REFERENCES");
...

from("direct:marshal").
    marshal(new XStreamDataFormat(xStream)).
    to("mock:marshaled");
```

187.3. XMLINPUTFACTORY AND XMLOUTPUTFACTORY

The [XStream library](#) uses the `javax.xml.stream.XMLInputFactory` and `javax.xml.stream.XMLOutputFactory`, you can control which implementation of this factory should be used.

The Factory is discovered using this algorithm: 1. Use the `javax.xml.stream.XMLInputFactory`, `javax.xml.stream.XMLOutputFactory` system property. 2. Use the `lib/xml.stream.properties` file in the `JRE_HOME` directory. 3. Use the Services API, if available, to determine the classname by looking in the `META-INF/services/javax.xml.stream.XMLInputFactory`, `META-INF/services/javax.xml.stream.XMLOutputFactory` files in jars available to the JRE. 4. Use the platform default `XMLInputFactory`, `XMLOutputFactory` instance.

187.4. HOW TO SET THE XML ENCODING IN XSTREAM DATAFORMAT?

From Camel 2.2.0, you can set the encoding of XML in Xstream DataFormat by setting the Exchange's property with the key `Exchange.CHARSET_NAME`, or setting the encoding property on Xstream from DSL or Spring config.

```
from("activemq:My.Queue").
  marshal().xstream("UTF-8").
  to("mqseries:Another.Queue");
```

187.5. SETTING THE TYPE PERMISSIONS OF XSTREAM DATAFORMAT

In Camel, one can always use its own processing step in the route to filter and block certain XML documents to be routed to the XStream's unmarshall step. From Camel 2.16.1, 2.15.5, you can set [XStream's type permissions](#) to automatically allow or deny the instantiation of certain types.

The default type permissions setting used by Camel denies all types except for those from `java.lang` and `java.util` packages. This setting can be changed by setting System property `org.apache.camel.xstream.permissions`. Its value is a string of comma-separated permission terms, each representing a type being allowed or denied, depending on whether the term is prefixed with `"` (note `"` may be omitted) or with `'-'`, respectively.

Each term may contain a wildcard character `*`. For example, value `"-java.lang,java.util."` indicates denying all types except for `java.lang.*` and `java.util.*` classes. Setting this value to an empty string `""` reverts to the default XStream's type permissions handling which denies certain blacklisted classes and allow others.

The type permissions setting can be extended at an individual XStream DataFormat instance by setting its type permissions property.

```
<dataFormats>
  <xstream id="xstream-default"
    permissions="org.apache.camel.samples.xstream.*"/>
  ...
```

CHAPTER 188. JSONPATH LANGUAGE

Available as of Camel version 2.13

Camel supports [JXPath](#) to allow using Expression or Predicate on json messages.

```
from("queue:books.new")
  .choice()
  .when().jsonpath("$.store.book[?(@.price < 10)]")
    .to("jms:queue:book.cheap")
  .when().jsonpath("$.store.book[?(@.price < 30)]")
    .to("jms:queue:book.average")
  .otherwise()
    .to("jms:queue:book.expensive")
```

188.1. JSONPATH OPTIONS

The JXPath language supports 7 options, which are listed below.

Name	Default	Java Type	Description
resultType		String	Sets the class name of the result type (type from output)
suppressExceptions	false	Boolean	Whether to suppress exceptions such as PathNotFoundException.
allowSimple	true	Boolean	Whether to allow inlined simple exceptions in the JXPath expression
allowEasyPredicate	true	Boolean	Whether to allow using the easy predicate parser to pre-parse predicates.
writeAsString	false	Boolean	Whether to write the output of each row/element as a JSON String value instead of a Map/POJO value.
headerName		String	Name of header to use as input, instead of the message body
trim	true	Boolean	Whether to trim the value to remove leading and trailing whitespaces and line breaks

188.2. SPRING BOOT AUTO-CONFIGURATION

The component supports 7 options, which are listed below.

Name	Description	Default	Type
<code>camel.language.js onpath.allow- easy-predicate</code>	Whether to allow using the easy predicate parser to pre-parse predicates.	true	Boolean
<code>camel.language.js onpath.allow- simple</code>	Whether to allow in inlined simple exceptions in the JsonPath expression	true	Boolean
<code>camel.language.js onpath.enabled</code>	Enable jsonpath language	true	Boolean
<code>camel.language.js onpath.header- name</code>	Name of header to use as input, instead of the message body		String
<code>camel.language.js onpath.suppress- exceptions</code>	Whether to suppress exceptions such as PathNotFoundException.	false	Boolean
<code>camel.language.js onpath.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks	true	Boolean
<code>camel.language.js onpath.write-as- string</code>	Whether to write the output of each row/element as a JSON String value instead of a Map/POJO value.	false	Boolean

188.3. USING XML CONFIGURATION

If you prefer to configure your routes in your Spring XML file then you can use [JXPath](#) expressions as follows

```
<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="direct:start"/>
    <choice>
      <when>
        <jsonpath>$.store.book[?(@.price < 10)]</jsonpath>
        <to uri="mock:cheap"/>
      </when>
      <when>
        <jsonpath>$.store.book[?(@.price < 30)]</jsonpath>
        <to uri="mock:average"/>
      </when>
      <otherwise>
        <to uri="mock:expensive"/>
      </otherwise>
    </choice>
  </route>
</camelContext>
```

```

</choice>
</route>
</camelContext>

```

188.4. SYNTAX

See the [JXPath](#) project page for further examples.

188.5. EASY SYNTAX

Available as of Camel 2.19

When you just want to define a basic predicate using jsonpath syntax it can be a bit hard to remember the syntax. So for example to find out all the cheap books you have to do

```
$.store.book[?(@.price < 20)]
```

However what if you could just write it as

```
store.book.price < 20
```

And you can omit the path if you just want to look at nodes with a price key

```
price < 20
```

To support this there is a **EasyPredicateParser** which kicks-in if you have define the predicate using a basic style. That means the predicate must not start with the **\$** sign, and only include one operator.

The easy syntax is:

```
left OP right
```

You can use Camel simple language in the right operator, eg

```
store.book.price < ${header.limit}
```

188.6. SUPPORTED MESSAGE BODY TYPES

Camel JXPath supports message body using the following types:

Type	Comment
File	Reading from files
String	Plain strings
Map	Message bodies as java.util.Map types
List	Message bodies as java.util.List types

Type	Comment
POJO	Optional If Jackson is on the classpath, then camel-jsonpath is able to use Jackson to read the message body as POJO and convert to java.util.Map which is supported by JXPath. For example you can add camel-jackson as dependency to include Jackson.
InputStream	If none of the above types matches, then Camel will attempt to read the message body as an java.io.InputStream .

If a message body is of unsupported type then an exception is thrown by default, however you can configure JXPath to suppress exceptions (see below)

188.7. SUPPRESS EXCEPTIONS

Available as of Camel 2.16

By default jsonpath will throw an exception if the json payload does not have a valid path accordingly to the configured jsonpath expression. In some use-cases you may want to ignore this in case the json payload contains optional data. Therefore you can set the option `suppressExceptions` to true to ignore this as shown:

```
from("direct:start")
  .choice()
    // use true to suppress exceptions
    .when().jsonpath("person.middlename", true)
      .to("mock:middle")
    .otherwise()
      .to("mock:other");
```

And in XML DSL:

```
<route>
  <from uri="direct:start"/>
  <choice>
    <when>
      <jsonpath suppressExceptions="true">person.middlename</jsonpath>
      <to uri="mock:middle"/>
    </when>
    <otherwise>
      <to uri="mock:other"/>
    </otherwise>
  </choice>
</route>
```

This option is also available on the `@JsonPath` annotation.

188.8. INLINE SIMPLE EXCEPTIONS

Available as of Camel 2.18

Its now possible to inlined Simple language expressions in the JXPath expression using the simple syntax `#{xxx}`. An example is shown below:

```
from("direct:start")
  .choice()
  .when().jsonpath("$.store.book[?(@.price < #{header.cheap})]")
  .to("mock:cheap")
  .when().jsonpath("$.store.book[?(@.price < #{header.average})]")
  .to("mock:average")
  .otherwise()
  .to("mock:expensive");
```

And in XML DSL:

```
<route>
  <from uri="direct:start"/>
  <choice>
    <when>
      <jsonpath>$.store.book[?(@.price < #{header.cheap})]</jsonpath>
      <to uri="mock:cheap"/>
    </when>
    <when>
      <jsonpath>$.store.book[?(@.price < #{header.average})]</jsonpath>
      <to uri="mock:average"/>
    </when>
    <otherwise>
      <to uri="mock:expensive"/>
    </otherwise>
  </choice>
</route>
```

You can turn off support for inlined simple expression by setting the option `allowSimple` to `false` as shown:

```
.when().jsonpath("$.store.book[?(@.price < 10)]", false, false)
```

And in XML DSL:

```
<jsonpath allowSimple="false">$.store.book[?(@.price < 10)]</jsonpath>
```

188.9. JSONPATH INJECTION

You can use Bean Integration to invoke a method on a bean and use various languages such as JXPath to extract a value from the message and bind it to a method parameter.

For example

```
public class Foo {

    @Consume(uri = "activemq:queue:books.new")
    public void doSomething(@JXPath("$.store.book[*].author") String author, @Body String json) {
```

```
// process the inbound message here
}
}
```

188.10. ENCODING DETECTION

Since Camel version 2.16, the encoding of the JSON document is detected automatically, if the document is encoded in unicode (UTF-8, UTF-16LE, UTF-16BE, UTF-32LE, UTF-32BE) as specified in RFC-4627. If the encoding is a non-unicode encoding, you can either make sure that you enter the document in String format to the JSONPath component or you can specify the encoding in the header "**CamelJsonPathJsonEncoding**" (JsonpathConstants.HEADER_JSON_ENCODING).

188.11. SPLIT JSON DATA INTO SUB ROWS AS JSON

You can use jsonpath to split a JSon document, such as:

```
from("direct:start")
  .split().jsonpath("$.store.book[*]")
  .to("log:book");
```

Then each book is logged, however the message body is a **Map** instance. Sometimes you may want to output this as plain String JSon value instead, which can be done from **Camel 2.20** onwards with the **writeAsString** option as shown:

```
from("direct:start")
  .split().jsonpathWriteAsString("$.store.book[*]")
  .to("log:book");
```

Then each book is logged as a String JSon value. For earlier versions of Camel you would need to use camel-jackson dataformat and marshal the message body to make it convert the message body from **Map** to a **String** type.

188.12. USING HEADER AS INPUT

Available as of Camel 2.20

By default jsonpath uses the message body as the input source. However you can also use a header as input by specifying the **headerName** option.

For example to count the number of books from a json document that was stored in a header named **books** you can do:

```
from("direct:start")
  .setHeader("numberOfBooks")
  .jsonpath("$.store.book.length()", false, int.class, "books")
  .to("mock:result");
```

In the **jsonpath** expression above we specify the name of the header as **books** and we also told that we wanted the result to be converted as an integer by **int.class**.

The same example in XML DSL would be:

```
<route>
```

```
<from uri="direct:start"/>
<setHeader headerName="numberOfBooks">
  <jsonpath headerName="books" resultType="int">$.store.book.length()</jsonpath>
</transform>
<to uri="mock:result"/>
</route>
```

188.13. DEPENDENCIES

To use JXPath in your camel routes you need to add the a dependency on **camel-jsonpath** which implements the JXPath language.

If you use maven you could just add the following to your pom.xml, substituting the version number for the latest & greatest release (see the download page for the latest versions).

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-jsonpath</artifactId>
  <version>x.x.x</version>
</dependency>
```

CHAPTER 189. JT400 COMPONENT

Available as of Camel version 1.5

The **jt400** component allows you to exchanges messages with an AS/400 system using data queues.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-jt400</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

189.1. URI FORMAT

```
jt400://user:password@system/QSYS.LIB/LIBRARY.LIB/QUEUE.DTAQ[?options]
```

To call remote program (**Camel 2.7**)

```
jt400://user:password@system/QSYS.LIB/LIBRARY.LIB/program.PGM[?options]
```

You can append query options to the URI in the following format, **?option=value&option=value&...**

189.2. JT400 OPTIONS

The JT400 component supports 2 options, which are listed below.

Name	Description	Default	Type
connectionPool (advanced)	Returns the default connection pool used by this component.		AS400Connection Pool
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The JT400 endpoint is configured using URI syntax:

```
jt400:userID:password/systemName/objectPath.type
```

with the following path and query parameters:

189.2.1. Path Parameters (5 parameters):

Name	Description	Default	Type
userID	Required Returns the ID of the AS/400 user.		String
password	Required Returns the password of the AS/400 user.		String
systemName	Required Returns the name of the AS/400 system.		String
objectPath	Required Returns the fully qualified integrated file system path name of the target object of this endpoint.		String
type	Required Whether to work with data queues or remote program call		Jt400Type

189.2.2. Query Parameters (30 parameters):

Name	Description	Default	Type
ccsid (common)	Sets the CCSID to use for the connection with the AS/400 system.		int
format (common)	Sets the data format for sending messages.	text	Format
guiAvailable (common)	Sets whether AS/400 prompting is enabled in the environment running Camel.	false	boolean
keyed (common)	Whether to use keyed or non-keyed data queues.	false	boolean
outputFieldsIdxArray (common)	Specifies which fields (program parameters) are output parameters.		Integer[]
outputFieldsLengthArray (common)	Specifies the fields (program parameters) length as in the AS/400 program definition.		Integer[]
searchKey (common)	Search key for keyed data queues.		String
searchType (common)	Search type such as EQ for equal etc.	EQ	SearchType

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
readTimeout (consumer)	Timeout in millis the consumer will wait while trying to read a new message of the data queue.	30000	int
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean
exceptionHandler (consumer)	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		<code>ExceptionHandler</code>
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		<code>ExchangePattern</code>
pollStrategy (consumer)	A pluggable <code>org.apache.camel.PollingConsumerPollingStrategy</code> allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		<code>PollingConsumerPollStrategy</code>
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the <code>backoffMultiplier</code> should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the <code>backoffMultiplier</code> should kick-in.		int

Name	Description	Default	Type
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then <code>backoffIdleThreshold</code> and/or <code>backoffErrorThreshold</code> must also be configured.		int
delay (scheduler)	Milliseconds before the next poll. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	500	long
greedy (scheduler)	If greedy is enabled, then the <code>ScheduledPollConsumer</code> will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	1000	long
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that.	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz2 component	none	ScheduledPollConsumer Scheduler
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz2, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for <code>initialDelay</code> and <code>delay</code> options.	MILLIS ECON DS	TimeUnit
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See <code>ScheduledExecutorService</code> in JDK for details.	true	boolean
procedureName (procedureName)	Procedure name from a service program to call		String

Name	Description	Default	Type
<code>secured</code> (security)	Whether connections to AS/400 are secured with SSL.	false	boolean

189.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 3 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.jt400.connection-pool</code>	Returns the default connection pool used by this component. The option is a <code>com.ibm.as400.access.AS400ConnectionPool</code> type.		String
<code>camel.component.jt400.enabled</code>	Enable jt400 component	true	Boolean
<code>camel.component.jt400.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

189.4. USAGE

When configured as a consumer endpoint, the endpoint will poll a data queue on a remote system. For every entry on the data queue, a new **Exchange** is sent with the entry's data in the `In` message's body, formatted either as a **String** or a **byte[]**, depending on the format. For a provider endpoint, the `In` message body contents will be put on the data queue as either raw bytes or text.

189.5. CONNECTION POOL

Available as of Camel 2.10

Connection pooling is in use from Camel 2.10 onwards. You can explicit configure a connection pool on the `Jt400Component`, or as an uri option on the endpoint.

189.5.1. Remote program call (Camel 2.7)

This endpoint expects the input to be either a String array or byte[] array (depending on format) and handles all the CCSID handling through the native jt400 library mechanisms. A parameter can be *omitted* by passing null as the value in its position (the remote program has to support it). After the program execution the endpoint returns either a String array or byte[] array with the values as they were returned by the program (the input only parameters will contain the same data as the beginning of the invocation). This endpoint does not implement a provider endpoint!

189.6. EXAMPLE

In the snippet below, the data for an exchange sent to the **direct:george** endpoint will be put in the data queue **PENNYLANE** in library **BEATLES** on a system named **LIVERPOOL**. Another user connects to the same data queue to receive the information from the data queue and forward it to the **mock:ringo** endpoint.

```
public class Jt400RouteBuilder extends RouteBuilder {
    @Override
    public void configure() throws Exception {

        from("direct:george").to("jt400://GEORGE:EGROEG@LIVERPOOL/QSYS.LIB/BEATLES.LIB/PENNY
        LANE.DTAQ");

        from("jt400://RINGO:OGNIR@LIVERPOOL/QSYS.LIB/BEATLES.LIB/PENNYLANE.DTAQ").to("mock
        :ringo");
    }
}
```

189.6.1. Remote program call example (Camel 2.7)

In the snippet below, the data Exchange sent to the **direct:work** endpoint will contain three string that will be used as the arguments for the program "compute" in the library "assets". This program will write the output values in the 2nd and 3rd parameters. All the parameters will be sent to the **direct:play** endpoint.

```
public class Jt400RouteBuilder extends RouteBuilder {
    @Override
    public void configure() throws Exception {
        from("direct:work").to("jt400://GRUPO:ATWORK@server/QSYS.LIB/assets.LIB/compute.PGM?
        fieldsLength=10,10,512&ouputFieldsIdx=2,3").to("direct:play");
    }
}
```

189.6.2. Writing to keyed data queues

```
from("jms:queue:input")
.to("jt400://username:password@system/lib.lib/MSGINDQ.DTAQ?keyed=true");
```

189.6.3. Reading from keyed data queues

```
from("jt400://username:password@system/lib.lib/MSGOUTDQ.DTAQ?
keyed=true&searchKey=MYKEY&searchType=GE")
.to("jms:queue:output");
```

189.7. SEE ALSO

- [Configuring Camel](#)
- [Component](#)
- [Endpoint](#)
- [Getting Started](#)

CHAPTER 190. KAFKA COMPONENT

Available as of Camel version 2.13

The **kafka:** component is used for communicating with [Apache Kafka](#) message broker.

Maven users will need to add the following dependency to their **pom.xml** for this component.

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-kafka</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

190.1. URI FORMAT

```
kafka:topic[?options]
```

190.2. OPTIONS

The Kafka component supports 8 options, which are listed below.

Name	Description	Default	Type
configuration (common)	Allows to pre-configure the Kafka component with common options that the endpoints will reuse.		KafkaConfiguration
brokers (common)	URL of the Kafka brokers to use. The format is host1:port1,host2:port2, and the list can be a subset of brokers or a VIP pointing to a subset of brokers. This option is known as bootstrap.servers in the Kafka documentation.		String
workerPool (advanced)	To use a shared custom worker pool for continue routing Exchange after kafka server has acknowledge the message that was sent to it from KafkaProducer using asynchronous non-blocking processing. If using this option then you must handle the lifecycle of the thread pool to shut the pool down when no longer needed.		ExecutorService
useGlobalSslContext Parameters (security)	Enable usage of global SSL context parameters.	false	boolean

Name	Description	Default	Type
breakOnFirstError (consumer)	This options controls what happens when a consumer is processing an exchange and it fails. If the option is false then the consumer continues to the next message and processes it. If the option is true then the consumer breaks out, and will seek back to offset of the message that caused a failure, and then re-attempt to process this message. However this can lead to endless processing of the same message if its bound to fail every time, eg a poison message. Therefore its recommended to deal with that for example by using Camel's error handler.	false	boolean
allowManualCommit (consumer)	Whether to allow doing manual commits via <code>KafkaManualCommit</code> . If this option is enabled then an instance of <code>KafkaManualCommit</code> is stored on the Exchange message header, which allows end users to access this API and perform manual offset commits via the Kafka consumer.	false	boolean
kafkaManualCommit Factory (consumer)	Factory to use for creating <code>KafkaManualCommit</code> instances. This allows to plugin a custom factory to create custom <code>KafkaManualCommit</code> instances in case special logic is needed when doing manual commits that deviates from the default implementation that comes out of the box.		<code>KafkaManualCommit Factory</code>
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Kafka endpoint is configured using URI syntax:

```
kafka:topic
```

with the following path and query parameters:

190.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
topic	Required Name of the topic to use. On the consumer you can use comma to separate multiple topics. A producer can only send a message to a single topic.		String

190.2.2. Query Parameters (93 parameters):

Name	Description	Default	Type
brokers (common)	URL of the Kafka brokers to use. The format is host1:port1,host2:port2, and the list can be a subset of brokers or a VIP pointing to a subset of brokers. This option is known as bootstrap.servers in the Kafka documentation.		String
clientId (common)	The client id is a user-specified string sent in each request to help trace calls. It should logically identify the application making the request.		String
headerFilterStrategy (common)	To use a custom HeaderFilterStrategy to filter header to and from Camel message.		HeaderFilterStrategy
reconnectBackoffMaxMs (common)	The maximum amount of time in milliseconds to wait when reconnecting to a broker that has repeatedly failed to connect. If provided, the backoff per host will increase exponentially for each consecutive connection failure, up to this maximum. After calculating the backoff increase, 20% random jitter is added to avoid connection storms.	1000	Integer
allowManualCommit (consumer)	Whether to allow doing manual commits via KafkaManualCommit. If this option is enabled then an instance of KafkaManualCommit is stored on the Exchange message header, which allows end users to access this API and perform manual offset commits via the Kafka consumer.	false	boolean
autoCommitEnable (consumer)	If true, periodically commit to ZooKeeper the offset of messages already fetched by the consumer. This committed offset will be used when the process fails as the position from which the new consumer will begin.	true	Boolean
autoCommitIntervalMs (consumer)	The frequency in ms that the consumer offsets are committed to zookeeper.	5000	Integer
autoCommitOnStop (consumer)	Whether to perform an explicit auto commit when the consumer stops to ensure the broker has a commit from the last consumed message. This requires the option autoCommitEnable is turned on. The possible values are: sync, async, or none. And sync is the default value.	sync	String
autoOffsetReset (consumer)	What to do when there is no initial offset in ZooKeeper or if an offset is out of range: earliest : automatically reset the offset to the earliest offset latest : automatically reset the offset to the latest offset fail: throw exception to the consumer	latest	String

Name	Description	Default	Type
breakOnFirstError (consumer)	This options controls what happens when a consumer is processing an exchange and it fails. If the option is false then the consumer continues to the next message and processes it. If the option is true then the consumer breaks out, and will seek back to offset of the message that caused a failure, and then re-attempt to process this message. However this can lead to endless processing of the same message if its bound to fail every time, eg a poison message. Therefore its recommended to deal with that for example by using Camel's error handler.	false	boolean
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
checkCrcs (consumer)	Automatically check the CRC32 of the records consumed. This ensures no on-the-wire or on-disk corruption to the messages occurred. This check adds some overhead, so it may be disabled in cases seeking extreme performance.	true	Boolean
consumerRequestTimeoutMs (consumer)	The configuration controls the maximum amount of time the client will wait for the response of a request. If the response is not received before the timeout elapses the client will resend the request if necessary or fail the request if retries are exhausted.	40000	Integer
consumersCount (consumer)	The number of consumers that connect to kafka server	1	int
consumerStreams (consumer)	Number of concurrent consumers on the consumer	10	int

Name	Description	Default	Type
fetchMaxBytes (consumer)	The maximum amount of data the server should return for a fetch request. This is not an absolute maximum, if the first message in the first non-empty partition of the fetch is larger than this value, the message will still be returned to ensure that the consumer can make progress. The maximum message size accepted by the broker is defined via <code>message.max.bytes</code> (broker config) or <code>max.message.bytes</code> (topic config). Note that the consumer performs multiple fetches in parallel.	52428800	Integer
fetchMinBytes (consumer)	The minimum amount of data the server should return for a fetch request. If insufficient data is available the request will wait for that much data to accumulate before answering the request.	1	Integer
fetchWaitMaxMs (consumer)	The maximum amount of time the server will block before answering the fetch request if there isn't sufficient data to immediately satisfy <code>fetch.min.bytes</code> .	500	Integer
groupId (consumer)	A string that uniquely identifies the group of consumer processes to which this consumer belongs. By setting the same group id multiple processes indicate that they are all part of the same consumer group. This option is required for consumers.		String
heartbeatIntervalMs (consumer)	The expected time between heartbeats to the consumer coordinator when using Kafka's group management facilities. Heartbeats are used to ensure that the consumer's session stays active and to facilitate rebalancing when new consumers join or leave the group. The value must be set lower than <code>session.timeout.ms</code> , but typically should be set no higher than 1/3 of that value. It can be adjusted even lower to control the expected time for normal rebalances.	3000	Integer
kafkaHeaderDeserializer (consumer)	Sets custom <code>KafkaHeaderDeserializer</code> for deserialization kafka headers values to camel headers values.		<code>KafkaHeaderDeserializer</code>

Name	Description	Default	Type
keyDeserializer (consumer)	Deserializer class for key that implements the Deserializer interface.	org.apache.kafka.common.serialization.StringDeserializer	String
maxPartitionFetchBytes (consumer)	The maximum amount of data per-partition the server will return. The maximum total memory used for a request will be #partitions max.partition.fetch.bytes. This size must be at least as large as the maximum message size the server allows or else it is possible for the producer to send messages larger than the consumer can fetch. If that happens, the consumer can get stuck trying to fetch a large message on a certain partition.	1048576	Integer
maxPollIntervals (consumer)	The maximum delay between invocations of poll() when using consumer group management. This places an upper bound on the amount of time that the consumer can be idle before fetching more records. If poll() is not called before expiration of this timeout, then the consumer is considered failed and the group will rebalance in order to reassign the partitions to another member.		Long
maxPollRecords (consumer)	The maximum number of records returned in a single call to poll()	500	Integer
offsetRepository (consumer)	The offset repository to use in order to locally store the offset of each partition of the topic. Defining one will disable the autocommit.		StateRepository
partitionAssignor (consumer)	The class name of the partition assignment strategy that the client will use to distribute partition ownership amongst consumer instances when group management is used	org.apache.kafka.clients.consumer.RangeAssignor	String
pollTimeoutMs (consumer)	The timeout used when polling the KafkaConsumer.	5000	Long

Name	Description	Default	Type
seekTo (consumer)	Set if KafkaConsumer will read from beginning or end on startup: beginning : read from beginning end : read from end This is replacing the earlier property seekToBeginning		String
sessionTimeoutMs (consumer)	The timeout used to detect failures when using Kafka's group management facilities.	10000	Integer
topicsPattern (consumer)	Whether the topic is a pattern (regular expression). This can be used to subscribe to dynamic number of topics matching the pattern.	false	boolean
valueDeserializer (consumer)	Deserializer class for value that implements the Deserializer interface.	org.apache.kafka.common.serialization.StringDeserializer	String
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
bridgeEndpoint (producer)	If the option is true, then KafkaProducer will ignore the KafkaConstants.TOPIC header setting of the inbound message.	false	boolean
bufferMemorySize (producer)	The total bytes of memory the producer can use to buffer records waiting to be sent to the server. If records are sent faster than they can be delivered to the server the producer will either block or throw an exception based on the preference specified by block.on.buffer.full.This setting should correspond roughly to the total memory the producer will use, but is not a hard bound since not all memory the producer uses is used for buffering. Some additional memory will be used for compression (if compression is enabled) as well as for maintaining in-flight requests.	33554432	Integer

Name	Description	Default	Type
circularTopicDetection (producer)	If the option is true, then KafkaProducer will detect if the message is attempted to be sent back to the same topic it may come from, if the message was original from a kafka consumer. If the KafkaConstants.TOPIC header is the same as the original kafka consumer topic, then the header setting is ignored, and the topic of the producer endpoint is used. In other words this avoids sending the same message back to where it came from. This option is not in use if the option bridgeEndpoint is set to true.	true	boolean
compressionCodec (producer)	This parameter allows you to specify the compression codec for all data generated by this producer. Valid values are none, gzip and snappy.	none	String
connectionMaxIdleMs (producer)	Close idle connections after the number of milliseconds specified by this config.	540000	Integer
enableIdempotence (producer)	If set to 'true' the producer will ensure that exactly one copy of each message is written in the stream. If 'false', producer retries may write duplicates of the retried message in the stream. If set to true this option will require max.in.flight.requests.per.connection to be set to 1 and retries cannot be zero and additionally acks must be set to 'all'.	false	boolean
kafkaHeaderSerializer (producer)	Sets custom KafkaHeaderDeserializer for serialization camel headers values to kafka headers values.		KafkaHeaderSerializer
key (producer)	The record key (or null if no key is specified). If this option has been configured then it take precedence over header KafkaConstants#KEY		String
keySerializerClass (producer)	The serializer class for keys (defaults to the same as for messages if nothing is given).	org.apache.kafka.common.serialization.StringSerializer	String

Name	Description	Default	Type
lingerMs (producer)	The producer groups together any records that arrive in between request transmissions into a single batched request. Normally this occurs only under load when records arrive faster than they can be sent out. However in some circumstances the client may want to reduce the number of requests even under moderate load. This setting accomplishes this by adding a small amount of artificial delay that is, rather than immediately sending out a record the producer will wait for up to the given delay to allow other records to be sent so that the sends can be batched together. This can be thought of as analogous to Nagle's algorithm in TCP. This setting gives the upper bound on the delay for batching: once we get batch.size worth of records for a partition it will be sent immediately regardless of this setting, however if we have fewer than this many bytes accumulated for this partition we will 'linger' for the specified time waiting for more records to show up. This setting defaults to 0 (i.e. no delay). Setting <code>linger.ms=5</code> , for example, would have the effect of reducing the number of requests sent but would add up to 5ms of latency to records sent in the absence of load.	0	Integer
maxBlockMs (producer)	The configuration controls how long sending to kafka will block. These methods can be blocked for multiple reasons. For e.g: buffer full, metadata unavailable. This configuration imposes maximum limit on the total time spent in fetching metadata, serialization of key and value, partitioning and allocation of buffer memory when doing a <code>send()</code> . In case of <code>partitionsFor()</code> , this configuration imposes a maximum time threshold on waiting for metadata	60000	Integer
maxInFlightRequest (producer)	The maximum number of unacknowledged requests the client will send on a single connection before blocking. Note that if this setting is set to be greater than 1 and there are failed sends, there is a risk of message re-ordering due to retries (i.e., if retries are enabled).	5	Integer
maxRequestSize (producer)	The maximum size of a request. This is also effectively a cap on the maximum record size. Note that the server has its own cap on record size which may be different from this. This setting will limit the number of record batches the producer will send in a single request to avoid sending huge requests.	1048576	Integer

Name	Description	Default	Type
metadataMaxAgeMs (producer)	The period of time in milliseconds after which we force a refresh of metadata even if we haven't seen any partition leadership changes to proactively discover any new brokers or partitions.	300000	Integer
metricReporters (producer)	A list of classes to use as metrics reporters. Implementing the MetricReporter interface allows plugging in classes that will be notified of new metric creation. The JmxReporter is always included to register JMX statistics.		String
metricsSampleWindowMs (producer)	The number of samples maintained to compute metrics.	30000	Integer
noOfMetricsSample (producer)	The number of samples maintained to compute metrics.	2	Integer
partitioner (producer)	The partitioner class for partitioning messages amongst sub-topics. The default partitioner is based on the hash of the key.	org.apache.kafka.clients.producer.internals.DefaultPartitioner	String
partitionKey (producer)	The partition to which the record will be sent (or null if no partition was specified). If this option has been configured then it take precedence over header <code>KafkaConstants#PARTITION_KEY</code>		Integer
producerBatchSize (producer)	The producer will attempt to batch records together into fewer requests whenever multiple records are being sent to the same partition. This helps performance on both the client and the server. This configuration controls the default batch size in bytes. No attempt will be made to batch records larger than this size. Requests sent to brokers will contain multiple batches, one for each partition with data available to be sent. A small batch size will make batching less common and may reduce throughput (a batch size of zero will disable batching entirely). A very large batch size may use memory a bit more wastefully as we will always allocate a buffer of the specified batch size in anticipation of additional records.	16384	Integer

Name	Description	Default	Type
queueBufferingMaxMessages (producer)	The maximum number of unsent messages that can be queued up the producer when using async mode before either the producer must be blocked or data must be dropped.	10000	Integer
receiveBufferBytes (producer)	The size of the TCP receive buffer (SO_RCVBUF) to use when reading data.	65536	Integer
reconnectBackoffMs (producer)	The amount of time to wait before attempting to reconnect to a given host. This avoids repeatedly connecting to a host in a tight loop. This backoff applies to all requests sent by the consumer to the broker.	50	Integer
recordMetadata (producer)	Whether the producer should store the RecordMetadata results from sending to Kafka. The results are stored in a List containing the RecordMetadata metadata's. The list is stored on a header with the key <code>KafkaConstants#KAFKA_RECORDMETA</code>	true	boolean
requestRequiredAcks (producer)	The number of acknowledgments the producer requires the leader to have received before considering a request complete. This controls the durability of records that are sent. The following settings are common: <code>acks=0</code> If set to zero then the producer will not wait for any acknowledgment from the server at all. The record will be immediately added to the socket buffer and considered sent. No guarantee can be made that the server has received the record in this case, and the retries configuration will not take effect (as the client won't generally know of any failures). The offset given back for each record will always be set to -1. <code>acks=1</code> This will mean the leader will write the record to its local log but will respond without awaiting full acknowledgement from all followers. In this case should the leader fail immediately after acknowledging the record but before the followers have replicated it then the record will be lost. <code>acks=all</code> This means the leader will wait for the full set of in-sync replicas to acknowledge the record. This guarantees that the record will not be lost as long as at least one in-sync replica remains alive. This is the strongest available guarantee.	1	String
requestTimeoutMs (producer)	The amount of time the broker will wait trying to meet the <code>request.required.acks</code> requirement before sending back an error to the client.	305000	Integer

Name	Description	Default	Type
retries (producer)	Setting a value greater than zero will cause the client to resend any record whose send fails with a potentially transient error. Note that this retry is no different than if the client resent the record upon receiving the error. Allowing retries will potentially change the ordering of records because if two records are sent to a single partition, and the first fails and is retried but the second succeeds, then the second record may appear first.	0	Integer
retryBackoffMs (producer)	Before each retry, the producer refreshes the metadata of relevant topics to see if a new leader has been elected. Since leader election takes a bit of time, this property specifies the amount of time that the producer waits before refreshing the metadata.	100	Integer
sendBufferBytes (producer)	Socket write buffer size	131072	Integer
serializerClass (producer)	The serializer class for messages.	org.apache.kafka.common.serialization.StringSerializer	String
workerPool (producer)	To use a custom worker pool for continue routing Exchange after kafka server has acknowledge the message that was sent to it from KafkaProducer using asynchronous non-blocking processing.		ExecutorService
workerPoolCoreSize (producer)	Number of core threads for the worker pool for continue routing Exchange after kafka server has acknowledge the message that was sent to it from KafkaProducer using asynchronous non-blocking processing.	10	Integer
workerPoolMaxSize (producer)	Maximum number of threads for the worker pool for continue routing Exchange after kafka server has acknowledge the message that was sent to it from KafkaProducer using asynchronous non-blocking processing.	20	Integer

Name	Description	Default	Type
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
interceptorClasses (monitoring)	Sets interceptors for producer or consumers. Producer interceptors have to be classes implementing <code>org.apache.kafka.clients.producer.ProducerInterceptor</code> or Consumer interceptors have to be classes implementing <code>org.apache.kafka.clients.consumer.ConsumerInterceptor</code> Note that if you use Producer interceptor on a consumer it will throw a class cast exception in runtime		String
kerberosBeforeRefreshMinTime (security)	Login thread sleep time between refresh attempts.	60000	Integer
kerberosInitCmd (security)	Kerberos kinit command path. Default is <code>/usr/bin/kinit</code>	<code>/usr/bin/kinit</code>	String
kerberosPrincipalToLocalRules (security)	A list of rules for mapping from principal names to short names (typically operating system usernames). The rules are evaluated in order and the first rule that matches a principal name is used to map it to a short name. Any later rules in the list are ignored. By default, principal names of the form <code>username/hostnameREALM</code> are mapped to <code>username</code> . For more details on the format please see security authorization and acls. Multiple values can be separated by comma	DEFAULT	String
kerberosRenewJitter (security)	Percentage of random jitter added to the renewal time.	0.05	Double
kerberosRenewWindowFactor (security)	Login thread will sleep until the specified window factor of time from last refresh to ticket's expiry has been reached, at which time it will try to renew the ticket.	0.8	Double
saslJaasConfig (security)	Expose the kafka <code>sasl.jaas.config</code> parameter Example: <code>org.apache.kafka.common.security.plain.PlainLoginModule required username=USERNAME password=PASSWORD;</code>		String

Name	Description	Default	Type
saslKerberosServiceName (security)	The Kerberos principal name that Kafka runs as. This can be defined either in Kafka's JAAS config or in Kafka's config.		String
saslMechanism (security)	The Simple Authentication and Security Layer (SASL) Mechanism used. For the valid values see http://www.iana.org/assignments/sasl-mechanisms/sasl-mechanisms.xhtml	GSSAPI	String
securityProtocol (security)	Protocol used to communicate with brokers. Currently only PLAINTEXT and SSL are supported.	PLAINTEXT	String
sslCipherSuites (security)	A list of cipher suites. This is a named combination of authentication, encryption, MAC and key exchange algorithm used to negotiate the security settings for a network connection using TLS or SSL network protocol. By default all the available cipher suites are supported.		String
sslContextParameters (security)	SSL configuration using a Camel SSLContextParameters object. If configured it's applied before the other SSL endpoint parameters.		SSLContextParameters
sslEnabledProtocols (security)	The list of protocols enabled for SSL connections. TLSv1.2, TLSv1.1 and TLSv1 are enabled by default.	TLSv1.2, TLSv1.1, TLSv1	String
sslEndpointAlgorithm (security)	The endpoint identification algorithm to validate server hostname using server certificate.		String
sslKeymanagerAlgorithm (security)	The algorithm used by key manager factory for SSL connections. Default value is the key manager factory algorithm configured for the Java Virtual Machine.	SunX509	String
sslKeyPassword (security)	The password of the private key in the key store file. This is optional for client.		String
sslKeystoreLocation (security)	The location of the key store file. This is optional for client and can be used for two-way authentication for client.		String
sslKeystorePassword (security)	The store password for the key store file. This is optional for client and only needed if <code>ssl.keystore.location</code> is configured.		String

Name	Description	Default	Type
sslKeystoreType (security)	The file format of the key store file. This is optional for client. Default value is JKS	JKS	String
sslProtocol (security)	The SSL protocol used to generate the SSLContext. Default setting is TLS, which is fine for most cases. Allowed values in recent JVMs are TLS, TLSv1.1 and TLSv1.2. SSL, SSLv2 and SSLv3 may be supported in older JVMs, but their usage is discouraged due to known security vulnerabilities.	TLS	String
sslProvider (security)	The name of the security provider used for SSL connections. Default value is the default security provider of the JVM.		String
sslTrustmanagerAlgorithm (security)	The algorithm used by trust manager factory for SSL connections. Default value is the trust manager factory algorithm configured for the Java Virtual Machine.	PKIX	String
sslTruststoreLocation (security)	The location of the trust store file.		String
sslTruststorePassword (security)	The password for the trust store file.		String
sslTruststoreType (security)	The file format of the trust store file. Default value is JKS.	JKS	String

190.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 98 options, which are listed below.

Name	Description	Default	Type
camel.component.kafka.allow-manual-commit	Whether to allow doing manual commits via KafkaManualCommit. If this option is enabled then an instance of KafkaManualCommit is stored on the Exchange message header, which allows end users to access this API and perform manual offset commits via the Kafka consumer.	false	Boolean

Name	Description	Default	Type
camel.component.kafka.break-on-first-error	This options controls what happens when a consumer is processing an exchange and it fails. If the option is false then the consumer continues to the next message and processes it. If the option is true then the consumer breaks out, and will seek back to offset of the message that caused a failure, and then re-attempt to process this message. However this can lead to endless processing of the same message if its bound to fail every time, eg a poison message. Therefore its recommended to deal with that for example by using Camel's error handler.	false	Boolean
camel.component.kafka.brokers	URL of the Kafka brokers to use. The format is host1:port1,host2:port2, and the list can be a subset of brokers or a VIP pointing to a subset of brokers. This option is known as bootstrap.servers in the Kafka documentation.		String
camel.component.kafka.configuration.allow-manual-commit	Whether to allow doing manual commits via KafkaManualCommit. If this option is enabled then an instance of KafkaManualCommit is stored on the Exchange message header, which allows end users to access this API and perform manual offset commits via the Kafka consumer.	false	Boolean
camel.component.kafka.configuration.auto-commit-enable	If true, periodically commit to ZooKeeper the offset of messages already fetched by the consumer. This committed offset will be used when the process fails as the position from which the new consumer will begin.	true	Boolean
camel.component.kafka.configuration.auto-commit-interval-ms	The frequency in ms that the consumer offsets are committed to zookeeper.	5000	Integer
camel.component.kafka.configuration.auto-commit-stop	Whether to perform an explicit auto commit when the consumer stops to ensure the broker has a commit from the last consumed message. This requires the option autoCommitEnable is turned on. The possible values are: sync, async, or none. And sync is the default value.	sync	String
camel.component.kafka.configuration.auto-offset-reset	What to do when there is no initial offset in ZooKeeper or if an offset is out of range: earliest : automatically reset the offset to the earliest offset latest : automatically reset the offset to the latest offset fail: throw exception to the consumer	latest	String

Name	Description	Default	Type
<code>camel.component.kafka.configuration.break-on-first-error</code>	This options controls what happens when a consumer is processing an exchange and it fails. If the option is false then the consumer continues to the next message and processes it. If the option is true then the consumer breaks out, and will seek back to offset of the message that caused a failure, and then re-attempt to process this message. However this can lead to endless processing of the same message if its bound to fail every time, eg a poison message. Therefore its recommended to deal with that for example by using Camel's error handler.	false	Boolean
<code>camel.component.kafka.configuration.bridge-endpoint</code>	If the option is true, then KafkaProducer will ignore the KafkaConstants.TOPIC header setting of the inbound message.	false	Boolean
<code>camel.component.kafka.configuration.brokers</code>	URL of the Kafka brokers to use. The format is host1:port1,host2:port2, and the list can be a subset of brokers or a VIP pointing to a subset of brokers. This option is known as bootstrap.servers in the Kafka documentation.		String
<code>camel.component.kafka.configuration.buffer-memory-size</code>	The total bytes of memory the producer can use to buffer records waiting to be sent to the server. If records are sent faster than they can be delivered to the server the producer will either block or throw an exception based on the preference specified by block.on.buffer.full.This setting should correspond roughly to the total memory the producer will use, but is not a hard bound since not all memory the producer uses is used for buffering. Some additional memory will be used for compression (if compression is enabled) as well as for maintaining in-flight requests.	33554432	Integer
<code>camel.component.kafka.configuration.check-crcs</code>	Automatically check the CRC32 of the records consumed. This ensures no on-the-wire or on-disk corruption to the messages occurred. This check adds some overhead, so it may be disabled in cases seeking extreme performance.	true	Boolean

Name	Description	Default	Type
<code>camel.component.kafka.configuration.circular-topic-detection</code>	If the option is true, then KafkaProducer will detect if the message is attempted to be sent back to the same topic it may come from, if the message was original from a kafka consumer. If the <code>KafkaConstants.TOPIC</code> header is the same as the original kafka consumer topic, then the header setting is ignored, and the topic of the producer endpoint is used. In other words this avoids sending the same message back to where it came from. This option is not in use if the option <code>bridgeEndpoint</code> is set to true.	true	Boolean
<code>camel.component.kafka.configuration.client-id</code>	The client id is a user-specified string sent in each request to help trace calls. It should logically identify the application making the request.		String
<code>camel.component.kafka.configuration.compression-codec</code>	This parameter allows you to specify the compression codec for all data generated by this producer. Valid values are none, gzip and snappy.	none	String
<code>camel.component.kafka.configuration.connection-max-idle-ms</code>	Close idle connections after the number of milliseconds specified by this config.	54000 0	Integer
<code>camel.component.kafka.configuration.consumer-request-timeout-ms</code>	The configuration controls the maximum amount of time the client will wait for the response of a request. If the response is not received before the timeout elapses the client will resend the request if necessary or fail the request if retries are exhausted.	40000	Integer
<code>camel.component.kafka.configuration.consumer-streams</code>	Number of concurrent consumers on the consumer	10	Integer
<code>camel.component.kafka.configuration.consumers-count</code>	The number of consumers that connect to kafka server	1	Integer

Name	Description	Default	Type
<code>camel.component.kafka.configuration.enable-idempotence</code>	If set to 'true' the producer will ensure that exactly one copy of each message is written in the stream. If 'false', producer retries may write duplicates of the retried message in the stream. If set to true this option will require <code>max.in.flight.requests.per.connection</code> to be set to 1 and retries cannot be zero and additionally acks must be set to 'all'.	false	Boolean
<code>camel.component.kafka.configuration.fetch-max-bytes</code>	The maximum amount of data the server should return for a fetch request This is not an absolute maximum, if the first message in the first non-empty partition of the fetch is larger than this value, the message will still be returned to ensure that the consumer can make progress. The maximum message size accepted by the broker is defined via <code>message.max.bytes</code> (broker config) or <code>max.message.bytes</code> (topic config). Note that the consumer performs multiple fetches in parallel.	52428800	Integer
<code>camel.component.kafka.configuration.fetch-min-bytes</code>	The minimum amount of data the server should return for a fetch request. If insufficient data is available the request will wait for that much data to accumulate before answering the request.	1	Integer
<code>camel.component.kafka.configuration.fetch-wait-max-ms</code>	The maximum amount of time the server will block before answering the fetch request if there isn't sufficient data to immediately satisfy <code>fetch.min.bytes</code>	500	Integer
<code>camel.component.kafka.configuration.group-id</code>	A string that uniquely identifies the group of consumer processes to which this consumer belongs. By setting the same group id multiple processes indicate that they are all part of the same consumer group. This option is required for consumers.		String
<code>camel.component.kafka.configuration.header-filter-strategy</code>	To use a custom <code>HeaderFilterStrategy</code> to filter header to and from Camel message.		<code>HeaderFilterStrategy</code>

Name	Description	Default	Type
<code>camel.component.kafka.configuration.heartbeat-interval-ms</code>	The expected time between heartbeats to the consumer coordinator when using Kafka's group management facilities. Heartbeats are used to ensure that the consumer's session stays active and to facilitate rebalancing when new consumers join or leave the group. The value must be set lower than <code>session.timeout.ms</code> , but typically should be set no higher than 1/3 of that value. It can be adjusted even lower to control the expected time for normal rebalances.	3000	Integer
<code>camel.component.kafka.configuration.interceptor-classes</code>	Sets interceptors for producer or consumers. Producer interceptors have to be classes implementing <code>org.apache.kafka.clients.producer.ProducerInterceptor</code> or Consumer interceptors have to be classes implementing <code>org.apache.kafka.clients.consumer.ConsumerInterceptor</code> Note that if you use Producer interceptor on a consumer it will throw a class cast exception in runtime		String
<code>camel.component.kafka.configuration.kafka-header-deserializer</code>	Sets custom <code>KafkaHeaderDeserializer</code> for deserialization kafka headers values to camel headers values.		<code>KafkaHeaderDeserializer</code>
<code>camel.component.kafka.configuration.kafka-header-serializer</code>	Sets custom <code>KafkaHeaderSerializer</code> for serialization camel headers values to kafka headers values.		<code>KafkaHeaderSerializer</code>
<code>camel.component.kafka.configuration.kerberos-before-relogin-min-time</code>	Login thread sleep time between refresh attempts.	60000	Integer
<code>camel.component.kafka.configuration.kerberos-init-cmd</code>	Kerberos kinit command path. Default is <code>/usr/bin/kinit</code>	<code>/usr/bin/kinit</code>	String

Name	Description	Default	Type
<code>camel.component.kafka.configuration.kerberos-principal-to-local-rules</code>	A list of rules for mapping from principal names to short names (typically operating system usernames). The rules are evaluated in order and the first rule that matches a principal name is used to map it to a short name. Any later rules in the list are ignored. By default, principal names of the form <code>username/hostnameREALM</code> are mapped to <code>username</code> . For more details on the format please see security authorization and acls. Multiple values can be separated by comma	DEFAULT	String
<code>camel.component.kafka.configuration.kerberos-renew-jitter</code>	Percentage of random jitter added to the renewal time.		Double
<code>camel.component.kafka.configuration.kerberos-renew-window-factor</code>	Login thread will sleep until the specified window factor of time from last refresh to ticket's expiry has been reached, at which time it will try to renew the ticket.		Double
<code>camel.component.kafka.configuration.key</code>	The record key (or null if no key is specified). If this option has been configured then it take precedence over header <code>KafkaConstants#KEY</code>		String
<code>camel.component.kafka.configuration.key-deserializer</code>	Deserializer class for key that implements the <code>Deserializer</code> interface.	<code>org.apache.kafka.common.serialization.StringDeserializer</code>	String
<code>camel.component.kafka.configuration.key-serializer-class</code>	The serializer class for keys (defaults to the same as for messages if nothing is given).	<code>org.apache.kafka.common.serialization.StringSerializer</code>	String

Name	Description	Default	Type
camel.component.kafka.configuration.linger-ms	The producer groups together any records that arrive in between request transmissions into a single batched request. Normally this occurs only under load when records arrive faster than they can be sent out. However in some circumstances the client may want to reduce the number of requests even under moderate load. This setting accomplishes this by adding a small amount of artificial delay that is, rather than immediately sending out a record the producer will wait for up to the given delay to allow other records to be sent so that the sends can be batched together. This can be thought of as analogous to Nagle's algorithm in TCP. This setting gives the upper bound on the delay for batching: once we get batch.size worth of records for a partition it will be sent immediately regardless of this setting, however if we have fewer than this many bytes accumulated for this partition we will 'linger' for the specified time waiting for more records to show up. This setting defaults to 0 (i.e. no delay). Setting linger.ms=5, for example, would have the effect of reducing the number of requests sent but would add up to 5ms of latency to records sent in the absence of load.	0	Integer
camel.component.kafka.configuration.max-block-ms	The configuration controls how long sending to kafka will block. These methods can be blocked for multiple reasons. For e.g: buffer full, metadata unavailable. This configuration imposes maximum limit on the total time spent in fetching metadata, serialization of key and value, partitioning and allocation of buffer memory when doing a send(). In case of partitionsFor(), this configuration imposes a maximum time threshold on waiting for metadata	60000	Integer
camel.component.kafka.configuration.max-in-flight-request	The maximum number of unacknowledged requests the client will send on a single connection before blocking. Note that if this setting is set to be greater than 1 and there are failed sends, there is a risk of message re-ordering due to retries (i.e., if retries are enabled).	5	Integer
camel.component.kafka.configuration.max-partition-fetch-bytes	The maximum amount of data per-partition the server will return. The maximum total memory used for a request will be #partitions max.partition.fetch.bytes. This size must be at least as large as the maximum message size the server allows or else it is possible for the producer to send messages larger than the consumer can fetch. If that happens, the consumer can get stuck trying to fetch a large message on a certain partition.	1048576	Integer

Name	Description	Default	Type
<code>camel.component.kafka.configuration.max-poll-interval-ms</code>	The maximum delay between invocations of <code>poll()</code> when using consumer group management. This places an upper bound on the amount of time that the consumer can be idle before fetching more records. If <code>poll()</code> is not called before expiration of this timeout, then the consumer is considered failed and the group will rebalance in order to reassign the partitions to another member.		Long
<code>camel.component.kafka.configuration.max-poll-records</code>	The maximum number of records returned in a single call to <code>poll()</code>	500	Integer
<code>camel.component.kafka.configuration.max-request-size</code>	The maximum size of a request. This is also effectively a cap on the maximum record size. Note that the server has its own cap on record size which may be different from this. This setting will limit the number of record batches the producer will send in a single request to avoid sending huge requests.	1048576	Integer
<code>camel.component.kafka.configuration.metadata-max-age-ms</code>	The period of time in milliseconds after which we force a refresh of metadata even if we haven't seen any partition leadership changes to proactively discover any new brokers or partitions.	300000	Integer
<code>camel.component.kafka.configuration.metric-reporters</code>	A list of classes to use as metrics reporters. Implementing the <code>MetricReporter</code> interface allows plugging in classes that will be notified of new metric creation. The <code>JmxReporter</code> is always included to register JMX statistics.		String
<code>camel.component.kafka.configuration.metrics-sample-window-ms</code>	The number of samples maintained to compute metrics.	30000	Integer
<code>camel.component.kafka.configuration.no-of-metrics-sample</code>	The number of samples maintained to compute metrics.	2	Integer
<code>camel.component.kafka.configuration.offset-repository</code>	The offset repository to use in order to locally store the offset of each partition of the topic. Defining one will disable the autocommit.		StateRepository

Name	Description	Default	Type
<code>camel.component.kafka.configuration.partition-assignor</code>	The class name of the partition assignment strategy that the client will use to distribute partition ownership amongst consumer instances when group management is used	<code>org.apache.kafka.clients.consumer.RangeAssignor</code>	String
<code>camel.component.kafka.configuration.partition-key</code>	The partition to which the record will be sent (or null if no partition was specified). If this option has been configured then it take precedence over header <code>KafkaConstants#PARTITION_KEY</code>		Integer
<code>camel.component.kafka.configuration.partitioners</code>	The partitioner class for partitioning messages amongst sub-topics. The default partitioner is based on the hash of the key.	<code>org.apache.kafka.clients.producer.internals.DefaultPartitioner</code>	String
<code>camel.component.kafka.configuration.poll-timeout-ms</code>	The timeout used when polling the <code>KafkaConsumer</code> .	5000	Long
<code>camel.component.kafka.configuration.producer.batch-size</code>	The producer will attempt to batch records together into fewer requests whenever multiple records are being sent to the same partition. This helps performance on both the client and the server. This configuration controls the default batch size in bytes. No attempt will be made to batch records larger than this size. Requests sent to brokers will contain multiple batches, one for each partition with data available to be sent. A small batch size will make batching less common and may reduce throughput (a batch size of zero will disable batching entirely). A very large batch size may use memory a bit more wastefully as we will always allocate a buffer of the specified batch size in anticipation of additional records.	16384	Integer
<code>camel.component.kafka.configuration.queue-buffering-max-messages</code>	The maximum number of unsent messages that can be queued up the producer when using async mode before either the producer must be blocked or data must be dropped.	10000	Integer

Name	Description	Default	Type
<code>camel.component.kafka.configuration.receive-buffer-bytes</code>	The size of the TCP receive buffer (SO_RCVBUF) to use when reading data.	65536	Integer
<code>camel.component.kafka.configuration.reconnect-backoff-max-ms</code>	The maximum amount of time in milliseconds to wait when reconnecting to a broker that has repeatedly failed to connect. If provided, the backoff per host will increase exponentially for each consecutive connection failure, up to this maximum. After calculating the backoff increase, 20% random jitter is added to avoid connection storms.	1000	Integer
<code>camel.component.kafka.configuration.reconnect-backoff-ms</code>	The amount of time to wait before attempting to reconnect to a given host. This avoids repeatedly connecting to a host in a tight loop. This backoff applies to all requests sent by the consumer to the broker.	50	Integer
<code>camel.component.kafka.configuration.record-metadata</code>	Whether the producer should store the RecordMetadata results from sending to Kafka. The results are stored in a List containing the RecordMetadata metadata's. The list is stored on a header with the key <code>KafkaConstants#KAFKA_RECORDMETA</code>	true	Boolean

Name	Description	Default	Type
camel.component.kafka.configuration.request-required-acks	The number of acknowledgments the producer requires the leader to have received before considering a request complete. This controls the durability of records that are sent. The following settings are common: <code>acks=0</code> If set to zero then the producer will not wait for any acknowledgment from the server at all. The record will be immediately added to the socket buffer and considered sent. No guarantee can be made that the server has received the record in this case, and the retries configuration will not take effect (as the client won't generally know of any failures). The offset given back for each record will always be set to <code>-1</code> . <code>acks=1</code> This will mean the leader will write the record to its local log but will respond without awaiting full acknowledgement from all followers. In this case should the leader fail immediately after acknowledging the record but before the followers have replicated it then the record will be lost. <code>acks=all</code> This means the leader will wait for the full set of in-sync replicas to acknowledge the record. This guarantees that the record will not be lost as long as at least one in-sync replica remains alive. This is the strongest available guarantee.	1	String
camel.component.kafka.configuration.request-timeout-ms	The amount of time the broker will wait trying to meet the <code>request.required.acks</code> requirement before sending back an error to the client.	305000	Integer
camel.component.kafka.configuration.retries	Setting a value greater than zero will cause the client to resend any record whose send fails with a potentially transient error. Note that this retry is no different than if the client resent the record upon receiving the error. Allowing retries will potentially change the ordering of records because if two records are sent to a single partition, and the first fails and is retried but the second succeeds, then the second record may appear first.	0	Integer
camel.component.kafka.configuration.retry-backoff-ms	Before each retry, the producer refreshes the metadata of relevant topics to see if a new leader has been elected. Since leader election takes a bit of time, this property specifies the amount of time that the producer waits before refreshing the metadata.	100	Integer

Name	Description	Default	Type
<code>camel.component.kafka.configuration.sasl-jaas-config</code>	Expose the kafka <code>sasl.jaas.config</code> parameter Example: <code>org.apache.kafka.common.security.plain.PlainLoginModule required username=USERNAME password=PASSWORD;</code>		String
<code>camel.component.kafka.configuration.sasl-kerberos-service-name</code>	The Kerberos principal name that Kafka runs as. This can be defined either in Kafka's JAAS config or in Kafka's config.		String
<code>camel.component.kafka.configuration.sasl-mechanism</code>	The Simple Authentication and Security Layer (SASL) Mechanism used. For the valid values see http://www.iana.org/assignments/sasl-mechanisms/sasl-mechanisms.xhtml	GSSAPI	String
<code>camel.component.kafka.configuration.security-protocol</code>	Protocol used to communicate with brokers. Currently only PLAINTEXT and SSL are supported.	PLAINTEXT	String
<code>camel.component.kafka.configuration.seek-to</code>	Set if KafkaConsumer will read from beginning or end on startup: <code>beginning</code> : read from beginning <code>end</code> : read from end This is replacing the earlier property <code>seekToBeginning</code>		String
<code>camel.component.kafka.configuration.send-buffer-bytes</code>	Socket write buffer size	131072	Integer
<code>camel.component.kafka.configuration.serializer-class</code>	The serializer class for messages.	<code>org.apache.kafka.common.serialization.StringSerializer</code>	String
<code>camel.component.kafka.configuration.session-timeout-ms</code>	The timeout used to detect failures when using Kafka's group management facilities.	10000	Integer

Name	Description	Default	Type
<code>camel.component.kafka.configuration.ssl-cipher-suites</code>	A list of cipher suites. This is a named combination of authentication, encryption, MAC and key exchange algorithm used to negotiate the security settings for a network connection using TLS or SSL network protocol. By default all the available cipher suites are supported.		String
<code>camel.component.kafka.configuration.ssl-context-parameters</code>	SSL configuration using a Camel <code>SSLContextParameters</code> object. If configured it's applied before the other SSL endpoint parameters.		<code>SSLContextParameters</code>
<code>camel.component.kafka.configuration.ssl-enabled-protocols</code>	The list of protocols enabled for SSL connections. <code>TLSv1.2</code> , <code>TLSv1.1</code> and <code>TLSv1</code> are enabled by default.	<code>TLSv1.2</code> , <code>TLSv1.1</code> , <code>TLSv1</code>	String
<code>camel.component.kafka.configuration.ssl-endpoint-algorithm</code>	The endpoint identification algorithm to validate server hostname using server certificate.		String
<code>camel.component.kafka.configuration.ssl-key-password</code>	The password of the private key in the key store file. This is optional for client.		String
<code>camel.component.kafka.configuration.ssl-keymanager-algorithm</code>	The algorithm used by key manager factory for SSL connections. Default value is the key manager factory algorithm configured for the Java Virtual Machine.	<code>SunX509</code>	String
<code>camel.component.kafka.configuration.ssl-keystore-location</code>	The location of the key store file. This is optional for client and can be used for two-way authentication for client.		String
<code>camel.component.kafka.configuration.ssl-keystore-password</code>	The store password for the key store file. This is optional for client and only needed if <code>ssl.keystore.location</code> is configured.		String
<code>camel.component.kafka.configuration.ssl-keystore-type</code>	The file format of the key store file. This is optional for client. Default value is <code>JKS</code>	<code>JKS</code>	String

Name	Description	Default	Type
<code>camel.component.kafka.configuration.ssl-protocol</code>	The SSL protocol used to generate the SSLContext. Default setting is TLS, which is fine for most cases. Allowed values in recent JVMs are TLS, TLSv1.1 and TLSv1.2. SSL, SSLv2 and SSLv3 may be supported in older JVMs, but their usage is discouraged due to known security vulnerabilities.	TLS	String
<code>camel.component.kafka.configuration.ssl-provider</code>	The name of the security provider used for SSL connections. Default value is the default security provider of the JVM.		String
<code>camel.component.kafka.configuration.ssl-trustmanager-algorithm</code>	The algorithm used by trust manager factory for SSL connections. Default value is the trust manager factory algorithm configured for the Java Virtual Machine.	PKIX	String
<code>camel.component.kafka.configuration.ssl-truststore-location</code>	The location of the trust store file.		String
<code>camel.component.kafka.configuration.ssl-truststore-password</code>	The password for the trust store file.		String
<code>camel.component.kafka.configuration.ssl-truststore-type</code>	The file format of the trust store file. Default value is JKS.	JKS	String
<code>camel.component.kafka.configuration.topic</code>	Name of the topic to use. On the consumer you can use comma to separate multiple topics. A producer can only send a message to a single topic.		String
<code>camel.component.kafka.configuration.topic-is-pattern</code>	Whether the topic is a pattern (regular expression). This can be used to subscribe to dynamic number of topics matching the pattern.	false	Boolean

Name	Description	Default	Type
<code>camel.component.kafka.configuration.value-deserializer</code>	Deserializer class for value that implements the Deserializer interface.	<code>org.apache.kafka.common.serialization.StringDeserializer</code>	String
<code>camel.component.kafka.configuration.worker-pool</code>	To use a custom worker pool for continue routing Exchange after kafka server has acknowledge the message that was sent to it from KafkaProducer using asynchronous non-blocking processing.		ExecutorService
<code>camel.component.kafka.configuration.worker-pool-core-size</code>	Number of core threads for the worker pool for continue routing Exchange after kafka server has acknowledge the message that was sent to it from KafkaProducer using asynchronous non-blocking processing.	10	Integer
<code>camel.component.kafka.configuration.worker-pool-max-size</code>	Maximum number of threads for the worker pool for continue routing Exchange after kafka server has acknowledge the message that was sent to it from KafkaProducer using asynchronous non-blocking processing.	20	Integer
<code>camel.component.kafka.enabled</code>	Enable kafka component	true	Boolean
<code>camel.component.kafka.kafka-manual-commit-factory</code>	Factory to use for creating KafkaManualCommit instances. This allows to plugin a custom factory to create custom KafkaManualCommit instances in case special logic is needed when doing manual commits that deviates from the default implementation that comes out of the box. The option is a <code>org.apache.camel.component.kafka.KafkaManualCommitFactory</code> type.		String
<code>camel.component.kafka.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.component.kafka.use-global-ssl-context-parameters</code>	Enable usage of global SSL context parameters.	false	Boolean

Name	Description	Default	Type
<code>camel.component.kafka.worker-pool</code>	To use a shared custom worker pool for continue routing Exchange after kafka server has acknowledge the message that was sent to it from KafkaProducer using asynchronous non-blocking processing. If using this option then you must handle the lifecycle of the thread pool to shut the pool down when no longer needed. The option is a <code>java.util.concurrent.ExecutorService</code> type.		String

For more information about Producer/Consumer configuration:

<http://kafka.apache.org/documentation.html#newconsumerconfigs><http://kafka.apache.org/documentation.html#newconsumerconfigs>

190.4. MESSAGE HEADERS

190.4.1. Consumer headers

The following headers are available when consuming messages from Kafka.

Header constant	Header value	Type	Description
<code>KafkaConstants.TOPIC</code>	"kafka.TOPIC"	String	The topic from where the message originated
<code>KafkaConstants.PARTITION</code>	"kafka.PARTITION"	Integer	The partition where the message was stored
<code>KafkaConstants.OFFSET</code>	"kafka.OFFSET"	Long	The offset of the message
<code>KafkaConstants.KEY</code>	"kafka.KEY"	Object	The key of the message if configured
<code>KafkaConstants.HEADERS</code>	"kafka.HEADERS"	<code>org.apache.kafka.common.header.Headers</code>	The record headers
<code>KafkaConstants.LAST_RECORD_BEFORE_COMMIT</code>	"kafka.LAST_RECORD_BEFORE_COMMIT"	Boolean	Whether or not it's the last record before commit (only available if <code>autoCommitEnable</code> endpoint parameter is <code>false</code>)

Header constant	Header value	Type	Description
KafkaConstants .MANUAL_COMMIT	"CamelKafkaManualCommit"	KafkaManualCommit	Can be used for forcing manual offset commit when using Kafka consumer.

190.4.2. Producer headers

Before sending a message to Kafka you can configure the following headers.

Header constant	Header value	Type	Description
KafkaConstants .KEY	"kafka.KEY"	Object	Required The key of the message in order to ensure that all related message goes in the same partition
KafkaConstants .TOPIC	"kafka.TOPIC"	String	The topic to which send the message (only read if the bridgeEndpoint endpoint parameter is true)
KafkaConstants .PARTITION_KEY	"kafka.PARTITION_KEY"	Integer	Explicitly specify the partition (only used if the KafkaConstants.KEY header is defined)

After the message is sent to Kafka, the following headers are available

Header constant	Header value	Type	Description
KafkaConstants .KAFKA_RECORDMETA	"org.apache.kafka.clients.producer.RecordMetadata"	List<RecordMetadata>	The metadata (only configured if recordMetadata endpoint parameter is true)

190.5. SAMPLES

190.5.1. Consuming messages from Kafka

Here is the minimal route you need in order to read messages from Kafka.

```
from("kafka:test?brokers=localhost:9092")
  .log("Message received from Kafka : ${body}")
  .log("  on the topic ${headers[kafka.TOPIC]}")
  .log("  on the partition ${headers[kafka.PARTITION]}")
  .log("  with the offset ${headers[kafka.OFFSET]}")
  .log("  with the key ${headers[kafka.KEY]}")
```

If you need to consume messages from multiple topics you can use a comma separated list of topic names

```
from("kafka:test,test1 ,test2?brokers=localhost:9092")
    .log("Message received from Kafka : ${body}")
    .log("  on the topic ${headers[kafka.TOPIC]}")
    .log("  on the partition ${headers[kafka.PARTITION]}")
    .log("  with the offset ${headers[kafka.OFFSET]}")
    .log("  with the key ${headers[kafka.KEY]}")
```

When consuming messages from Kafka you can use your own offset management and not delegate this management to Kafka. In order to keep the offsets the component needs a **StateRepository** implementation such as **FileStateRepository**. This bean should be available in the registry. Here how to use it :

```
// Create the repository in which the Kafka offsets will be persisted
FileStateRepository repository = FileStateRepository.fileStateRepository(new
File("/path/to/repo.dat"));

// Bind this repository into the Camel registry
JndiRegistry registry = new JndiRegistry();
registry.bind("offsetRepo", repository);

// Configure the camel context
DefaultCamelContext camelContext = new DefaultCamelContext(registry);
camelContext.addRoutes(new RouteBuilder() {
    @Override
    public void configure() throws Exception {
        from("kafka:" + TOPIC + "?brokers=localhost:{{kafkaPort}}" +
            // Setup the topic and broker address
            "&groupId=A" +
            // The consumer processor group ID
            "&autoOffsetReset=earliest" +
            // Ask to start from the beginning if we have unknown offset
            "&offsetRepository=#offsetRepo")
            // Keep the offsets in the previously configured repository
            .to("mock:result");
    }
});
```

190.5.2. Producing messages to Kafka

Here is the minimal route you need in order to write messages to Kafka.

```
from("direct:start")
    .setBody(constant("Message from Camel")) // Message to send
    .setHeader(KafkaConstants.KEY, constant("Camel")) // Key of the message
    .to("kafka:test?brokers=localhost:9092");
```

190.6. SSL CONFIGURATION

You have 2 different ways to configure the SSL communication on the Kafka` component.

The first way is through the many SSL endpoint parameters

```
from("kafka:" + TOPIC + "?brokers=localhost:{{kafkaPort}}" +
    "&groupId=A" +
    "&sslKeystoreLocation=/path/to/keystore.jks" +
    "&sslKeystorePassword=changeit" +
    "&sslKeyPassword=changeit" +
    "&securityProtocol=SSL")
    .to("mock:result");
```

The second way is to use the **sslContextParameters** endpoint parameter.

```
// Configure the SSLContextParameters object
KeyStoreParameters ksp = new KeyStoreParameters();
ksp.setResource("/path/to/keystore.jks");
ksp.setPassword("changeit");
KeyManagersParameters kmp = new KeyManagersParameters();
kmp.setKeyStore(ksp);
kmp.setKeyPassword("changeit");
SSLContextParameters scp = new SSLContextParameters();
scp.setKeyManagers(kmp);

// Bind this SSLContextParameters into the Camel registry
JndiRegistry registry = new JndiRegistry();
registry.bind("ssl", scp);

// Configure the camel context
DefaultCamelContext camelContext = new DefaultCamelContext(registry);
camelContext.addRoutes(new RouteBuilder() {
    @Override
    public void configure() throws Exception {
        from("kafka:" + TOPIC + "?brokers=localhost:{{kafkaPort}}" +
            // Setup the topic and broker address
            "&groupId=A" +
            // The consumer processor group ID
            "&sslContextParameters=#ssl" +
            // The security protocol
            "&securityProtocol=SSL")
            // Reference the SSL configuration
            .to("mock:result");
    }
});
```

190.7. USING THE KAFKA IDEMPOTENT REPOSITORY

Available from Camel 2.19

The **camel-kafka** library provides a Kafka topic-based idempotent repository. This repository stores broadcasts all changes to idempotent state (add/remove) in a Kafka topic, and populates a local in-memory cache for each repository's process instance through event sourcing.

The topic used must be unique per idempotent repository instance. The mechanism does not have any requirements about the number of topic partitions; as the repository consumes from all partitions at the same time. It also does not have any requirements about the replication factor of the topic.

Each repository instance that uses the topic (e.g. typically on different machines running in parallel) controls its own consumer group, so in a cluster of 10 Camel processes using the same topic each will control its own offset.

On startup, the instance subscribes to the topic and rewinds the offset to the beginning, rebuilding the cache to the latest state. The cache will not be considered warmed up until one poll of **pollDurationMs** in length returns 0 records. Startup will not be completed until either the cache has warmed up, or 30 seconds go by; if the latter happens the idempotent repository may be in an inconsistent state until its consumer catches up to the end of the topic.

A **KafkaldempotentRepository** has the following properties:

Property	Description
topic	The name of the Kafka topic to use to broadcast changes. (required)
bootstrapServers	The bootstrap.servers property on the internal Kafka producer and consumer. Use this as shorthand if not setting consumerConfig and producerConfig . If used, this component will apply sensible default configurations for the producer and consumer.
producerConfig	Sets the properties that will be used by the Kafka producer that broadcasts changes. Overrides bootstrapServers , so must define the Kafka bootstrap.servers property itself
consumerConfig	Sets the properties that will be used by the Kafka consumer that populates the cache from the topic. Overrides bootstrapServers , so must define the Kafka bootstrap.servers property itself
maxCacheSize	How many of the most recently used keys should be stored in memory (default 1000).
pollDurationMs	The poll duration of the Kafka consumer. The local caches are updated immediately. This value will affect how far behind other peers that update their caches from the topic are relative to the idempotent consumer instance that sent the cache action message. The default value of this is 100 ms. If setting this value explicitly, be aware that there is a tradeoff between the remote cache liveness and the volume of network traffic between this repository's consumer and the Kafka brokers. The cache warmup process also depends on there being one poll that fetches nothing - this indicates that the stream has been consumed up to the current point. If the poll duration is excessively long for the rate at which messages are sent on the topic, there exists a possibility that the cache cannot be warmed up and will operate in an inconsistent state relative to its peers until it catches up.

The repository can be instantiated by defining the **topic** and **bootstrapServers**, or the **producerConfig** and **consumerConfig** property sets can be explicitly defined to enable features such as SSL/SASL.

To use, this repository must be placed in the Camel registry, either manually or by registration as a bean in Spring/Blueprint, as it is **CamelContext** aware.

Sample usage is as follows:

■

```

KafkaldempotentRepository kafkaldempotentRepository = new
KafkaldempotentRepository("idempotent-db-inserts", "localhost:9091");

SimpleRegistry registry = new SimpleRegistry();
registry.put("insertDbldemRepo", kafkaldempotentRepository); // must be registered in the registry, to
enable access to the CamelContext
CamelContext context = new CamelContext(registry);

// later in RouteBuilder...
from("direct:performInsert")
    .idempotentConsumer(header("id")).messageIdRepositoryRef("insertDbldemRepo")
        // once-only insert into database
    .end()

```

In XML:

```

<!-- simple -->
<bean id="insertDbldemRepo"
    class="org.apache.camel.processor.idempotent.kafka.KafkaldempotentRepository">
    <property name="topic" value="idempotent-db-inserts"/>
    <property name="bootstrapServers" value="localhost:9091"/>
</bean>

<!-- complex -->
<bean id="insertDbldemRepo"
    class="org.apache.camel.processor.idempotent.kafka.KafkaldempotentRepository">
    <property name="topic" value="idempotent-db-inserts"/>
    <property name="maxCacheSize" value="10000"/>
    <property name="consumerConfig">
        <props>
            <prop key="bootstrap.servers">localhost:9091</prop>
        </props>
    </property>
    <property name="producerConfig">
        <props>
            <prop key="bootstrap.servers">localhost:9091</prop>
        </props>
    </property>
</bean>

```

190.8. USING MANUAL COMMIT WITH KAFKA CONSUMER

Available as of Camel 2.21

By default the Kafka consumer will use auto commit, where the offset will be committed automatically in the background using a given interval.

In case you want to force manual commits, you can use **KafkaManualCommit** API from the Camel Exchange, stored on the message header. This requires to turn on manual commits by either setting the option **allowManualCommit** to **true** on the **KafkaComponent** or on the endpoint, for example:

```

KafkaComponent kafka = new KafkaComponent();
kafka.setAllowManualCommit(true);
...
camelContext.addComponent("kafka", kafka);

```

You can then use the **KafkaManualCommit** from Java code such as a Camel **Processor**:

```
public void process(Exchange exchange) {
    KafkaManualCommit manual =
        exchange.getIn().getHeader(KafkaConstants.MANUAL_COMMIT, KafkaManualCommit.class);
    manual.commitSync();
}
```

This will force a synchronous commit which will block until the commit is acknowledged on Kafka, or if it fails an exception is thrown.

If you want to use a custom implementation of **KafkaManualCommit** then you can configure a custom **KafkaManualCommitFactory** on the **KafkaComponent** that creates instances of your custom implementation.

190.9. KAFKA HEADERS PROPAGATION

Available as of Camel 2.22

When consuming messages from Kafka, headers will be propagated to camel exchange headers automatically. Producing flow backed by same behaviour - camel headers of particular exchange will be propagated to kafka message headers.

Since kafka headers allows only **byte[]** values, in order camel exchange header to be propagated its value should be serialized to **bytes[]**, otherwise header will be skipped. Following header value types are supported: **String, Integer, Long, Double, Boolean, byte[]**. Note: all headers propagated **from** kafka **to** camel exchange will contain **byte[]** value by default. In order to override default functionality uri parameters can be set: **kafkaHeaderDeserializer** for **from** route and **kafkaHeaderSerializer** for **to** route. Example:

```
from("kafka:my_topic?kafkaHeaderDeserializer=#myDeserializer")
...
.to("kafka:my_topic?kafkaHeaderSerializer=#mySerializer")
```

By default all headers are being filtered by **KafkaHeaderFilterStrategy**. Strategy filters out headers which start with **Camel** or **org.apache.camel** prefixes. Default strategy can be overridden by using **headerFilterStrategy** uri parameter in both **to** and **from** routes:

```
from("kafka:my_topic?headerFilterStrategy=#myStrategy")
...
.to("kafka:my_topic?headerFilterStrategy=#myStrategy")
```

myStrategy object should be subclass of **HeaderFilterStrategy** and must be placed in the Camel registry, either manually or by registration as a bean in Spring/Blueprint, as it is **CamelContext** aware.

CHAPTER 191. KESTREL COMPONENT (DEPRECATED)

Available as of Camel version 2.6

The Kestrel component allows messages to be sent to a [Kestrel](#) queue, or messages to be consumed from a Kestrel queue. This component uses the [spymemcached](#) client for memcached protocol communication with Kestrel servers.

WARNING

The kestrel project is inactive and the Camel team regard this components as deprecated.

191.1. URI FORMAT

```
kestrel://[addresslist]/queuename[?options]
```

Where **queuename** is the name of the queue on Kestrel. The **addresslist** part of the URI may include one or more **host:port** pairs. For example, to connect to the queue **foo** on **kserver01:22133**, use:

```
kestrel://kserver01:22133/foo
```

If the addresslist is omitted, **localhost:22133** is assumed, i.e.:

```
kestrel://foo
```

Likewise, if a port is omitted from a **host:port** pair in addresslist, the default port 22133 is assumed, i.e.:

```
kestrel://kserver01/foo
```

Here is an example of a Kestrel endpoint URI used for producing to a clustered queue:

```
kestrel://kserver01:22133,kserver02:22133,kserver03:22133/massive
```

Here is an example of a Kestrel endpoint URI used for consuming concurrently from a queue:

```
kestrel://kserver03:22133/massive?concurrentConsumers=25&waitTimeMs=500
```

191.2. OPTIONS

The Kestrel component supports 2 options, which are listed below.

Name	Description	Default	Type
configuration (advanced)	To use a shared configured configuration as base for creating new endpoints.		KestrelConfiguration
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Kestrel endpoint is configured using URI syntax:

```
kestrel:addresses/queue
```

with the following path and query parameters:

191.2.1. Path Parameters (2 parameters):

Name	Description	Default	Type
addresses	The address(es) on which kestrel is running	localhost:22133	String[]
queue	Required The queue we are polling		String

191.2.2. Query Parameters (6 parameters):

Name	Description	Default	Type
concurrentConsumers (common)	How many concurrent listeners to schedule for the thread pool	1	int
waitTimeMs (common)	How long a given wait should block (server side), in milliseconds	100	int
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean

Name	Description	Default	Type
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

191.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 5 options, which are listed below.

Name	Description	Default	Type
camel.component.kestrel.configuration.addresses	The address(es) on which kestrel is running		String[]
camel.component.kestrel.configuration.concurrent-consumers	How many concurrent listeners to schedule for the thread pool	1	Integer
camel.component.kestrel.configuration.wait-time-ms	How long a given wait should block (server side), in milliseconds	100	Integer
camel.component.kestrel.enabled	Enable kestrel component	true	Boolean
camel.component.kestrel.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

191.4. CONFIGURING THE KESTREL COMPONENT USING SPRING XML

The simplest form of explicit configuration is as follows:

```
<beans xmlns="http://www.springframework.org/schema/beans"
```

```

xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="
http://www.springframework.org/schema/beans
http://www.springframework.org/schema/beans/spring-beans.xsd
http://camel.apache.org/schema/spring http://camel.apache.org/schema/spring/camel-
spring.xsd">

<bean id="kestrel" class="org.apache.camel.component.kestrel.KestrelComponent"/>

<camelContext xmlns="http://camel.apache.org/schema/spring">
</camelContext>

</beans>

```

That will enable the Kestrel component with all default settings, i.e. it will use **localhost:22133**, 100ms wait time, and a single non-concurrent consumer by default.

To use specific options in the base configuration (which supplies configuration to endpoints whose **properties** are not specified), you can set up a KestrelConfiguration POJO as follows:

```

<beans xmlns="http://www.springframework.org/schema/beans"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xsi:schemaLocation="
http://www.springframework.org/schema/beans
http://www.springframework.org/schema/beans/spring-beans.xsd
http://camel.apache.org/schema/spring http://camel.apache.org/schema/spring/camel-
spring.xsd">

<bean id="kestrelConfiguration" class="org.apache.camel.component.kestrel.KestrelConfiguration">
<property name="addresses" value="kestrel01:22133"/>
<property name="waitTimeMs" value="100"/>
<property name="concurrentConsumers" value="1"/>
</bean>

<bean id="kestrel" class="org.apache.camel.component.kestrel.KestrelComponent">
<property name="configuration" ref="kestrelConfiguration"/>
</bean>

<camelContext xmlns="http://camel.apache.org/schema/spring">
</camelContext>

</beans>

```

191.5. USAGE EXAMPLES

191.5.1. Example 1: Consuming

```

from("kestrel://kserver02:22133/massive?concurrentConsumers=10&waitTimeMs=500")
.bean("myConsumer", "onMessage");

```

```

public class MyConsumer {
public void onMessage(String message) {
...

```

```

    }
}

```

191.5.2. Example 2: Producing

```

public class MyProducer {
    @EndpointInject(uri = "kestrel://kserver01:22133,kserver02:22133/myqueue")
    ProducerTemplate producerTemplate;

    public void produceSomething() {
        producerTemplate.sendBody("Hello, world.");
    }
}

```

191.5.3. Example 3: Spring XML Configuration

```

<camelContext xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="kestrel://ks01:22133/sequential?concurrentConsumers=1&waitTimeMs=500"/>
    <bean ref="myBean" method="onMessage"/>
  </route>
  <route>
    <from uri="direct:start"/>
    <to uri="kestrel://ks02:22133/stuff"/>
  </route>
</camelContext>

```

```

public class MyBean {
    public void onMessage(String message) {
        ...
    }
}

```

191.6. DEPENDENCIES

The Kestrel component has the following dependencies:

- **spymemcached** 2.5 (or greater)

191.6.1. spymemcached

You **must** have the **spymemcached** jar on your classpath. Here is a snippet you can use in your pom.xml:

```

<dependency>
  <groupId>spy</groupId>
  <artifactId>memcached</artifactId>
  <version>2.5</version>
</dependency>

```

Alternatively, you can [download the jar](#) directly.

Warning: Limitations

NOTE

The spymemcached client library does **not** work properly with kestrel when JVM assertions are enabled. There is a known issue with spymemcached when assertions are enabled and a requested key contains the `/t=...` extension (i.e. if you're using the **waitTimeMs** option on an endpoint URI, which is highly encouraged). Fortunately, JVM assertions are **disabled by default**, unless you [explicitly enable them](#), so this should not present a problem under normal circumstances. Something to note is that Maven's Surefire test plugin **enables** assertions. If you're using this component in a Maven test environment, you may need to set **enableAssertions** to **false**. Please refer to the [surefire:test reference](#) for details.

CHAPTER 192. KIE-CAMEL

192.1. OVERVIEW

The **kie-camel** component is an Apache Camel endpoint provided by Red Hat Fuse that integrates Fuse with Red Hat Process Automation Manager. It enables you to specify a Red Hat Process Automation Manager module by using a Maven group ID, artifact ID, and version (GAV) identifier which you can pull into the route and execute. It also enables you to specify portions of the message body as facts. You can use the **kie-camel** component with embedded engines or with Process Server.

For more details about the **kie-camel** component, see [Integrating Red Hat Fuse with Red Hat Process Automation Manager](#).

CHAPTER 193. KRATI COMPONENT (DEPRECATED)

Available as of Camel version 2.9

This component allows the use krati datastores and datasets inside Camel. Krati is a simple persistent data store with very low latency and high throughput. It is designed for easy integration with read-write-intensive applications with little effort in tuning configuration, performance and JVM garbage collection.

Camel provides a producer and consumer for krati datastore_(key/value engine)_. It also provides an idempotent repository for filtering out duplicate messages.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-krati</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

193.1. URI FORMAT

```
krati:[the path of the datastore][?options]
```

The **path of the datastore** is the relative path of the folder that krati will use for its datastore.

You can append query options to the URI in the following format, **?option=value&option=value&...**

193.2. KRATI OPTIONS

The Krati component has no options.

The Krati endpoint is configured using URI syntax:

```
krati:path
```

with the following path and query parameters:

193.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
path	Required Path of the datastore is the relative path of the folder that krati will use for its datastore.		String

193.2.2. Query Parameters (29 parameters):

Name	Description	Default	Type
hashFunction (common)	The hash function to use.		HashFunction
initialCapacity (common)	The initial capacity of the store.	100	int
keySerializer (common)	The serializer that will be used to serialize the key.		Serializer
segmentFactory (common)	Sets the segment factory of the target store.		SegmentFactory
segmentFileSize (common)	Data store segments size in MB.	64	int
valueSerializer (common)	The serializer that will be used to serialize the value.		Serializer
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which means any exceptions occurred while the consumer is trying to pick up incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
maxMessagesPerPoll (consumer)	The maximum number of messages which can be received in one poll. This can be used to avoid reading in too much data and taking up too much memory.		int
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean
exceptionHandler (consumer)	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern

Name	Description	Default	Type
pollStrategy (consumer)	A pluggable <code>org.apache.camel.PollingConsumerPollingStrategy</code> allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		PollingConsumerPollStrategy
key (producer)	The key.		String
operation (producer)	Specifies the type of operation that will be performed to the datastore.		String
value (producer)	The Value.		String
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the <code>backoffMultiplier</code> should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the <code>backoffMultiplier</code> should kick-in.		int
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then <code>backoffIdleThreshold</code> and/or <code>backoffErrorThreshold</code> must also be configured.		int
delay (scheduler)	Milliseconds before the next poll. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	500	long
greedy (scheduler)	If greedy is enabled, then the <code>ScheduledPollConsumer</code> will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	1000	long

Name	Description	Default	Type
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that.	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz2 component	none	ScheduledPollConsumerScheduler
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz2, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for initialDelay and delay options.	MILLIS SECONDS	TimeUnit
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.	true	boolean

193.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.component.krati.enabled	Enable krati component	true	Boolean
camel.component.krati.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

```
krati:/tmp/krati?operation=CamelKratiGet&initialCapacity=10000&keySerializer=#myCustomSerializer
```

For producer endpoint you can override all of the above URI options by passing the appropriate headers to the message.

193.3.1. Message Headers for datastore

Header	Description
Camel KratiOperation	The operation to be performed on the datastore. The valid options are CamelKратиAdd, CamelKратиGet, CamelKратиDelete, CamelKратиDeleteAll
Camel KratiKey	The key.
Camel KratiValue	The value.

193.4. USAGE SAMPLES

193.4.1. Example 1: Putting to the datastore.

This example will show you how you can store any message inside a datastore.

```
from("direct:put").to("krati:target/test/producerstest");
```

In the above example you can override any of the URI parameters with headers on the message. Here is how the above example would look like using xml to define our route.

```
<route>
  <from uri="direct:put"/>
  <to uri="krati:target/test/producerspringstest"/>
</route>
```

193.4.2. Example 2: Getting/Reading from a datastore

This example will show you how you can read the content of a datastore.

```
from("direct:get")
  .setHeader(KratiConstants.KRATI_OPERATION,
  constant(KratiConstants.KRATI_OPERATION_GET))
  .to("krati:target/test/producerstest");
```

In the above example you can override any of the URI parameters with headers on the message. Here is how the above example would look like using xml to define our route.

```
<route>
  <from uri="direct:get"/>
  <to uri="krati:target/test/producerspringstest?operation=CamelKратиGet"/>
</route>
```

193.4.3. Example 3: Consuming from a datastore

This example will consume all items that are under the specified datastore.

```
from("krati:target/test/consumertest")  
  .to("direct:next");
```

You can achieve the same goal by using xml, as you can see below.

```
<route>  
  <from uri="krati:target/test/consumerspringtest"/>  
  <to uri="mock:results"/>  
</route>
```

193.5. IDEMPOTENT REPOSITORY

As already mentioned this component also offers an idempotent repository which can be used for filtering out duplicate messages.

```
from("direct://in").idempotentConsumer(header("messageId"), new  
  KratiIdempotentRepository("/tmp/idempotent").to("log://out");
```

193.5.1. See also

[Kрати Website](#)

CHAPTER 194. KUBERNETES COMPONENTS

Available as of Camel version 2.17

The **Kubernetes** components integrate your application with Kubernetes standalone or on top of OpenShift.

The camel-kubernetes consists of 13 components:

- [Kubernetes ConfigMap](#)
- [Kubernetes Namespace](#)
- [Kubernetes Node](#)
- [Kubernetes Persistent Volume](#)
- [Kubernetes Persistent Volume Claim](#)
- [Kubernetes Pod](#)
- [Kubernetes Replication Controller](#)
- [Kubernetes Resource Quota](#)
- [Kubernetes Secrets](#)
- [Kubernetes Service Account](#)
- [Kubernetes Service](#)

In OpenShift, also:

- [Kubernetes Build Config](#)
- [Kubernetes Build](#)

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-kubernetes</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

194.1. HEADERS

194.2. USAGE

194.2.1. Producer examples

Here we show some examples of producer using camel-kubernetes.

194.2.2. Create a pod

```
from("direct:createPod")
  .toF("kubernetes-pods://%s?oauthToken=%s&operation=createPod", host, authToken);
```

By using the `KubernetesConstants.KUBERNETES_POD_SPEC` header you can specify your `PodSpec` and pass it to this operation.

194.2.3. Delete a pod

```
from("direct:createPod")
  .toF("kubernetes-pods://%s?oauthToken=%s&operation=deletePod", host, authToken);
```

By using the `KubernetesConstants.KUBERNETES_POD_NAME` header you can specify your Pod name and pass it to this operation.

CHAPTER 195. KUBERNETES COMPONENT (DEPRECATED)

Available as of Camel version 2.17

IMPORTANT

The composite kubernetes component has been deprecated. Use individual component splitted as following.

- [Kubernetes Components](#)
 - [Kubernetes Build Config](#)
 - [Kubernetes Build](#)
 - [Kubernetes ConfigMap](#)
 - [Kubernetes Namespace](#)
 - [Kubernetes Node](#)
 - [Kubernetes Persistent Volume](#)
 - [Kubernetes Persistent Volume Claim](#)
 - [Kubernetes Pod](#)
 - [Kubernetes Replication Controller](#)
 - [Kubernetes Resource Quota](#)
 - [Kubernetes Secrets](#)
 - [Kubernetes Service Account](#)
 - [Kubernetes Service](#)

The **Kubernetes** component is a component for integrating your application with Kubernetes standalone or on top of Openshift.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-kubernetes</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

195.1. URI FORMAT

```
kubernetes:masterUrl[?options]
```

You can append query options to the URI in the following format, **?option=value&option=value&...**

195.2. OPTIONS

The Kubernetes component has no options.

The Kubernetes endpoint is configured using URI syntax:

```
kubernetes:masterUrl
```

with the following path and query parameters:

195.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
<code>masterUrl</code>	Required Kubernetes Master url		String

195.2.2. Query Parameters (29 parameters):

Name	Description	Default	Type
<code>apiVersion</code> (common)	The Kubernetes API Version to use		String
<code>category</code> (common)	Required Kubernetes Producer and Consumer category		String
<code>dnsDomain</code> (common)	The dns domain, used for ServiceCall EIP		String
<code>kubernetesClient</code> (common)	Default KubernetesClient to use if provided		KubernetesClient
<code>portName</code> (common)	The port name, used for ServiceCall EIP		String
<code>portProtocol</code> (common)	The port protocol, used for ServiceCall EIP	tcp	String
<code>bridgeErrorHandler</code> (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean

Name	Description	Default	Type
labelKey (consumer)	The Consumer Label key when watching at some resources		String
labelValue (consumer)	The Consumer Label value when watching at some resources		String
namespace (consumer)	The namespace		String
poolSize (consumer)	The Consumer pool size	1	int
resourceName (consumer)	The Consumer Resource Name we would like to watch		String
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
operation (producer)	Producer operation to do on Kubernetes		String
connectionTimeout (advanced)	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
caCertData (security)	The CA Cert Data		String
caCertFile (security)	The CA Cert File		String
clientCertData (security)	The Client Cert Data		String
clientCertFile (security)	The Client Cert File		String

Name	Description	Default	Type
clientKeyAlgo (security)	The Key Algorithm used by the client		String
clientKeyData (security)	The Client Key data		String
clientKeyFile (security)	The Client Key file		String
clientKeyPassphrase (security)	The Client Key Passphrase		String
oauthToken (security)	The Auth Token		String
password (security)	Password to connect to Kubernetes		String
trustCerts (security)	Define if the certs we used are trusted anyway or not		Boolean
username (security)	Username to connect to Kubernetes		String

195.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 16 options, which are listed below.

Name	Description	Default	Type
camel.component.kubernetes.cluster.service.attributes	Custom service attributes.		Map
camel.component.kubernetes.cluster.service.cluster-labels	Set the labels used to identify the pods composing the cluster.		Map
camel.component.kubernetes.cluster.service.config-map-name	Set the name of the ConfigMap used to do optimistic locking (defaults to 'leaders').		String

Name	Description	Default	Type
<code>camel.component.kubernetes.cluster.service.connection-timeout-millis</code>	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
<code>camel.component.kubernetes.cluster.service.enabled</code>	Sets if the Kubernetes cluster service should be enabled or not, default is false.	false	Boolean
<code>camel.component.kubernetes.cluster.service.id</code>	Cluster Service ID		String
<code>camel.component.kubernetes.cluster.service.jitter-factor</code>	A jitter factor to apply in order to prevent all pods to call Kubernetes APIs in the same instant.		Double
<code>camel.component.kubernetes.cluster.service.kubernetes-namespace</code>	Set the name of the Kubernetes namespace containing the pods and the configmap (autodetected by default)		String
<code>camel.component.kubernetes.cluster.service.lease-duration-millis</code>	The default duration of the lease for the current leader.		Long
<code>camel.component.kubernetes.cluster.service.master-url</code>	Set the URL of the Kubernetes master (read from Kubernetes client properties by default).		String
<code>camel.component.kubernetes.cluster.service.order</code>	Service lookup order/priority.		Integer
<code>camel.component.kubernetes.cluster.service.pod-name</code>	Set the name of the current pod (autodetected from container host name by default).		String
<code>camel.component.kubernetes.cluster.service.renew-deadline-millis</code>	The deadline after which the leader must stop its services because it may have lost the leadership.		Long

Name	Description	Default	Type
<code>camel.component.kubernetes.cluster.service.retry-period-millis</code>	The time between two subsequent attempts to check and acquire the leadership. It is randomized using the jitter factor.		Long
<code>camel.component.kubernetes.enabled</code>	Whether to enable auto configuration of the kubernetes component. This is enabled by default.		Boolean
<code>camel.component.kubernetes.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

195.4. HEADERS

Name	Type	Description
<code>CamelKubernetesOperation</code>	String	The Producer operation
<code>CamelKubernetesNamespaceName</code>	String	The Namespace name
<code>CamelKubernetesNamespaceLabels</code>	Map	The Namespace Labels
<code>CamelKubernetesServiceLabels</code>	Map	The Service labels

CamelKubernetesNodesLabels	Map	Node labels
CamelKubernetesNodeName	String	Node name
CamelKubernetesBuildsLabels	Map	Openshift Build labels

Name	Type	Description
CamelK uberne tesBuil dName	String	Openshift Build name
CamelK uberne tesBuil dConfi gsLabe ls	Map	Openshift Build Config labels
CamelK uberne tesBuil dConfi gName	String	Openshift Build Config name
CamelK uberne tesEve ntActio n	io.fabri c8.kub ernetes .client. Watche r.Actio n	Action watched by the consumer
CamelK uberne tesEve ntTime stamp	String	Timestamp of the action watched by the consumer
CamelK uberne tesCon figMap Name	String	ConfigMap name
CamelK uberne tesCon figMap sLabels	Map	ConfigMap labels
CamelK uberne tesCon figData	Map	ConfigMap Data

195.5. CATEGORIES

Actually the camel-kubernetes component supports the following Kubernetes resources

- Namespaces
- Pods
- Replication Controllers
- Services
- Persistent Volumes
- Persistent Volume Claims
- Secrets
- Resource Quota
- Service Accounts
- Nodes
- Configmaps

In Openshift also

- Builds
- BuildConfigs

195.6. USAGE

195.6.1. Producer examples

Here we show some examples of producer using camel-kubernetes.

195.6.2. Create a pod

```
from("direct:createPod")  
  .toF("kubernetes://%s?oauthToken=%s&category=pods&operation=createPod", host, authToken);
```

By using the `KubernetesConstants.KUBERNETES_POD_SPEC` header you can specify your `PodSpec` and pass it to this operation.

195.6.3. Delete a pod

```
from("direct:createPod")  
  .toF("kubernetes://%s?oauthToken=%s&category=pods&operation=deletePod", host, authToken);
```

By using the `KubernetesConstants.KUBERNETES_POD_NAME` header you can specify your Pod name and pass it to this operation.

CHAPTER 196. KUBERNETES CONFIGMAP COMPONENT

Available as of Camel version 2.17

The **Kubernetes ConfigMap** component is one of [Kubernetes Components](#) which provides a producer to execute kubernetes ConfigMap operations.

196.1. COMPONENT OPTIONS

The Kubernetes ConfigMap component has no options.

196.2. ENDPOINT OPTIONS

The Kubernetes ConfigMap endpoint is configured using URI syntax:

```
kubernetes-config-maps:masterUrl
```

with the following path and query parameters:

196.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
masterUrl	Required Kubernetes Master url		String

196.2.2. Query Parameters (20 parameters):

Name	Description	Default	Type
apiVersion (producer)	The Kubernetes API Version to use		String
dnsDomain (producer)	The dns domain, used for ServiceCall EIP		String
kubernetesClient (producer)	Default KubernetesClient to use if provided		KubernetesClient
operation (producer)	Producer operation to do on Kubernetes		String
portName (producer)	The port name, used for ServiceCall EIP		String
portProtocol (producer)	The port protocol, used for ServiceCall EIP	tcp	String

Name	Description	Default	Type
connectionTimeout (advanced)	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
caCertData (security)	The CA Cert Data		String
caCertFile (security)	The CA Cert File		String
clientCertData (security)	The Client Cert Data		String
clientCertFile (security)	The Client Cert File		String
clientKeyAlgo (security)	The Key Algorithm used by the client		String
clientKeyData (security)	The Client Key data		String
clientKeyFile (security)	The Client Key file		String
clientKeyPassphrase (security)	The Client Key Passphrase		String
oauthToken (security)	The Auth Token		String
password (security)	Password to connect to Kubernetes		String
trustCerts (security)	Define if the certs we used are trusted anyway or not		Boolean
username (security)	Username to connect to Kubernetes		String

196.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.kubernetes-config-maps.enabled</code>	Whether to enable auto configuration of the kubernetes-config-maps component. This is enabled by default.		Boolean
<code>camel.component.kubernetes-config-maps.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

CHAPTER 197. KUBERNETES DEPLOYMENTS COMPONENT

Available as of Camel version 2.20

The **Kubernetes Deployments** component is one of [Kubernetes Components](#) which provides a producer to execute kubernetes secret operations.

197.1. COMPONENT OPTIONS

The Kubernetes Deployments component has no options.

197.2. ENDPOINT OPTIONS

The Kubernetes Deployments endpoint is configured using URI syntax:

```
kubernetes-deployments:masterUrl
```

with the following path and query parameters:

197.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
masterUrl	Required Kubernetes Master url		String

197.2.2. Query Parameters (28 parameters):

Name	Description	Default	Type
apiVersion (common)	The Kubernetes API Version to use		String
dnsDomain (common)	The dns domain, used for ServiceCall EIP		String
kubernetesClient (common)	Default KubernetesClient to use if provided		KubernetesClient
portName (common)	The port name, used for ServiceCall EIP		String
portProtocol (common)	The port protocol, used for ServiceCall EIP	tcp	String

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
labelKey (consumer)	The Consumer Label key when watching at some resources		String
labelValue (consumer)	The Consumer Label value when watching at some resources		String
namespace (consumer)	The namespace		String
poolSize (consumer)	The Consumer pool size	1	int
resourceName (consumer)	The Consumer Resource Name we would like to watch		String
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
operation (producer)	Producer operation to do on Kubernetes		String
connectionTimeout (advanced)	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
caCertData (security)	The CA Cert Data		String

Name	Description	Default	Type
caCertFile (security)	The CA Cert File		String
clientCertData (security)	The Client Cert Data		String
clientCertFile (security)	The Client Cert File		String
clientKeyAlgo (security)	The Key Algorithm used by the client		String
clientKeyData (security)	The Client Key data		String
clientKeyFile (security)	The Client Key file		String
clientKeyPassphrase (security)	The Client Key Passphrase		String
oauthToken (security)	The Auth Token		String
password (security)	Password to connect to Kubernetes		String
trustCerts (security)	Define if the certs we used are trusted anyway or not		Boolean
username (security)	Username to connect to Kubernetes		String

197.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.component.kubernetes-deployments.enabled	Whether to enable auto configuration of the kubernetes-deployments component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.kubernetes-deployments.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

CHAPTER 198. KUBERNETES HPA COMPONENT

Available as of Camel version 2.23

The **Kubernetes HPA** component is one of [Kubernetes Components](#) which provides a producer to execute kubernetes hpa operations and a consumer to consume kubernetes hpa events.

198.1. COMPONENT OPTIONS

The Kubernetes HPA component has no options.

198.2. ENDPOINT OPTIONS

The Kubernetes HPA endpoint is configured using URI syntax:

```
kubernetes-hpa:masterUrl
```

with the following path and query parameters:

198.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
masterUrl	Required Kubernetes Master url		String

198.2.2. Query Parameters (28 parameters):

Name	Description	Default	Type
apiVersion (common)	The Kubernetes API Version to use		String
dnsDomain (common)	The dns domain, used for ServiceCall EIP		String
kubernetesClient (common)	Default KubernetesClient to use if provided		KubernetesClient
portName (common)	The port name, used for ServiceCall EIP		String
portProtocol (common)	The port protocol, used for ServiceCall EIP	tcp	String

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
labelKey (consumer)	The Consumer Label key when watching at some resources		String
labelValue (consumer)	The Consumer Label value when watching at some resources		String
namespace (consumer)	The namespace		String
poolSize (consumer)	The Consumer pool size	1	int
resourceName (consumer)	The Consumer Resource Name we would like to watch		String
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
operation (producer)	Producer operation to do on Kubernetes		String
connectionTimeout (advanced)	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
caCertData (security)	The CA Cert Data		String

Name	Description	Default	Type
caCertFile (security)	The CA Cert File		String
clientCertData (security)	The Client Cert Data		String
clientCertFile (security)	The Client Cert File		String
clientKeyAlgo (security)	The Key Algorithm used by the client		String
clientKeyData (security)	The Client Key data		String
clientKeyFile (security)	The Client Key file		String
clientKeyPassphrase (security)	The Client Key Passphrase		String
oauthToken (security)	The Auth Token		String
password (security)	Password to connect to Kubernetes		String
trustCerts (security)	Define if the certs we used are trusted anyway or not		Boolean
username (security)	Username to connect to Kubernetes		String

198.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.component.kubernetes-hpa.enabled	Whether to enable auto configuration of the kubernetes-hpa component. This is enabled by default.		Boolean

Name	Description	Default	Type
<code>camel.component.kubernetes-hpa.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

CHAPTER 199. KUBERNETES JOB COMPONENT

Available as of Camel version 2.23

The **Kubernetes Job** component is one of [Kubernetes Components](#) which provides a producer to execute kubernetes job operations.

199.1. COMPONENT OPTIONS

The Kubernetes Job component has no options.

199.2. ENDPOINT OPTIONS

The Kubernetes Job endpoint is configured using URI syntax:

```
kubernetes-job:masterUrl
```

with the following path and query parameters:

199.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
masterUrl	Required Kubernetes Master url		String

199.2.2. Query Parameters (28 parameters):

Name	Description	Default	Type
apiVersion (common)	The Kubernetes API Version to use		String
dnsDomain (common)	The dns domain, used for ServiceCall EIP		String
kubernetesClient (common)	Default KubernetesClient to use if provided		KubernetesClient
portName (common)	The port name, used for ServiceCall EIP		String
portProtocol (common)	The port protocol, used for ServiceCall EIP	tcp	String

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
labelKey (consumer)	The Consumer Label key when watching at some resources		String
labelValue (consumer)	The Consumer Label value when watching at some resources		String
namespace (consumer)	The namespace		String
poolSize (consumer)	The Consumer pool size	1	int
resourceName (consumer)	The Consumer Resource Name we would like to watch		String
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
operation (producer)	Producer operation to do on Kubernetes		String
connectionTimeout (advanced)	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
caCertData (security)	The CA Cert Data		String

Name	Description	Default	Type
caCertFile (security)	The CA Cert File		String
clientCertData (security)	The Client Cert Data		String
clientCertFile (security)	The Client Cert File		String
clientKeyAlgo (security)	The Key Algorithm used by the client		String
clientKeyData (security)	The Client Key data		String
clientKeyFile (security)	The Client Key file		String
clientKeyPassphrase (security)	The Client Key Passphrase		String
oauthToken (security)	The Auth Token		String
password (security)	Password to connect to Kubernetes		String
trustCerts (security)	Define if the certs we used are trusted anyway or not		Boolean
username (security)	Username to connect to Kubernetes		String

199.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.component.kubernetes-job.enabled	Whether to enable auto configuration of the kubernetes-job component. This is enabled by default.		Boolean

Name	Description	Default	Type
camel.component.kubernetes-job.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

CHAPTER 200. KUBERNETES NAMESPACES COMPONENT

Available as of Camel version 2.17

The **Kubernetes Namespaces** component is one of [Kubernetes Components](#) which provides a producer to execute kubernetes namespace operations and a consumer to consume kubernetes namespace events.

200.1. COMPONENT OPTIONS

The Kubernetes Namespaces component has no options.

200.2. ENDPOINT OPTIONS

The Kubernetes Namespaces endpoint is configured using URI syntax:

```
kubernetes-namespaces:masterUrl
```

with the following path and query parameters:

200.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
masterUrl	Required Kubernetes Master url		String

200.2.2. Query Parameters (28 parameters):

Name	Description	Default	Type
apiVersion (common)	The Kubernetes API Version to use		String
dnsDomain (common)	The dns domain, used for ServiceCall EIP		String
kubernetesClient (common)	Default KubernetesClient to use if provided		KubernetesClient
portName (common)	The port name, used for ServiceCall EIP		String
portProtocol (common)	The port protocol, used for ServiceCall EIP	tcp	String

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
labelKey (consumer)	The Consumer Label key when watching at some resources		String
labelValue (consumer)	The Consumer Label value when watching at some resources		String
namespace (consumer)	The namespace		String
poolSize (consumer)	The Consumer pool size	1	int
resourceName (consumer)	The Consumer Resource Name we would like to watch		String
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
operation (producer)	Producer operation to do on Kubernetes		String
connectionTimeout (advanced)	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
caCertData (security)	The CA Cert Data		String

Name	Description	Default	Type
caCertFile (security)	The CA Cert File		String
clientCertData (security)	The Client Cert Data		String
clientCertFile (security)	The Client Cert File		String
clientKeyAlgo (security)	The Key Algorithm used by the client		String
clientKeyData (security)	The Client Key data		String
clientKeyFile (security)	The Client Key file		String
clientKeyPassphrase (security)	The Client Key Passphrase		String
oauthToken (security)	The Auth Token		String
password (security)	Password to connect to Kubernetes		String
trustCerts (security)	Define if the certs we used are trusted anyway or not		Boolean
username (security)	Username to connect to Kubernetes		String

200.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.component.kubernetes-namespaces.enabled	Whether to enable auto configuration of the kubernetes-namespaces component. This is enabled by default.		Boolean

Name	Description	Default	Type
<code>camel.component.kubernetes-namespaces.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

CHAPTER 201. KUBERNETES NODES COMPONENT

Available as of Camel version 2.17

The **Kubernetes Nodes** component is one of [Kubernetes Components](#) which provides a producer to execute kubernetes node operations and a consumer to consume kubernetes node events.

201.1. COMPONENT OPTIONS

The Kubernetes Nodes component has no options.

201.2. ENDPOINT OPTIONS

The Kubernetes Nodes endpoint is configured using URI syntax:

```
kubernetes-nodes:masterUrl
```

with the following path and query parameters:

201.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
masterUrl	Required Kubernetes Master url		String

201.2.2. Query Parameters (28 parameters):

Name	Description	Default	Type
apiVersion (common)	The Kubernetes API Version to use		String
dnsDomain (common)	The dns domain, used for ServiceCall EIP		String
kubernetesClient (common)	Default KubernetesClient to use if provided		KubernetesClient
portName (common)	The port name, used for ServiceCall EIP		String
portProtocol (common)	The port protocol, used for ServiceCall EIP	tcp	String

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
labelKey (consumer)	The Consumer Label key when watching at some resources		String
labelValue (consumer)	The Consumer Label value when watching at some resources		String
namespace (consumer)	The namespace		String
poolSize (consumer)	The Consumer pool size	1	int
resourceName (consumer)	The Consumer Resource Name we would like to watch		String
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
operation (producer)	Producer operation to do on Kubernetes		String
connectionTimeout (advanced)	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
caCertData (security)	The CA Cert Data		String

Name	Description	Default	Type
caCertFile (security)	The CA Cert File		String
clientCertData (security)	The Client Cert Data		String
clientCertFile (security)	The Client Cert File		String
clientKeyAlgo (security)	The Key Algorithm used by the client		String
clientKeyData (security)	The Client Key data		String
clientKeyFile (security)	The Client Key file		String
clientKeyPassphrase (security)	The Client Key Passphrase		String
oauthToken (security)	The Auth Token		String
password (security)	Password to connect to Kubernetes		String
trustCerts (security)	Define if the certs we used are trusted anyway or not		Boolean
username (security)	Username to connect to Kubernetes		String

201.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.component.kubernetes-nodes.enabled	Whether to enable auto configuration of the kubernetes-nodes component. This is enabled by default.		Boolean

Name	Description	Default	Type
<code>camel.component.kubernetes-nodes.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

CHAPTER 202. KUBERNETES PERSISTENT VOLUME CLAIM COMPONENT

Available as of Camel version 2.17

The **Kubernetes Persistent Volume Claim** component is one of [Kubernetes Components](#) which provides a producer to execute kubernetes persistent volume claim operations.

202.1. COMPONENT OPTIONS

The Kubernetes Persistent Volume Claim component has no options.

202.2. ENDPOINT OPTIONS

The Kubernetes Persistent Volume Claim endpoint is configured using URI syntax:

```
kubernetes-persistent-volumes-claims:masterUrl
```

with the following path and query parameters:

202.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
masterUrl	Required Kubernetes Master url		String

202.2.2. Query Parameters (20 parameters):

Name	Description	Default	Type
apiVersion (producer)	The Kubernetes API Version to use		String
dnsDomain (producer)	The dns domain, used for ServiceCall EIP		String
kubernetesClient (producer)	Default KubernetesClient to use if provided		KubernetesClient
operation (producer)	Producer operation to do on Kubernetes		String
portName (producer)	The port name, used for ServiceCall EIP		String

Name	Description	Default	Type
portProtocol (producer)	The port protocol, used for ServiceCall EIP	tcp	String
connectionTimeout (advanced)	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
caCertData (security)	The CA Cert Data		String
caCertFile (security)	The CA Cert File		String
clientCertData (security)	The Client Cert Data		String
clientCertFile (security)	The Client Cert File		String
clientKeyAlgo (security)	The Key Algorithm used by the client		String
clientKeyData (security)	The Client Key data		String
clientKeyFile (security)	The Client Key file		String
clientKeyPassphrase (security)	The Client Key Passphrase		String
oauthToken (security)	The Auth Token		String
password (security)	Password to connect to Kubernetes		String
trustCerts (security)	Define if the certs we used are trusted anyway or not		Boolean
username (security)	Username to connect to Kubernetes		String

202.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.kubernetes-persistent-volumes-claims.enabled</code>	Whether to enable auto configuration of the kubernetes-persistent-volumes-claims component. This is enabled by default.		Boolean
<code>camel.component.kubernetes-persistent-volumes-claims.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

CHAPTER 203. KUBERNETES PERSISTENT VOLUME COMPONENT

Available as of Camel version 2.17

The **Kubernetes Persistent Volume** component is one of [Kubernetes Components](#) which provides a producer to execute kubernetes persistent volume operations.

203.1. COMPONENT OPTIONS

The Kubernetes Persistent Volume component has no options.

203.2. ENDPOINT OPTIONS

The Kubernetes Persistent Volume endpoint is configured using URI syntax:

```
kubernetes-persistent-volumes:masterUrl
```

with the following path and query parameters:

203.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
masterUrl	Required Kubernetes Master url		String

203.2.2. Query Parameters (20 parameters):

Name	Description	Default	Type
apiVersion (producer)	The Kubernetes API Version to use		String
dnsDomain (producer)	The dns domain, used for ServiceCall EIP		String
kubernetesClient (producer)	Default KubernetesClient to use if provided		KubernetesClient
operation (producer)	Producer operation to do on Kubernetes		String
portName (producer)	The port name, used for ServiceCall EIP		String

Name	Description	Default	Type
portProtocol (producer)	The port protocol, used for ServiceCall EIP	tcp	String
connectionTimeout (advanced)	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
caCertData (security)	The CA Cert Data		String
caCertFile (security)	The CA Cert File		String
clientCertData (security)	The Client Cert Data		String
clientCertFile (security)	The Client Cert File		String
clientKeyAlgo (security)	The Key Algorithm used by the client		String
clientKeyData (security)	The Client Key data		String
clientKeyFile (security)	The Client Key file		String
clientKeyPassphrase (security)	The Client Key Passphrase		String
oauthToken (security)	The Auth Token		String
password (security)	Password to connect to Kubernetes		String
trustCerts (security)	Define if the certs we used are trusted anyway or not		Boolean
username (security)	Username to connect to Kubernetes		String

203.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.kubernetes-persistent-volumes.enabled</code>	Whether to enable auto configuration of the kubernetes-persistent-volumes component. This is enabled by default.		Boolean
<code>camel.component.kubernetes-persistent-volumes.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

CHAPTER 204. KUBERNETES PODS COMPONENT

Available as of Camel version 2.17

The **Kubernetes Pods** component is one of [Kubernetes Components](#) which provides a producer to execute kubernetes pod operations.

204.1. COMPONENT OPTIONS

The Kubernetes Pods component has no options.

204.2. ENDPOINT OPTIONS

The Kubernetes Pods endpoint is configured using URI syntax:

```
kubernetes-pods:masterUrl
```

with the following path and query parameters:

204.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
<code>masterUrl</code>	Required Kubernetes Master url		String

204.2.2. Query Parameters (28 parameters):

Name	Description	Default	Type
<code>apiVersion</code> (common)	The Kubernetes API Version to use		String
<code>dnsDomain</code> (common)	The dns domain, used for ServiceCall EIP		String
<code>kubernetesClient</code> (common)	Default KubernetesClient to use if provided		KubernetesClient
<code>portName</code> (common)	The port name, used for ServiceCall EIP		String
<code>portProtocol</code> (common)	The port protocol, used for ServiceCall EIP	tcp	String

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
labelKey (consumer)	The Consumer Label key when watching at some resources		String
labelValue (consumer)	The Consumer Label value when watching at some resources		String
namespace (consumer)	The namespace		String
poolSize (consumer)	The Consumer pool size	1	int
resourceName (consumer)	The Consumer Resource Name we would like to watch		String
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
operation (producer)	Producer operation to do on Kubernetes		String
connectionTimeout (advanced)	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
caCertData (security)	The CA Cert Data		String

Name	Description	Default	Type
caCertFile (security)	The CA Cert File		String
clientCertData (security)	The Client Cert Data		String
clientCertFile (security)	The Client Cert File		String
clientKeyAlgo (security)	The Key Algorithm used by the client		String
clientKeyData (security)	The Client Key data		String
clientKeyFile (security)	The Client Key file		String
clientKeyPassphrase (security)	The Client Key Passphrase		String
oauthToken (security)	The Auth Token		String
password (security)	Password to connect to Kubernetes		String
trustCerts (security)	Define if the certs we used are trusted anyway or not		Boolean
username (security)	Username to connect to Kubernetes		String

204.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.component.kubernetes-pods.enabled	Whether to enable auto configuration of the kubernetes-pods component. This is enabled by default.		Boolean

Name	Description	Default	Type
<code>camel.component.kubernetes-pods.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

CHAPTER 205. KUBERNETES REPLICATION CONTROLLER COMPONENT

Available as of Camel version 2.17

The **Kubernetes Replication Controller** component is one of [Kubernetes Components](#) which provides a producer to execute kubernetes replication controller operations and a consumer to consume kubernetes replication controller events.

205.1. COMPONENT OPTIONS

The Kubernetes Replication Controller component has no options.

205.2. ENDPOINT OPTIONS

The Kubernetes Replication Controller endpoint is configured using URI syntax:

```
kubernetes-replication-controllers:masterUrl
```

with the following path and query parameters:

205.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
masterUrl	Required Kubernetes Master url		String

205.2.2. Query Parameters (28 parameters):

Name	Description	Default	Type
apiVersion (common)	The Kubernetes API Version to use		String
dnsDomain (common)	The dns domain, used for ServiceCall EIP		String
kubernetesClient (common)	Default KubernetesClient to use if provided		KubernetesClient
portName (common)	The port name, used for ServiceCall EIP		String
portProtocol (common)	The port protocol, used for ServiceCall EIP	tcp	String

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
labelKey (consumer)	The Consumer Label key when watching at some resources		String
labelValue (consumer)	The Consumer Label value when watching at some resources		String
namespace (consumer)	The namespace		String
poolSize (consumer)	The Consumer pool size	1	int
resourceName (consumer)	The Consumer Resource Name we would like to watch		String
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
operation (producer)	Producer operation to do on Kubernetes		String
connectionTimeout (advanced)	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
caCertData (security)	The CA Cert Data		String

Name	Description	Default	Type
caCertFile (security)	The CA Cert File		String
clientCertData (security)	The Client Cert Data		String
clientCertFile (security)	The Client Cert File		String
clientKeyAlgo (security)	The Key Algorithm used by the client		String
clientKeyData (security)	The Client Key data		String
clientKeyFile (security)	The Client Key file		String
clientKeyPassphrase (security)	The Client Key Passphrase		String
oauthToken (security)	The Auth Token		String
password (security)	Password to connect to Kubernetes		String
trustCerts (security)	Define if the certs we used are trusted anyway or not		Boolean
username (security)	Username to connect to Kubernetes		String

205.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.component.kubernetes-replication-controllers.enabled	Whether to enable auto configuration of the kubernetes-replication-controllers component. This is enabled by default.		Boolean

Name	Description	Default	Type
<code>camel.component.kubernetes-replication-controllers.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

CHAPTER 206. KUBERNETES RESOURCES QUOTA COMPONENT

Available as of Camel version 2.17

The **Kubernetes Resources Quota** component is one of [Kubernetes Components](#) which provides a producer to execute kubernetes resource quota operations.

206.1. COMPONENT OPTIONS

The Kubernetes Resources Quota component has no options.

206.2. ENDPOINT OPTIONS

The Kubernetes Resources Quota endpoint is configured using URI syntax:

```
kubernetes-resources-quota:masterUrl
```

with the following path and query parameters:

206.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
masterUrl	Required Kubernetes Master url		String

206.2.2. Query Parameters (20 parameters):

Name	Description	Default	Type
apiVersion (producer)	The Kubernetes API Version to use		String
dnsDomain (producer)	The dns domain, used for ServiceCall EIP		String
kubernetesClient (producer)	Default KubernetesClient to use if provided		KubernetesClient
operation (producer)	Producer operation to do on Kubernetes		String
portName (producer)	The port name, used for ServiceCall EIP		String

Name	Description	Default	Type
portProtocol (producer)	The port protocol, used for ServiceCall EIP	tcp	String
connectionTimeout (advanced)	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
caCertData (security)	The CA Cert Data		String
caCertFile (security)	The CA Cert File		String
clientCertData (security)	The Client Cert Data		String
clientCertFile (security)	The Client Cert File		String
clientKeyAlgo (security)	The Key Algorithm used by the client		String
clientKeyData (security)	The Client Key data		String
clientKeyFile (security)	The Client Key file		String
clientKeyPassphrase (security)	The Client Key Passphrase		String
oauthToken (security)	The Auth Token		String
password (security)	Password to connect to Kubernetes		String
trustCerts (security)	Define if the certs we used are trusted anyway or not		Boolean
username (security)	Username to connect to Kubernetes		String

206.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.kubernetes-resources-quota.enabled</code>	Whether to enable auto configuration of the kubernetes-resources-quota component. This is enabled by default.		Boolean
<code>camel.component.kubernetes-resources-quota.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

CHAPTER 207. KUBERNETES SECRETS COMPONENT

Available as of Camel version 2.17

The **Kubernetes Secrets** component is one of [Kubernetes Components](#) which provides a producer to execute kubernetes secret operations.

207.1. COMPONENT OPTIONS

The Kubernetes Secrets component has no options.

207.2. ENDPOINT OPTIONS

The Kubernetes Secrets endpoint is configured using URI syntax:

```
kubernetes-secrets:masterUrl
```

with the following path and query parameters:

207.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
masterUrl	Required Kubernetes Master url		String

207.2.2. Query Parameters (20 parameters):

Name	Description	Default	Type
apiVersion (producer)	The Kubernetes API Version to use		String
dnsDomain (producer)	The dns domain, used for ServiceCall EIP		String
kubernetesClient (producer)	Default KubernetesClient to use if provided		KubernetesClient
operation (producer)	Producer operation to do on Kubernetes		String
portName (producer)	The port name, used for ServiceCall EIP		String
portProtocol (producer)	The port protocol, used for ServiceCall EIP	tcp	String

Name	Description	Default	Type
connectionTimeout (advanced)	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
caCertData (security)	The CA Cert Data		String
caCertFile (security)	The CA Cert File		String
clientCertData (security)	The Client Cert Data		String
clientCertFile (security)	The Client Cert File		String
clientKeyAlgo (security)	The Key Algorithm used by the client		String
clientKeyData (security)	The Client Key data		String
clientKeyFile (security)	The Client Key file		String
clientKeyPassphrase (security)	The Client Key Passphrase		String
oauthToken (security)	The Auth Token		String
password (security)	Password to connect to Kubernetes		String
trustCerts (security)	Define if the certs we used are trusted anyway or not		Boolean
username (security)	Username to connect to Kubernetes		String

207.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.kubernetes-secrets.enabled</code>	Whether to enable auto configuration of the kubernetes-secrets component. This is enabled by default.		Boolean
<code>camel.component.kubernetes-secrets.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

CHAPTER 208. KUBERNETES SERVICE ACCOUNT COMPONENT

Available as of Camel version 2.17

The **Kubernetes Service Account** component is one of [Kubernetes Components](#) which provides a producer to execute kubernetes Service Account operations.

208.1. COMPONENT OPTIONS

The Kubernetes Service Account component has no options.

208.2. ENDPOINT OPTIONS

The Kubernetes Service Account endpoint is configured using URI syntax:

```
kubernetes-service-accounts:masterUrl
```

with the following path and query parameters:

208.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
masterUrl	Required Kubernetes Master url		String

208.2.2. Query Parameters (20 parameters):

Name	Description	Default	Type
apiVersion (producer)	The Kubernetes API Version to use		String
dnsDomain (producer)	The dns domain, used for ServiceCall EIP		String
kubernetesClient (producer)	Default KubernetesClient to use if provided		KubernetesClient
operation (producer)	Producer operation to do on Kubernetes		String
portName (producer)	The port name, used for ServiceCall EIP		String

Name	Description	Default	Type
portProtocol (producer)	The port protocol, used for ServiceCall EIP	tcp	String
connectionTimeout (advanced)	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
caCertData (security)	The CA Cert Data		String
caCertFile (security)	The CA Cert File		String
clientCertData (security)	The Client Cert Data		String
clientCertFile (security)	The Client Cert File		String
clientKeyAlgo (security)	The Key Algorithm used by the client		String
clientKeyData (security)	The Client Key data		String
clientKeyFile (security)	The Client Key file		String
clientKeyPassphrase (security)	The Client Key Passphrase		String
oauthToken (security)	The Auth Token		String
password (security)	Password to connect to Kubernetes		String
trustCerts (security)	Define if the certs we used are trusted anyway or not		Boolean
username (security)	Username to connect to Kubernetes		String

208.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.kubernetes-service-accounts.enabled</code>	Whether to enable auto configuration of the kubernetes-service-accounts component. This is enabled by default.		Boolean
<code>camel.component.kubernetes-service-accounts.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

CHAPTER 209. KUBERNETES SERVICES COMPONENT

Available as of Camel version 2.17

The **Kubernetes Services** component is one of [Kubernetes Components](#) which provides a producer to execute kubernetes service operations and a consumer to consume kubernetes service events.

209.1. COMPONENT OPTIONS

The Kubernetes Services component has no options.

209.2. ENDPOINT OPTIONS

The Kubernetes Services endpoint is configured using URI syntax:

```
kubernetes-services:masterUrl
```

with the following path and query parameters:

209.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
masterUrl	Required Kubernetes Master url		String

209.2.2. Query Parameters (28 parameters):

Name	Description	Default	Type
apiVersion (common)	The Kubernetes API Version to use		String
dnsDomain (common)	The dns domain, used for ServiceCall EIP		String
kubernetesClient (common)	Default KubernetesClient to use if provided		KubernetesClient
portName (common)	The port name, used for ServiceCall EIP		String
portProtocol (common)	The port protocol, used for ServiceCall EIP	tcp	String

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
labelKey (consumer)	The Consumer Label key when watching at some resources		String
labelValue (consumer)	The Consumer Label value when watching at some resources		String
namespace (consumer)	The namespace		String
poolSize (consumer)	The Consumer pool size	1	int
resourceName (consumer)	The Consumer Resource Name we would like to watch		String
exceptionHandler (consumer)	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		<code>ExceptionHandler</code>
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		<code>ExchangePattern</code>
operation (producer)	Producer operation to do on Kubernetes		String
connectionTimeout (advanced)	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
caCertData (security)	The CA Cert Data		String

Name	Description	Default	Type
caCertFile (security)	The CA Cert File		String
clientCertData (security)	The Client Cert Data		String
clientCertFile (security)	The Client Cert File		String
clientKeyAlgo (security)	The Key Algorithm used by the client		String
clientKeyData (security)	The Client Key data		String
clientKeyFile (security)	The Client Key file		String
clientKeyPassphrase (security)	The Client Key Passphrase		String
oauthToken (security)	The Auth Token		String
password (security)	Password to connect to Kubernetes		String
trustCerts (security)	Define if the certs we used are trusted anyway or not		Boolean
username (security)	Username to connect to Kubernetes		String

209.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.component.kubernetes-services.enabled	Whether to enable auto configuration of the kubernetes-services component. This is enabled by default.		Boolean

Name	Description	Default	Type
<code>camel.component.kubernetes-services.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

209.4. ECLIPSE KURA COMPONENT

Available as of Camel 2.15

This documentation page covers the integration options of Camel with the [Eclipse Kura](#) M2M gateway. The common reason to deploy Camel routes into the Eclipse Kura is to provide enterprise integration patterns and Camel components to the messaging M2M gateway. For example you might want to install Kura on Raspberry PI, then read temperature from the sensor attached to that Raspberry PI using Kura services and finally forward the current temperature value to your data center service using Camel EIP and components.

209.4.1. KuraRouter activator

Bundles deployed to the Eclipse Kura are usually [developed as bundle activators](#). So the easiest way to deploy Apache Camel routes into the Kura is to create an OSGi bundle containing the class extending `org.apache.camel.kura.KuraRouter` class:

```
public class MyKuraRouter extends KuraRouter {

    @Override
    public void configure() throws Exception {
        from("timer:trigger").
            to("netty-http:http://app.mydatacenter.com/api");
    }
}
```

Keep in mind that `KuraRouter` implements the `org.osgi.framework.BundleActivator` interface, so you need to register its `start` and `stop` lifecycle methods while [creating Kura bundle component class](#).

Kura router starts its own OSGi-aware `CamelContext`. It means that for every class extending `KuraRouter`, there will be a dedicated `CamelContext` instance. Ideally we recommend to deploy one `KuraRouter` per OSGi bundle.

209.4.2. Deploying KuraRouter

Bundle containing your Kura router class should import the following packages in the OSGi manifest:

```
Import-Package: org.osgi.framework;version="1.3.0",
               org.slf4j;version="1.6.4",
```

```
org.apache.camel,org.apache.camel.impl,org.apache.camel.core.osgi,org.apache.camel.builder,org.apa
che.camel.model,
org.apache.camel.component.kura
```

Keep in mind that you don't have to import every Camel component bundle you plan to use in your routes, as Camel components are resolved as the services on the runtime level.

Before you deploy your router bundle, be sure that you have deployed (and started) the following Camel core bundles (using Kura GoGo shell)...

```
install file:///home/user/.m2/repository/org/apache/camel/camel-core/2.15.0/camel-core-2.15.0.jar
start <camel-core-bundle-id>
install file:///home/user/.m2/repository/org/apache/camel/camel-core-osgi/2.15.0/camel-core-osgi-
2.15.0.jar
start <camel-core-osgi-bundle-id>
install file:///home/user/.m2/repository/org/apache/camel/camel-kura/2.15.0/camel-kura-2.15.0.jar
start <camel-kura-bundle-id>
```

...and all the components you plan to use in your routes:

```
install file:///home/user/.m2/repository/org/apache/camel/camel-stream/2.15.0/camel-stream-
2.15.0.jar
start <camel-stream-bundle-id>
```

Then finally deploy your router bundle:

```
install file:///home/user/.m2/repository/com/example/myrouter/1.0/myrouter-1.0.jar
start <your-bundle-id>
```

209.4.3. KuraRouter utilities

Kura router base class provides many useful utilities. This section explores each of them.

209.4.3.1. SLF4J logger

Kura uses SLF4J facade for logging purposes. Protected member **log** returns SLF4J logger instance associated with the given Kura router.

```
public class MyKuraRouter extends KuraRouter {
    @Override
    public void configure() throws Exception {
        log.info("Configuring Camel routes!");
        ...
    }
}
```

209.4.3.2. BundleContext

Protected member **bundleContext** returns bundle context associated with the given Kura router.

```
public class MyKuraRouter extends KuraRouter {
```

```

@Override
public void configure() throws Exception {
    ServiceReference<MyService> serviceRef =
bundleContext.getServiceReference(LogService.class.getName());
    MyService myService = bundleContext.getService(serviceRef);
    ...
}
}

```

209.4.3.3. CamelContext

Protected member **camelContext** is the **CamelContext** associated with the given Kura router.

```

public class MyKuraRouter extends KuraRouter {

@Override
public void configure() throws Exception {
    camelContext.getStatus();
    ...
}
}

```

209.4.3.4. ProducerTemplate

Protected member **producerTemplate** is the **ProducerTemplate** instance associated with the given Camel context.

```

public class MyKuraRouter extends KuraRouter {

@Override
public void configure() throws Exception {
    producerTemplate.sendBody("jms:temperature", 22.0);
    ...
}
}

```

209.4.3.5. ConsumerTemplate

Protected member **consumerTemplate** is the **ConsumerTemplate** instance associated with the given Camel context.

```

public class MyKuraRouter extends KuraRouter {

@Override
public void configure() throws Exception {
    double currentTemperature = producerTemplate.receiveBody("jms:temperature", Double.class);
    ...
}
}

```

```
}

```

```
}

```

209.4.3.6. OSGi service resolver

OSGi service resolver (**service(Class<T> serviceType)**) can be used to easily retrieve service by type from the OSGi bundle context.

```
public class MyKuraRouter extends KuraRouter {
    @Override
    public void configure() throws Exception {
        MyService myService = service(MyService.class);
        ...
    }
}
```

If service is not found, a **null** value is returned. If you want your application to fail if the service is not available, use **requiredService(Class)** method instead. The **requiredService** throws **IllegalStateException** if a service cannot be found.

```
public class MyKuraRouter extends KuraRouter {
    @Override
    public void configure() throws Exception {
        MyService myService = requiredService(MyService.class);
        ...
    }
}
```

209.4.4. KuraRouter activator callbacks

Kura router comes with the lifecycle callbacks that can be used to customize the way the Camel router works. For example to configure the **CamelContext** instance associated with the router just before the former is started, override **beforeStart** method of the **KuraRouter** class:

```
public class MyKuraRouter extends KuraRouter {
    ...
    protected void beforeStart(CamelContext camelContext) {
        OsgiDefaultCamelContext osgiContext = (OsgiCamelContext) camelContext;
        osgiContext.setName("NameOfTheRouter");
    }
}
```

209.4.5. Loading XML routes from ConfigurationAdmin

Sometimes it is desired to read the XML definition of the routes from the server configuration. This a

common scenario for IoT gateways where over-the-air redeployment cost may be significant. To address this requirement each **KuraRouter** looks for the **kura.camel.BUNDLE-SYMBOLIC-NAME.route** property from the **kura.camel** PID using the OSGi ConfigurationAdmin. This approach allows you to define Camel XML routes file per deployed **KuraRouter**. In order to update a route, just edit an appropriate configuration property and restart a bundle associated with it. The content of the **kura.camel.BUNDLE-SYMBOLIC-NAME.route** property is expected to be Camel XML route file, for example:

```
<routes xmlns="http://camel.apache.org/schema/spring">
  <route id="loaded">
    <from uri="direct:bar"/>
    <to uri="mock:bar"/>
  </route>
</routes>
```

209.4.6. Deploying Kura router as a declarative OSGi service

If you would like to deploy your Kura router as a declarative OSGi service, you can use **activate** and **deactivate** methods provided by **KuraRouter**.

```
<scr:component name="org.eclipse.kura.example.camel.MyKuraRouter" activate="activate"
deactivate="deactivate" enabled="true" immediate="true">
  <implementation class="org.eclipse.kura.example.camel.MyKuraRouter"/>
</scr:component>
```

- [Getting Started](#)

CHAPTER 210. LANGUAGE COMPONENT

Available as of Camel version 2.5

The language component allows you to send Exchange to an endpoint which executes a script by any of the supported Languages in Camel.

By having a component to execute language scripts, it allows more dynamic routing capabilities. For example by using the Routing Slip or [Dynamic Router](#) EIPs you can send messages to **language** endpoints where the script is dynamic defined as well.

This component is provided out of the box in **camel-core** and hence no additional JARs is needed. You only have to include additional Camel components if the language of choice mandates it, such as using [Groovy](#) or [JavaScript](#) languages.

210.1. URI FORMAT

```
language://languageName[:script][?options]
```

And from Camel 2.11 onwards you can refer to an external resource for the script using same notation as supported by the other [Languages](#) in Camel

```
language://languageName:resource:scheme:location][?options]
```

210.2. URI OPTIONS

The Language component has no options.

The Language endpoint is configured using URI syntax:

```
language:languageName:resourceUri
```

with the following path and query parameters:

210.2.1. Path Parameters (2 parameters):

Name	Description	Default	Type
languageName	Required Sets the name of the language to use		String
resourceUri	Path to the resource, or a reference to lookup a bean in the Registry to use as the resource		String

210.2.2. Query Parameters (6 parameters):

Name	Description	Default	Type
------	-------------	---------	------

Name	Description	Default	Type
binary (producer)	Whether the script is binary content or text content. By default the script is read as text content (eg java.lang.String)	false	boolean
cacheScript (producer)	Whether to cache the compiled script and reuse. Notice reusing the script can cause side effects from processing one Camel org.apache.camel.Exchange to the next org.apache.camel.Exchange.	false	boolean
contentCache (producer)	Sets whether to use resource content cache or not.	false	boolean
script (producer)	Sets the script to execute		String
transform (producer)	Whether or not the result of the script should be used as message body. This options is default true.	true	boolean
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

210.3. MESSAGE HEADERS

The following message headers can be used to affect the behavior of the component

Header	Description
Camel LanguageScript	The script to execute provided in the header. Takes precedence over script configured on the endpoint.

210.4. EXAMPLES

For example you can use the [Simple](#) language to Message Translator a message:

In case you want to convert the message body type you can do this as well:

You can also use the [Groovy](#) language, such as this example where the input message will be multiplied with 2:

You can also provide the script as a header as shown below. Here we use [XPath](#) language to extract the text from the **<foo>** tag.

```
Object out = producer.requestBodyAndHeader("language:xpath", "<foo>Hello World</foo>",  
Exchange.LANGUAGE_SCRIPT, "/foo/text()");  
assertEquals("Hello World", out);
```

210.5. LOADING SCRIPTS FROM RESOURCES

Available as of Camel 2.9

You can specify a resource uri for a script to load in either the endpoint uri, or in the **Exchange.LANGUAGE_SCRIPT** header.

The uri must start with one of the following schemes: file:, classpath:, or http:

For example to load a script from the classpath:

By default the script is loaded once and cached. However you can disable the **contentCache** option and have the script loaded on each evaluation.

For example if the file myscript.txt is changed on disk, then the updated script is used:

From **Camel 2.11** onwards you can refer to the resource similar to the other [Languages](#) in Camel by prefixing with **"resource:"** as shown below:

CHAPTER 211. LDAP COMPONENT

Available as of Camel version 1.5

The **ldap** component allows you to perform searches in LDAP servers using filters as the message payload.

This component uses standard JNDI (**javax.naming** package) to access the server.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-ldap</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

211.1. URI FORMAT

```
ldap:ldapServerBean[?options]
```

The *ldapServerBean* portion of the URI refers to a [DirContext](#) bean in the registry. The LDAP component only supports producer endpoints, which means that an **ldap** URI cannot appear in the **from** at the start of a route.

You can append query options to the URI in the following format, **?option=value&option=value&...**

211.2. OPTIONS

The LDAP component has no options.

The LDAP endpoint is configured using URI syntax:

```
ldap:dirContextName
```

with the following path and query parameters:

211.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
		t	

Name	Description	Default	Type
dirContextName	Required Name of either a <code>javax.naming.directory.DirContext</code> , or <code>java.util.Hashtable</code> , or <code>Map</code> bean to lookup in the registry. If the bean is either a <code>Hashtable</code> or <code>Map</code> then a new <code>javax.naming.directory.DirContext</code> instance is created for each use. If the bean is a <code>javax.naming.directory.DirContext</code> then the bean is used as given. The latter may not be possible in all situations where the <code>javax.naming.directory.DirContext</code> must not be shared, and in those situations it can be better to use <code>java.util.Hashtable</code> or <code>Map</code> instead.		String

211.2.2. Query Parameters (5 parameters):

Name	Description	Default	Type
base (producer)	The base DN for searches.	ou=system	String
pageSize (producer)	When specified the ldap module uses paging to retrieve all results (most LDAP Servers throw an exception when trying to retrieve more than 1000 entries in one query). To be able to use this a <code>LdapContext</code> (subclass of <code>DirContext</code>) has to be passed in as <code>LdapServerBean</code> (otherwise an exception is thrown)		Integer
returnedAttributes (producer)	Comma-separated list of attributes that should be set in each entry of the result		String
scope (producer)	Specifies how deeply to search the tree of entries, starting at the base DN.	subtree	String
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

211.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.ldap.enabled</code>	Enable ldap component	true	Boolean
<code>camel.component.ldap.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

211.4. RESULT

The result is returned in the Out body as a `ArrayList<javax.naming.directory.SearchResult>` object.

211.5. DIRCONTEXT

The URI, `ldap:ldapserver`, references a Spring bean with the ID, `ldapserver`. The `ldapserver` bean may be defined as follows:

```
<bean id="ldapserver" class="javax.naming.directory.InitialDirContext" scope="prototype">
  <constructor-arg>
    <props>
      <prop key="java.naming.factory.initial">com.sun.jndi.ldap.LdapCtxFactory</prop>
      <prop key="java.naming.provider.url">ldap://localhost:10389</prop>
      <prop key="java.naming.security.authentication">none</prop>
    </props>
  </constructor-arg>
</bean>
```

The preceding example declares a regular Sun based LDAP **DirContext** that connects anonymously to a locally hosted LDAP server.

NOTE

DirContext objects are **not** required to support concurrency by contract. It is therefore important that the directory context is declared with the setting, `scope="prototype"`, in the **bean** definition or that the context supports concurrency. In the Spring framework, **prototype** scoped objects are instantiated each time they are looked up.

211.6. SAMPLES

Following on from the Spring configuration above, the code sample below sends an LDAP request to filter search a group for a member. The Common Name is then extracted from the response.

```
ProducerTemplate<Exchange> template = exchange
    .getContext().createProducerTemplate();

Collection<?> results = (Collection<?>) (template
    .sendBody(
        "ldap:ldapserver?base=ou=mygroup,ou=groups,ou=system",
```

```

        "(member=uid=huntc,ou=users,ou=system)"));

if (results.size() > 0) {
    // Extract what we need from the device's profile

    Iterator<?> resultIter = results.iterator();
    SearchResult searchResult = (SearchResult) resultIter
        .next();
    Attributes attributes = searchResult
        .getAttributes();
    Attribute deviceCNAttr = attributes.get("cn");
    String deviceCN = (String) deviceCNAttr.get();

    ...

```

If no specific filter is required - for example, you just need to look up a single entry - specify a wildcard filter expression. For example, if the LDAP entry has a Common Name, use a filter expression like:

```
(cn=*)
```

211.6.1. Binding using credentials

A Camel end user donated this sample code he used to bind to the ldap server using credentials.

```

Properties props = new Properties();
props.setProperty(Context.INITIAL_CONTEXT_FACTORY, "com.sun.jndi.ldap.LdapCtxFactory");
props.setProperty(Context.PROVIDER_URL, "ldap://localhost:389");
props.setProperty(Context.URL_PKG_PREFIXES, "com.sun.jndi.url");
props.setProperty(Context.REFERRAL, "ignore");
props.setProperty(Context.SECURITY_AUTHENTICATION, "simple");
props.setProperty(Context.SECURITY_PRINCIPAL, "cn=Manager");
props.setProperty(Context.SECURITY_CREDENTIALS, "secret");

SimpleRegistry reg = new SimpleRegistry();
reg.put("myldap", new InitialLdapContext(props, null));

CamelContext context = new DefaultCamelContext(reg);
context.addRoutes(
    new RouteBuilder() {
        public void configure() throws Exception {
            from("direct:start").to("ldap:myldap?base=ou=test");
        }
    }
);
context.start();

ProducerTemplate template = context.createProducerTemplate();

Endpoint endpoint = context.getEndpoint("direct:start");
Exchange exchange = endpoint.createExchange();
exchange.getIn().setBody("uid=test");
Exchange out = template.send(endpoint, exchange);

Collection<SearchResult> data = out.getOut().getBody(Collection.class);
assert data != null;

```

```

assert !data.isEmpty();

System.out.println(out.getOut().getBody());

context.stop();

```

211.7. CONFIGURING SSL

All required is to create a custom socket factory and reference it in the InitialDirContext bean - see below sample.

SSL Configuration

```

<?xml version="1.0" encoding="UTF-8"?>
<blueprint xmlns="http://www.osgi.org/xmlns/blueprint/v1.0.0"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://www.osgi.org/xmlns/blueprint/v1.0.0
http://www.osgi.org/xmlns/blueprint/v1.0.0/blueprint.xsd
  http://camel.apache.org/schema/blueprint http://camel.apache.org/schema/blueprint/camel-
blueprint.xsd">

  <sslContextParameters xmlns="http://camel.apache.org/schema/blueprint"
    id="sslContextParameters">
    <keyManagers
      keyPassword="{{keystore.pwd}}">
      <keyStore
        resource="{{keystore.url}}"
        password="{{keystore.pwd}}"/>
      </keyManagers>
    </sslContextParameters>

    <bean id="customSocketFactory" class="zotix.co.util.CustomSocketFactory">
      <argument ref="sslContextParameters" />
    </bean>
    <bean id="ldapserver" class="javax.naming.directory.InitialDirContext" scope="prototype">
      <argument>
        <props>
          <prop key="java.naming.factory.initial" value="com.sun.jndi.ldap.LdapCtxFactory"/>
          <prop key="java.naming.provider.url" value="ldaps://lab.zotix.co:636"/>
          <prop key="java.naming.security.protocol" value="ssl"/>
          <prop key="java.naming.security.authentication" value="simple" />
          <prop key="java.naming.security.principal" value="cn=Manager,dc=example,dc=com"/>
          <prop key="java.naming.security.credentials" value="passw0rd"/>
          <prop key="java.naming.ldap.factory.socket"
            value="zotix.co.util.CustomSocketFactory"/>
        </props>
      </argument>
    </bean>
</blueprint>

```

Custom Socket Factory

```

import org.apache.camel.util.jsse.SSLContextParameters;

```

```

import javax.net.SocketFactory;
import javax.net.ssl.SSLContext;
import javax.net.ssl.SSLSocketFactory;
import javax.net.ssl.TrustManagerFactory;
import java.io.IOException;
import java.net.InetAddress;
import java.net.Socket;
import java.security.KeyStore;

/**
 * The CustomSocketFactory. Loads the KeyStore and creates an instance of SSLSocketFactory
 */
public class CustomSocketFactory extends SSLSocketFactory {

    private static SSLSocketFactory socketFactory;

    /**
     * Called by the getDefault() method.
     */
    public CustomSocketFactory() {

    }

    /**
     * Called by Blueprint DI to initialise an instance of SocketFactory
     *
     * @param sslContextParameters
     */
    public CustomSocketFactory(SSLContextParameters sslContextParameters) {
        try {
            KeyStore keyStore =
sslContextParameters.getKeyManagers().getKeyStore().createKeyStore();
            TrustManagerFactory tmf = TrustManagerFactory.getInstance("SunX509");
            tmf.init(keyStore);
            SSLContext ctx = SSLContext.getInstance("TLS");
            ctx.init(null, tmf.getTrustManagers(), null);
            socketFactory = ctx.getSocketFactory();
        } catch (Exception ex) {
            ex.printStackTrace(System.err); /* handle exception */
        }
    }

    /**
     * Getter for the SocketFactory
     *
     * @return
     */
    public static SocketFactory getDefault() {
        return new CustomSocketFactory();
    }

    @Override
    public String[] getDefaultCipherSuites() {
        return socketFactory.getDefaultCipherSuites();
    }
}

```

```
@Override
public String[] getSupportedCipherSuites() {
    return socketFactory.getSupportedCipherSuites();
}

@Override
public Socket createSocket(Socket socket, String string, int i, boolean bln) throws IOException {
    return socketFactory.createSocket(socket, string, i, bln);
}

@Override
public Socket createSocket(String string, int i) throws IOException {
    return socketFactory.createSocket(string, i);
}

@Override
public Socket createSocket(String string, int i, InetAddress ia, int i1) throws IOException {
    return socketFactory.createSocket(string, i, ia, i1);
}

@Override
public Socket createSocket(InetAddress ia, int i) throws IOException {
    return socketFactory.createSocket(ia, i);
}

@Override
public Socket createSocket(InetAddress ia, int i, InetAddress ia1, int i1) throws IOException {
    return socketFactory.createSocket(ia, i, ia1, i1);
}
}
```

211.8. SEE ALSO

- [Configuring Camel](#)
- [Component](#)
- [Endpoint](#)
- [Getting Started](#)

CHAPTER 212. LDIF COMPONENT

Available as of Camel version 2.20

The **ldif** component allows you to do updates on an LDAP server from a LDIF body content.

This component uses a basic URL syntax to access the server. It uses the Apache DS LDAP library to process the LDIF. After processing the LDIF, the response body will be a list of statuses for success/failure of each entry.

NOTE

The Apache LDAP API is very sensitive to LDIF syntax errors. If in doubt, refer to the unit tests to see an example of each change type.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-ldif</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

212.1. URI FORMAT

```
ldap:ldapServerBean[?options]
```

The *ldapServerBean* portion of the URI refers to a [LdapConnection](#). This should be constructed from a factory at the point of use to avoid connection timeouts. The LDIF component only supports producer endpoints, which means that an **ldif** URI cannot appear in the **from** at the start of a route.

For SSL configuration, refer to the **camel-ldap** component where there is an example of setting up a custom `SocketFactory` instance.

You can append query options to the URI in the following format, **?option=value&option=value&...**

212.2. OPTIONS

The LDIF component has no options.

The LDIF endpoint is configured using URI syntax:

```
ldif:ldapConnectionName
```

with the following path and query parameters:

212.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
ldapConnectionName	Required The name of the LdapConnection bean to pull from the registry. Note that this must be of scope prototype to avoid it being shared among threads or using a connection that has timed out.		String

212.2.2. Query Parameters (1 parameters):

Name	Description	Default	Type
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

212.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.component.ldif.enabled	Whether to enable auto configuration of the Ldif component. This is enabled by default.		Boolean
camel.component.ldif.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

212.4. BODY TYPES:

The body can be a URL to an LDIF file or an inline LDIF file. To signify the difference in body types, an inline LDIF must start with:

```
version: 1
```

If not, the component will try to parse the body as a URL.

212.5. RESULT

The result is returned in the Out body as a **ArrayList<java.lang.String>** object. This contains either "success" or an Exception message for each LDIF entry.

212.6. LDAPCONNECTION

The URI, **ldif:ldapConnectionName**, references a bean with the ID, **ldapConnectionName**. The `ldapConnection` can be configured using a **LdapConnectionConfig** bean. Note that the scope must have a scope of **prototype** to avoid the connection being shared or picking up a stale connection.

The **LdapConnection** bean may be defined as follows in Spring XML:

```
<bean id="ldapConnectionOptions"
class="org.apache.directory.ldap.client.api.LdapConnectionConfig">
  <property name="ldapHost" value="${ldap.host}"/>
  <property name="ldapPort" value="${ldap.port}"/>
  <property name="name" value="${ldap.username}"/>
  <property name="credentials" value="${ldap.password}"/>
  <property name="useSsl" value="false"/>
  <property name="useTls" value="false"/>
</bean>

<bean id="ldapConnectionFactory"
class="org.apache.directory.ldap.client.api.DefaultLdapConnectionFactory">
  <constructor-arg index="0" ref="ldapConnectionOptions"/>
</bean>

<bean id="ldapConnection" factory-bean="ldapConnectionFactory" factory-
method="newLdapConnection" scope="prototype"/>
```

or in a OSGi blueprint.xml:

```
<bean id="ldapConnectionOptions"
class="org.apache.directory.ldap.client.api.LdapConnectionConfig">
  <property name="ldapHost" value="${ldap.host}"/>
  <property name="ldapPort" value="${ldap.port}"/>
  <property name="name" value="${ldap.username}"/>
  <property name="credentials" value="${ldap.password}"/>
  <property name="useSsl" value="false"/>
  <property name="useTls" value="false"/>
</bean>

<bean id="ldapConnectionFactory"
class="org.apache.directory.ldap.client.api.DefaultLdapConnectionFactory">
  <argument ref="ldapConnectionOptions"/>
</bean>

<bean id="ldapConnection" factory-ref="ldapConnectionFactory" factory-
method="newLdapConnection" scope="prototype"/>
```

212.7. SAMPLES

Following on from the Spring configuration above, the code sample below sends an LDAP request to filter search a group for a member. The Common Name is then extracted from the response.

```
ProducerTemplate<Exchange> template = exchange.getContext().createProducerTemplate();

List<?> results = (Collection<?>) template.sendBody("ldif:ldapConnection, "LDiff goes here");

if (results.size() > 0) {
```

```

// Check for no errors

for (String result : results) {
    if ("success".equals(result)) {
        // LDIF entry success
    } else {
        // LDIF entry failure
    }
}
}
}

```

212.8. LEVELDB

Available as of Camel 2.10

[Leveldb](#) is a very lightweight and embedable key value database. It allows together with Camel to provide persistent support for various Camel features such as Aggregator.

Current features it provides:

- `LevelDBAggregationRepository`

212.8.1. Using LevelDBAggregationRepository

LevelDBAggregationRepository is an **AggregationRepository** which on the fly persists the aggregated messages. This ensures that you will not loose messages, as the default aggregator will use an in memory only **AggregationRepository**.

It has the following options:

Option	Type	Description
repositoryName	String	A mandatory repository name. Allows you to use a shared LevelDBFile for multiple repositories.
persistentFileName	String	Filename for the persistent storage. If no file exists on startup a new file is created.
levelDBFile	LevelDBFile	Use an existing configured org.apache.camel.component.leveldb.LevelDBFile instance.
sync	boolean	Camel 2.12: Whether or not the LevelDBFile should sync on write or not. Default is false. By sync on write ensures that its always waiting for all writes to be spooled to disk and thus will not loose updates. See LevelDB docs for more details about async vs sync writes.

Option	Type	Description
returnOldExchange	boolean	Whether the get operation should return the old existing Exchange if any existed. By default this option is false to optimize as we do not need the old exchange when aggregating.
useRecovery	boolean	Whether or not recovery is enabled. This option is by default true . When enabled the Camel Aggregator automatic recover failed aggregated exchange and have them resubmitted.
recoveryInterval	long	If recovery is enabled then a background task is run every x'th time to scan for failed exchanges to recover and resubmit. By default this interval is 5000 millis.
maximumRedeliveries	int	Allows you to limit the maximum number of redelivery attempts for a recovered exchange. If enabled then the Exchange will be moved to the dead letter channel if all redelivery attempts failed. By default this option is disabled. If this option is used then the deadLetterUri option must also be provided.
deadLetterUri	String	An endpoint uri for a Dead Letter Channel where exhausted recovered Exchanges will be moved. If this option is used then the maximumRedeliveries option must also be provided.

The **repositoryName** option must be provided. Then either the **persistentFileName** or the **levelDBFile** must be provided.

212.8.2. What is preserved when persisting

LevelDBAggregationRepository will only preserve any **Serializable** compatible message body data types. Message headers must be primitive / string / numbers / etc. If a data type is not such a type its dropped and a **WARN** is logged. And it only persists the **Message** body and the **Message** headers. The **Exchange** properties are **not** persisted.

212.8.3. Recovery

The **LevelDBAggregationRepository** will by default recover any failed Exchange. It does this by having a background tasks that scans for failed Exchanges in the persistent store. You can use the **checkInterval** option to set how often this task runs. The recovery works as transactional which ensures that Camel will try to recover and redeliver the failed Exchange. Any Exchange which was found to be recovered will be restored from the persistent store and resubmitted and send out again.

The following headers is set when an Exchange is being recovered/redelivered:

Header	Type	Description
--------	------	-------------

Header	Type	Description
Exchange.REDELIVERED	Boolean	Is set to true to indicate the Exchange is being redelivered.
Exchange.REDELIVERY_COUNTER	Integer	The redelivery attempt, starting from 1.

Only when an Exchange has been successfully processed it will be marked as complete which happens when the **confirm** method is invoked on the **AggregationRepository**. This means if the same Exchange fails again it will be kept retried until it success.

You can use option **maximumRedeliveries** to limit the maximum number of redelivery attempts for a given recovered Exchange. You must also set the **deadLetterUri** option so Camel knows where to send the Exchange when the **maximumRedeliveries** was hit.

You can see some examples in the unit tests of camel-leveldb, for example [this test](#).

212.8.3.1. Using LevelDBAggregationRepository in Java DSL

In this example we want to persist aggregated messages in the **target/data/leveldb.dat** file.

212.8.3.2. Using LevelDBAggregationRepository in Spring XML

The same example but using Spring XML instead:

212.8.4. Dependencies

To use LevelDB in your camel routes you need to add the a dependency on **camel-leveldb**.

If you use maven you could just add the following to your pom.xml, substituting the version number for the latest & greatest release (see the download page for the latest versions).

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-leveldb</artifactId>
  <version>2.10.0</version>
</dependency>
```

CHAPTER 213. LOG COMPONENT

Available as of Camel version 1.1

The **log**: component logs message exchanges to the underlying logging mechanism.

Camel uses [sfl4j](#) which allows you to configure logging via, among others:

- Log4j
- Logback
- Java Util Logging

213.1. URI FORMAT

```
log:loggingCategory[?options]
```

Where **loggingCategory** is the name of the logging category to use. You can append query options to the URI in the following format, **?option=value&option=value&...**

INFO:*Using Logger instance from the Registry* As of **Camel 2.12.4/2.13.1**, if there's single instance of **org.slf4j.Logger** found in the Registry, the **loggingCategory** is no longer used to create logger instance. The registered instance is used instead. Also it is possible to reference particular **Logger** instance using **?logger=#myLogger** URI parameter. Eventually, if there's no registered and URI **logger** parameter, the logger instance is created using **loggingCategory**.

For example, a log endpoint typically specifies the logging level using the **level** option, as follows:

```
log:org.apache.camel.example?level=DEBUG
```

The default logger logs every exchange (*regular logging*). But Camel also ships with the **Throughput** logger, which is used whenever the **groupSize** option is specified.

TIP:*Also a log in the DSL* There is also a **log** directly in the DSL, but it has a different purpose. Its meant for lightweight and human logs. See more details at LogEIP.

213.2. OPTIONS

The Log component supports 2 options, which are listed below.

Name	Description	Default	Type
exchangeFormatter (advanced)	Sets a custom ExchangeFormatter to convert the Exchange to a String suitable for logging. If not specified, we default to DefaultExchangeFormatter.		ExchangeFormatter
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Log endpoint is configured using URI syntax:

```
log:loggerName
```

with the following path and query parameters:

213.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
loggerName	Required The logger name to use		String

213.2.2. Query Parameters (26 parameters):

Name	Description	Default	Type
groupActiveOnly (producer)	If true, will hide stats when no new messages have been received for a time interval, if false, show stats regardless of message traffic.	true	Boolean
groupDelay (producer)	Set the initial delay for stats (in millis)		Long
groupInterval (producer)	If specified will group message stats by this time interval (in millis)		Long
groupSize (producer)	An integer that specifies a group size for throughput logging.		Integer
level (producer)	Logging level to use. The default value is INFO.	INFO	String
logMask (producer)	If true, mask sensitive information like password or passphrase in the log.		Boolean
marker (producer)	An optional Marker name to use.		String
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
maxChars (formatting)	Limits the number of characters logged per line.	10000	int
multiline (formatting)	If enabled then each information is outputted on a newline.	false	boolean

Name	Description	Default	Type
showAll (formatting)	Quick option for turning all options on. (multiline, maxChars has to be manually set if to be used)	false	boolean
showBody (formatting)	Show the message body.	true	boolean
showBodyType (formatting)	Show the body Java type.	true	boolean
showCaughtException (formatting)	If the exchange has a caught exception, show the exception message (no stack trace). A caught exception is stored as a property on the exchange (using the key <code>org.apache.camel.Exchange#EXCEPTION_CAUGHT</code> and for instance a <code>doCatch</code> can catch exceptions.	false	boolean
showException (formatting)	If the exchange has an exception, show the exception message (no stacktrace)	false	boolean
showExchangeId (formatting)	Show the unique exchange ID.	false	boolean
showExchangePattern (formatting)	Shows the Message Exchange Pattern (or MEP for short).	true	boolean
showFiles (formatting)	If enabled Camel will output files	false	boolean
showFuture (formatting)	If enabled Camel will on Future objects wait for it to complete to obtain the payload to be logged.	false	boolean
showHeaders (formatting)	Show the message headers.	false	boolean
showOut (formatting)	If the exchange has an out message, show the out message.	false	boolean
showProperties (formatting)	Show the exchange properties.	false	boolean
showStackTrace (formatting)	Show the stack trace, if an exchange has an exception. Only effective if one of <code>showAll</code> , <code>showException</code> or <code>showCaughtException</code> are enabled.	false	boolean

Name	Description	Default	Type
showStreams (formatting)	Whether Camel should show stream bodies or not (eg such as java.io.InputStream). Beware if you enable this option then you may not be able later to access the message body as the stream have already been read by this logger. To remedy this you will have to use Stream Caching.	false	boolean
skipBodyLineSeparator (formatting)	Whether to skip line separators when logging the message body. This allows to log the message body in one line, setting this option to false will preserve any line separators from the body, which then will log the body as is.	true	boolean
style (formatting)	Sets the outputs style to use.	Default	OutputStyle

213.3. REGULAR LOGGER SAMPLE

In the route below we log the incoming orders at **DEBUG** level before the order is processed:

```
from("activemq:orders").to("log:com.mycompany.order?level=DEBUG").to("bean:processOrder");
```

Or using Spring XML to define the route:

```
<route>
  <from uri="activemq:orders"/>
  <to uri="log:com.mycompany.order?level=DEBUG"/>
  <to uri="bean:processOrder"/>
</route>
```

213.4. REGULAR LOGGER WITH FORMATTER SAMPLE

In the route below we log the incoming orders at **INFO** level before the order is processed.

```
from("activemq:orders").
  to("log:com.mycompany.order?showAll=true&multiline=true").to("bean:processOrder");
```

213.5. THROUGHPUT LOGGER WITH GROUPSIZE SAMPLE

In the route below we log the throughput of the incoming orders at **DEBUG** level grouped by 10 messages.

```
from("activemq:orders").
  to("log:com.mycompany.order?level=DEBUG&groupSize=10").to("bean:processOrder");
```

213.6. THROUGHPUT LOGGER WITH GROUPINTERVAL SAMPLE

This route will result in message stats logged every 10s, with an initial 60s delay and stats should be displayed even if there isn't any message traffic.

```
from("activemq:orders").
  to("log:com.mycompany.order?
  level=DEBUG&groupInterval=10000&groupDelay=60000&groupActiveOnly=false").to("bean:process
  Order");
```

The following will be logged:

```
"Received: 1000 new messages, with total 2000 so far. Last group took: 10000 millis which is: 100
  messages per second. average: 100"
```

213.7. MASKING SENSITIVE INFORMATION LIKE PASSWORD

Available as of Camel 2.19

You can enable security masking for logging by setting **logMask** flag to **true**. Note that this option also affects Log EIP.

To enable mask in Java DSL at CamelContext level:

```
camelContext.setLogMask(true);
```

And in XML:

```
<camelContext logMask="true">
```

You can also turn it on/off at endpoint level. To enable mask in Java DSL at endpoint level, add `logMask=true` option in the URI for the log endpoint:

```
from("direct:start").to("log:foo?logMask=true");
```

And in XML:

```
<route>
  <from uri="direct:foo"/>
  <to uri="log:foo?logMask=true"/>
</route>
```

org.apache.camel.processor.DefaultMaskingFormatter is used for the masking by default. If you want to use a custom masking formatter, put it into registry with the name **CamelCustomLogMask**. Note that the masking formatter must implement **org.apache.camel.spi.MaskingFormatter**.

213.8. FULL CUSTOMIZATION OF THE LOGGING OUTPUT

Available as of Camel 2.11

With the options outlined in the [#Formatting](#) section, you can control much of the output of the logger. However, log lines will always follow this structure:

```
Exchange[Id:ID-machine-local-50656-1234567901234-1-2, ExchangePattern:InOut,
```

```
Properties:{CamelToEndpoint=log://org.apache.camel.component.log.TEST?showAll=true,
CamelCreatedTimestamp=Thu Mar 28 00:00:00 WET 2013},
Headers:{breadcrumbsId=ID-machine-local-50656-1234567901234-1-1}, BodyType:String, Body:Hello
World, Out: null]
```

This format is unsuitable in some cases, perhaps because you need to...

- ... filter the headers and properties that are printed, to strike a balance between insight and verbosity.
- ... adjust the log message to whatever you deem most readable.
- ... tailor log messages for digestion by log mining systems, e.g. Splunk.
- ... print specific body types differently.
- ... etc.

Whenever you require absolute customization, you can create a class that implements the **ExchangeFormatter** interface. Within the **format(Exchange)** method you have access to the full Exchange, so you can select and extract the precise information you need, format it in a custom manner and return it. The return value will become the final log message.

You can have the Log component pick up your custom **ExchangeFormatter** in either of two ways:

Explicitly instantiating the LogComponent in your Registry:

```
<bean name="log" class="org.apache.camel.component.log.LogComponent">
  <property name="exchangeFormatter" ref="myCustomFormatter" />
</bean>
```

213.8.1. Convention over configuration:*

Simply by registering a bean with the name **logFormatter**; the Log Component is intelligent enough to pick it up automatically.

```
<bean name="logFormatter" class="com.xyz.MyCustomExchangeFormatter" />
```

NOTE

the **ExchangeFormatter** gets applied to **all Log endpoints within that Camel Context**. If you need different ExchangeFormatters for different endpoints, just instantiate the LogComponent as many times as needed, and use the relevant bean name as the endpoint prefix.

From **Camel 2.11.2/2.12** onwards when using a custom log formatter, you can specify parameters in the log uri, which gets configured on the custom log formatter. Though when you do that you should define the "logFormatter" as prototype scoped so its not shared if you have different parameters, eg:

```
<bean name="logFormatter" class="com.xyz.MyCustomExchangeFormatter" scope="prototype"/>
```

And then we can have Camel routes using the log uri with different options:

```
<to uri="log:foo?param1=foo&param2=100"/>
```

```
<to uri="log:bar?param1=bar&param2=200"/>
```

213.9. USING LOG COMPONENT IN OSGI

Improvement as of Camel 2.12.4/2.13.1

When using Log component inside OSGi (e.g., in Karaf), the underlying logging mechanisms are provided by PAX logging. It searches for a bundle which invokes **org.slf4j.LoggerFactory.getLogger()** method and associates the bundle with the logger instance. Without specifying custom **org.slf4j.Logger** instance, the logger created by Log component is associated with **camel-core** bundle.

In some scenarios it is required that the bundle associated with logger should be the bundle which contains route definition. To do this, either register single instance of **org.slf4j.Logger** in the Registry or reference it using **logger** URI parameter.

213.10. SEE ALSO

- LogEIP for using **log** directly in the DSL for human logs.

CHAPTER 214. LUCENE COMPONENT

Available as of Camel version 2.2

The **lucene** component is based on the Apache Lucene project. Apache Lucene is a powerful high-performance, full-featured text search engine library written entirely in Java. For more details about Lucene, please see the following links

- <http://lucene.apache.org/java/docs/>
- <http://lucene.apache.org/java/docs/features.html>

The lucene component in camel facilitates integration and utilization of Lucene endpoints in enterprise integration patterns and scenarios. The lucene component does the following

- builds a searchable index of documents when payloads are sent to the Lucene Endpoint
- facilitates performing of indexed searches in Camel

This component only supports producer endpoints.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-lucene</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

214.1. URI FORMAT

```
lucene:searcherName:insert[?options]
lucene:searcherName:query[?options]
```

You can append query options to the URI in the following format, **?option=value&option=value&...**

214.2. INSERT OPTIONS

The Lucene component supports 2 options, which are listed below.

Name	Description	Default	Type
config (advanced)	To use a shared lucene configuration		LuceneConfiguration
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Lucene endpoint is configured using URI syntax:

```
lucene:host:operation
```

with the following path and query parameters:

214.2.1. Path Parameters (2 parameters):

Name	Description	Default	Type
host	Required The URL to the lucene server		String
operation	Required Operation to do such as insert or query.		LuceneOperation

214.2.2. Query Parameters (5 parameters):

Name	Description	Default	Type
analyzer (producer)	An Analyzer builds TokenStreams, which analyze text. It thus represents a policy for extracting index terms from text. The value for analyzer can be any class that extends the abstract class <code>org.apache.lucene.analysis.Analyzer</code> . Lucene also offers a rich set of analyzers out of the box		Analyzer
indexDir (producer)	A file system directory in which index files are created upon analysis of the document by the specified analyzer		File
maxHits (producer)	An integer value that limits the result set of the search operation		int
srcDir (producer)	An optional directory containing files to be used to be analyzed and added to the index at producer startup.		File
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

214.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 11 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.lucene.config.analyzer</code>	An Analyzer builds TokenStreams, which analyze text. It thus represents a policy for extracting index terms from text. The value for analyzer can be any class that extends the abstract class <code>org.apache.lucene.analysis.Analyzer</code> . Lucene also offers a rich set of analyzers out of the box		Analyzer
<code>camel.component.lucene.config.authority</code>			String
<code>camel.component.lucene.config.host</code>	The URL to the lucene server		String
<code>camel.component.lucene.config.index-directory</code>	A file system directory in which index files are created upon analysis of the document by the specified analyzer		File
<code>camel.component.lucene.config.lucene-version</code>			Version
<code>camel.component.lucene.config.max-hits</code>	An integer value that limits the result set of the search operation		Integer
<code>camel.component.lucene.config.operation</code>	Operation to do such as insert or query.		LuceneOperation
<code>camel.component.lucene.config.source-directory</code>	An optional directory containing files to be used to be analyzed and added to the index at producer startup.		File
<code>camel.component.lucene.config.uri</code>			URI
<code>camel.component.lucene.enabled</code>	Enable lucene component	true	Boolean
<code>camel.component.lucene.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

214.4. SENDING/RECEIVING MESSAGES TO/FROM THE CACHE

214.4.1. Message Headers

Header	Description
QUERY	The Lucene Query to performed on the index. The query may include wildcards and phrases
RETURN_LUCENE_DOCUMENTS	Camel 2.15: Set this header to true to include the actual Lucene documentation when returning hit information.

214.4.2. Lucene Producers

This component supports 2 producer endpoints.

insert - The insert producer builds a searchable index by analyzing the body in incoming exchanges and associating it with a token ("content"). **query** - The query producer performs searches on a pre-created index. The query uses the searchable index to perform score & relevance based searches. Queries are sent via the incoming exchange contains a header property name called 'QUERY'. The value of the header property 'QUERY' is a Lucene Query. For more details on how to create Lucene Queries check out http://lucene.apache.org/java/3_0_0/queryparsersyntax.html

214.4.3. Lucene Processor

There is a processor called LuceneQueryProcessor available to perform queries against lucene without the need to create a producer.

214.5. LUCENE USAGE SAMPLES

214.5.1. Example 1: Creating a Lucene index

```
RouteBuilder builder = new RouteBuilder() {
    public void configure() {
        from("direct:start").
            to("lucene:whitespaceQuotesIndex:insert?
                analyzer=#whitespaceAnalyzer&indexDir=#whitespace&srcDir=#load_dir").
            to("mock:result");
    }
};
```

214.5.2. Example 2: Loading properties into the JNDI registry in the Camel Context

```
@Override
protected JndiRegistry createRegistry() throws Exception {
    JndiRegistry registry =
        new JndiRegistry(createJndiContext());
    registry.bind("whitespace", new File("./whitespaceIndexDir"));
    registry.bind("load_dir",
        new File("src/test/resources/sources"));
}
```

```

registry.bind("whitespaceAnalyzer",
    new WhitespaceAnalyzer());
return registry;
}
...
CamelContext context = new DefaultCamelContext(createRegistry());

```

214.5.3. Example 2: Performing searches using a Query Producer

```

RouteBuilder builder = new RouteBuilder() {
    public void configure() {
        from("direct:start").
            setHeader("QUERY", constant("Seinfeld")).
            to("lucene:searchIndex:query?
                analyzer=#whitespaceAnalyzer&indexDir=#whitespace&maxHits=20").
            to("direct:next");

        from("direct:next").process(new Processor() {
            public void process(Exchange exchange) throws Exception {
                Hits hits = exchange.getIn().getBody(Hits.class);
                printResults(hits);
            }

            private void printResults(Hits hits) {
                LOG.debug("Number of hits: " + hits.getNumberOfHits());
                for (int i = 0; i < hits.getNumberOfHits(); i++) {
                    LOG.debug("Hit " + i + " Index Location:" + hits.getHit().get(i).getHitLocation());
                    LOG.debug("Hit " + i + " Score:" + hits.getHit().get(i).getScore());
                    LOG.debug("Hit " + i + " Data:" + hits.getHit().get(i).getData());
                }
            }
        }).to("mock:searchResult");
    }
};

```

214.5.4. Example 3: Performing searches using a Query Processor

```

RouteBuilder builder = new RouteBuilder() {
    public void configure() {
        try {
            from("direct:start").
                setHeader("QUERY", constant("Rodney Dangerfield")).
                process(new LuceneQueryProcessor("target/stdindexDir", analyzer, null, 20)).
                to("direct:next");
        } catch (Exception e) {
            e.printStackTrace();
        }

        from("direct:next").process(new Processor() {
            public void process(Exchange exchange) throws Exception {
                Hits hits = exchange.getIn().getBody(Hits.class);
                printResults(hits);
            }
        });
    }
};

```

```
private void printResults(Hits hits) {
    LOG.debug("Number of hits: " + hits.getNumberOfHits());
    for (int i = 0; i < hits.getNumberOfHits(); i++) {
        LOG.debug("Hit " + i + " Index Location:" + hits.getHit().get(i).getHitLocation());
        LOG.debug("Hit " + i + " Score:" + hits.getHit().get(i).getScore());
        LOG.debug("Hit " + i + " Data:" + hits.getHit().get(i).getData());
    }
}
}).to("mock:searchResult");
};
```

CHAPTER 215. LUMBERJACK COMPONENT

Available as of Camel version 2.18

The **Lumberjack** component retrieves logs sent over the network using the Lumberjack protocol, from [Filebeat](#) for instance. The network communication can be secured with SSL.

This component only supports consumer endpoints.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-lumberjack</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

215.1. URI FORMAT

```
lumberjack:host
lumberjack:host:port
```

You can append query options to the URI in the following format, **?option=value&option=value&...**

215.2. OPTIONS

The Lumberjack component supports 3 options, which are listed below.

Name	Description	Default	Type
sslContextParameters (security)	Sets the default SSL configuration to use for all the endpoints. You can also configure it directly at the endpoint level.		SSLContextParameters
useGlobalSslContextParameters (security)	Enable usage of global SSL context parameters.	false	boolean
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Lumberjack endpoint is configured using URI syntax:

```
lumberjack:host:port
```

with the following path and query parameters:

215.2.1. Path Parameters (2 parameters):

Name	Description	Default	Type
host	Required Network interface on which to listen for Lumberjack		String
port	Network port on which to listen for Lumberjack	5044	int

215.2.2. Query Parameters (5 parameters):

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
sslContextParameters (consumer)	SSL configuration		SSLContextParameters
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

215.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 4 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.lumberjack.enabled</code>	Enable lumberjack component	true	Boolean
<code>camel.component.lumberjack.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.component.lumberjack.ssl-context-parameters</code>	Sets the default SSL configuration to use for all the endpoints. You can also configure it directly at the endpoint level. The option is a <code>org.apache.camel.util.jsse.SSLContextParameters</code> type.		String
<code>camel.component.lumberjack.use-global-ssl-context-parameters</code>	Enable usage of global SSL context parameters.	false	Boolean

215.4. RESULT

The result body is a `Map<String, Object>` object.

215.5. LUMBERJACK USAGE SAMPLES

215.5.1. Example 1: Streaming the log messages

```
RouteBuilder builder = new RouteBuilder() {
    public void configure() {
        from("lumberjack:0.0.0.0").           // Listen on all network interfaces using the default port
            setBody(simple("${body[message]}")). // Select only the log message
            to("stream:out");                 // Write it into the output stream
    }
};
```

CHAPTER 216. LZF DEFLATE COMPRESSION DATAFORMAT

Available as of Camel version 2.17

The LZF [Data Format](#) is a message compression and de-compression format. It uses the LZF deflate algorithm. Messages marshalled using LZF compression can be unmarshalled using LZF decompression just prior to being consumed at the endpoint. The compression capability is quite useful when you deal with large XML and Text based payloads or when you read messages previously compressed using LZF algorithm.

216.1. OPTIONS

The LZF Deflate Compression dataformat supports 2 options, which are listed below.

Name	Default	Java Type	Description
<code>usingParallelCompression</code>	false	Boolean	Enable encoding (compress) using multiple processing cores.
<code>contentTypeHeader</code>	false	Boolean	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSon etc.

216.2. SPRING BOOT AUTO-CONFIGURATION

The component supports 3 options, which are listed below.

Name	Description	Default	Type
<code>camel.dataformat.lzf.content-type-header</code>	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSon etc.	false	Boolean
<code>camel.dataformat.lzf.enabled</code>	Enable lzf dataformat	true	Boolean
<code>camel.dataformat.lzf.using-parallel-compression</code>	Enable encoding (compress) using multiple processing cores.	false	Boolean

ND

216.3. MARSHAL

In this example we marshal a regular text/XML payload to a compressed payload employing LZFL compression format and send it an ActiveMQ queue called MY_QUEUE.

```
from("direct:start").marshal().lzf().to("activemq:queue:MY_QUEUE");
```

216.4. UNMARSHAL

In this example we unmarshal a LZFL payload from an ActiveMQ queue called MY_QUEUE to its original format, and forward it for processing to the **UnGZippedMessageProcessor**.

```
from("activemq:queue:MY_QUEUE").unmarshal().lzf().process(new  
UnCompressedMessageProcessor());
```

216.5. DEPENDENCIES

To use LZFL compression in your camel routes you need to add a dependency on **camel-lzf** which implements this data format.

If you use Maven you can just add the following to your **pom.xml**, substituting the version number for the latest & greatest release (see [the download page for the latest versions](#)).

```
<dependency>  
  <groupId>org.apache.camel</groupId>  
  <artifactId>camel-lzf</artifactId>  
  <version>x.x.x</version>  
  <!-- use the same version as your Camel core version -->  
</dependency>
```

CHAPTER 217. MAIL COMPONENT

Available as of Camel version 1.0

The mail component provides access to Email via Spring's Mail support and the underlying JavaMail system.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-mail</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

WARNING

Geronimo mail .jar

We have discovered that the geronimo mail **.jar** (v1.6) has a bug when polling mails with attachments. It cannot correctly identify the **Content-Type**. So, if you attach a **.jpeg** file to a mail and you poll it, the **Content-Type** is resolved as **text/plain** and not as **image/jpeg**. For that reason, we have added an **org.apache.camel.component.ContentTypeResolver** SPI interface which enables you to provide your own implementation and fix this bug by returning the correct Mime type based on the file name. So if the file name ends with **jpeg/jpg**, you can return **image/jpeg**.

You can set your custom resolver on the **MailComponent** instance or on the **MailEndpoint** instance.

TIP

POP3 or IMAP POP3 has some limitations and end users are encouraged to use IMAP if possible.

INFO: Using mock-mail for testing You can use a mock framework for unit testing, which allows you to test without the need for a real mail server. However you should remember to not include the mock-mail when you go into production or other environments where you need to send mails to a real mail server. Just the presence of the `mock-javamail.jar` on the classpath means that it will kick in and avoid sending the mails.

217.1. URI FORMAT

Mail endpoints can have one of the following URI formats (for the protocols, SMTP, POP3, or IMAP, respectively):

```
smtp://[username@]host[:port][?options]
pop3://[username@]host[:port][?options]
imap://[username@]host[:port][?options]
```

The mail component also supports secure variants of these protocols (layered over SSL). You can enable the secure protocols by adding **s** to the scheme:

```
smtps://[username@]host[:port][?options]
pop3s://[username@]host[:port][?options]
imaps://[username@]host[:port][?options]
```

You can append query options to the URI in the following format, **?option=value&option=value&...**

217.2.

The Mail component supports 4 options, which are listed below.

Name	Description	Default	Type
configuration (advanced)	Sets the Mail configuration		MailConfiguration
contentTypeResolver (advanced)	Resolver to determine Content-Type for file attachments.		ContentTypeResolver
useGlobalSslContext Parameters (security)	Enable usage of global SSL context parameters.	false	boolean
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

217.3.

The Mail endpoint is configured using URI syntax:

```
imap:host:port
```

with the following path and query parameters:

217.3.1. Path Parameters (2 parameters):

Name	Description	Default	Type
host	Required The mail server host name		String
port	The port number of the mail server		int

217.3.2. Query Parameters (62 parameters):

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
closeFolder (consumer)	Whether the consumer should close the folder after polling. Setting this option to false and having <code>disconnect=false</code> as well, then the consumer keep the folder open between polls.	true	boolean
copyTo (consumer)	After processing a mail message, it can be copied to a mail folder with the given name. You can override this configuration value, with a header with the key <code>copyTo</code> , allowing you to copy messages to folder names configured at runtime.		String
delete (consumer)	Deletes the messages after they have been processed. This is done by setting the DELETED flag on the mail message. If false, the SEEN flag is set instead. As of Camel 2.10 you can override this configuration option by setting a header with the key <code>delete</code> to determine if the mail should be deleted or not.	false	boolean
disconnect (consumer)	Whether the consumer should disconnect after polling. If enabled this forces Camel to connect on each poll.	false	boolean
handleFailedMessage (consumer)	If the mail consumer cannot retrieve a given mail message, then this option allows to handle the caused exception by the consumer's error handler. By enable the bridge error handler on the consumer, then the Camel routing error handler can handle the exception instead. The default behavior would be the consumer throws an exception and no mails from the batch would be able to be routed by Camel.	false	boolean
maxMessagesPerPoll (consumer)	Specifies the maximum number of messages to gather per poll. By default, no maximum is set. Can be used to set a limit of e.g. 1000 to avoid downloading thousands of files when the server starts up. Set a value of 0 or negative to disable this option.		int

Name	Description	Default	Type
mimeDecodeHeaders (consumer)	This option enables transparent MIME decoding and unfolding for mail headers.	false	boolean
peek (consumer)	Will mark the <code>javax.mail.Message</code> as peeked before processing the mail message. This applies to <code>IMAPMessage</code> messages types only. By using <code>peek</code> the mail will not be eager marked as SEEN on the mail server, which allows us to rollback the mail message if there is an error processing in Camel.	true	boolean
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean
skipFailedMessage (consumer)	If the mail consumer cannot retrieve a given mail message, then this option allows to skip the message and move on to retrieve the next mail message. The default behavior would be the consumer throws an exception and no mails from the batch would be able to be routed by Camel.	false	boolean
unseen (consumer)	Whether to limit by unseen mails only.	true	boolean
exceptionHandler (consumer)	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		<code>ExceptionHandler</code>
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		<code>ExchangePattern</code>
fetchSize (consumer)	Sets the maximum number of messages to consume during a poll. This can be used to avoid overloading a mail server, if a mailbox folder contains a lot of messages. Default value of -1 means no fetch size and all messages will be consumed. Setting the value to 0 is a special corner case, where Camel will not consume any messages at all.	-1	int
folderName (consumer)	The folder to poll.	INBOX	String
mailUidGenerator (consumer)	A pluggable <code>MailUidGenerator</code> that allows to use custom logic to generate UUID of the mail message.		<code>MailUidGenerator</code>

Name	Description	Default	Type
mapMailMessage (consumer)	Specifies whether Camel should map the received mail message to Camel body/headers. If set to true, the body of the mail message is mapped to the body of the Camel IN message and the mail headers are mapped to IN headers. If this option is set to false then the IN message contains a raw <code>javax.mail.Message</code> . You can retrieve this raw message by calling <code>exchange.getIn().getBody(javax.mail.Message.class)</code> .	true	boolean
pollStrategy (consumer)	A pluggable <code>org.apache.camel.PollingConsumerPollingStrategy</code> allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		PollingConsumerPollStrategy
postProcessAction (consumer)	Refers to an <code>MailBoxPostProcessAction</code> for doing post processing tasks on the mailbox once the normal processing ended.		MailBoxPostProcessAction
bcc (producer)	Sets the BCC email address. Separate multiple email addresses with comma.		String
cc (producer)	Sets the CC email address. Separate multiple email addresses with comma.		String
from (producer)	The from email address	camel@localhost	String
replyTo (producer)	The Reply-To recipients (the receivers of the response mail). Separate multiple email addresses with a comma.		String
subject (producer)	The Subject of the message being sent. Note: Setting the subject in the header takes precedence over this option.		String
to (producer)	Sets the To email address. Separate multiple email addresses with comma.		String
javaMailSender (producer)	To use a custom <code>org.apache.camel.component.mail.JavaMailSender</code> for sending emails.		JavaMailSender

Name	Description	Default	Type
additionalJavaMailProperties (advanced)	Sets additional java mail properties, that will append/override any default properties that is set based on all the other options. This is useful if you need to add some special options but want to keep the others as is.		Properties
alternativeBodyHeader (advanced)	Specifies the key to an IN message header that contains an alternative email body. For example, if you send emails in text/html format and want to provide an alternative mail body for non-HTML email clients, set the alternative mail body with this key as a header.	CamelMailAlternativeBody	String
attachmentsContentTransferEncodingResolver (advanced)	To use a custom AttachmentsContentTransferEncodingResolver to resolve what content-type-encoding to use for attachments.		AttachmentsContentTransferEncodingResolver
binding (advanced)	Sets the binding used to convert from a Camel message to and from a Mail message		MailBinding
connectionTimeout (advanced)	The connection timeout in milliseconds.	30000	int
contentType (advanced)	The mail message content type. Use text/html for HTML mails.	text/plain	String
contentTypeResolver (advanced)	Resolver to determine Content-Type for file attachments.		ContentTypeResolver
debugMode (advanced)	Enable debug mode on the underlying mail framework. The SUN Mail framework logs the debug messages to System.out by default.	false	boolean
headerFilterStrategy (advanced)	To use a custom org.apache.camel.spi.HeaderFilterStrategy to filter headers.		HeaderFilterStrategy
ignoreUnsupportedCharset (advanced)	Option to let Camel ignore unsupported charset in the local JVM when sending mails. If the charset is unsupported then charset=XXX (where XXX represents the unsupported charset) is removed from the content-type and it relies on the platform default instead.	false	boolean

Name	Description	Default	Type
ignoreUriScheme (advanced)	Option to let Camel ignore unsupported charset in the local JVM when sending mails. If the charset is unsupported then charset=XXX (where XXX represents the unsupported charset) is removed from the content-type and it relies on the platform default instead.	false	boolean
session (advanced)	Specifies the mail session that camel should use for all mail interactions. Useful in scenarios where mail sessions are created and managed by some other resource, such as a JavaEE container. If this is not specified, Camel automatically creates the mail session for you.		Session
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
useInlineAttachments (advanced)	Whether to use disposition inline or attachment.	false	boolean
idempotentRepository (filter)	A pluggable repository <code>org.apache.camel.spi.IdempotentRepository</code> which allows to cluster consuming from the same mailbox, and let the repository coordinate whether a mail message is valid for the consumer to process. By default no repository is in use.		IdempotentRepository
idempotentRepositoryRemoveOnCommit (filter)	When using idempotent repository, then when the mail message has been successfully processed and is committed, should the message id be removed from the idempotent repository (default) or be kept in the repository. By default its assumed the message id is unique and has no value to be kept in the repository, because the mail message will be marked as seen/moved or deleted to prevent it from being consumed again. And therefore having the message id stored in the idempotent repository has little value. However this option allows to store the message id, for whatever reason you may have.	true	boolean
searchTerm (filter)	Refers to a <code>javax.mail.search.SearchTerm</code> which allows to filter mails based on search criteria such as subject, body, from, sent after a certain date etc.		SearchTerm
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the <code>backoffMultiplier</code> should kick-in.		int

Name	Description	Default	Type
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.		int
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.		int
delay (scheduler)	Milliseconds before the next poll.	60000	long
greedy (scheduler)	If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	1000	long
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that.	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz2 component	none	ScheduledPollConsumerScheduler
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz2, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for initialDelay and delay options.	MILLIS ECON DS	TimeUnit
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.	true	boolean

Name	Description	Default	Type
sortTerm (sort)	Sorting order for messages. Only natively supported for IMAP. Emulated to some degree when using POP3 or when IMAP server does not have the SORT capability.		String
dummyTrustManager (security)	To use a dummy security setting for trusting all certificates. Should only be used for development mode, and not production.	false	boolean
password (security)	The password for login		String
sslContextParameters (security)	To configure security using SSLContextParameters.		SSLContextParameters
username (security)	The username for login		String

217.4. SPRING BOOT AUTO-CONFIGURATION

The component supports 48 options, which are listed below.

Name	Description	Default	Type
camel.component.mail.configuration.additional-java-mail-properties	Sets additional java mail properties, that will append/override any default properties that is set based on all the other options. This is useful if you need to add some special options but want to keep the others as is.		Properties
camel.component.mail.configuration.alternative-body-header	Specifies the key to an IN message header that contains an alternative email body. For example, if you send emails in text/html format and want to provide an alternative mail body for non-HTML email clients, set the alternative mail body with this key as a header.	Camel MailAlternativeBody	String
camel.component.mail.configuration.attachments-content-transfer-encoding-resolver	To use a custom AttachmentsContentTransferEncodingResolver to resolve what content-type-encoding to use for attachments.		AttachmentsContentTransferEncodingResolver

Name	Description	Default	Type
<code>camel.component.mail.configuration.bcc</code>	Sets the BCC email address. Separate multiple email addresses with comma.		String
<code>camel.component.mail.configuration.cc</code>	Sets the CC email address. Separate multiple email addresses with comma.		String
<code>camel.component.mail.configuration.close-folder</code>	Whether the consumer should close the folder after polling. Setting this option to false and having <code>disconnect=false</code> as well, then the consumer keep the folder open between polls.	true	Boolean
<code>camel.component.mail.configuration.connection-timeout</code>	The connection timeout in milliseconds.	30000	Integer
<code>camel.component.mail.configuration.content-type</code>	The mail message content type. Use text/html for HTML mails.	text/plain	String
<code>camel.component.mail.configuration.copy-to</code>	After processing a mail message, it can be copied to a mail folder with the given name. You can override this configuration value, with a header with the key <code>copyTo</code> , allowing you to copy messages to folder names configured at runtime.		String
<code>camel.component.mail.configuration.debug-mode</code>	Enable debug mode on the underlying mail framework. The SUN Mail framework logs the debug messages to <code>System.out</code> by default.	false	Boolean
<code>camel.component.mail.configuration.delete</code>	Deletes the messages after they have been processed. This is done by setting the DELETED flag on the mail message. If false, the SEEN flag is set instead. As of Camel 2.10 you can override this configuration option by setting a header with the key <code>delete</code> to determine if the mail should be deleted or not.	false	Boolean
<code>camel.component.mail.configuration.disconnect</code>	Whether the consumer should disconnect after polling. If enabled this forces Camel to connect on each poll.	false	Boolean
<code>camel.component.mail.configuration.dummy-trust-manager</code>	To use a dummy security setting for trusting all certificates. Should only be used for development mode, and not production.	false	Boolean

Name	Description	Default	Type
<code>camel.component.mail.configuration.fetch-size</code>	Sets the maximum number of messages to consume during a poll. This can be used to avoid overloading a mail server, if a mailbox folder contains a lot of messages. Default value of -1 means no fetch size and all messages will be consumed. Setting the value to 0 is a special corner case, where Camel will not consume any messages at all.	-1	Integer
<code>camel.component.mail.configuration.folder-name</code>	The folder to poll.	INBOX	String
<code>camel.component.mail.configuration.from</code>	The from email address	camel@localhost	String
<code>camel.component.mail.configuration.handle-failed-message</code>	If the mail consumer cannot retrieve a given mail message, then this option allows to handle the caused exception by the consumer's error handler. By enable the bridge error handler on the consumer, then the Camel routing error handler can handle the exception instead. The default behavior would be the consumer throws an exception and no mails from the batch would be able to be routed by Camel.	false	Boolean
<code>camel.component.mail.configuration.host</code>	The mail server host name		String
<code>camel.component.mail.configuration.ignore-unsupported-charset</code>	Option to let Camel ignore unsupported charset in the local JVM when sending mails. If the charset is unsupported then charset=XXX (where XXX represents the unsupported charset) is removed from the content-type and it relies on the platform default instead.	false	Boolean
<code>camel.component.mail.configuration.ignore-uri-scheme</code>	Option to let Camel ignore unsupported charset in the local JVM when sending mails. If the charset is unsupported then charset=XXX (where XXX represents the unsupported charset) is removed from the content-type and it relies on the platform default instead.	false	Boolean
<code>camel.component.mail.configuration.java-mail-properties</code>	Sets the java mail options. Will clear any default properties and only use the properties provided for this method.		Properties

Name	Description	Default	Type
<code>camel.component.mail.configuration.java-mail-sender</code>	To use a custom <code>org.apache.camel.component.mail.JavaMailSender</code> for sending emails.		JavaMailSender
<code>camel.component.mail.configuration.map-mail-message</code>	Specifies whether Camel should map the received mail message to Camel body/headers. If set to true, the body of the mail message is mapped to the body of the Camel IN message and the mail headers are mapped to IN headers. If this option is set to false then the IN message contains a raw <code>javax.mail.Message</code> . You can retrieve this raw message by calling <code>exchange.getIn().getBody(javax.mail.Message.class)</code> .	true	Boolean
<code>camel.component.mail.configuration.mime-decode-headers</code>	This option enables transparent MIME decoding and unfolding for mail headers.	false	Boolean
<code>camel.component.mail.configuration.password</code>	The password for login		String
<code>camel.component.mail.configuration.peek</code>	Will mark the <code>javax.mail.Message</code> as peeked before processing the mail message. This applies to IMAPMessage messages types only. By using peek the mail will not be eager marked as SEEN on the mail server, which allows us to rollback the mail message if there is an error processing in Camel.	true	Boolean
<code>camel.component.mail.configuration.port</code>	The port number of the mail server		Integer
<code>camel.component.mail.configuration.protocol</code>	The protocol for communicating with the mail server		String
<code>camel.component.mail.configuration.reply-to</code>	The Reply-To recipients (the receivers of the response mail). Separate multiple email addresses with a comma.		String

Name	Description	Default	Type
<code>camel.component.mail.configuration.session</code>	Specifies the mail session that camel should use for all mail interactions. Useful in scenarios where mail sessions are created and managed by some other resource, such as a JavaEE container. If this is not specified, Camel automatically creates the mail session for you.		Session
<code>camel.component.mail.configuration.skip-failed-message</code>	If the mail consumer cannot retrieve a given mail message, then this option allows to skip the message and move on to retrieve the next mail message. The default behavior would be the consumer throws an exception and no mails from the batch would be able to be routed by Camel.	false	Boolean
<code>camel.component.mail.configuration.ssl-context-parameters</code>	To configure security using SSLContextParameters.		SSLContextParameters
<code>camel.component.mail.configuration.subject</code>	The Subject of the message being sent. Note: Setting the subject in the header takes precedence over this option.		String
<code>camel.component.mail.configuration.to</code>	Sets the To email address. Separate multiple email addresses with comma.		String
<code>camel.component.mail.configuration.unseen</code>	Whether to limit by unseen mails only.	true	Boolean
<code>camel.component.mail.configuration.use-inline-attachments</code>	Whether to use disposition inline or attachment.	false	Boolean
<code>camel.component.mail.configuration.username</code>	The username for login		String
<code>camel.component.mail.content-type-resolver</code>	Resolver to determine Content-Type for file attachments. The option is a <code>org.apache.camel.component.mail.ContentTypeResolver</code> type.		String
<code>camel.component.mail.enabled</code>	Enable mail component	true	Boolean

Name	Description	Default	Type
<code>camel.component.mail.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.component.mail.use-global-ssl-context-parameters</code>	Enable usage of global SSL context parameters.	false	Boolean
<code>camel.dataformat.mime-multipart.binary-content</code>	Defines whether the content of binary parts in the MIME multipart is binary (true) or Base-64 encoded (false) Default is false.	false	Boolean
<code>camel.dataformat.mime-multipart.content-type-header</code>	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON etc.	false	Boolean
<code>camel.dataformat.mime-multipart.enabled</code>	Enable mime-multipart dataformat	true	Boolean
<code>camel.dataformat.mime-multipart.headers-inline</code>	Defines whether the MIME-Multipart headers are part of the message body (true) or are set as Camel headers (false). Default is false.	false	Boolean
<code>camel.dataformat.mime-multipart.include-headers</code>	A regex that defines which Camel headers are also included as MIME headers into the MIME multipart. This will only work if headersInline is set to true. Default is to include no headers		String
<code>camel.dataformat.mime-multipart.multipart-sub-type</code>	Specify the subtype of the MIME Multipart. Default is mixed.	mixed	String
<code>camel.dataformat.mime-multipart.multipart-without-attachment</code>	Defines whether a message without attachment is also marshaled into a MIME Multipart (with only one body part). Default is false.	false	Boolean

217.4.1. Sample endpoints

Typically, you specify a URI with login credentials as follows (taking SMTP as an example):

```
smtp://[username@]host[:port][?password=somepwd]
```

Alternatively, it is possible to specify both the user name and the password as query options:

```
smtp://host[:port]?password=somepwd&username=someuser
```

For example:

```
smtp://mycompany.mailserver:30?password=tiger&username=scott
```

217.5. COMPONENTS

- IMAP
- IMAPs
- POP3s
- POP3s
- SMTP
- SMTPs

217.5.1. Default ports

Default port numbers are supported. If the port number is omitted, Camel determines the port number to use based on the protocol.

Protocol	Default Port Number
SMTP	25
SMTPS	465
POP3	110
POP3S	995
IMAP	143
IMAPS	993

217.6. SSL SUPPORT

The underlying mail framework is responsible for providing SSL support. You may either configure SSL/TLS support by completely specifying the necessary Java Mail API configuration options, or you may provide a configured `SSLContextParameters` through the component or endpoint configuration.

217.6.1. Using the JSSE Configuration Utility

As of **Camel 2.10**, the mail component supports SSL/TLS configuration through the [Camel JSSE Configuration Utility](#). This utility greatly decreases the amount of component specific code you need to write and is configurable at the endpoint and component levels. The following examples demonstrate how to use the utility with the mail component.

Programmatic configuration of the endpoint

```
KeyStoreParameters ksp = new KeyStoreParameters();
ksp.setResource("/users/home/server/truststore.jks");
ksp.setPassword("keystorePassword");
TrustManagersParameters tmp = new TrustManagersParameters();
tmp.setKeyStore(ksp);
SSLContextParameters scp = new SSLContextParameters();
scp.setTrustManagers(tmp);
Registry registry = ...
registry.bind("sslContextParameters", scp);
...
from(...)
    &nbsp; &nbsp; &nbsp; .to("smtps://smtp.google.com?
    username=user@gmail.com&password=password&sslContextParameters=#sslContextParameters");
```

Spring DSL based configuration of endpoint

```
...
<camel:sslContextParameters id="sslContextParameters">
  <camel:trustManagers>
    <camel:keyStore resource="/users/home/server/truststore.jks" password="keystorePassword"/>
  </camel:trustManagers>
</camel:sslContextParameters>...
...
<to uri="smtps://smtp.google.com?
username=user@gmail.com&password=password&sslContextParameters=#sslContextParameters"/
>...
```

217.6.2. Configuring JavaMail Directly

Camel uses SUN JavaMail, which only trusts certificates issued by well known Certificate Authorities (the default JVM trust configuration). If you issue your own certificates, you have to import the CA certificates into the JVM's Java trust/key store files, override the default JVM trust/key store files (see **SSLNOTES.txt** in JavaMail for details).

217.7. MAIL MESSAGE CONTENT

Camel uses the message exchange's IN body as the [MimeMessage](#) text content. The body is converted to **String.class**.

Camel copies all of the exchange's IN headers to the [MimeMessage](#) headers.

The subject of the [MimeMessage](#) can be configured using a header property on the IN message. The code below demonstrates this:

The same applies for other MimeMessage headers such as recipients, so you can use a header property as **To**:

Since Camel 2.11 When using the MailProducer to send the mail to server, you should be able to get the message id of the [MimeMessage](#) with the key **CamelMailMessageId** from the Camel message header.

217.8. HEADERS TAKE PRECEDENCE OVER PRE-CONFIGURED RECIPIENTS

The recipients specified in the message headers always take precedence over recipients pre-configured in the endpoint URI. The idea is that if you provide any recipients in the message headers, that is what you get. The recipients pre-configured in the endpoint URI are treated as a fallback.

In the sample code below, the email message is sent to **davsclaus@apache.org**, because it takes precedence over the pre-configured recipient, **info@mycompany.com**. Any **CC** and **BCC** settings in the endpoint URI are also ignored and those recipients will not receive any mail. The choice between headers and pre-configured settings is all or nothing: the mail component *either* takes the recipients exclusively from the headers or exclusively from the pre-configured settings. It is not possible to mix and match headers and pre-configured settings.

```
Map<String, Object> headers = new HashMap<String, Object>();
headers.put("to", "davsclaus@apache.org");

template.sendBodyAndHeaders("smtp://admin@localhost?to=info@mycompany.com", "Hello
World", headers);
```

217.9. MULTIPLE RECIPIENTS FOR EASIER CONFIGURATION

It is possible to set multiple recipients using a comma-separated or a semicolon-separated list. This applies both to header settings and to settings in an endpoint URI. For example:

```
Map<String, Object> headers = new HashMap<String, Object>();
headers.put("to", "davsclaus@apache.org ; jstrachan@apache.org ; ningjiang@apache.org");
```

The preceding example uses a semicolon, **;**, as the separator character.

217.10. SETTING SENDER NAME AND EMAIL

You can specify recipients in the format, **name <email>**, to include both the name and the email address of the recipient.

For example, you define the following headers on the a Message:

```
Map headers = new HashMap();
map.put("To", "Claus Ibsen <davsclaus@apache.org>");
map.put("From", "James Strachan <jstrachan@apache.org>");
map.put("Subject", "Camel is cool");
```

217.11. JAVAMAIL API (EX SUN JAVAMAIL)

[JavaMail API](#) is used under the hood for consuming and producing mails.

We encourage end-users to consult these references when using either POP3 or IMAP protocol. Note particularly that POP3 has a much more limited set of features than IMAP.

- [JavaMail POP3 API](#)
- [JavaMail IMAP API](#)
- And generally about the [MAIL Flags](#)

217.12. SAMPLES

We start with a simple route that sends the messages received from a JMS queue as emails. The email account is the **admin** account on **mymailserver.com**.

```
from("jms://queue:subscription").to("smtp://admin@mymailserver.com?password=secret");
```

In the next sample, we poll a mailbox for new emails once every minute. Notice that we use the special **consumer** option for setting the poll interval, **consumer.delay**, as 60000 milliseconds = 60 seconds.

```
from("imap://admin@mymailserver.com
    password=secret&unseen=true&consumer.delay=60000")
.to("seda://mails");
```

In this sample we want to send a mail to multiple recipients:

217.13. SENDING MAIL WITH ATTACHMENT SAMPLE

WARNING

Attachments are not support by all Camel components The *Attachments API* is based on the Java Activation Framework and is generally only used by the Mail API. Since many of the other Camel components do not support attachments, the attachments could potentially be lost as they propagate along the route. The rule of thumb, therefore, is to add attachments just before sending a message to the mail endpoint.

The mail component supports attachments. In the sample below, we send a mail message containing a plain text message with a logo file attachment.

217.14. SSL SAMPLE

In this sample, we want to poll our Google mail inbox for mails. To download mail onto a local mail client, Google mail requires you to enable and configure SSL. This is done by logging into your Google mail account and changing your settings to allow IMAP access. Google have extensive documentation on how to do this.

```
from("imaps://imap.gmail.com?
username=YOUR_USERNAME@gmail.com&password=YOUR_PASSWORD"
+ "&delete=false&unseen=true&consumer.delay=60000").to("log:newmail");
```

The preceding route polls the Google mail inbox for new mails once every minute and logs the received messages to the **newmail** logger category.

Running the sample with **DEBUG** logging enabled, we can monitor the progress in the logs:

```
2008-05-08 06:32:09,640 DEBUG MailConsumer - Connecting to MailStore
imaps://imap.gmail.com:993 (SSL enabled), folder=INBOX
2008-05-08 06:32:11,203 DEBUG MailConsumer - Polling mailfolder: imaps://imap.gmail.com:993
(SSL enabled), folder=INBOX
2008-05-08 06:32:11,640 DEBUG MailConsumer - Fetching 1 messages. Total 1 messages.
2008-05-08 06:32:12,171 DEBUG MailConsumer - Processing message: messageNumber=[332],
from=[James Bond <007@mi5.co.uk>], to=YOUR_USERNAME@gmail.com], subject=[...
2008-05-08 06:32:12,187 INFO newmail - Exchange[MailMessage: messageNumber=[332], from=
[James Bond <007@mi5.co.uk>], to=YOUR_USERNAME@gmail.com], subject=[...
```

217.15. CONSUMING MAILS WITH ATTACHMENT SAMPLE

In this sample we poll a mailbox and store all attachments from the mails as files. First, we define a route to poll the mailbox. As this sample is based on google mail, it uses the same route as shown in the SSL sample:

```
from("imaps://imap.gmail.com?
username=YOUR_USERNAME@gmail.com&password=YOUR_PASSWORD"
+ "&delete=false&unseen=true&consumer.delay=60000").process(new MyMailProcessor());
```

Instead of logging the mail we use a processor where we can process the mail from java code:

```
public void process(Exchange exchange) throws Exception {
    // the API is a bit clunky so we need to loop
    Map<String, DataHandler> attachments = exchange.getIn().getAttachments();
    if (attachments.size() > 0) {
        for (String name : attachments.keySet()) {
            DataHandler dh = attachments.get(name);
            // get the file name
            String filename = dh.getName();

            // get the content and convert it to byte[]
            byte[] data = exchange.getContext().getTypeConverter()
                .convertTo(byte[].class, dh.getInputStream());

            // write the data to a file
            FileOutputStream out = new FileOutputStream(filename);
            out.write(data);
            out.flush();
            out.close();
        }
    }
}
```

As you can see the API to handle attachments is a bit clunky but it's there so you can get the **javax.activation.DataHandler** so you can handle the attachments using standard API.

217.16. HOW TO SPLIT A MAIL MESSAGE WITH ATTACHMENTS

In this example we consume mail messages which may have a number of attachments. What we want to do is to use the Splitter EIP per individual attachment, to process the attachments separately. For example if the mail message has 5 attachments, we want the Splitter to process five messages, each having a single attachment. To do this we need to provide a custom Expression to the Splitter where we provide a List<Message> that contains the five messages with the single attachment.

The code is provided out of the box in Camel 2.10 onwards in the **camel-mail** component. The code is in the class: **org.apache.camel.component.mail.SplitAttachmentsExpression**, which you can find the source code [here](#)

In the Camel route you then need to use this Expression in the route as shown below:

If you use XML DSL then you need to declare a method call expression in the Splitter as shown below

```
<split>
  <method beanType="org.apache.camel.component.mail.SplitAttachmentsExpression"/>
  <to uri="mock:split"/>
</split>
```

From Camel 2.16 onwards you can also split the attachments as byte[] to be stored as the message body. This is done by creating the expression with boolean true

```
SplitAttachmentsExpression split = SplitAttachmentsExpression(true);
```

And then use the expression with the splitter eip.

217.17. USING CUSTOM SEARCHTERM

Available as of Camel 2.11

You can configure a **searchTerm** on the **MailEndpoint** which allows you to filter out unwanted mails.

For example to filter mails to contain Camel in either Subject or Text you can do as follows:

```
<route>
  <from uri="imaps://mymailserver?
  username=foo&password=secret&searchTerm.subjectOrBody=Camel"/>
  <to uri="bean:myBean"/>
</route>
```

Notice we use the **"searchTerm.subjectOrBody"** as parameter key to indicate that we want to search on mail subject or body, to contain the word "Camel".

The class **org.apache.camel.component.mail.SimpleSearchTerm** has a number of options you can configure:

Or to get the new unseen emails going 24 hours back in time you can do. Notice the "now-24h" syntax. See the table below for more details.

```
<route>
  <from uri="imaps://mymailserver?
```

```
username=foo&password=secret&searchTerm.fromSentDate=now-24h"/>
  <to uri="bean:myBean"/>
</route>
```

You can have multiple searchTerm in the endpoint uri configuration. They would then be combined together using AND operator, eg so both conditions must match. For example to get the last unseen emails going back 24 hours which has Camel in the mail subject you can do:

```
<route>
  <from uri="imaps://mymailserver?
username=foo&password=secret&searchTerm.subject=Camel&searchTerm.fromSentDate=now-
24h"/>
  <to uri="bean:myBean"/>
</route>
```

The **SimpleSearchTerm** is designed to be easily configurable from a POJO, so you can also configure it using a <bean> style in XML

```
<bean id="mySearchTerm" class="org.apache.camel.component.mail.SimpleSearchTerm">
  <property name="subject" value="Order"/>
  <property name="to" value="acme-order@acme.com"/>
  <property name="fromSentDate" value="now"/>
</bean>
```

You can then refer to this bean, using #beanId in your Camel route as shown:

```
<route>
  <from uri="imaps://mymailserver?
username=foo&password=secret&searchTerm=#mySearchTerm"/>
  <to uri="bean:myBean"/>
</route>
```

In Java there is a builder class to build compound **SearchTerms** using the **org.apache.camel.component.mail.SearchTermBuilder** class. This allows you to build complex terms such as:

```
// we just want the unseen mails which is not spam
SearchTermBuilder builder = new SearchTermBuilder();

builder.unseen().body(Op.not, "Spam").subject(Op.not, "Spam")
// which was sent from either foo or bar
.from("foo@somewhere.com").from(Op.or, "bar@somewhere.com");
// .. and we could continue building the terms

SearchTerm term = builder.build();
```

217.18. SEE ALSO

- [Configuring Camel](#)
- [Component](#)
- [Endpoint](#)

- Getting Started

CHAPTER 218. MASTER COMPONENT

Available as of Camel version 2.20

The **camel-master**: endpoint provides a way to ensure only a single consumer in a cluster consumes from a given endpoint; with automatic failover if that JVM dies.

This can be very useful if you need to consume from some legacy back end which either doesn't support concurrent consumption or due to commercial or stability reasons you can only have a single connection at any point in time.

218.1. USING THE MASTER ENDPOINT

Just prefix any camel endpoint with **master:someName**: where *someName* is a logical name and is used to acquire the master lock. e.g.

```
from("master:cheese:jms:foo").to("activemq:wine");
```

The above simulates the [Exclusive Consumers](<http://activemq.apache.org/exclusive-consumer.html>) type feature in ActiveMQ; but on any third party JMS provider which maybe doesn't support exclusive consumers.

218.2. URI FORMAT

```
master:namespace:endpoint[?options]
```

Where endpoint is any Camel endpoint you want to run in master/slave mode.

218.3. OPTIONS

The Master component supports 3 options, which are listed below.

Name	Description	Default	Type
service (advanced)	Inject the service to use.		CamelClusterService
serviceSelector (advanced)	Inject the service selector used to lookup the CamelClusterService to use.		Selector
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Master endpoint is configured using URI syntax:

```
master:namespace:delegateUri
```

with the following path and query parameters:

218.3.1. Path Parameters (2 parameters):

Name	Description	Default	Type
namespace	Required The name of the cluster namespace to use		String
delegateUri	Required The endpoint uri to use in master/slave mode		String

218.3.2. Query Parameters (4 parameters):

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

218.4. SPRING BOOT AUTO-CONFIGURATION

The component supports 4 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.master.enabled</code>	Whether to enable auto configuration of the master component. This is enabled by default.		Boolean
<code>camel.component.master.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.component.master.service</code>	Inject the service to use. The option is a <code>org.apache.camel.cluster.CamelClusterService</code> type.		String
<code>camel.component.master.service-selector</code>	Inject the service selector used to lookup the <code>CamelClusterService</code> to use. The option is a <code>org.apache.camel.cluster.CamelClusterService.Selector</code> type.		String

218.5. EXAMPLE

You can protect a clustered Camel application to only consume files from one active node.

```
// the file endpoint we want to consume from
String url = "file:target/inbox?delete=true";

// use the camel master component in the clustered group named myGroup
// to run a master/slave mode in the following Camel url
from("master:myGroup:" + url)
    .log(name + " - Received file: ${file:name}")
    .delay(delay)
    .log(name + " - Done file:  ${file:name}")
    .to("file:target/outbox");
```

The master component leverages `CamelClusterService` you can configure using

- **Java**

```
ZooKeeperClusterService service = new ZooKeeperClusterService();
service.setId("camel-node-1");
service.setNodes("myzk:2181");
service.setBasePath("/camel/cluster");

context.addService(service)
```

- **Xml (Spring/Blueprint)**

```
<beans xmlns="http://www.springframework.org/schema/beans"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="
        http://www.springframework.org/schema/beans
        http://www.springframework.org/schema/beans/spring-beans.xsd
```

```

    http://camel.apache.org/schema/spring
    http://camel.apache.org/schema/spring/camel-spring.xsd">

    <bean id="cluster"
    class="org.apache.camel.component.zookeeper.cluster.ZooKeeperClusterService">
      <property name="id" value="camel-node-1"/>
      <property name="basePath" value="/camel/cluster"/>
      <property name="nodes" value="myzk:2181"/>
    </bean>

    <camelContext xmlns="http://camel.apache.org/schema/spring" autoStartup="false">
      ...
    </camelContext>

  </beans>

```

- **Spring boot**

```

camel.component.zookeeper.cluster.service.enabled = true
camel.component.zookeeper.cluster.service.id      = camel-node-1
camel.component.zookeeper.cluster.service.base-path = /camel/cluster
camel.component.zookeeper.cluster.service.nodes    = myzk:2181

```

218.6. IMPLEMENTATIONS

Camel provide the following ClusterService implementations:

- camel-atomix
- camel-consul
- camel-file
- camel-kubernetes
- camel-zookeeper

CHAPTER 219. METRICS COMPONENT

219.1. METRICS COMPONENT

The **metrics**: component allows to collect various metrics directly from Camel routes. Supported metric types are [counter](#), [histogram](#), [meter](#), [timer](#) and [gauge](#). **Metrics** provides simple way to measure behaviour of application. Configurable reporting backend is enabling different integration options for collecting and visualizing statistics. The component also provides a **MetricsRoutePolicyFactory** which allows to expose route statistics using Dropwizard Metrics, see bottom of page for details.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-metrics</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

219.2. URI FORMAT

```
metrics:[ meter | counter | histogram | timer | gauge ]:metricname[?options]
```

219.3. OPTIONS

The Metrics component supports 2 options, which are listed below.

Name	Description	Default	Type
metricRegistry (advanced)	To use a custom configured MetricRegistry.		MetricRegistry
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Metrics endpoint is configured using URI syntax:

```
metrics:metricsType:metricsName
```

with the following path and query parameters:

219.3.1. Path Parameters (2 parameters):

Name	Description	Default	Type
metricsType	Required Type of metrics		MetricsType
metricsName	Required Name of metrics		String

219.3.2. Query Parameters (7 parameters):

Name	Description	Default	Type
action (producer)	Action when using timer type		MetricsTimerAction
decrement (producer)	Decrement value when using counter type		Long
increment (producer)	Increment value when using counter type		Long
mark (producer)	Mark when using meter type		Long
subject (producer)	Subject value when using gauge type		Object
value (producer)	Value value when using histogram type		Long
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

219.4. SPRING BOOT AUTO-CONFIGURATION

The component supports 3 options, which are listed below.

Name	Description	Default	Type
camel.component.metrics.enabled	Enable metrics component	true	Boolean
camel.component.metrics.metric-registry	To use a custom configured MetricRegistry. The option is a com.codahale.metrics.MetricRegistry type.		String

Name	Description	Default	Type
<code>camel.component.metrics.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

219.5. METRIC REGISTRY

Camel Metrics component uses by default a **MetricRegistry** instance with a **Slf4jReporter** that has a 60 second reporting interval. This default registry can be replaced with a custom one by providing a **MetricRegistry** bean. If multiple **MetricRegistry** beans exist in the application, the one with name **metricRegistry** is used.

For example using Spring Java Configuration:

```
@Configuration
public static class MyConfig extends SingleRouteCamelConfiguration {

    @Bean
    @Override
    public RouteBuilder route() {
        return new RouteBuilder() {
            @Override
            public void configure() throws Exception {
                // define Camel routes here
            }
        };
    }

    @Bean(name = MetricsComponent.METRIC_REGISTRY_NAME)
    public MetricRegistry getMetricRegistry() {
        MetricRegistry registry = ...;
        return registry;
    }
}
```

Or using CDI:

```
class MyBean extends RouteBuilder {

    @Override
    public void configure() {
        from("...")
            // Register the 'my-meter' meter in the MetricRegistry below
            .to("metrics:meter:my-meter");
    }

    @Produces
    // If multiple MetricRegistry beans
    // @Named(MetricsComponent.METRIC_REGISTRY_NAME)
    MetricRegistry registry() {
```

```

MetricRegistry registry = new MetricRegistry();
// ...
return registry;
}
}

```

219.6. USAGE

Each metric has type and name. Supported types are [counter](#), [histogram](#), [meter](#), [timer](#) and [gauge](#). Metric name is simple string. If metric type is not provided then type meter is used by default.

219.6.1. Headers

Metric name defined in URI can be overridden by using header with name **CamelMetricsName**.

For example

```

from("direct:in")
.setHeader(MetricsConstants.HEADER_METRIC_NAME, constant("new.name"))
.to("metrics:counter:name.not.used")
.to("direct:out");

```

will update counter with name **new.name** instead of **name.not.used**.

All Metrics specific headers are removed from the message once Metrics endpoint finishes processing of exchange. While processing exchange Metrics endpoint will catch all exceptions and write log entry using level **warn**.

219.7. METRICS TYPE COUNTER

```
metrics:counter:metricname[?options]
```

219.7.1. Options

Name	Default	Description
increment	-	Long value to add to the counter
decrement	-	Long value to subtract from the counter

If neither **increment** or **decrement** is defined then counter value will be incremented by one. If **increment** and **decrement** are both defined only increment operation is called.

```

// update counter simple.counter by 7
from("direct:in")
.to("metric:counter:simple.counter?increment=7")
.to("direct:out");

```

```
// increment counter simple.counter by 1
from("direct:in")
  .to("metric:counter:simple.counter")
  .to("direct:out");
```

```
// decrement counter simple.counter by 3
from("direct:in")
  .to("metrics:counter:simple.counter?decrement=3")
  .to("direct:out");
```

219.7.2. Headers

Message headers can be used to override **increment** and **decrement** values specified in Metrics component URI.

Name	Description	Expected type
Camel Metrics CounterIncrement	Override increment value in URI	Long
Camel Metrics CounterDecrement	Override decrement value in URI	Long

```
// update counter simple.counter by 417
from("direct:in")
  .setHeader(MetricsConstants.HEADER_COUNTER_INCREMENT, constant(417L))
  .to("metrics:counter:simple.counter?increment=7")
  .to("direct:out");
```

```
// updates counter using simple language to evaluate body.length
from("direct:in")
  .setHeader(MetricsConstants.HEADER_COUNTER_INCREMENT, simple("${body.length}"))
  .to("metrics:counter:body.length")
  .to("mock:out");
```

219.8. METRIC TYPE HISTOGRAM

```
metrics:histogram:metricname[?options]
```

219.8.1. Options

Name	Default	Description
value	-	Value to use in histogram

If no **value** is not set nothing is added to histogram and warning is logged.

```
// adds value 9923 to simple.histogram
from("direct:in")
  .to("metric:histogram:simple.histogram?value=9923")
  .to("direct:out");
```

```
// nothing is added to simple.histogram; warning is logged
from("direct:in")
  .to("metric:histogram:simple.histogram")
  .to("direct:out");
```

219.8.2. Headers

Message header can be used to override value specified in Metrics component URI.

Name	Description	Expected type
Camel Metrics HistogramValue	Override histogram value in URI	Long

```
// adds value 992 to simple.histogram
from("direct:in")
  .setHeader(MetricsConstants.HEADER_HISTOGRAM_VALUE, constant(992L))
  .to("metrics:histogram:simple.histogram?value=700")
  .to("direct:out")
```

219.9. METRIC TYPE METER

```
metrics:meter:metricname[?options]
```

219.9.1. Options

Name	Default	Description
mark	-	Long value to use as mark

If **mark** is not set then **meter.mark()** is called without argument.

```
// marks simple.meter without value
from("direct:in")
  .to("metric:simple.meter")
  .to("direct:out");
```

```
// marks simple.meter with value 81
from("direct:in")
  .to("metric:meter:simple.meter?mark=81")
  .to("direct:out");
```

219.9.2. Headers

Message header can be used to override **mark** value specified in Metrics component URI.

Name	Description	Expected type
Camel Metrics Meter Mark	Override mark value in URI	Long

```
// updates meter simple.meter with value 345
from("direct:in")
  .setHeader(MetricsConstants.HEADER_METER_MARK, constant(345L))
  .to("metrics:meter:simple.meter?mark=123")
  .to("direct:out");
```

219.10. METRICS TYPE TIMER

```
metrics:timer:metricname[?options]
```

219.10.1. Options

Name	Default	Description
action	-	start or stop

If no **action** or invalid value is provided then warning is logged without any timer update. If action **start** is called on already running timer or **stop** is called on not running timer then nothing is updated and warning is logged.

```
// measure time taken by route "calculate"
from("direct:in")
  .to("metrics:timer:simple.timer?action=start")
```

```
.to("direct:calculate")
.to("metrics:timer:simple.timer?action=stop");
```

TimerContext objects are stored as Exchange properties between different Metrics component calls.

219.10.2. Headers

Message header can be used to override action value specified in Metrics component URI.

Name	Description	Expected type
Camel Metrics TimerAction	Override timer action in URI	org.apache.camel.component.metrics.timer.TimerEndpoint.TimerAction

```
// sets timer action using header
from("direct:in")
.setHeader(MetricsConstants.HEADER_TIMER_ACTION, TimerAction.start)
.to("metrics:timer:simple.timer")
.to("direct:out");
```

219.11. METRIC TYPE GAUGE

```
metrics:gauge:metricname[?options]
```

219.11.1. Options

Name	Default	Description
subject	-	Any object to be observed by the gauge

If **subject** is not defined it's simply ignored, i.e. the gauge is not registered.

```
// update gauge "simple.gauge" by a bean "mySubjectBean"
from("direct:in")
.to("metrics:gauge:simple.gauge?subject=#mySubjectBean")
```

```
.to("direct:out");
```

219.11.2. Headers

Message headers can be used to override **subject** values specified in Metrics component URI. Note: if **CamelMetricsName** header is specified, then new gauge is registered in addition to default one specified in a URI.

Name	Description	Expected type
Camel Metrics Gauge Subject	Override subject value in URI	Object

```
// update gauge simple.gauge by a String literal "myUpdatedSubject"
from("direct:in")
  .setHeader(MetricsConstants.HEADER_GAUGE_SUBJECT, constant("myUpdatedSubject"))
  .to("metrics:counter:simple.gauge?subject=#mySubjectBean")
  .to("direct:out");
```

219.12. METRICSROUTEPOLICYFACTORY

This factory allows to add a RoutePolicy for each route which exposes route utilization statistics using Dropwizard metrics. This factory can be used in Java and XML as the examples below demonstrates.

NOTE

Instead of using the MetricsRoutePolicyFactory you can define a MetricsRoutePolicy per route you want to instrument, in case you only want to instrument a few selected routes.

From Java you just add the factory to the **CamelContext** as shown below:

```
context.addRoutePolicyFactory(new MetricsRoutePolicyFactory());
```

And from XML DSL you define a <bean> as follows:

```
<!-- use camel-metrics route policy to gather metrics for all routes -->
<bean id="metricsRoutePolicyFactory"
class="org.apache.camel.component.metrics.routepolicy.MetricsRoutePolicyFactory"/>
```

The **MetricsRoutePolicyFactory** and **MetricsRoutePolicy** supports the following options:

Name	Default	Description
useJmx	false	Whether to report fine grained statistics to JMX by using the com.codahale.metrics.JmxReporter . Notice that if JMX is enabled on CamelContext then a MetricsRegistryService mbean is enlisted under the services type in the JMX tree. That mbean has a single operation to output the statistics using json. Setting useJmx to true is only needed if you want fine grained mbeans per statistics type.
jmxDomain	org.apache.camel.metrics	The JMX domain name
prettyPrint	false	Whether to use pretty print when outputting statistics in json format
metricsRegistry		Allow to use a shared com.codahale.metrics.MetricRegistry . If none is provided then Camel will create a shared instance used by the this CamelContext.
rateUnit	TimeUnit.SECONDS	The unit to use for rate in the metrics reporter or when dumping the statistics as json.
durationUnit	TimeUnit.MILLISECONDS	The unit to use for duration in the metrics reporter or when dumping the statistics as json.
namePattern	name.routeld.type	Camel 2.17: The name pattern to use. Uses dot as separators, but you can change that. The values name , routeld , and type will be replaced with actual value. Where name is the name of the CamelContext. routeld is the name of the route. And type is the value of responses.

From Java code you can get hold of the **com.codahale.metrics.MetricRegistry** from the **org.apache.camel.component.metrics.routepolicy.MetricsRegistryService** as shown below:

```
MetricRegistryService registryService = context.hasService(MetricsRegistryService.class);
if (registryService != null) {
    MetricsRegistry registry = registryService.getMetricsRegistry();
    ...
}
```

219.13. METRICSMESSAGEHISTORYFACTORY

Available as of Camel 2.17

This factory allows to use metrics to capture Message History performance statistics while routing messages. It works by using a metrics Timer for each node in all the routes. This factory can be used in Java and XML as the examples below demonstrates.

From Java you just set the factory to the **CamelContext** as shown below:

```
context.setMessageHistoryFactory(new MetricsMessageHistoryFactory());
```

And from XML DSL you define a <bean> as follows:

```
<!-- use camel-metrics message history to gather metrics for all messages being routed -->
<bean id="metricsMessageHistoryFactory"
class="org.apache.camel.component.metrics.messagehistory.MetricsMessageHistoryFactory"/>
```

The following options is supported on the factory:

Name	Default	Description
useJmx	false	Whether to report fine grained statistics to JMX by using the com.codahale.metrics.JmxReporter . Notice that if JMX is enabled on CamelContext then a MetricsRegistryService mbean is enlisted under the services type in the JMX tree. That mbean has a single operation to output the statistics using json. Setting useJmx to true is only needed if you want fine grained mbeans per statistics type.
jmxDomain	org.apache.camel.metrics	The JMX domain name
prettyPrint	false	Whether to use pretty print when outputting statistics in json format
metricsRegistry		Allow to use a shared com.codahale.metrics.MetricRegistry . If none is provided then Camel will create a shared instance used by the this CamelContext.
rateUnit	TimeUnit.SECONDS	The unit to use for rate in the metrics reporter or when dumping the statistics as json.
durationUnit	TimeUnit.MILLISECONDS	The unit to use for duration in the metrics reporter or when dumping the statistics as json.
namePattern	name.routelid.type	The name pattern to use. Uses dot as separators, but you can change that. The values name , routelid , type , and id will be replaced with actual value. Where name is the name of the CamelContext. routelid is the name of the route. The id pattern represents the node id. And type is the value of history.

At runtime the metrics can be accessed from Java API or JMX which allows to gather the data as json output.

From Java code you can do get the service from the CamelContext as shown:

```
MetricsMessageHistoryService service = context.hasService(MetricsMessageHistoryService.class);  
String json = service.dumpStatisticsAsJson();
```

And the JMX API the MBean is registered in the **type=services** tree with **name=MetricsMessageHistoryService**.

219.14. INSTRUMENTEDTHREADPOOLFACTORY

Available as of Camel 2.18

This factory allows you to gather performance information about Camel Thread Pools by injecting a InstrumentedThreadPoolFactory which collects information from inside of Camel. See more details at [Advanced configuration of CamelContext using Spring](#)

219.15. SEE ALSO

- The **camel-example-cdi-metrics** example that illustrates the integration between Camel, Metrics and CDI.

CHAPTER 220. MICROMETER COMPONENT

220.1. MICROMETER COMPONENT

The **micrometer** component allows to collect various metrics directly from Camel routes. Supported metric types are [counter](#), [summary](#), and [timer](#). **Micrometer** provides simple way to measure the behaviour of an application. Configurable reporting backends (via Micrometer registries) enable different integration options for collecting and visualizing statistics.

The component also provides a **MicrometerRoutePolicyFactory** which allows to expose route statistics using Micrometer as well as **EventNotifier** implementations for counting routes and timing exchanges from their creation to their completion.

Maven users need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-micrometer</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

220.2. URI FORMAT

```
micrometer:[ counter | summary | timer ]:metricname[?options]
```

220.3. OPTIONS

The Micrometer component supports 2 options, which are listed below.

Name	Description	Default	Type
metricsRegistry (advanced)	To use a custom configured MetricRegistry.		MeterRegistry
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Micrometer endpoint is configured using URI syntax:

```
micrometer:metricsType:metricsName
```

with the following path and query parameters:

220.3.1. Path Parameters (3 parameters):

Name	Description	Default	Type
metricsType	Required Type of metrics		Type
metricsName	Required Name of metrics		String
tags	Tags of metrics		Iterable

220.3.2. Query Parameters (5 parameters):

Name	Description	Default	Type
action (producer)	Action expression when using timer type		String
decrement (producer)	Decrement value expression when using counter type		String
increment (producer)	Increment value expression when using counter type		String
value (producer)	Value expression when using histogram type		String
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

220.4. SPRING BOOT AUTO-CONFIGURATION

The component supports 3 options, which are listed below.

Name	Description	Default	Type
camel.component.micrometer.enabled	Whether to enable auto configuration of the micrometer component. This is enabled by default.		Boolean
camel.component.micrometer.metrics-registry	To use a custom configured MetricRegistry. The option is a <code>io.micrometer.core.instrument.MeterRegistry</code> type.		String
camel.component.micrometer.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

220.5. METER REGISTRY

By default the Camel Micrometer component creates a **SimpleMeterRegistry** instance, suitable mainly for testing. You should define a dedicated registry by providing a **MeterRegistry** bean. Micrometer registries primarily determine the backend monitoring system to be used. A **CompositeMeterRegistry** can be used to address more than one monitoring target.

For example using Spring Java Configuration:

```
@Configuration
public static class MyConfig extends SingleRouteCamelConfiguration {

    @Bean
    @Override
    public RouteBuilder route() {
        return new RouteBuilder() {
            @Override
            public void configure() throws Exception {
                // define Camel routes here
            }
        };
    }
}

@Bean(name = MicrometerComponent.METRICS_REGISTRY_NAME)
public MeterRegistry getMeterRegistry() {
    CompositeMeterRegistry registry = ...;
    registry.add(...);
    // ...
    return registry;
}
}
```

Or using CDI:

```
class MyBean extends RouteBuilder {

    @Override
    public void configure() {
        from("...")
            // Register the 'my-meter' meter in the MetricRegistry below
            .to("metrics:meter:my-meter");
    }

    @Produces
    // If multiple MetricRegistry beans
    // @Named(MicrometerComponent.METRIC_REGISTRY_NAME)
    MetricRegistry registry() {
        CompositeMeterRegistry registry = ...;
        registry.add(...);
        // ...
        return registry;
    }
}
```

220.6. USAGE OF PRODUCERS

Each meter has type and name. Supported types are [counter](#), [distribution summary](#) and [timer](#). If no type is provided then a counter is used by default.

The meter name is a string that is evaluated as **Simple** expression. In addition to using the **CamelMetricsName** header (see below), this allows to select the meter depending on exchange data.

The optional **tags** URI parameter is a comma-separated string, consisting of **key=value** expressions. Both **key** and **value** are strings that are also evaluated as **Simple** expression. E.g. the URI parameter **tags=X=\${header.Y}** would assign the current value of header **Y** to the key **X**.

220.6.1. Headers

The meter name defined in URI can be overridden by populating a header with name **CamelMetricsName**. The meter tags defined as URI parameters can be augmented by populating a header with name **CamelMetricsTags**.

For example

```
from("direct:in")
  .setHeader(MicrometerConstants.HEADER_METRIC_NAME, constant("new.name"))
  .setHeader(MicrometerConstants.HEADER_METRIC_TAGS, constant(Tags.of("dynamic-key",
    "dynamic-value")))
  .to("metrics:counter:name.not.used?tags=key=value")
  .to("direct:out");
```

will update a counter with name **new.name** instead of **name.not.used** using the tag **dynamic-key** with value **dynamic-value** in addition to the tag **key** with value **value**.

All Metrics specific headers are removed from the message once the Micrometer endpoint finishes processing of exchange. While processing exchange Micrometer endpoint will catch all exceptions and write log entry using level **warn**.

220.7. COUNTER

```
micrometer:counter:name[?options]
```

220.7.1. Options

Name	Default	Description
increment	-	Double value to add to the counter
decrement	-	Double value to subtract from the counter

If neither **increment** or **decrement** is defined then counter value will be incremented by one. If **increment** and **decrement** are both defined only increment operation is called.

```
// update counter simple.counter by 7
from("direct:in")
  .to("micrometer:counter:simple.counter?increment=7")
  .to("direct:out");
```

```
// increment counter simple.counter by 1
from("direct:in")
  .to("micrometer:counter:simple.counter")
  .to("direct:out");
```

Both **increment** and **decrement** values are evaluated as **Simple** expressions with a Double result, e.g. if header **X** contains a value that evaluates to 3.0, the **simple.counter** counter is decremented by 3.0:

```
// decrement counter simple.counter by 3
from("direct:in")
  .to("micrometer:counter:simple.counter?decrement=${header.X}")
  .to("direct:out");
```

220.7.2. Headers

Like in **camel-metrics**, specific Message headers can be used to override **increment** and **decrement** values specified in the Micrometer endpoint URI.

Name	Description	Expected type
Camel Metrics CounterIncrement	Override increment value in URI	Double
Camel Metrics CounterDecrement	Override decrement value in URI	Double

```
// update counter simple.counter by 417
from("direct:in")
  .setHeader(MicrometerConstants.HEADER_COUNTER_INCREMENT, constant(417.0D))
  .to("micrometer:counter:simple.counter?increment=7")
  .to("direct:out");
```

```
// updates counter using simple language to evaluate body.length
from("direct:in")
  .setHeader(MicrometerConstants.HEADER_COUNTER_INCREMENT, simple("${body.length}"))
  .to("micrometer:counter:body.length")
  .to("direct:out");
```

220.8. DISTRIBUTION SUMMARY

```
micrometer:summary:metricname[?options]
```

220.8.1. Options

Name	Default	Description
value	-	Value to use in histogram

If no **value** is not set, nothing is added to histogram and warning is logged.

```
// adds value 9923 to simple.histogram
from("direct:in")
  .to("micrometer:summary:simple.histogram?value=9923")
  .to("direct:out");
```

```
// nothing is added to simple.histogram; warning is logged
from("direct:in")
  .to("micrometer:summary:simple.histogram")
  .to("direct:out");
```

value is evaluated as **Simple** expressions with a Double result, e.g. if header **X** contains a value that evaluates to 3.0, this value is registered with the **simple.histogram**:

```
from("direct:in")
  .to("micrometer:summary:simple.histogram?value=${header.X}")
  .to("direct:out");
```

220.8.2. Headers

Like in **camel-metrics**, a specific Message header can be used to override the value specified in the Micrometer endpoint URI.

Name	Description	Expected type
Camel Metrics HistogramValue	Override histogram value in URI	Long

```
// adds value 992.0 to simple.histogram
from("direct:in")
  .setHeader(MicrometerConstants.HEADER_HISTOGRAM_VALUE, constant(992.0D))
  .to("micrometer:summary:simple.histogram?value=700")
  .to("direct:out")
```

220.9. TIMER

```
micrometer:timer:metricname[?options]
```

220.9.1. Options

Name	Default	Description
action	-	start or stop

If no **action** or invalid value is provided then warning is logged without any timer update. If action **start** is called on an already running timer or **stop** is called on an unknown timer, nothing is updated and warning is logged.

```
// measure time spent in route "direct:calculate"
from("direct:in")
  .to("micrometer:timer:simple.timer?action=start")
  .to("direct:calculate")
  .to("micrometer:timer:simple.timer?action=stop");
```

Timer.Sample objects are stored as Exchange properties between different Metrics component calls.

action is evaluated as a **Simple** expression returning a result of type **MicrometerTimerAction**.

220.9.2. Headers

Like in **camel-metrics**, a specific Message header can be used to override action value specified in the Micrometer endpoint URI.

Name	Description	Expected type
Camel Metrics TimerAction	Override timer action in URI	org.apache.camel.component.micrometer.MicrometerTimerAction

```
// sets timer action using header
from("direct:in")
```

```
.setHeader(MicrometerConstants.HEADER_TIMER_ACTION, MicrometerTimerAction.start)
.to("micrometer:timer:simple.timer")
.to("direct:out");
```

220.10. MICROMETERROUTEPOLICYFACTORY

This factory allows to add a `RoutePolicy` for each route in order to exposes route utilization statistics using Micrometer. This factory can be used in Java and XML as the examples below demonstrates.

NOTE

Instead of using the **MicrometerRoutePolicyFactory** you can define a dedicated **MicrometerRoutePolicy** per route you want to instrument, in case you only want to instrument a few selected routes.

From Java you just add the factory to the **CamelContext** as shown below:

```
context.addRoutePolicyFactory(new MicrometerRoutePolicyFactory());
```

And from XML DSL you define a `<bean>` as follows:

```
<!-- use camel-micrometer route policy to gather metrics for all routes -->
<bean id="metricsRoutePolicyFactory"
class="org.apache.camel.component.micrometer.routepolicy.MicrometerRoutePolicyFactory"/>
```

The **MicrometerRoutePolicyFactory** and **MicrometerRoutePolicy** supports the following options:

Name	Default	Description
prettyPrint	false	Whether to use pretty print when outputting statistics in json format
meterRegistry		Allow to use a shared MeterRegistry . If none is provided then Camel will create a shared instance used by the this CamelContext.
durationUnit	TimeUnit.MILLISECOND	The unit to use for duration in when dumping the statistics as json.

If JMX is enabled in the CamelContext, the MBean is registered in the **type=services** tree with **name=MicrometerRoutePolicy**.

220.11. MICROMETERMESSAGEHISTORYFACTORY

This factory allows to use metrics to capture Message History performance statistics while routing messages. It works by using a Micrometer Timer for each node in all the routes. This factory can be used in Java and XML as the examples below demonstrates.

From Java you just set the factory to the **CamelContext** as shown below:

-

```
context.setMessageHistoryFactory(new MicrometerMessageHistoryFactory());
```

And from XML DSL you define a <bean> as follows:

```
<!-- use camel-micrometer message history to gather metrics for all messages being routed -->
<bean id="metricsMessageHistoryFactory"
class="org.apache.camel.component.micrometer.messagehistory.MicrometerMessageHistoryFactory"
/>
```

The following options is supported on the factory:

Name	Default	Description
prettyPrint	false	Whether to use pretty print when outputting statistics in json format
meterRegistry		Allow to use a shared MeterRegistry . If none is provided then Camel will create a shared instance used by the this CamelContext.
durationUnit	TimeUnit.MILLISECONDS	The unit to use for duration when dumping the statistics as json.

At runtime the metrics can be accessed from Java API or JMX which allows to gather the data as json output.

From Java code you can get the service from the CamelContext as shown:

```
MicrometerMessageHistoryService service =
context.getService(MicrometerMessageHistoryService.class);
String json = service.dumpStatisticsAsJson();
```

If JMX is enabled in the CamelContext, the MBean is registered in the **type=services** tree with **name=MicrometerMessageHistory**.

220.12. MICROMETEREVENTNOTIFIERS

There is a **MicrometerRouteEventNotifier** (counting added and running routes) and a **MicrometerExchangeEventNotifier** (timing exchanges from their creation to their completion).

EventNotifiers can be added to the CamelContext, e.g.:

```
camelContext.getManagementStrategy().addEventNotifier(new MicrometerExchangeEventNotifier())
```

At runtime the metrics can be accessed from Java API or JMX which allows to gather the data as json output.

From Java code you can do get the service from the CamelContext as shown:

```
MicrometerEventNotifierService service = context.hasService(MicrometerEventNotifierService.class);
String json = service.dumpStatisticsAsJson();
```

If JMX is enabled in the CamelContext, the MBean is registered in the **type=services** tree with **name=MicrometerEventNotifier**.

220.13. INSTRUMENTEDTHREADPOOLFACTORY

This factory allows you to gather performance information about Camel Thread Pools by injecting a **InstrumentedThreadPoolFactory** which collects information from inside of Camel. See more details at Advanced configuration of CamelContext using Spring.

220.14. EXPOSING MICROMETER STATISTICS IN JMX

Micrometer uses **MeterRegistry** implementations in order to publish statistics. While in production scenarios it is advisable to select a dedicated backend like Prometheus or Graphite, it may be sufficient for test or local deployments to publish statistics to JMX.

In order to achieve this, add the following dependency:

```
<dependency>
  <groupId>io.micrometer</groupId>
  <artifactId>micrometer-registry-jmx</artifactId>
  <version>${micrometer-version}</version>
</dependency>
```

and add a **JmxMeterRegistry** instance:

```
@Bean(name = MicrometerComponent.METRICS_REGISTRY_NAME)
public MeterRegistry getMeterRegistry() {
    CompositeMeterRegistry meterRegistry = new CompositeMeterRegistry();
    meterRegistry.add(...);
    meterRegistry.add(new JmxMeterRegistry(
        CamelJmxConfig.DEFAULT,
        Clock.SYSTEM,
        HierarchicalNameMapper.DEFAULT));
    return meterRegistry;
}
```

The **HierarchicalNameMapper** strategy determines how meter name and tags are assembled into an MBean name.

220.15. EXAMPLE

camel-example-micrometer provides an example how to set up Micrometer monitoring with Camel using Java configuration and a Prometheus backend.

CHAPTER 221. OPC UA CLIENT COMPONENT

Available as of Camel version 2.19

The **Milo Client** component provides access to OPC UA servers using the [Eclipse Milo™](#) implementation.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-milo</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

The OPC UA Client component supports 6 options, which are listed below.

Name	Description	Default	Type
defaultConfiguration (common)	All default options for client		MiloClientConfiguration
applicationName (common)	Default application name		String
applicationUri (common)	Default application URI		String
productUri (common)	Default product URI		String
reconnectTimeout (common)	Default reconnect timeout		Long
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

221.1. URI FORMAT

The URI syntax of the endpoint is:

```
milo-client:tcp://[user:password@]host:port/path/to/service?node=RAW(nsu=urn:foo:bar;s=item-1)
```

If the server does not use a path, then it is possible to simply omit it:

```
milo-client:tcp://[user:password@]host:port?node=RAW(nsu=urn:foo:bar;s=item-1)
```

If no user credentials are provided the client will switch to anonymous mode.

221.2. URI OPTIONS

All configuration options in the group client are applicable to the shared client instance. Endpoints will share client instances for each endpoint URI. So the first time a request for that endpoint URI is made, the options of the client group are applied. All further instances will be ignored.

If you need alternate options for the same endpoint URI it is possible though to set the `clientId` option which will be added internally to the endpoint URI in order to select a different shared connection instance. In other words, shared connections located by the combination of endpoint URI and client id.

The OPC UA Client endpoint is configured using URI syntax:

```
milo-client:endpointUri
```

with the following path and query parameters:

221.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
<code>endpointUri</code>	Required The OPC UA server endpoint		String

221.2.2. Query Parameters (27 parameters):

Name	Description	Default	Type
<code>clientId</code> (common)	A virtual client id to force the creation of a new connection instance		String
<code>defaultAwaitWrites</code> (common)	Default await setting for writes	false	boolean
<code>discoveryEndpointSuffix</code> (common)	A suffix for endpoint URI when discovering		String
<code>discoveryEndpointUri</code> (common)	An alternative discovery URI		String
<code>method</code> (common)	The method definition (see Method ID)		ExpandedNodeId
<code>node</code> (common)	The node definition (see Node ID)		ExpandedNodeId
<code>samplingInterval</code> (common)	The sampling interval in milliseconds		Double

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
allowedSecurityPolicies (client)	A set of allowed security policy URIs. Default is to accept all and use the highest.		String
applicationName (client)	The application name	Apache Camel adapter for Eclipse Milo	String
applicationUri (client)	The application URI	http://camel.apache.org/EclipseMilo/Client	String
channelLifetime (client)	Channel lifetime in milliseconds		Long
keyAlias (client)	The name of the key in the keystore file		String

Name	Description	Default	Type
keyPassword (client)	The key password		String
keyStorePassword (client)	The keystore password		String
keyStoreType (client)	The key store type		String
keyStoreUrl (client)	The URL where the key should be loaded from		URL
maxPendingPublishRequests (client)	The maximum number of pending publish requests		Long
maxResponseMessageSize (client)	The maximum number of bytes a response message may have		Long
overrideHost (client)	Override the server reported endpoint host with the host from the endpoint URI.	false	boolean
productUri (client)	The product URI	http://camel.apache.org/EclipseMilo	String
requestTimeout (client)	Request timeout in milliseconds		Long
sessionName (client)	Session name		String
sessionTimeout (client)	Session timeout in milliseconds		Long

221.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 24 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.milo-client.application-name</code>	Default application name		String
<code>camel.component.milo-client.application-uri</code>	Default application URI		String
<code>camel.component.milo-client.default-configuration.allowed-security-policies</code>	A set of allowed security policy URIs. Default is to accept all and use the highest.		Set
<code>camel.component.milo-client.default-configuration.application-name</code>	The application name	Apache Camel adapter for Eclipse Milo	String
<code>camel.component.milo-client.default-configuration.application-uri</code>	The application URI	http://camel.apache.org/EclipseMilo/Client	String
<code>camel.component.milo-client.default-configuration.channel-lifetime</code>	Channel lifetime in milliseconds		Long
<code>camel.component.milo-client.default-configuration.client-id</code>	A virtual client id to force the creation of a new connection instance		String

Name	Description	Default	Type
<code>camel.component.milo-client.default-configuration.discovery-endpoint-suffix</code>	A suffix for endpoint URI when discovering		String
<code>camel.component.milo-client.default-configuration.discovery-endpoint-uri</code>	An alternative discovery URI		String
<code>camel.component.milo-client.default-configuration.key-alias</code>	The name of the key in the keystore file		String
<code>camel.component.milo-client.default-configuration.key-password</code>	The key password		String
<code>camel.component.milo-client.default-configuration.key-store-password</code>	The keystore password		String
<code>camel.component.milo-client.default-configuration.key-store-type</code>	The key store type		String
<code>camel.component.milo-client.default-configuration.max-pending-publish-requests</code>	The maximum number of pending publish requests		Long

Name	Description	Default	Type
<code>camel.component.milo-client.default-configuration.max-response-message-size</code>	The maximum number of bytes a response message may have		Long
<code>camel.component.milo-client.default-configuration.override-host</code>	Override the server reported endpoint host with the host from the endpoint URI.	false	Boolean
<code>camel.component.milo-client.default-configuration.product-uri</code>	The product URI	http://camel.apache.org/EclipseMilo	String
<code>camel.component.milo-client.default-configuration.request-timeout</code>	Request timeout in milliseconds		Long
<code>camel.component.milo-client.default-configuration.session-name</code>	Session name		String
<code>camel.component.milo-client.default-configuration.session-timeout</code>	Session timeout in milliseconds		Long
<code>camel.component.milo-client.enabled</code>	Enable milo-client component	true	Boolean
<code>camel.component.milo-client.product-uri</code>	Default product URI		String

Name	Description	Default	Type
<code>camel.component.milo-client.reconnect-timeout</code>	Default reconnect timeout		Long
<code>camel.component.milo-client.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

221.3.1. Discovery

If the server uses a dedicated discovery endpoint (e.g. `/discovery`), which may support different (less secure) security policies, then you can make use of this via the parameter `discoveryEndpointSuffix`, which will be appended to the `endpointUri`. Or by using an explicit `discoveryEndpointUri`.

221.3.2. Overriding the host name

The client uses the host information from the endpoint information, queried from the server. However in some situations this endpoint URI might be different, and wrong from the point of view of the connecting client (e.g. an internal hostname).

In this case it is possible to set the parameter `overrideHost` to `true`, which will take the discovered endpoint information, but override the host information with the value of the original URI.

221.3.3. Node ID

In order to define a target node a namespace and node id is required. In previous versions this was possible by specifying `nodeId` and either `namespaceUri` or `namespaceIndex`. However this only allowed for using string based node IDs. And while this configuration is still possible, the newer one is preferred.

The new approach is to specify a full namespace+node ID in the format `ns=1;i=1` which also allows to use the other node ID formats (like numeric, GUID/UUID or opaque). If the `node` parameter is used the older ones must not be used. The syntax of this node format is a set of `key=value` pairs delimited by a semi-colon (;).

Exactly one namespace and one node id key must be used. See the following table for possible keys:

Key	Type	Description
<code>ns</code>	namespace	Numeric namespace index
<code>nsu</code>	namespace	Namespace URI
<code>s</code>	node	String node ID

Key	Type	Description
i	node	Numeric node ID
g	node	GUID/UUID node ID
b	node	Base64 encoded string for opaque node ID

As the values generated by the syntax cannot be transparently encoded into a URI parameter value, it is necessary to escape them. However Camel allows to wrap the actual value inside **RAW(...)**, which makes escaping unnecessary. For example:

```
milo-client:tcp://user:password@localhost:12345?node=RAW(nsu=http://foo.bar;s=foo/bar)
```

221.3.4. Method ID

It is possible to perform methods calls on OPC UA nodes. If the parameter **method** is set to the Node ID of a method call (the node ID must be set to the parent object in this case), then a method call will be performed instead of a write operation.

Input parameters are taken from the body:

- If the body is null, then an empty **Variant[]** will be used
- If the body is a **Variant[]**, then it will be used as is
- If the body is a **Variant**, then it will be wrapped in a **Variant[]** array
- Otherwise the body will be converted into a **Variant** and wrapped in an array of **Variant[]**

221.3.5. Security policies

When setting the allowing security policies is it possible to use the well known OPC UA URIs (e.g. <http://opcfoundation.org/UA/SecurityPolicy#Basic128Rsa15>) or to use the Milo enum literals (e.g. **None**). Specifying an unknown security policy URI or enum is an error.

The known security policy URIs and enum literals are can be seen here: [SecurityPolicy.java](#)

Note: In any case security policies are considered case sensitive.

221.4. SEE ALSO

- [Getting Started](#)

CHAPTER 222. OPC UA SERVER COMPONENT

Available as of Camel version 2.19

The **Milo Server** component provides an OPC UA server using the [Eclipse Milo™](#) implementation.

Java 8: This component requires Java 8 at runtime.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-milo</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

Messages sent to the endpoint from Camel will be available from the OPC UA server to OPC UA Clients. Value write requests from OPC UA Client will trigger messages which are sent into Apache Camel.

The OPC UA Server component supports 20 options, which are listed below.

Name	Description	Default	Type
namespaceUri (common)	The URI of the namespace, defaults to urn:org:apache:camel		String
applicationName (common)	The application name		String
applicationUri (common)	The application URI		String
productUri (common)	The product URI		String
bindPort (common)	The TCP port the server binds to		int
strictEndpointUrls Enabled (common)	Set whether strict endpoint URLs are enforced	false	boolean
serverName (common)	Server name		String
hostname (common)	Server hostname		String

Name	Description	Default	Type
securityPolicies (common)	Security policies		Set
securityPoliciesBy Id (common)	Security policies by URI or name		Collection
userAuthentication Credentials (common)	Set user password combinations in the form of user1:pwd1,user2:pwd2 Usernames and passwords will be URL decoded		String
enableAnonymous Authentication (common)	Enable anonymous authentication, disabled by default	false	boolean
usernameSecurity Policy Uri (common)	Set the UserTokenPolicy used when		SecurityPolicy
bindAddresses (common)	Set the addresses of the local addresses the server should bind to		String
buildInfo (common)	Server build info		BuildInfo
serverCertificate (common)	Server certificate		Result
certificateManager (common)	Server certificate manager		CertificateManager
certificateValidator (common)	Validator for client certificates		Supplier
defaultCertificate Validator (common)	Validator for client certificates using default file based approach		File
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

222.1. URI FORMAT

`milo-server:itemId[?options]`

222.2. URI OPTIONS

The OPC UA Server endpoint is configured using URI syntax:

```
miloserver:itemId
```

with the following path and query parameters:

222.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
itemId	Required ID of the item		String

222.2.2. Query Parameters (4 parameters):

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

222.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 21 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.milo-server.application-name</code>	The application name		String
<code>camel.component.milo-server.application-uri</code>	The application URI		String
<code>camel.component.milo-server.bind-addresses</code>	Set the addresses of the local addresses the server should bind to		String
<code>camel.component.milo-server.bind-port</code>	The TCP port the server binds to		Integer
<code>camel.component.milo-server.build-info</code>	Server build info. The option is a <code>org.eclipse.milo.opcua.stack.core.types.structured.BuildInfo</code> type.		String
<code>camel.component.milo-server.certificate-manager</code>	Server certificate manager. The option is a <code>org.eclipse.milo.opcua.stack.core.application.CertificateManager</code> type.		String
<code>camel.component.milo-server.certificate-validator</code>	Validator for client certificates. The option is a <code>java.util.function.Supplier<org.eclipse.milo.opcua.stack.core.application.CertificateValidator></code> type.		String
<code>camel.component.milo-server.default-certificate-validator</code>	Validator for client certificates using default file based approach		File
<code>camel.component.milo-server.enable-anonymous-authentication</code>	Enable anonymous authentication, disabled by default	false	Boolean
<code>camel.component.milo-server.enabled</code>	Enable milo-server component	true	Boolean

Name	Description	Default	Type
<code>camel.component.milo-server.hostname</code>	Server hostname		String
<code>camel.component.milo-server.namespace-uri</code>	The URI of the namespace, defaults to <code>urn:org:apache:camel</code>		String
<code>camel.component.milo-server.product-uri</code>	The product URI		String
<code>camel.component.milo-server.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.component.milo-server.security-policies</code>	Security policies		Set
<code>camel.component.milo-server.security-policies-by-id</code>	Security policies by URI or name		Collection
<code>camel.component.milo-server.server-certificate</code>	Server certificate. The option is a <code>org.apache.camel.component.milo.KeyStoreLoader.Result</code> type.		String
<code>camel.component.milo-server.server-name</code>	Server name		String
<code>camel.component.milo-server.strict-endpoint-urls-enabled</code>	Set whether strict endpoint URLs are enforced	false	Boolean

Name	Description	Default	Type
<code>camel.component.milo-server.user-authentication-credentials</code>	Set user password combinations in the form of user1:pwd1,user2:pwd2. Usernames and passwords will be URL decoded.		String
<code>camel.component.milo-server.username-security-policy-uri</code>	Set the UserTokenPolicy used when		SecurityPolicy

CHAPTER 223. MIME MULTIPART DATAFORMAT

Available as of Camel version 2.17

This data format that can convert a Camel message with attachments into a Camel message having a MIME-Multipart message as message body (and no attachments).

The use case for this is to enable the user to send attachments over endpoints that do not directly support attachments, either as special protocol implementation (e.g. send a MIME-multipart over an HTTP endpoint) or as a kind of tunneling solution (e.g. because camel-jms does not support attachments but by marshalling the message with attachments into a MIME-Multipart, sending that to a JMS queue, receiving the message from the JMS queue and unmarshalling it again (into a message body with attachments)).

The marshal option of the mime-multipart data format will convert a message with attachments into a MIME-Multipart message. If the parameter "multipartWithoutAttachment" is set to true it will also marshal messages without attachments into a multipart message with a single part, if the parameter is set to false it will leave the message alone.

MIME headers of the multipart as "MIME-Version" and "Content-Type" are set as camel headers to the message. If the parameter "headersInline" is set to true it will also create a MIME multipart message in any case.

Furthermore the MIME headers of the multipart are written as part of the message body, not as camel headers.

The unmarshal option of the mime-multipart data format will convert a MIME-Multipart message into a camel message with attachments and leaves other messages alone. MIME-Headers of the MIME-Multipart message have to be set as Camel headers. The unmarshalling will only take place if the "Content-Type" header is set to a "multipart" type. If the option "headersInline" is set to true, the body is always parsed as a MIME message. As a consequence if the message body is a stream and stream caching is not enabled, a message body that is actually not a MIME message with MIME headers in the message body will be replaced by an empty message. Up to Camel version 2.17.1 this will happen all message bodies that do not contain a MIME multipart message regardless of body type and stream cache setting.

223.1. OPTIONS

The MIME Multipart dataformat supports 6 options, which are listed below.

Name	Default	Java Type	Description
multipartSubType	mixed	String	Specify the subtype of the MIME Multipart. Default is mixed.
multipartWithout Attachment	false	Boolean	Defines whether a message without attachment is also marshaled into a MIME Multipart (with only one body part). Default is false.
headersInline	false	Boolean	Defines whether the MIME-Multipart headers are part of the message body (true) or are set as Camel headers (false). Default is false.

Name	Default	Java Type	Description
includeHeaders		String	A regex that defines which Camel headers are also included as MIME headers into the MIME multipart. This will only work if headersInline is set to true. Default is to include no headers
binaryContent	false	Boolean	Defines whether the content of binary parts in the MIME multipart is binary (true) or Base-64 encoded (false) Default is false.
contentTypeHeader	false	Boolean	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON etc.

223.2. MESSAGE HEADERS (MARSHAL)

Name	Type	Description
Message-Id	String	The marshal operation will set this parameter to the generated MIME message id if the "headersInline" parameter is set to false.
MIME-Version	String	The marshal operation will set this parameter to the applied MIME version (1.0) if the "headersInline" parameter is set to false.
Content-Type	String	The content of this header will be used as a content type for the message body part. If no content type is set, "application/octet-stream" is assumed. After the marshal operation the content type is set to "multipart/related" or empty if the "headersInline" parameter is set to true.
Content-Encoding	String	If the incoming content type is "text/*" the content encoding will be set to the encoding parameter of the Content-Type MIME header of the body part. Furthermore the given charset is applied for text to binary conversions.

223.3. MESSAGE HEADERS (UNMARSHAL)

Name	Type	Description
------	------	-------------

Name	Type	Description
Content-Type	String	If this header is not set to "multipart/*" the unmarshal operation will not do anything. In other cases the multipart will be parsed into a camel message with attachments and the header is set to the Content-Type header of the body part, except if this is application/octet-stream. In the latter case the header is removed.
Content-Encoding	String	If the content-type of the body part contains an encoding parameter this header will be set to the value of this encoding parameter (converted from MIME encoding descriptor to Java encoding descriptor)
MIME-Version	String	The unmarshal operation will read this header and use it for parsing the MIME multipart. The header is removed afterwards

223.4. EXAMPLES

```
from(...).marshal().mimeMultipart()
```

With a message where no Content-Type header is set, will create a Message with the following message Camel headers:

Camel Message Headers

```
Content-Type=multipart/mixed; \n boundary="----=_Part_0_14180567.1447658227051"
Message-Id=<...>
MIME-Version=1.0
```

The message body will be:

Camel Message Body

```
-----=_Part_0_14180567.1447658227051
Content-Type: application/octet-stream
Content-Transfer-Encoding: base64
Qm9keSB0ZXh0
-----=_Part_0_14180567.1447658227051
Content-Type: application/binary
Content-Transfer-Encoding: base64
Content-Disposition: attachment; filename="Attachment File Name"
AAECAwQFBgc=
-----=_Part_0_14180567.1447658227051--
```

A message with the header Content-Type set to "text/plain" sent to the route

```
from("...").marshal().mimeMultipart("related", true, true, "(included|x-.*)", true);
```

will create a message without any specific MIME headers set as Camel headers (the Content-Type header is removed from the Camel message) and the following message body that includes also all headers of the original message starting with "x-" and the header with name "included":

Camel Message Body

```

Message-ID: <...>
MIME-Version: 1.0
Content-Type: multipart/related;
    boundary="-----_Part_0_1134128170.1447659361365"
x-bar: also there
included: must be included
x-foo: any value

-----=_Part_0_1134128170.1447659361365
Content-Type: text/plain
Content-Transfer-Encoding: 8bit

223.5. DEPENDENCIES

To use MIME-Multipart in your Camel routes you need to add a dependency on **camel-mail** which implements this data format.

If you use Maven you can just add the following to your pom.xml:

```

<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-mail</artifactId>
  <version>x.x.x</version> <!-- use the same version as your Camel core version -->
</dependency>

```

CHAPTER 224. MINA2 COMPONENT

Available as of Camel version 2.10

The **mina2**: component is a transport for working with [Apache MINA 2.x](#)

TIP

Favor using [Netty](#) as Netty is a much more active maintained and popular project than Apache Mina currently is

INFO: Be careful with `sync=false` on consumer endpoints. Since camel-mina2 all consumer exchanges are InOut. This is different to camel-mina.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-mina2</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

224.1. URI FORMAT

```
mina2:tcp://hostname[:port][?options]
mina2:udp://hostname[:port][?options]
mina2:vm://hostname[:port][?options]
```

You can specify a codec in the Registry using the **codec** option. If you are using TCP and no codec is specified then the **textline** flag is used to determine if text line based codec or object serialization should be used instead. By default the object serialization is used.

For UDP if no codec is specified the default uses a basic **ByteBuffer** based codec.

The VM protocol is used as a direct forwarding mechanism in the same JVM.

A Mina producer has a default timeout value of 30 seconds, while it waits for a response from the remote server.

In normal use, **camel-mina** only supports marshalling the body content—message headers and exchange properties are not sent.

However, the option, **transferExchange**, does allow you to transfer the exchange itself over the wire. See options below.

You can append query options to the URI in the following format, **?option=value&option=value&...**

224.2. OPTIONS

The Mina2 component supports 3 options, which are listed below.

Name	Description	Default	Type
configuration (advanced)	To use the shared mina configuration.		Mina2Configuration
useGlobalSslContext Parameters (security)	Enable usage of global SSL context parameters.	false	boolean
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Mina2 endpoint is configured using URI syntax:

```
mina2:protocol:host:port
```

with the following path and query parameters:

224.2.1. Path Parameters (3 parameters):

Name	Description	Default	Type
protocol	Required Protocol to use		String
host	Required Hostname to use. Use localhost or 0.0.0.0 for local server as consumer. For producer use the hostname or ip address of the remote server.		String
port	Required Port number		int

224.2.2. Query Parameters (27 parameters):

Name	Description	Default	Type
disconnect (common)	Whether or not to disconnect(close) from Mina session right after use. Can be used for both consumer and producer.	false	boolean
minaLogger (common)	You can enable the Apache MINA logging filter. Apache MINA uses slf4j logging at INFO level to log all input and output.	false	boolean

Name	Description	Default	Type
sync (common)	Setting to set endpoint as one-way or request-response.	true	boolean
timeout (common)	You can configure the timeout that specifies how long to wait for a response from a remote server. The timeout unit is in milliseconds, so 60000 is 60 seconds.	30000	long
writeTimeout (common)	Maximum amount of time it should take to send data to the MINA session. Default is 10000 milliseconds.	10000	long
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
clientMode (consumer)	If the clientMode is true, mina consumer will connect the address as a TCP client.	false	boolean
disconnectOnNoReply (consumer)	If sync is enabled then this option dictates MinaConsumer if it should disconnect where there is no reply to send back.	true	boolean
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
noReplyLogLevel (consumer)	If sync is enabled this option dictates MinaConsumer which logging level to use when logging a there is no reply to send back.	WARN	LoggingLevel
cachedAddress (producer)	Whether to create the InetAddress once and reuse. Setting this to false allows to pickup DNS changes in the network.	true	boolean

Name	Description	Default	Type
lazySessionCreation (producer)	Sessions can be lazily created to avoid exceptions, if the remote server is not up and running when the Camel producer is started.	true	boolean
maximumPoolSize (advanced)	Number of worker threads in the worker pool for TCP and UDP	16	int
orderedThreadPoolExecutor (advanced)	Whether to use ordered thread pool, to ensure events are processed orderly on the same channel.	true	boolean
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
transferExchange (advanced)	Only used for TCP. You can transfer the exchange over the wire instead of just the body. The following fields are transferred: In body, Out body, fault body, In headers, Out headers, fault headers, exchange properties, exchange exception. This requires that the objects are serializable. Camel will exclude any non-serializable objects and log it at WARN level.	false	boolean
allowDefaultCodec (codec)	The mina component installs a default codec if both, codec is null and textline is false. Setting allowDefaultCodec to false prevents the mina component from installing a default codec as the first element in the filter chain. This is useful in scenarios where another filter must be the first in the filter chain, like the SSL filter.	true	boolean
codec (codec)	To use a custom mina codec implementation.		ProtocolCodecFactory
decoderMaxLineLength (codec)	To set the textline protocol decoder max line length. By default the default value of Mina itself is used which are 1024.	1024	int
encoderMaxLineLength (codec)	To set the textline protocol encoder max line length. By default the default value of Mina itself is used which are Integer.MAX_VALUE.	-1	int
encoding (codec)	You can configure the encoding (a charset name) to use for the TCP textline codec and the UDP protocol. If not provided, Camel will use the JVM default Charset		String

Name	Description	Default	Type
filters (codec)	You can set a list of Mina IoFilters to use.		List
textline (codec)	Only used for TCP. If no codec is specified, you can use this flag to indicate a text line based codec; if not specified or the value is false, then Object Serialization is assumed over TCP.	false	boolean
textlineDelimiter (codec)	Only used for TCP and if textline=true. Sets the text line delimiter to use. If none provided, Camel will use DEFAULT. This delimiter is used to mark the end of text.		Mina2TextLineDelimiter
autoStartTls (security)	Whether to auto start SSL handshake.	true	boolean
sslContextParameters (security)	To configure SSL security.		SSLContextParameters

224.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 29 options, which are listed below.

Name	Description	Default	Type
camel.component.mina2.configuration.allow-default-codec	The mina component installs a default codec if both, codec is null and textline is false. Setting allowDefaultCodec to false prevents the mina component from installing a default codec as the first element in the filter chain. This is useful in scenarios where another filter must be the first in the filter chain, like the SSL filter.	true	Boolean
camel.component.mina2.configuration.auto-start-tls	Whether to auto start SSL handshake.	true	Boolean
camel.component.mina2.configuration.cached-address	Whether to create the InetAddress once and reuse. Setting this to false allows to pickup DNS changes in the network.	true	Boolean
camel.component.mina2.configuration.client-mode	If the clientMode is true, mina consumer will connect the address as a TCP client.	false	Boolean

Name	Description	Default	Type
<code>camel.component.mina2.configuration.codec</code>	To use a custom mina codec implementation.		ProtocolCodecFactory
<code>camel.component.mina2.configuration.decoder-max-line-length</code>	To set the textline protocol decoder max line length. By default the default value of Mina itself is used which are 1024.	1024	Integer
<code>camel.component.mina2.configuration.disconnect</code>	Whether or not to disconnect(close) from Mina session right after use. Can be used for both consumer and producer.	false	Boolean
<code>camel.component.mina2.configuration.disconnect-no-reply</code>	If sync is enabled then this option dictates MinaConsumer if it should disconnect where there is no reply to send back.	true	Boolean
<code>camel.component.mina2.configuration.encoder-max-line-length</code>	To set the textline protocol encoder max line length. By default the default value of Mina itself is used which are Integer.MAX_VALUE.	-1	Integer
<code>camel.component.mina2.configuration.encoding</code>	You can configure the encoding (a charset name) to use for the TCP textline codec and the UDP protocol. If not provided, Camel will use the JVM default Charset		String
<code>camel.component.mina2.configuration.filters</code>	You can set a list of Mina IoFilters to use.		List
<code>camel.component.mina2.configuration.host</code>	Hostname to use. Use localhost or 0.0.0.0 for local server as consumer. For producer use the hostname or ip address of the remote server.		String
<code>camel.component.mina2.configuration.lazy-session-creation</code>	Sessions can be lazily created to avoid exceptions, if the remote server is not up and running when the Camel producer is started.	true	Boolean
<code>camel.component.mina2.configuration.maximum-pool-size</code>	Number of worker threads in the worker pool for TCP and UDP	16	Integer

Name	Description	Default	Type
<code>camel.component.mina2.configuration.mina-logger</code>	You can enable the Apache MINA logging filter. Apache MINA uses slf4j logging at INFO level to log all input and output.	false	Boolean
<code>camel.component.mina2.configuration.no-reply-log-level</code>	If sync is enabled this option dictates MinaConsumer which logging level to use when logging a there is no reply to send back.		LogLevel
<code>camel.component.mina2.configuration.ordered-thread-pool-executor</code>	Whether to use ordered thread pool, to ensure events are processed orderly on the same channel.	true	Boolean
<code>camel.component.mina2.configuration.port</code>	Port number		Integer
<code>camel.component.mina2.configuration.protocol</code>	Protocol to use		String
<code>camel.component.mina2.configuration.ssl-context-parameters</code>	To configure SSL security.		SSLContextParameters
<code>camel.component.mina2.configuration.sync</code>	Setting to set endpoint as one-way or request-response.	true	Boolean
<code>camel.component.mina2.configuration.textline</code>	Only used for TCP. If no codec is specified, you can use this flag to indicate a text line based codec; if not specified or the value is false, then Object Serialization is assumed over TCP.	false	Boolean
<code>camel.component.mina2.configuration.textline-delimiter</code>	Only used for TCP and if textline=true. Sets the text line delimiter to use. If none provided, Camel will use DEFAULT. This delimiter is used to mark the end of text.		Mina2TextLineDelimiter
<code>camel.component.mina2.configuration.timeout</code>	You can configure the timeout that specifies how long to wait for a response from a remote server. The timeout unit is in milliseconds, so 60000 is 60 seconds.	30000	Long

Name	Description	Default	Type
<code>camel.component.mina2.configuration.transfer-exchange</code>	Only used for TCP. You can transfer the exchange over the wire instead of just the body. The following fields are transferred: In body, Out body, fault body, In headers, Out headers, fault headers, exchange properties, exchange exception. This requires that the objects are serializable. Camel will exclude any non-serializable objects and log it at WARN level.	false	Boolean
<code>camel.component.mina2.configuration.write-timeout</code>	Maximum amount of time it should take to send data to the MINA session. Default is 10000 milliseconds.	10000	Long
<code>camel.component.mina2.enabled</code>	Enable mina2 component	true	Boolean
<code>camel.component.mina2.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.component.mina2.use-global-ssl-context-parameters</code>	Enable usage of global SSL context parameters.	false	Boolean

224.4. USING A CUSTOM CODEC

See the Mina how to write your own codec. To use your custom codec with **camel-mina**, you should register your codec in the Registry; for example, by creating a bean in the Spring XML file. Then use the **codec** option to specify the bean ID of your codec. See [HL7](#) that has a custom codec.

224.5. SAMPLE WITH SYNC=FALSE

In this sample, Camel exposes a service that listens for TCP connections on port 6200. We use the **textline** codec. In our route, we create a Mina consumer endpoint that listens on port 6200:

```
from("mina2:tcp://localhost:" + port1 + "?textline=true&sync=false").to("mock:result");
```

As the sample is part of a unit test, we test it by sending some data to it on port 6200.

```
MockEndpoint mock = getMockEndpoint("mock:result");
mock.expectedBodiesReceived("Hello World");

template.sendBody("mina2:tcp://localhost:" + port1 + "?textline=true&sync=false", "Hello World");

assertMockEndpointsSatisfied();
```

224.6. SAMPLE WITH SYNC=TRUE

In the next sample, we have a more common use case where we expose a TCP service on port 6201 also use the textline codec. However, this time we want to return a response, so we set the **sync** option to **true** on the consumer.

```
from("mina2:tcp://localhost:" + port2 + "?textline=true&sync=true").process(new Processor() {
    public void process(Exchange exchange) throws Exception {
        String body = exchange.getIn().getBody(String.class);
        exchange.getOut().setBody("Bye " + body);
    }
});
```

Then we test the sample by sending some data and retrieving the response using the **template.requestBody()** method. As we know the response is a **String**, we cast it to **String** and can assert that the response is, in fact, something we have dynamically set in our processor code logic.

```
String response = (String)template.requestBody("mina2:tcp://localhost:" + port2 + "?
textline=true&sync=true", "World");
assertEquals("Bye World", response);
```

224.7. SAMPLE WITH SPRING DSL

Spring DSL can, of course, also be used for **MINA**. In the sample below we expose a TCP server on port 5555:

```
<route>
  <from uri="mina2:tcp://localhost:5555?textline=true"/>
  <to uri="bean:myTCPOrderHandler"/>
</route>
```

In the route above, we expose a TCP server on port 5555 using the textline codec. We let the Spring bean with ID, **myTCPOrderHandler**, handle the request and return a reply. For instance, the handler bean could be implemented as follows:

```
public String handleOrder(String payload) {
    ...
    return "Order: OK"
}
```

224.8. CLOSING SESSION WHEN COMPLETE

When acting as a server you sometimes want to close the session when, for example, a client conversion is finished. To instruct Camel to close the session, you should add a header with the key **CamelMinaCloseSessionWhenComplete** set to a boolean **true** value.

For instance, the example below will close the session after it has written the **bye** message back to the client:

```
from("mina2:tcp://localhost:8080?sync=true&textline=true").process(new Processor() {
    public void process(Exchange exchange) throws Exception {
        String body = exchange.getIn().getBody(String.class);
```

```
        exchange.getOut().setBody("Bye " + body);  
    exchange.getOut().setHeader(Mina2Constants.MINA_CLOSE_SESSION_WHEN_COMPLETE,  
    true);  
    }  
});
```

224.9. GET THE IOSESSION FOR MESSAGE

You can get the `IoSession` from the message header with this key **`Mina2Constants.MINA_IOSESSION`**, and also get the local host address with the key **`Mina2Constants.MINA_LOCAL_ADDRESS`** and remote host address with the key **`Mina2Constants.MINA_REMOTE_ADDRESS`**.

224.10. CONFIGURING MINA FILTERS

Filters permit you to use some Mina Filters, such as **`SslFilter`**. You can also implement some customized filters. Please note that **`codec`** and **`logger`** are also implemented as Mina filters of type, **`IoFilter`**. Any filters you may define are appended to the end of the filter chain; that is, after **`codec`** and **`logger`**.

CHAPTER 225. MLLP COMPONENT

Available as of Camel version 2.17

The MLLP component is specifically designed to handle the nuances of the MLLP protocol and provide the functionality required by Healthcare providers to communicate with other systems using the MLLP protocol. The MLLP component provides a simple configuration URI, automated HL7 acknowledgment generation and automatic acknowledgement interrogation.

The MLLP protocol does not typically use a large number of concurrent TCP connections - a single active TCP connection is the normal case. Therefore, the MLLP component uses a simple thread-per-connection model based on standard Java Sockets. This keeps the implementation simple and eliminates the dependencies other than Camel itself.

The component supports the following:

- A Camel consumer using a TCP Server
- A Camel producer using a TCP Client

The MLLP component uses byte[] payloads, and relies on Camel Type Conversion to convert byte[] to other types.

Maven users will need to add the following dependency to their pom.xml for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-mlp</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

225.1. MLLP OPTIONS

The MLLP component supports 5 options, which are listed below.

Name	Description	Default	Type
logPhi (advanced)	Set the component to log PHI data.	true	Boolean
logPhiMaxBytes (advanced)	Set the maximum number of bytes of PHI that will be logged in a log entry.	5120	Integer
defaultCharset (advanced)	Set the default character set to use for byte to/from String conversions.	ISO-8859-1	String
configuration (common)	Sets the default configuration to use when creating MLLP endpoints.		MllpConfiguration

Name	Description	Default	Type
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The MLLP endpoint is configured using URI syntax:

```
mllp:hostname:port
```

with the following path and query parameters:

225.1.1. Path Parameters (2 parameters):

Name	Description	Default	Type
hostname	Required Hostname or IP for connection for the TCP connection. The default value is null, which means any local IP address		String
port	Required Port number for the TCP connection		int

225.1.2. Query Parameters (27 parameters):

Name	Description	Default	Type
autoAck (common)	Enable/Disable the automatic generation of a MLLP Acknowledgement MLLP Consumers only	true	boolean
bufferWrites (common)	Deprecated Enable/Disable the buffering of HL7 payloads before writing to the socket.	false	boolean
hl7Headers (common)	Enable/Disable the automatic generation of message headers from the HL7 Message MLLP Consumers only	true	boolean
requireEndOfData (common)	Enable/Disable strict compliance to the MLLP standard. The MLLP standard specifies START_OF_BLOCKhl7 payloadEND_OF_BLOCKEND_OF_DATA, however, some systems do not send the final END_OF_DATA byte. This setting controls whether or not the final END_OF_DATA byte is required or optional.	true	boolean

Name	Description	Default	Type
stringPayload (common)	Enable/Disable converting the payload to a String. If enabled, HL7 Payloads received from external systems will be validated converted to a String. If the charsetName property is set, that character set will be used for the conversion. If the charsetName property is not set, the value of MSH-18 will be used to determine the appropriate character set. If MSH-18 is not set, then the default ISO-8859-1 character set will be used.	true	boolean
validatePayload (common)	Enable/Disable the validation of HL7 Payloads. If enabled, HL7 Payloads received from external systems will be validated (see <code>HL7Util.generateInvalidPayloadExceptionMessage</code> for details on the validation). If an invalid payload is detected, a <code>MllpInvalidMessageException</code> (for consumers) or a <code>MllpInvalidAcknowledgementException</code> will be thrown.	false	boolean
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which means any exceptions occurred while the consumer is trying to receive incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. If disabled, the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions by logging them at WARN or ERROR level and ignored.	true	boolean
exceptionHandler (consumer)	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		<code>ExceptionHandler</code>
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.	InOut	<code>ExchangePattern</code>
synchronous (advanced)	Sets whether synchronous processing should be strictly used (this component only supports synchronous operations).	true	boolean
backlog (tcp)	The maximum queue length for incoming connection indications (a request to connect) is set to the backlog parameter. If a connection indication arrives when the queue is full, the connection is refused.	5	Integer

Name	Description	Default	Type
lenientBind (tcp)	TCP Server Only - Allow the endpoint to start before the TCP ServerSocket is bound. In some environments, it may be desirable to allow the endpoint to start before the TCP ServerSocket is bound.	false	boolean
maxConcurrentConsumers (tcp)	The maximum number of concurrent MLLP Consumer connections that will be allowed. If a new connection is received and the maximum is number are already established, the new connection will be reset immediately.	5	int
reuseAddress (tcp)	Enable/disable the SO_REUSEADDR socket option.	false	Boolean
acceptTimeout (timeout)	Timeout (in milliseconds) while waiting for a TCP connection TCP Server Only	60000	int
bindRetryInterval (timeout)	TCP Server Only - The number of milliseconds to wait between bind attempts	5000	int
bindTimeout (timeout)	TCP Server Only - The number of milliseconds to retry binding to a server port	30000	int
connectTimeout (timeout)	Timeout (in milliseconds) for establishing for a TCP connection TCP Client only	30000	int
idleTimeout (timeout)	The approximate idle time allowed before the Client TCP Connection will be reset. A null value or a value less than or equal to zero will disable the idle timeout.		Integer
maxReceiveTimeouts (timeout)	Deprecated The maximum number of timeouts (specified by receiveTimeout) allowed before the TCP Connection will be reset.		Integer
keepAlive (tcp)	Enable/disable the SO_KEEPALIVE socket option.	true	Boolean
receiveBufferSize (tcp)	Sets the SO_RCVBUF option to the specified value (in bytes)	8192	Integer
sendBufferSize (tcp)	Sets the SO_SNDBUF option to the specified value (in bytes)	8192	Integer
tcpNoDelay (tcp)	Enable/disable the TCP_NODELAY socket option.	true	Boolean
readTimeout (timeout)	The SO_TIMEOUT value (in milliseconds) used after the start of an MLLP frame has been received	5000	int

Name	Description	Default	Type
receiveTimeout (timeout)	The SO_TIMEOUT value (in milliseconds) used when waiting for the start of an MLLP frame	15000	int
charsetName (codec)	Set the CamelCharsetName property on the exchange		String

225.2. SPRING BOOT AUTO-CONFIGURATION

The component supports 31 options, which are listed below.

Name	Description	Default	Type
camel.component.mllp.configuration.accept-timeout	Timeout (in milliseconds) while waiting for a TCP connection TCP Server Only	60000	Integer
camel.component.mllp.configuration.auto-ack	Enable/Disable the automatic generation of a MLLP Acknowledgement MLLP Consumers only	true	Boolean
camel.component.mllp.configuration.backlog	The maximum queue length for incoming connection indications (a request to connect) is set to the backlog parameter. If a connection indication arrives when the queue is full, the connection is refused.	5	Integer
camel.component.mllp.configuration.bind-retry-interval	TCP Server Only - The number of milliseconds to wait between bind attempts	5000	Integer
camel.component.mllp.configuration.bind-timeout	TCP Server Only - The number of milliseconds to retry binding to a server port	30000	Integer
camel.component.mllp.configuration.bridge-error-handler	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to receive incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. If disabled, the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions by logging them at WARN or ERROR level and ignored.	true	Boolean

Name	Description	Default	Type
<code>camel.component.mllp.configuration.charset-name</code>	Set the CamelCharsetName property on the exchange		String
<code>camel.component.mllp.configuration.connect-timeout</code>	Timeout (in milliseconds) for establishing for a TCP connection TCP Client only	30000	Integer
<code>camel.component.mllp.configuration.exchange-pattern</code>	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
<code>camel.component.mllp.configuration.hl7-headers</code>	Enable/Disable the automatic generation of message headers from the HL7 Message MLLP Consumers only	true	Boolean
<code>camel.component.mllp.configuration.idle-timeout</code>	The approximate idle time allowed before the Client TCP Connection will be reset. A null value or a value less than or equal to zero will disable the idle timeout.		Integer
<code>camel.component.mllp.configuration.keep-alive</code>	Enable/disable the SO_KEEPALIVE socket option.	true	Boolean
<code>camel.component.mllp.configuration.lenient-bind</code>	TCP Server Only - Allow the endpoint to start before the TCP ServerSocket is bound. In some environments, it may be desirable to allow the endpoint to start before the TCP ServerSocket is bound.	false	Boolean
<code>camel.component.mllp.configuration.max-concurrent-consumers</code>	The maximum number of concurrent MLLP Consumer connections that will be allowed. If a new connection is received and the maximum is number are already established, the new connection will be reset immediately.	5	Integer
<code>camel.component.mllp.configuration.read-timeout</code>	The SO_TIMEOUT value (in milliseconds) used after the start of an MLLP frame has been received	5000	Integer
<code>camel.component.mllp.configuration.receive-buffer-size</code>	Sets the SO_RCVBUF option to the specified value (in bytes)	8192	Integer

Name	Description	Default	Type
<code>camel.component.mllp.configuration.receive-timeout</code>	The SO_TIMEOUT value (in milliseconds) used when waiting for the start of an MLLP frame	15000	Integer
<code>camel.component.mllp.configuration.require-end-of-data</code>	Enable/Disable strict compliance to the MLLP standard. The MLLP standard specifies START_OF_BLOCKHI7 payloadEND_OF_BLOCKEND_OF_DATA, however, some systems do not send the final END_OF_DATA byte. This setting controls whether or not the final END_OF_DATA byte is required or optional.	true	Boolean
<code>camel.component.mllp.configuration.reuse-address</code>	Enable/disable the SO_REUSEADDR socket option.	false	Boolean
<code>camel.component.mllp.configuration.send-buffer-size</code>	Sets the SO_SNDBUF option to the specified value (in bytes)	8192	Integer
<code>camel.component.mllp.configuration.string-payload</code>	Enable/Disable converting the payload to a String. If enabled, HL7 Payloads received from external systems will be validated converted to a String. If the charsetName property is set, that character set will be used for the conversion. If the charsetName property is not set, the value of MSH-18 will be used to determine the appropriate character set. If MSH-18 is not set, then the default ISO-8859-1 character set will be use.	true	Boolean
<code>camel.component.mllp.configuration.synchronous</code>	Sets whether synchronous processing should be strictly used (this component only supports synchronous operations).	true	Boolean
<code>camel.component.mllp.configuration.tcp-no-delay</code>	Enable/disable the TCP_NODELAY socket option.	true	Boolean
<code>camel.component.mllp.configuration.validate-payload</code>	Enable/Disable the validation of HL7 Payloads If enabled, HL7 Payloads received from external systems will be validated (see HI7Util.generateInvalidPayloadExceptionMessage for details on the validation). If and invalid payload is detected, a MllpInvalidMessageException (for consumers) or a MllpInvalidAcknowledgementException will be thrown.	false	Boolean

Name	Description	Default	Type
<code>camel.component.mllp.default-charset</code>	Set the default character set to use for byte to/from String conversions.	ISO-8859-1	String
<code>camel.component.mllp.enabled</code>	Enable mllp component	true	Boolean
<code>camel.component.mllp.log-phi</code>	Set the component to log PHI data.	true	Boolean
<code>camel.component.mllp.log-phi-max-bytes</code>	Set the maximum number of bytes of PHI that will be logged in a log entry.	5120	Integer
<code>camel.component.mllp.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.component.mllp.configuration.buffer-writes</code>	Enable/Disable the buffering of HL7 payloads before writing to the socket.	false	Boolean
<code>camel.component.mllp.configuration.max-receive-timeouts</code>	The maximum number of timeouts (specified by <code>receiveTimeout</code>) allowed before the TCP Connection will be reset.		Integer

225.3. MLLP CONSUMER

The MLLP Consumer supports receiving MLLP-framed messages and sending HL7 Acknowledgements. The MLLP Consumer can automatically generate the HL7 Acknowledgement (HL7 Application Acknowledgements only - AA, AE and AR), or the acknowledgement can be specified using the `CamelMllpAcknowledgement` exchange property. Additionally, the type of acknowledgement that will be generated can be controlled by setting the `CamelMllpAcknowledgementType` exchange property.

225.4. MESSAGE HEADERS

The MLLP Consumer adds these headers on the Camel message:

Key	Description
<code>CamelMllpLocalAddress</code>	The local TCP Address of the Socket

CamelMllpRemoteAddress	The local TCP Address of the Socket	
CamelMllpSendingApplication	MSH-3 value	
CamelMllpSendingFacility	MSH-4 value	
CamelMllpReceivingApplication	MSH-5 value	
CamelMllpReceivingFacility	MSH-6 value	
CamelMllpTimestamp	MSH-7 value	
CamelMllpSecurity	MSH-8 value	
CamelMllpMessageType	MSH-9 value	
CamelMllpEventType	MSH-9-1 value	
CamelMllpTriggerEvent	MSH-9-2 value	
CamelMllpMessageControllId	MSH-10 value	
CamelMllpProcessingId	MSH-11 value	
CamelMllpVersionId	MSH-12 value	
CamelMllpCharset	MSH-18 value	

All headers are String types. If a header value is missing, its value is null.

225.5. EXCHANGE PROPERTIES

The type of acknowledgment the MLLP Consumer generates and state of the TCP Socket can be controlled by these properties on the Camel exchange:

Key	Type	Description
CamelMllpAcknowledgement	byte[]	If present, this property will be sent to client as the MLLP Acknowledgement

CamelMllpAcknowledgementString	String	If present and CamelMllpAcknowledgement is not present, this property will be sent to client as the MLLP Acknowledgement
CamelMllpAcknowledgementMsaText	String	If neither CamelMllpAcknowledgement or CamelMllpAcknowledgementString are present and autoAck is true, this property can be used to specify the contents of MSA-3 in the generated HL7 acknowledgement
CamelMllpAcknowledgementType	String	If neither CamelMllpAcknowledgement or CamelMllpAcknowledgementString are present and autoAck is true, this property can be used to specify the HL7 acknowledgement type (i.e. AA, AE, AR)
CamelMllpAutoAcknowledge	Boolean	Overrides the autoAck query parameter
CamelMllpCloseConnectionBeforeSend	Boolean	If true, the Socket will be closed before sending data
CamelMllpResetConnectionBeforeSend	Boolean	If true, the Socket will be reset before sending data
CamelMllpCloseConnectionAfterSend	Boolean	If true, the Socket will be closed immediately after sending data
CamelMllpResetConnectionAfterSend	Boolean	If true, the Socket will be reset immediately after sending any data

225.6. MLLP PRODUCER

The MLLP Producer supports sending MLLP-framed messages and receiving HL7 Acknowledgements. The MLLP Producer interrogates the HL7 Acknowledgments and raises exceptions if a negative acknowledgement is received. The received acknowledgement is interrogated and an exception is raised in the event of a negative acknowledgement.

225.7. MESSAGE HEADERS

The MLLP Producer adds these headers on the Camel message:

Key	Description	
CamelMllpLocalAddress	The local TCP Address of the Socket	
CamelMllpRemoteAddress	The remote TCP Address of the Socket	
CamelMllpAcknowledgement	The HL7 Acknowledgment byte[] received	
CamelMllpAcknowledgementString	The HL7 Acknowledgment received, converted to a String	

225.8. EXCHANGE PROPERTIES

The state of the TCP Socket can be controlled by these properties on the Camel exchange:

Key	Type	Description
CamelMllpCloseConnectionBeforeSend	Boolean	If true, the Socket will be closed before sending data
CamelMllpResetConnectionBeforeSend	Boolean	If true, the Socket will be reset before sending data
CamelMllpCloseConnectionAfterSend	Boolean	If true, the Socket will be closed immediately after sending data
CamelMllpResetConnectionAfterSend	Boolean	If true, the Socket will be reset immediately after sending any data

CHAPTER 226. MOCK COMPONENT

Available as of Camel version 1.0

Testing of distributed and asynchronous processing is notoriously difficult. The [Mock](#), [Test](#) and [DataSet](#) endpoints work great with the Camel Testing Framework to simplify your unit and integration testing using [Enterprise Integration Patterns](#) and Camel's large range of Components together with the powerful Bean Integration.

The Mock component provides a powerful declarative testing mechanism, which is similar to [jMock](#) in that it allows declarative expectations to be created on any Mock endpoint before a test begins. Then the test is run, which typically fires messages to one or more endpoints, and finally the expectations can be asserted in a test case to ensure the system worked as expected.

This allows you to test various things like:

- The correct number of messages are received on each endpoint,
- The correct payloads are received, in the right order,
- Messages arrive on an endpoint in order, using some Expression to create an order testing function,
- Messages arrive match some kind of Predicate such as that specific headers have certain values, or that parts of the messages match some predicate, such as by evaluating an [XPath](#) or [XQuery](#) Expression.

NOTE

There is also the [Test endpoint](#) which is a Mock endpoint, but which uses a second endpoint to provide the list of expected message bodies and automatically sets up the Mock endpoint assertions. In other words, it's a Mock endpoint that automatically sets up its assertions from some sample messages in a File or [database](#), for example.

CAUTION

Mock endpoints keep received Exchanges in memory indefinitely.

Remember that Mock is designed for testing. When you add Mock endpoints to a route, each Exchange sent to the endpoint will be stored (to allow for later validation) in memory until explicitly reset or the JVM is restarted. If you are sending high volume and/or large messages, this may cause excessive memory use. If your goal is to test deployable routes inline, consider using [NotifyBuilder](#) or [AdviceWith](#) in your tests instead of adding Mock endpoints to routes directly.

From Camel 2.10 onwards there are two new options **retainFirst**, and **retainLast** that can be used to limit the number of messages the Mock endpoints keep in memory.

226.1. URI FORMAT

```
mock:someName[?options]
```

Where **someName** can be any string that uniquely identifies the endpoint.

You can append query options to the URI in the following format, **?option=value&option=value&...**

226.2. OPTIONS

The Mock component has no options.

The Mock endpoint is configured using URI syntax:

```
mock:name
```

with the following path and query parameters:

226.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
name	Required Name of mock endpoint	t	String

226.2.2. Query Parameters (10 parameters):

Name	Description	Default	Type
assertPeriod (producer)	Sets a grace period after which the mock endpoint will re-assert to ensure the preliminary assertion is still valid. This is used for example to assert that exactly a number of messages arrives. For example if <code>expectedMessageCount(int)</code> was set to 5, then the assertion is satisfied when 5 or more message arrives. To ensure that exactly 5 messages arrives, then you would need to wait a little period to ensure no further message arrives. This is what you can use this <code>setAssertPeriod(long)</code> method for. By default this period is disabled.	0	long
expectedCount (producer)	Specifies the expected number of message exchanges that should be received by this endpoint. Beware: If you want to expect that 0 messages, then take extra care, as 0 matches when the tests starts, so you need to set a assert period time to let the test run for a while to make sure there are still no messages arrived; for that use <code>setAssertPeriod(long)</code> . An alternative is to use <code>NotifyBuilder</code> , and use the notifier to know when Camel is done routing some messages, before you call the <code>assertIsSatisfied()</code> method on the mocks. This allows you to not use a fixed assert period, to speedup testing times. If you want to assert that exactly n'th message arrives to this mock endpoint, then see also the <code>setAssertPeriod(long)</code> method for further details.	-1	int

Name	Description	Default	Type
reportGroup (producer)	A number that is used to turn on throughput logging based on groups of the size.		int
resultMinimumWaitTime (producer)	Sets the minimum expected amount of time (in millis) the <code>assertIsSatisfied()</code> will wait on a latch until it is satisfied	0	long
resultWaitTime (producer)	Sets the maximum amount of time (in millis) the <code>assertIsSatisfied()</code> will wait on a latch until it is satisfied	0	long
retainFirst (producer)	Specifies to only retain the first n'th number of received Exchanges. This is used when testing with big data, to reduce memory consumption by not storing copies of every Exchange this mock endpoint receives. Important: When using this limitation, then the <code>getReceivedCounter()</code> will still return the actual number of received Exchanges. For example if we have received 5000 Exchanges, and have configured to only retain the first 10 Exchanges, then the <code>getReceivedCounter()</code> will still return 5000 but there is only the first 10 Exchanges in the <code>getExchanges()</code> and <code>getReceivedExchanges()</code> methods. When using this method, then some of the other expectation methods is not supported, for example the <code>expectedBodiesReceived(Object...)</code> sets a expectation on the first number of bodies received. You can configure both <code>setRetainFirst(int)</code> and <code>setRetainLast(int)</code> methods, to limit both the first and last received.	-1	int
retainLast (producer)	Specifies to only retain the last n'th number of received Exchanges. This is used when testing with big data, to reduce memory consumption by not storing copies of every Exchange this mock endpoint receives. Important: When using this limitation, then the <code>getReceivedCounter()</code> will still return the actual number of received Exchanges. For example if we have received 5000 Exchanges, and have configured to only retain the last 20 Exchanges, then the <code>getReceivedCounter()</code> will still return 5000 but there is only the last 20 Exchanges in the <code>getExchanges()</code> and <code>getReceivedExchanges()</code> methods. When using this method, then some of the other expectation methods is not supported, for example the <code>expectedBodiesReceived(Object...)</code> sets a expectation on the first number of bodies received. You can configure both <code>setRetainFirst(int)</code> and <code>setRetainLast(int)</code> methods, to limit both the first and last received.	-1	int

Name	Description	Default	Type
sleepForEmptyTest (producer)	Allows a sleep to be specified to wait to check that this endpoint really is empty when <code>expectedMessageCount(int)</code> is called with zero	0	long
copyOnExchange (producer)	Sets whether to make a deep copy of the incoming Exchange when received at this mock endpoint. Is by default true.	true	boolean
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

226.3. SIMPLE EXAMPLE

Here's a simple example of Mock endpoint in use. First, the endpoint is resolved on the context. Then we set an expectation, and then, after the test has run, we assert that our expectations have been met:

```
MockEndpoint resultEndpoint = context.resolveEndpoint("mock:foo", MockEndpoint.class);

// set expectations
resultEndpoint.expectedMessageCount(2);

// send some messages

// now lets assert that the mock:foo endpoint received 2 messages
resultEndpoint.assertIsSatisfied();
```

You typically always call the **assertIsSatisfied()** method to test that the expectations were met after running a test.

Camel will by default wait 10 seconds when the **assertIsSatisfied()** is invoked. This can be configured by setting the **setResultWaitTime(millis)** method.

226.4. USING ASSERTPERIOD

Available as of Camel 2.7

When the assertion is satisfied then Camel will stop waiting and continue from the **assertIsSatisfied** method. That means if a new message arrives on the mock endpoint, just a bit later, that arrival will not affect the outcome of the assertion. Suppose you do want to test that no new messages arrives after a period thereafter, then you can do that by setting the **setAssertPeriod** method, for example:

```
MockEndpoint resultEndpoint = context.resolveEndpoint("mock:foo", MockEndpoint.class);
resultEndpoint.setAssertPeriod(5000);
resultEndpoint.expectedMessageCount(2);

// send some messages
```

```
// now lets assert that the mock:foo endpoint received 2 messages
resultEndpoint.assertIsSatisfied();
```

226.5. SETTING EXPECTATIONS

You can see from the Javadoc of [MockEndpoint](#) the various helper methods you can use to set expectations. The main methods are as follows:

Method	Description
expectedMessageCount(int)	To define the expected message count on the endpoint.
expectedMinimumMessageCount(int)	To define the minimum number of expected messages on the endpoint.
expectedBodiesReceived(...)	To define the expected bodies that should be received (in order).
expectedHeaderReceived(...)	To define the expected header that should be received
expectsAscending(Expression)	To add an expectation that messages are received in order, using the given Expression to compare messages.
expectsDescending(Expression)	To add an expectation that messages are received in order, using the given Expression to compare messages.
expectsNoDuplicates(Expression)	To add an expectation that no duplicate messages are received; using an Expression to calculate a unique identifier for each message. This could be something like the JMSMessageID if using JMS, or some unique reference number within the message.

Here's another example:

```
resultEndpoint.expectedBodiesReceived("firstMessageBody", "secondMessageBody",
"thirdMessageBody");
```

226.6. ADDING EXPECTATIONS TO SPECIFIC MESSAGES

In addition, you can use the [message\(int messageIndex\)](#) method to add assertions about a specific message that is received.

For example, to add expectations of the headers or body of the first message (using zero-based indexing like [java.util.List](#)), you can use the following code:

```
resultEndpoint.message(0).header("foo").isEqualTo("bar");
```

There are some examples of the Mock endpoint in use in the [camel-core processor tests](#).

226.7. MOCKING EXISTING ENDPOINTS

Available as of Camel 2.7

Camel now allows you to automatically mock existing endpoints in your Camel routes.

NOTE

How it works The endpoints are still in action. What happens differently is that a [Mock](#) endpoint is injected and receives the message first and then delegates the message to the target endpoint. You can view this as a kind of intercept and delegate or endpoint listener.

Suppose you have the given route below:

Route

```
@Override
protected RouteBuilder createRouteBuilder() throws Exception {
    return new RouteBuilder() {
        @Override
        public void configure() throws Exception {
            from("direct:start").to("direct:foo").to("log:foo").to("mock:result");

            from("direct:foo").transform(constant("Bye World"));
        }
    };
}
```

You can then use the **adviceWith** feature in Camel to mock all the endpoints in a given route from your unit test, as shown below:

adviceWith mocking all endpoints

```
public void testAdvisedMockEndpoints() throws Exception {
    // advice the first route using the inlined AdviceWith route builder
    // which has extended capabilities than the regular route builder
    context.getRouteDefinitions().get(0).adviceWith(context, new AdviceWithRouteBuilder() {
        @Override
        public void configure() throws Exception {
            // mock all endpoints
            mockEndpoints();
        }
    });

    getMockEndpoint("mock:direct:start").expectedBodiesReceived("Hello World");
    getMockEndpoint("mock:direct:foo").expectedBodiesReceived("Hello World");
    getMockEndpoint("mock:log:foo").expectedBodiesReceived("Bye World");
    getMockEndpoint("mock:result").expectedBodiesReceived("Bye World");
}
```

```

template.sendBody("direct:start", "Hello World");

assertMockEndpointsSatisfied();

// additional test to ensure correct endpoints in registry
assertNotNull(context.hasEndpoint("direct:start"));
assertNotNull(context.hasEndpoint("direct:foo"));
assertNotNull(context.hasEndpoint("log:foo"));
assertNotNull(context.hasEndpoint("mock:result"));
// all the endpoints was mocked
assertNotNull(context.hasEndpoint("mock:direct:start"));
assertNotNull(context.hasEndpoint("mock:direct:foo"));
assertNotNull(context.hasEndpoint("mock:log:foo"));
}

```

Notice that the mock endpoints is given the URI **mock:<endpoint>**, for example **mock:direct:foo**. Camel logs at **INFO** level the endpoints being mocked:

```
INFO  Advised endpoint [direct://foo] with mock endpoint [mock:direct:foo]
```

NOTE

Mocked endpoints are without parameters

Endpoints which are mocked will have their parameters stripped off. For example the endpoint **log:foo?showAll=true** will be mocked to the following endpoint **mock:log:foo**. Notice the parameters have been removed.

Its also possible to only mock certain endpoints using a pattern. For example to mock all **log** endpoints you do as shown:

adviceWith mocking only log endpoints using a pattern

```

public void testAdvisedMockEndpointsWithPattern() throws Exception {
    // advice the first route using the inlined AdviceWith route builder
    // which has extended capabilities than the regular route builder
    context.getRouteDefinitions().get(0).adviceWith(context, new AdviceWithRouteBuilder() {
        @Override
        public void configure() throws Exception {
            // mock only log endpoints
            mockEndpoints("log*");
        }
    });

    // now we can refer to log:foo as a mock and set our expectations
    getMockEndpoint("mock:log:foo").expectedBodiesReceived("Bye World");

    getMockEndpoint("mock:result").expectedBodiesReceived("Bye World");

    template.sendBody("direct:start", "Hello World");

    assertMockEndpointsSatisfied();

    // additional test to ensure correct endpoints in registry

```

```

assertNotNull(context.hasEndpoint("direct:start"));
assertNotNull(context.hasEndpoint("direct:foo"));
assertNotNull(context.hasEndpoint("log:foo"));
assertNotNull(context.hasEndpoint("mock:result"));
// only the log:foo endpoint was mocked
assertNotNull(context.hasEndpoint("mock:log:foo"));
assertNull(context.hasEndpoint("mock:direct:start"));
assertNull(context.hasEndpoint("mock:direct:foo"));
}

```

The pattern supported can be a wildcard or a regular expression. See more details about this at Intercept as its the same matching function used by Camel.

NOTE

Mind that mocking endpoints causes the messages to be copied when they arrive on the mock.

That means Camel will use more memory. This may not be suitable when you send in a lot of messages.

226.8. MOCKING EXISTING ENDPOINTS USING THE CAMEL-TEST COMPONENT

Instead of using the **adviceWith** to instruct Camel to mock endpoints, you can easily enable this behavior when using the **camel-test** Test Kit.

The same route can be tested as follows. Notice that we return **""** from the **isMockEndpoints** method, which tells Camel to mock all endpoints.

If you only want to mock all **log** endpoints you can return **"log*"** instead.

isMockEndpoints using camel-test kit

```

public class IsMockEndpointsJUnit4Test extends CamelTestSupport {

    @Override
    public String isMockEndpoints() {
        // override this method and return the pattern for which endpoints to mock.
        // use * to indicate all
        return "";
    }

    @Test
    public void testMockAllEndpoints() throws Exception {
        // notice we have automatic mocked all endpoints and the name of the endpoints is "mock:uri"
        getMockEndpoint("mock:direct:start").expectedBodiesReceived("Hello World");
        getMockEndpoint("mock:direct:foo").expectedBodiesReceived("Hello World");
        getMockEndpoint("mock:log:foo").expectedBodiesReceived("Bye World");
        getMockEndpoint("mock:result").expectedBodiesReceived("Bye World");

        template.sendBody("direct:start", "Hello World");

        assertMockEndpointsSatisfied();
    }
}

```

```

// additional test to ensure correct endpoints in registry
assertNotNull(context.hasEndpoint("direct:start"));
assertNotNull(context.hasEndpoint("direct:foo"));
assertNotNull(context.hasEndpoint("log:foo"));
assertNotNull(context.hasEndpoint("mock:result"));
// all the endpoints was mocked
assertNotNull(context.hasEndpoint("mock:direct:start"));
assertNotNull(context.hasEndpoint("mock:direct:foo"));
assertNotNull(context.hasEndpoint("mock:log:foo"));
}

@Override
protected RouteBuilder createRouteBuilder() throws Exception {
    return new RouteBuilder() {
        @Override
        public void configure() throws Exception {
            from("direct:start").to("direct:foo").to("log:foo").to("mock:result");

            from("direct:foo").transform(constant("Bye World"));
        }
    };
}
}
}

```

226.9. MOCKING EXISTING ENDPOINTS WITH XML DSL

If you do not use the **camel-test** component for unit testing (as shown above) you can use a different approach when using XML files for routes.

The solution is to create a new XML file used by the unit test and then include the intended XML file which has the route you want to test.

Suppose we have the route in the **camel-route.xml** file:

camel-route.xml 1

```

<!-- this camel route is in the camel-route.xml file -->
<camelContext xmlns="http://camel.apache.org/schema/spring">

    <route>
        <from uri="direct:start"/>
        <to uri="direct:foo"/>
        <to uri="log:foo"/>
        <to uri="mock:result"/>
    </route>

    <route>
        <from uri="direct:foo"/>
        <transform>
            <constant>Bye World</constant>
        </transform>
    </route>

</camelContext>

```

Then we create a new XML file as follows, where we include the **camel-route.xml** file and define a spring bean with the class **org.apache.camel.impl.InterceptSendToMockEndpointStrategy** which tells Camel to mock all endpoints:

test-camel-route.xml

```
<!-- the Camel route is defined in another XML file -->
<import resource="camel-route.xml"/>

<!-- bean which enables mocking all endpoints -->
<bean id="mockAllEndpoints"
class="org.apache.camel.component.mock.InterceptSendToMockEndpointStrategy"/>
```

Then in your unit test you load the new XML file (**test-camel-route.xml**) instead of **camel-route.xml**.

To only mock all [Log](#) endpoints you can define the pattern in the constructor for the bean:

```
<bean id="mockAllEndpoints"
class="org.apache.camel.impl.InterceptSendToMockEndpointStrategy">
  <constructor-arg index="0" value="log*" />
</bean>
```

226.10. MOCKING ENDPOINTS AND SKIP SENDING TO ORIGINAL ENDPOINT

Available as of Camel 2.10

Sometimes you want to easily mock and skip sending to a certain endpoints. So the message is detoured and send to the mock endpoint only. From Camel 2.10 onwards you can now use the **mockEndpointsAndSkip** method using `AdviceWith` or the [Test Kit](#). The example below will skip sending to the two endpoints **"direct:foo"**, and **"direct:bar"**.

adviceWith mock and skip sending to endpoints

```
public void testAdvisedMockEndpointsWithSkip() throws Exception {
    // advice the first route using the inlined AdviceWith route builder
    // which has extended capabilities than the regular route builder
    context.getRouteDefinitions().get(0).adviceWith(context, new AdviceWithRouteBuilder() {
        @Override
        public void configure() throws Exception {
            // mock sending to direct:foo and direct:bar and skip send to it
            mockEndpointsAndSkip("direct:foo", "direct:bar");
        }
    });

    getMockEndpoint("mock:result").expectedBodiesReceived("Hello World");
    getMockEndpoint("mock:direct:foo").expectedMessageCount(1);
    getMockEndpoint("mock:direct:bar").expectedMessageCount(1);

    template.sendBody("direct:start", "Hello World");

    assertMockEndpointsSatisfied();

    // the message was not send to the direct:foo route and thus not sent to the seda endpoint
```

```

    SedaEndpoint seda = context.getEndpoint("seda:foo", SedaEndpoint.class);
    assertEquals(0, seda.getCurrentQueueSize());
}

```

The same example using the Test Kit

isMockEndpointsAndSkip using camel-test kit

```

public class IsMockEndpointsAndSkipJUnit4Test extends CamelTestSupport {

    @Override
    public String isMockEndpointsAndSkip() {
        // override this method and return the pattern for which endpoints to mock,
        // and skip sending to the original endpoint.
        return "direct:foo";
    }

    @Test
    public void testMockEndpointAndSkip() throws Exception {
        // notice we have automatic mocked the direct:foo endpoints and the name of the endpoints is
        "mock:uri"
        getMockEndpoint("mock:result").expectedBodiesReceived("Hello World");
        getMockEndpoint("mock:direct:foo").expectedMessageCount(1);

        template.sendBody("direct:start", "Hello World");

        assertMockEndpointsSatisfied();

        // the message was not send to the direct:foo route and thus not sent to the seda endpoint
        SedaEndpoint seda = context.getEndpoint("seda:foo", SedaEndpoint.class);
        assertEquals(0, seda.getCurrentQueueSize());
    }

    @Override
    protected RouteBuilder createRouteBuilder() throws Exception {
        return new RouteBuilder() {
            @Override
            public void configure() throws Exception {
                from("direct:start").to("direct:foo").to("mock:result");

                from("direct:foo").transform(constant("Bye World")).to("seda:foo");
            }
        };
    }
}

```

226.11. LIMITING THE NUMBER OF MESSAGES TO KEEP

Available as of Camel 2.10

The [Mock](#) endpoints will by default keep a copy of every Exchange that it received. So if you test with a lot of messages, then it will consume memory.

From Camel 2.10 onwards we have introduced two options **retainFirst** and **retainLast** that can be used to specify to only keep N'th of the first and/or last Exchanges.

For example in the code below, we only want to retain a copy of the first 5 and last 5 Exchanges the mock receives.

```
MockEndpoint mock = getMockEndpoint("mock:data");
mock.setRetainFirst(5);
mock.setRetainLast(5);
mock.expectedMessageCount(2000);

mock.assertIsSatisfied();
```

Using this has some limitations. The **getExchanges()** and **getReceivedExchanges()** methods on the **MockEndpoint** will return only the retained copies of the Exchanges. So in the example above, the list will contain 10 Exchanges; the first five, and the last five.

The **retainFirst** and **retainLast** options also have limitations on which expectation methods you can use. For example the **expectedXXX** methods that work on message bodies, headers, etc. will only operate on the retained messages. In the example above they can test only the expectations on the 10 retained messages.

226.12. TESTING WITH ARRIVAL TIMES

Available as of Camel 2.7

The **Mock** endpoint stores the arrival time of the message as a property on the Exchange.

```
Date time = exchange.getProperty(Exchange.RECEIVED_TIMESTAMP, Date.class);
```

You can use this information to know when the message arrived on the mock. But it also provides foundation to know the time interval between the previous and next message arrived on the mock. You can use this to set expectations using the **arrives** DSL on the **Mock** endpoint.

For example to say that the first message should arrive between 0-2 seconds before the next you can do:

```
mock.message(0).arrives().noLaterThan(2).seconds().beforeNext();
```

You can also define this as that 2nd message (0 index based) should arrive no later than 0-2 seconds after the previous:

```
mock.message(1).arrives().noLaterThan(2).seconds().afterPrevious();
```

You can also use **between** to set a lower bound. For example suppose that it should be between 1-4 seconds:

```
mock.message(1).arrives().between(1, 4).seconds().afterPrevious();
```

You can also set the expectation on all messages, for example to say that the gap between them should be at most 1 second:

```
mock.allMessages().arrives().noLaterThan(1).seconds().beforeNext();
```

TIP

Time units

In the example above we use **seconds** as the time unit, but Camel offers **milliseconds**, and **minutes** as well.

CHAPTER 227. MONGODB COMPONENT (DEPRECATED)

Available as of Camel version 2.10

Available as of Camel version 2.10

According to Wikipedia: "NoSQL is a movement promoting a loosely defined class of non-relational data stores that break with a long history of relational databases and ACID guarantees." NoSQL solutions have grown in popularity in the last few years, and major extremely-used sites and services such as Facebook, LinkedIn, Twitter, etc. are known to use them extensively to achieve scalability and agility.

Basically, NoSQL solutions differ from traditional RDBMS (Relational Database Management Systems) in that they don't use SQL as their query language and generally don't offer ACID-like transactional behaviour nor relational data. Instead, they are designed around the concept of flexible data structures and schemas (meaning that the traditional concept of a database table with a fixed schema is dropped), extreme scalability on commodity hardware and blazing-fast processing.

MongoDB is a very popular NoSQL solution and the camel-mongodb component integrates Camel with MongoDB allowing you to interact with MongoDB collections both as a producer (performing operations on the collection) and as a consumer (consuming documents from a MongoDB collection).

MongoDB revolves around the concepts of documents (not as is office documents, but rather hierarchical data defined in JSON/BSON) and collections. This component page will assume you are familiar with them. Otherwise, visit <http://www.mongodb.org/>.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-mongodb</artifactId>
  <version>x.y.z</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

227.1. URI FORMAT

```
mongodb:connectionBean?
database=databaseName&collection=collectionName&operation=operationName[&moreOptions...]
```

227.2. MONGODB OPTIONS

The MongoDB component has no options.

The MongoDB endpoint is configured using URI syntax:

```
mongodb:connectionBean
```

with the following path and query parameters:

227.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
connectionBean	Required Name of com.mongodb.Mongo to use.		String

227.2.2. Query Parameters (23 parameters):

Name	Description	Default	Type
collection (common)	Sets the name of the MongoDB collection to bind to this endpoint		String
collectionIndex (common)	Sets the collection index (JSON FORMAT : field1 : order1, field2 : order2)		String
createCollection (common)	Create collection during initialisation if it doesn't exist. Default is true.	true	boolean
database (common)	Sets the name of the MongoDB database to target		String
operation (common)	Sets the operation this endpoint will execute against MongoDB. For possible values, see MongoDBOperation.		MongoDbOperation
outputType (common)	Convert the output of the producer to the selected type : DBObjectList DBObject or DBCursor. DBObjectList or DBCursor applies to findAll and aggregate. DBObject applies to all other operations.		MongoDbOutputType
writeConcern (common)	Set the WriteConcern for write operations on MongoDB using the standard ones. Resolved from the fields of the WriteConcern class by calling the WriteConcern#valueOf(String) method.	ACKNOWLEDGED	WriteConcern
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean

Name	Description	Default	Type
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
cursorRegenerationDelay (advanced)	MongoDB tailable cursors will block until new data arrives. If no new data is inserted, after some time the cursor will be automatically freed and closed by the MongoDB server. The client is expected to regenerate the cursor if needed. This value specifies the time to wait before attempting to fetch a new cursor, and if the attempt fails, how long before the next attempt is made. Default value is 1000ms.	1000	long
dynamicity (advanced)	Sets whether this endpoint will attempt to dynamically resolve the target database and collection from the incoming Exchange properties. Can be used to override at runtime the database and collection specified on the otherwise static endpoint URI. It is disabled by default to boost performance. Enabling it will take a minimal performance hit.	false	boolean
readPreference (advanced)	Sets a MongoDB ReadPreference on the Mongo connection. Read preferences set directly on the connection will be overridden by this setting. The ReadPreference#valueOf(String) utility method is used to resolve the passed readPreference value. Some examples for the possible values are nearest, primary or secondary etc.		ReadPreference
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
writeResultAsHeader (advanced)	In write operations, it determines whether instead of returning WriteResult as the body of the OUT message, we transfer the IN message to the OUT and attach the WriteResult as a header.	false	boolean
persistentId (tail)	One tail tracking collection can host many trackers for several tailable consumers. To keep them separate, each tracker should have its own unique persistentId.		String

Name	Description	Default	Type
persistentTailTracking (tail)	Enable persistent tail tracking, which is a mechanism to keep track of the last consumed message across system restarts. The next time the system is up, the endpoint will recover the cursor from the point where it last stopped slurping records.	false	boolean
persistRecords (tail)	Sets the number of tailed records after which the tail tracking data is persisted to MongoDB.	-1	int
tailTrackCollection (tail)	Collection where tail tracking information will be persisted. If not specified, <code>MongoDbTailTrackingConfig#DEFAULT_COLLECTION</code> will be used by default.		String
tailTrackDb (tail)	Indicates what database the tail tracking mechanism will persist to. If not specified, the current database will be picked by default. Dynamicity will not be taken into account even if enabled, i.e. the tail tracking database will not vary past endpoint initialisation.		String
tailTrackField (tail)	Field where the last tracked value will be placed. If not specified, <code>MongoDbTailTrackingConfig#DEFAULT_FIELD</code> will be used by default.		String
tailTrackIncreasingField (tail)	Correlation field in the incoming record which is of increasing nature and will be used to position the tailing cursor every time it is generated. The cursor will be (re)created with a query of type: <code>tailTrackIncreasingField lastValue</code> (possibly recovered from persistent tail tracking). Can be of type Integer, Date, String, etc. NOTE: No support for dot notation at the current time, so the field should be at the top level of the document.		String
tailTrackingStrategy (tail)	Sets the strategy used to extract the increasing field value and to create the query to position the tail cursor.	LITERAL	MongoDBTailTracking Enum

227.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.mongodb.enabled</code>	Enable mongodb component	true	Boolean
<code>camel.component.mongodb.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

227.4. CONFIGURATION OF DATABASE IN SPRING XML

The following Spring XML creates a bean defining the connection to a MongoDB instance.

```
<?xml version="1.0" encoding="UTF-8"?>
<beans xmlns="http://www.springframework.org/schema/beans"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://www.springframework.org/schema/beans
http://www.springframework.org/schema/beans/spring-beans.xsd">
  <bean id="mongoBean" class="com.mongodb.Mongo">
    <constructor-arg name="host" value="{mongodb.host}" />
    <constructor-arg name="port" value="{mongodb.port}" />
  </bean>
</beans>
```

227.5. SAMPLE ROUTE

The following route defined in Spring XML executes the operation `dbStats` on a collection.

Get DB stats for specified collection

```
<route>
  <from uri="direct:start" />
  <!-- using bean 'mongoBean' defined above -->
  <to uri="mongodb:mongoBean?
database={mongodb.database}&collection={mongodb.collection}&operation=getDbStats"
/>
  <to uri="direct:result" />
</route>
```

227.6. MONGODB OPERATIONS - PRODUCER ENDPOINTS

227.6.1. Query operations

227.6.1.1. findById

This operation retrieves only one element from the collection whose `_id` field matches the content of the IN message body. The incoming object can be anything that has an equivalent to a BSON type. See <http://bsonspec.org//specification> and <http://www.mongodb.org/display/DOCS/Java+Types>.

```
from("direct:findById")
  .to("mongodb:myDb?database=flights&collection=tickets&operation=findById")
  .to("mock:resultFindById");
```

TIP

Supports optional parameters. This operation supports specifying a fields filter. See [Specifying optional parameters](#).

227.6.1.2. findOneByQuery

Use this operation to retrieve just one element from the collection that matches a MongoDB query. **The query object is extracted from the IN message body**, i.e. it should be of type **DBObject** or convertible to **DBObject**. It can be a JSON String or a Hashmap. See [#Type conversions](#) for more info.

Example with no query (returns any object of the collection):

```
from("direct:findOneByQuery")
  .to("mongodb:myDb?database=flights&collection=tickets&operation=findOneByQuery")
  .to("mock:resultFindOneByQuery");
```

Example with a query (returns one matching result):

```
from("direct:findOneByQuery")
  .setBody().constant("{ \"name\": \"Raul Kripalani\" }")
  .to("mongodb:myDb?database=flights&collection=tickets&operation=findOneByQuery")
  .to("mock:resultFindOneByQuery");
```

TIP

Supports optional parameters. This operation supports specifying a fields filter and/or a sort clause. See [Specifying optional parameters](#).

227.6.1.3. findAll

The **findAll** operation returns all documents matching a query, or none at all, in which case all documents contained in the collection are returned. **The query object is extracted from the IN message body**, i.e. it should be of type **DBObject** or convertible to **DBObject**. It can be a JSON String or a Hashmap. See [#Type conversions](#) for more info.

Example with no query (returns all object in the collection):

```
from("direct:findAll")
  .to("mongodb:myDb?database=flights&collection=tickets&operation=findAll")
  .to("mock:resultFindAll");
```

Example with a query (returns all matching results):

```

from("direct:findAll")
  .setBody().constant("{ \"name\": \"Raul Kripalani\" }")
  .to("mongodb:myDb?database=flights&collection=tickets&operation=findAll")
  .to("mock:resultFindAll");

```

Paging and efficient retrieval is supported via the following headers:

Header key	Quick constant	Description (extracted from MongoDB API doc)	Expected type
Camel MongoDBNumToSkip	MongoDbConstants.NUM_SKIP	Discards a given number of elements at the beginning of the cursor.	int/Integer
Camel MongoDBLimit	MongoDbConstants.LIMIT	Limits the number of elements returned.	int/Integer
Camel MongoDBBatchSize	MongoDbConstants.BATCH_SIZE	Limits the number of elements returned in one batch. A cursor typically fetches a batch	int/Integer

Header key	Quick constant	Description (extracted from MongoDB API doc)	Expected type
		<p>batchSize is positive, it represents the size of each batch of objects retrieved. It can be adjusted to optimize performance and limit data transfer. If batchSize is negative, it will limit of number objects returned, that fit within the max batch size limit (usually 4MB), and cursor will be closed. For</p>	

Header key	Quick constant	Description (extracted from MongoDB API doc)	Expected type
		<p>return a maximum of 10 documents and as many as can fit in 4MB, then close the cursor. Note that this feature is different from <code>limit()</code> in that documents must fit within a maximum size, and it removes the need to send a request to close the cursor server-side. The batch size can be change</p>	

Header key	Quick constant	Description (extracted from MongoDB API doc)	Expected type
		setting will apply on the next batch retrieval.	

You can also "stream" the documents returned from the server into your route by including `outputType=DBCursor` (Camel 2.16+) as an endpoint option which may prove simpler than setting the above headers. This hands your Exchange the `DBCursor` from the Mongo driver, just as if you were executing the `findAll()` within the Mongo shell, allowing your route to iterate over the results. By default and without this option, this component will load the documents from the driver's cursor into a List and return this to your route - which may result in a large number of in-memory objects. Remember, with a `DBCursor` do not ask for the number of documents matched - see the MongoDB documentation site for details.

Example with option `outputType=DBCursor` and batch size :

```
from("direct:findAll")
  .setHeader(MongoDbConstants.BATCH_SIZE).constant(10)
  .setBody().constant("{\"name\": \"Raul Kripalani\"}")
  .to("mongodb:myDb?
database=flights&collection=tickets&operation=findAll&outputType=DBCursor")
  .to("mock:resultFindAll");
```

The **findAll** operation will also return the following OUT headers to enable you to iterate through result pages if you are using paging:

Header key	Quick constant	Description (extracted from MongoDB API doc)	Data type
Camel MongoDB ResultTotalSize	MongoDbConstants.RESULT_TOTAL_SIZE	Number of objects matching the query. This does not take limit/skip into consideration.	int/Integer
Camel MongoDB ResultPageSize	MongoDbConstants.RESULT_PAGE_SIZE	Number of objects matching the query. This does not take limit/skip into consideration.	int/Integer

TIP

Supports optional parameters. This operation supports specifying a fields filter and/or a sort clause. See [Specifying optional parameters](#).

227.6.1.4. count

Returns the total number of objects in a collection, returning a Long as the OUT message body. The following example will count the number of records in the "dynamicCollectionName" collection. Notice how dynamicity is enabled, and as a result, the operation will not run against the "notableScientists" collection, but against the "dynamicCollectionName" collection.

```
// from("direct:count").to("mongodb:myDb?
database=tickets&collection=flights&operation=count&dynamicity=true");
```

```
Long result = template.requestBodyAndHeader("direct:count", "irrelevantBody",
MongoDbConstants.COLLECTION, "dynamicCollectionName");
assertTrue("Result is not of type Long", result instanceof Long);
```

From **Camel 2.14** onwards you can provide a **com.mongodb.DBObject** object in the message body as a query, and operation will return the amount of documents matching this criteria.

```
DBObject query = ...
Long count = template.requestBodyAndHeader("direct:count", query,
MongoDbConstants.COLLECTION, "dynamicCollectionName");
```

227.6.1.5. Specifying a fields filter (projection)

Query operations will, by default, return the matching objects in their entirety (with all their fields). If your documents are large and you only require retrieving a subset of their fields, you can specify a field filter in all query operations, simply by setting the relevant **DBObject** (or type convertible to **DBObject**, such as a JSON String, Map, etc.) on the **CamelMongoDbFieldsFilter** header, constant shortcut:

MongoDbConstants.FIELDS_FILTER.

Here is an example that uses MongoDB's BasicDBObjectBuilder to simplify the creation of DBObjects. It retrieves all fields except **_id** and **boringField**:

```
// route: from("direct:findAll").to("mongodb:myDb?
database=flights&collection=tickets&operation=findAll")
DBObject fieldFilter = BasicDBObjectBuilder.start().add("_id", 0).add("boringField", 0).get();
Object result = template.requestBodyAndHeader("direct:findAll", (Object) null,
MongoDbConstants.FIELDS_FILTER, fieldFilter);
```

227.6.1.6. Specifying a sort clause

There is often a requirement to fetch the min/max record from a collection based on sorting by a particular field. In Mongo the operation is performed using syntax similar to:

```
db.collection.find().sort({_id: -1}).limit(1)
// or
db.collection.findOne({$query:{},$orderby:{_id:-1}}
```

In a Camel route the **SORT_BY** header can be used with the **findOneByQuery** operation to achieve the same result. If the **FIELDS_FILTER** header is also specified the operation will return a single field/value pair that can be passed directly to another component (for example, a parameterized MyBatis SELECT query). This example demonstrates fetching the temporally newest document from a collection and reducing the result to a single field, based on the **documentTimestamp** field:

```
.from("direct:someTriggeringEvent")
.setHeader(MongoDbConstants.SORT_BY).constant("{\"documentTimestamp\": -1}")
.setHeader(MongoDbConstants.FIELDS_FILTER).constant("{\"documentTimestamp\": 1}")
.setBody().constant("{}")
.to("mongodb:myDb?database=local&collection=myDemoCollection&operation=findOneByQuery")
.to("direct:aMyBatisParameterizedSelect")
;
```

227.6.2. Create/update operations

227.6.2.1. insert

Inserts a new object into the MongoDB collection, taken from the IN message body. Type conversion is attempted to turn it into **DBObject** or a **List**.

Two modes are supported: single insert and multiple insert. For multiple insert, the endpoint will expect a List, Array or Collections of objects of any type, as long as they are – or can be converted to – **DBObject**. All objects are inserted at once. The endpoint will intelligently decide which backend operation to invoke (single or multiple insert) depending on the input.

Example:

```
from("direct:insert")
  .to("mongodb:myDb?database=flights&collection=tickets&operation=insert");
```

The operation will return a **WriteResult**, and depending on the **WriteConcern** or the value of the **invokeGetLastError** option, **getLastError()** would have been called already or not. If you want to access the ultimate result of the write operation, you need to retrieve the **CommandResult** by calling **getLastError()** or **getCachedLastError()** on the **WriteResult**. Then you can verify the result by calling **CommandResult.ok()**, **CommandResult.getErrorMessage()** and/or **CommandResult.getException()**.

Note that the new object's **_id** must be unique in the collection. If you don't specify the value, MongoDB will automatically generate one for you. But if you do specify it and it is not unique, the insert operation will fail (and for Camel to notice, you will need to enable **invokeGetLastError** or set a **WriteConcern** that waits for the write result).

This is not a limitation of the component, but it is how things work in MongoDB for higher throughput. If you are using a custom **_id**, you are expected to ensure at the application level that it is unique (and this is a good practice too).

Since Camel 2.15: **OID(s)** of the inserted record(s) is stored in the message header under **CamelMongoOid** key (**MongoDbConstants.OID** constant). The value stored is **org.bson.types.ObjectId** for single insert or **java.util.List<org.bson.types.ObjectId>** if multiple records have been inserted.

227.6.2.2. save

The save operation is equivalent to an *upsert* (UPdate, inSERT) operation, where the record will be updated, and if it doesn't exist, it will be inserted, all in one atomic operation. MongoDB will perform the matching based on the **_id** field.

Beware that in case of an update, the object is replaced entirely and the usage of MongoDB's **\$modifiers** is not permitted. Therefore, if you want to manipulate the object if it already exists, you have two options:

1. perform a query to retrieve the entire object first along with all its fields (may not be efficient), alter it inside Camel and then save it.
2. use the update operation with **\$modifiers**, which will execute the update at the server-side instead. You can enable the upsert flag, in which case if an insert is required, MongoDB will apply the **\$modifiers** to the filter query object and insert the result.

For example:

■

```
from("direct:insert")
  .to("mongodb:myDb?database=flights&collection=tickets&operation=save");
```

227.6.2.3. update

Update one or multiple records on the collection. Requires a List<DBObject> as the IN message body containing exactly 2 elements:

- Element 1 (index 0) ⇒ filter query ⇒ determines what objects will be affected, same as a typical query object
- Element 2 (index 1) ⇒ update rules ⇒ how matched objects will be updated. All [modifier operations](#) from MongoDB are supported.

NOTE

Multiupdates. By default, MongoDB will only update 1 object even if multiple objects match the filter query. To instruct MongoDB to update **all** matching records, set the **CamelMongoDbMultiUpdate** IN message header to **true**.

A header with key **CamelMongoDbRecordsAffected** will be returned (**MongoDbConstants.RECORDS_AFFECTED** constant) with the number of records updated (copied from **WriteResult.getN()**).

Supports the following IN message headers:

Header key	Quick constant	Description (extracted from MongoDB API doc)	Expected type
CamelMongoDbMultiUpdate	MongoDbConstants.MULTIUPDATE	If the update should be applied to all objects matching. See http://www.mongodb.org/display/DOCS/Atomic+Operations	boolean/Boolean

Header key	Quick constant	Description (extracted from MongoDB API doc)	Expected type
CamelMongoDbUpsert	MongoDbConstants.UPSERT	If the database should create the element if it does not exist	boolean/Boolean

For example, the following will update **all** records whose `filterField` field equals `true` by setting the value of the `"scientist"` field to `"Darwin"`:

```
// route: from("direct:update").to("mongodb:myDb?
database=science&collection=notableScientists&operation=update");
DBObject filterField = new BasicDBObject("filterField", true);
DBObject updateObj = new BasicDBObject("$set", new BasicDBObject("scientist", "Darwin"));
Object result = template.requestBodyAndHeader("direct:update", new Object[] {filterField, updateObj},
MongoDbConstants.MULTIUPDATE, true);
```

227.6.3. Delete operations

227.6.3.1. remove

Remove matching records from the collection. The IN message body will act as the removal filter query, and is expected to be of type **DBObject** or a type convertible to it.

The following example will remove all objects whose field `'conditionField'` equals `true`, in the `science` database, `notableScientists` collection:

```
// route: from("direct:remove").to("mongodb:myDb?
database=science&collection=notableScientists&operation=remove");
DBObject conditionField = new BasicDBObject("conditionField", true);
Object result = template.requestBody("direct:remove", conditionField);
```

A header with key **CamelMongoDbRecordsAffected** is returned (**MongoDbConstants.RECORDS_AFFECTED** constant) with type **int**, containing the number of records deleted (copied from **WriteResult.getN()**).

227.6.4. Bulk Write Operations

227.6.4.1. bulkWrite

Available as of Camel 2.21

Performs write operations in bulk with controls for order of execution. Requires a **List<WriteModel<DBObject>>** as the IN message body containing commands for insert, update, and delete operations.

The following example will insert a new scientist "Pierre Curie", update record with id "5" by setting the value of the "scientist" field to "Marie Curie" and delete record with id "3" :

```
// route: from("direct:bulkWrite").to("mongodb:myDb?
database=science&collection=notableScientists&operation=bulkWrite");
List<WriteModel<DBObject>> bulkOperations = Arrays.asList(
    new InsertOneModel<>(new BasicDBObject("scientist", "Pierre Curie")),
    new UpdateOneModel<>(new BasicDBObject("_id", "5"),
        new BasicDBObject("$set", new BasicDBObject("scientist", "Marie Curie"))),
    new DeleteOneModel<>(new BasicDBObject("_id", "3")));

BulkWriteResult result = template.requestBody("direct:bulkWrite", bulkOperations,
BulkWriteResult.class);
```

By default, operations are executed in order and interrupted on the first write error without processing any remaining write operations in the list. To instruct MongoDB to continue to process remaining write operations in the list, set the **CamelMongoDbBulkOrdered** IN message header to **false**. Unordered operations are executed in parallel and this behavior is not guaranteed.

Header key	Quick constant	Description (extracted from MongoDB API doc)	Expected type
CamelMongoDbBulkOrdered	MongoDbConstants.BULK_ORDERED	Perform an ordered or unordered operation execution. Defaults to true.	boolean/Boolean

227.6.5. Other operations

227.6.5.1. aggregate

Available as of Camel 2.14

Perform a aggregation with the given pipeline contained in the body. **Aggregations could be long and heavy operations. Use with care.**

```
// route: from("direct:aggregate").to("mongodb:myDb?
database=science&collection=notableScientists&operation=aggregate");
from("direct:aggregate")
  .setBody().constant("[{ $match : { $or : [ { \"scientist\" : \"Darwin\" }, { \"scientist\" : \"Einstein\" } ] }, {
$group: { _id: \" $scientist\", count: { $sum: 1 } } } ]")
  .to("mongodb:myDb?database=science&collection=notableScientists&operation=aggregate")
  .to("mock:resultAggregate");
```

Supports the following IN message headers:

Header key	Quick constant	Description (extracted from MongoDB API doc)	Expected type
CamelMongoDbBatchSize	MongoDbConstants.BATCH_SIZE	Sets the number of documents to return per batch.	int/Integer
CamelMongoDbAllowDiskUse	MongoDbConstants.ALLOW_DISK_USE	Enable aggregation pipeline stages to write data to temporary files.	boolean/Boolean

Efficient retrieval is supported via `outputType=DBCursor`.

You can also "stream" the documents returned from the server into your route by including `outputType=DBCursor` (Camel 2.21+) as an endpoint option which may prove simpler than setting the above headers. This hands your Exchange the `DBCursor` from the Mongo driver, just as if you were executing the `aggregate()` within the Mongo shell, allowing your route to iterate over the results. By default and without this option, this component will load the documents from the driver's cursor into a

List and return this to your route - which may result in a large number of in-memory objects. Remember, with a `DBCursor` do not ask for the number of documents matched - see the MongoDB documentation site for details.

Example with option `outputType=DBCursor` and batch size:

```
// route: from("direct:aggregate").to("mongodb:myDb?
database=science&collection=notableScientists&operation=aggregate");
from("direct:aggregate")
  .setHeader(MongoDbConstants.BATCH_SIZE).constant(10)
  .setBody().constant("[{ $match : { $or : [{ \"scientist\" : \"Darwin\" }, { \"scientist\" : \"Einstein\" } ] }, {
$group: { _id: \"${scientist}\", count: { $sum: 1 } } } ]")
  .to("mongodb:myDb?
database=science&collection=notableScientists&operation=aggregate&outputType=DBCursor")
  .to("mock:resultAggregate");
```

227.6.5.2. `getDbStats`

Equivalent of running the `db.stats()` command in the MongoDB shell, which displays useful statistic figures about the database.

For example:

```
> db.stats();
{
  "db" : "test",
  "collections" : 7,
  "objects" : 719,
  "avgObjSize" : 59.73296244784423,
  "dataSize" : 42948,
  "storageSize" : 1000058880,
  "numExtents" : 9,
  "indexes" : 4,
  "indexSize" : 32704,
  "fileSize" : 1275068416,
  "nsSizeMB" : 16,
  "ok" : 1
}
```

Usage example:

```
// from("direct:getDbStats").to("mongodb:myDb?
database=flights&collection=tickets&operation=getDbStats");
Object result = template.requestBody("direct:getDbStats", "irrelevantBody");
assertTrue("Result is not of type DBObject", result instanceof DBObject);
```

The operation will return a data structure similar to the one displayed in the shell, in the form of a **DBObject** in the OUT message body.

227.6.5.3. `getColStats`

Equivalent of running the `db.collection.stats()` command in the MongoDB shell, which displays useful statistic figures about the collection.

For example:

```
> db.camelTest.stats();
{
  "ns" : "test.camelTest",
  "count" : 100,
  "size" : 5792,
  "avgObjSize" : 57.92,
  "storageSize" : 20480,
  "numExtents" : 2,
  "nindexes" : 1,
  "lastExtentSize" : 16384,
  "paddingFactor" : 1,
  "flags" : 1,
  "totalIndexSize" : 8176,
  "indexSizes" : {
    "_id_" : 8176
  },
  "ok" : 1
}
```

Usage example:

```
// from("direct:getColStats").to("mongodb:myDb?
database=flights&collection=tickets&operation=getColStats");
Object result = template.requestBody("direct:getColStats", "irrelevantBody");
assertTrue("Result is not of type DBObject", result instanceof DBObject);
```

The operation will return a data structure similar to the one displayed in the shell, in the form of a **DBObject** in the OUT message body.

227.6.5.4. command

Available as of Camel 2.15

Run the body as a command on database. Usefull for admin operation as getting host informations, replication or sharding status.

Collection parameter is not use for this operation.

```
// route: from("command").to("mongodb:myDb?database=science&operation=command");
DBObject commandBody = new BasicDBObject("hostInfo", "1");
Object result = template.requestBody("direct:command", commandBody);
```

227.6.6. Dynamic operations

An Exchange can override the endpoint's fixed operation by setting the **CamelMongoDbOperation** header, defined by the **MongoDbConstants.OPERATION_HEADER** constant.

The values supported are determined by the **MongoDbOperation** enumeration and match the accepted values for the **operation** parameter on the endpoint URI.

For example:

```
// from("direct:insert").to("mongodb:myDb?database=flights&collection=tickets&operation=insert");
Object result = template.requestBodyAndHeader("direct:insert", "irrelevantBody",
MongoDbConstants.OPERATION_HEADER, "count");
```

```
assertTrue("Result is not of type Long", result instanceof Long);
```

227.7. TAILABLE CURSOR CONSUMER

MongoDB offers a mechanism to instantaneously consume ongoing data from a collection, by keeping the cursor open just like the **tail -f** command of *nix systems. This mechanism is significantly more efficient than a scheduled poll, due to the fact that the server pushes new data to the client as it becomes available, rather than making the client ping back at scheduled intervals to fetch new data. It also reduces otherwise redundant network traffic.

There is only one requisite to use tailable cursors: the collection must be a "capped collection", meaning that it will only hold N objects, and when the limit is reached, MongoDB flushes old objects in the same order they were originally inserted. For more information, please refer to:

<http://www.mongodb.org/display/DOCS/Tailable+Cursors>.

The Camel MongoDB component implements a tailable cursor consumer, making this feature available for you to use in your Camel routes. As new objects are inserted, MongoDB will push them as `DBObject`s in natural order to your tailable cursor consumer, who will transform them to an Exchange and will trigger your route logic.

227.8. HOW THE TAILABLE CURSOR CONSUMER WORKS

To turn a cursor into a tailable cursor, a few special flags are to be signalled to MongoDB when first generating the cursor. Once created, the cursor will then stay open and will block upon calling the **`DBCursor.next()`** method until new data arrives. However, the MongoDB server reserves itself the right to kill your cursor if new data doesn't appear after an indeterminate period. If you are interested to continue consuming new data, you have to regenerate the cursor. And to do so, you will have to remember the position where you left off or else you will start consuming from the top again.

The Camel MongoDB tailable cursor consumer takes care of all these tasks for you. You will just need to provide the key to some field in your data of increasing nature, which will act as a marker to position your cursor every time it is regenerated, e.g. a timestamp, a sequential ID, etc. It can be of any datatype supported by MongoDB. Date, Strings and Integers are found to work well. We call this mechanism "tail tracking" in the context of this component.

The consumer will remember the last value of this field and whenever the cursor is to be regenerated, it will run the query with a filter like: **`increasingField > lastValue`**, so that only unread data is consumed.

Setting the increasing field: Set the key of the increasing field on the endpoint URI **`tailTrackingIncreasingField`** option. In Camel 2.10, it must be a top-level field in your data, as nested navigation for this field is not yet supported. That is, the "timestamp" field is okay, but "nested.timestamp" will not work. Please open a ticket in the Camel JIRA if you do require support for nested increasing fields.

Cursor regeneration delay: One thing to note is that if new data is not already available upon initialisation, MongoDB will kill the cursor instantly. Since we don't want to overwhelm the server in this case, a **`cursorRegenerationDelay`** option has been introduced (with a default value of 1000ms.), which you can modify to suit your needs.

An example:

```
from("mongodb:myDb?
database=flights&collection=cancellations&tailTrackIncreasingField=departureTime")
.id("tailableCursorConsumer1")
```

```
.autoStartup(false)
.to("mock:test");
```

The above route will consume from the "flights.cancellations" capped collection, using "departureTime" as the increasing field, with a default regeneration cursor delay of 1000ms.

227.9. PERSISTENT TAIL TRACKING

Standard tail tracking is volatile and the last value is only kept in memory. However, in practice you will need to restart your Camel container every now and then, but your last value would then be lost and your tailable cursor consumer would start consuming from the top again, very likely sending duplicate records into your route.

To overcome this situation, you can enable the **persistent tail tracking** feature to keep track of the last consumed increasing value in a special collection inside your MongoDB database too. When the consumer initialises again, it will restore the last tracked value and continue as if nothing happened.

The last read value is persisted on two occasions: every time the cursor is regenerated and when the consumer shuts down. We may consider persisting at regular intervals too in the future (flush every 5 seconds) for added robustness if the demand is there. To request this feature, please open a ticket in the Camel JIRA.

227.10. ENABLING PERSISTENT TAIL TRACKING

To enable this function, set at least the following options on the endpoint URI:

- **persistentTailTracking** option to **true**
- **persistentId** option to a unique identifier for this consumer, so that the same collection can be reused across many consumers

Additionally, you can set the **tailTrackDb**, **tailTrackCollection** and **tailTrackField** options to customise where the runtime information will be stored. Refer to the endpoint options table at the top of this page for descriptions of each option.

For example, the following route will consume from the "flights.cancellations" capped collection, using "departureTime" as the increasing field, with a default regeneration cursor delay of 1000ms, with persistent tail tracking turned on, and persisting under the "cancellationsTracker" id on the "flights.camelTailTracking", storing the last processed value under the "lastTrackingValue" field (**camelTailTracking** and **lastTrackingValue** are defaults).

```
from("mongodb:myDb?
database=flights&collection=cancellations&tailTrackIncreasingField=departureTime&persistentTailTrack
ng=true" +
"&persistentId=cancellationsTracker")
.id("tailableCursorConsumer2")
.autoStartup(false)
.to("mock:test");
```

Below is another example identical to the one above, but where the persistent tail tracking runtime information will be stored under the "trackers.camelTrackers" collection, in the "lastProcessedDepartureTime" field:

```
from("mongodb:myDb?
database=flights&collection=cancellations&tailTrackIncreasingField=departureTime&persistentTailTrack
```

```

ng=true" +
"&persistentId=cancellationsTracker&tailTrackDb=trackers&tailTrackCollection=camelTrackers" +
"&tailTrackField=lastProcessedDepartureTime")
.id("tailableCursorConsumer3")
.autoStartup(false)
.to("mock:test");

```

227.11. OPLOG TAIL TRACKING

The **oplog** collection tracking feature allows to implement trigger like functionality in MongoDB. In order to activate this collection you will have first to activate a replica set. For more information on this topic please check <https://docs.mongodb.com/manual/tutorial/deploy-replica-set/>.

Below you can find an example of a Java DSL based route demonstrating how you can use the component to track the **oplog** collection. In this specific case we are filtering the events which affect a collection **customers** in database **optlog_test**. Note that the **tailTrackIncreasingField** is a timestamp field ('ts') which implies that you have to use the **tailTrackingStrategy** parameter with the **TIMESTAMP** value.

```

import com.mongodb.BasicDBObject;
import com.mongodb.MongoClient;
import org.apache.camel.Exchange;
import org.apache.camel.Message;
import org.apache.camel.Processor;
import org.apache.camel.builder.RouteBuilder;
import org.apache.camel.component.mongodb.MongoDBTailTrackingEnum;
import org.apache.camel.main.Main;

import java.io.InputStream;

/**
 * For this to work you need to turn on the replica set
 * <p>
 * Commands to create a replica set:
 * <p>
 * rs.initiate( {
 *   _id : "rs0",
 *   members: [ { _id : 0, host : "localhost:27017" } ]
 * })
 */
public class MongoDbTracker {

    private final String database;

    private final String collection;

    private final String increasingField;

    private MongoDBTailTrackingEnum trackingStrategy;

    private int persistRecords = -1;

    private boolean persistenTailTracking;

    public MongoDbTracker(String database, String collection, String increasingField) {

```

```

    this.database = database;
    this.collection = collection;
    this.increasingField = increasingField;
}

public static void main(String[] args) throws Exception {
    final MongoDBTracker mongoDbTracker = new MongoDBTracker("local", "oplog.rs", "ts");
    mongoDbTracker.setTrackingStrategy(MongoDBTailTrackingEnum.TIMESTAMP);
    mongoDbTracker.setPersistRecords(5);
    mongoDbTracker.setPersistenTailTracking(true);
    mongoDbTracker.startRouter();
    // run until you terminate the JVM
    System.out.println("Starting Camel. Use ctrl + c to terminate the JVM.\n");
}

public void setTrackingStrategy(MongoDBTailTrackingEnum trackingStrategy) {
    this.trackingStrategy = trackingStrategy;
}

public void setPersistRecords(int persistRecords) {
    this.persistRecords = persistRecords;
}

public void setPersistenTailTracking(boolean persistenTailTracking) {
    this.persistenTailTracking = persistenTailTracking;
}

void startRouter() throws Exception {
    // create a Main instance
    Main main = new Main();
    main.bind(MongoConstants.CONN_NAME, new MongoClient("localhost", 27017));
    main.addRouteBuilder(new RouteBuilder() {
        @Override
        public void configure() throws Exception {
            getContext().getTypeConverterRegistry().addTypeConverter(InputStream.class,
BasicDBObject.class,
                new MongoToInputStreamConverter());
            from("mongodb://" + MongoConstants.CONN_NAME + "?database=" + database
                + "&collection=" + collection
                + "&persistentTailTracking=" + persistenTailTracking
                + "&persistentId=trackerName" + "&tailTrackDb=local"
                + "&tailTrackCollection=talendTailTracking"
                + "&tailTrackField=lastTrackingValue"
                + "&tailTrackIncreasingField=" + increasingField
                + "&tailTrackingStrategy=" + trackingStrategy.toString()
                + "&persistRecords=" + persistRecords
                + "&cursorRegenerationDelay=1000")
                .filter().jsonpath("$[?(@.ns=='optlog_test.customers')]")
                .id("logger")
                .to("log:logger?level=WARN")
                .process(new Processor() {
                    public void process(Exchange exchange) throws Exception {
                        Message message = exchange.getIn();
                        System.out.println(message.getBody().toString());
                        exchange.getOut().setBody(message.getBody().toString());
                    }
                });
        }
    });
}

```

```

    }
    });
  }
  main.run();
}
}

```

227.12. TYPE CONVERSIONS

The **MongoDbBasicConverters** type converter included with the camel-mongodb component provides the following conversions:

Name	From type	To type	How?
fromMapToDBObject	Map	DBObject	constructs a new BasicDBObject via the new BasicDBObject(Map m) constructor
fromBasicDBObjectToMap	BasicDBObject	Map	BasicDBObject already implements Map
fromStringToDBObject	String	DBObject	uses com.mongodb.util.JSON.parse(String s)
fromAnyObjectToDBObject	Object	DBObject	uses the Jackson library to convert the object to a Map , which is in turn used to initialise a new BasicDBObject

This type converter is auto-discovered, so you don't need to configure anything manually.

CHAPTER 228. MONGODB GRIDFS COMPONENT

Available as of Camel version 2.18

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-mongodb-gridfs</artifactId>
  <version>x.y.z</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

228.1. URI FORMAT

```
mongodb-gridfs:connectionBean?database=databaseName&bucket=bucketName[&moreOptions...]
```

228.2. MONGODB GRIDFS OPTIONS

The MongoDB GridFS component has no options.

The MongoDB GridFS endpoint is configured using URI syntax:

```
mongodb-gridfs:connectionBean
```

with the following path and query parameters:

228.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
<code>connectionBean</code>	Required Name of com.mongodb.Mongo to use.		String

228.2.2. Query Parameters (17 parameters):

Name	Description	Default	Type
<code>bucket</code> (common)	Sets the name of the GridFS bucket within the database. Default is fs.	fs	String
<code>database</code> (common)	Required Sets the name of the MongoDB database to target		String

Name	Description	Default	Type
readPreference (common)	Sets a MongoDB ReadPreference on the Mongo connection. Read preferences set directly on the connection will be overridden by this setting. The <code>com.mongodb.ReadPreference#valueOf(String)</code> utility method is used to resolve the passed <code>readPreference</code> value. Some examples for the possible values are <code>nearest</code> , <code>primary</code> or <code>secondary</code> etc.		ReadPreference
writeConcern (common)	Set the WriteConcern for write operations on MongoDB using the standard ones. Resolved from the fields of the WriteConcern class by calling the <code>WriteConcern#valueOf(String)</code> method.		WriteConcern
writeConcernRef (common)	Set the WriteConcern for write operations on MongoDB, passing in the bean ref to a custom WriteConcern which exists in the Registry. You can also use standard WriteConcerns by passing in their key. See the link <code>#setWriteConcern(String)</code> <code>setWriteConcern</code> method.		WriteConcern
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
delay (consumer)	Sets the delay between polls within the Consumer. Default is 500ms	500	long
fileAttributeName (consumer)	If the QueryType uses a FileAttribute, this sets the name of the attribute that is used. Default is <code>camel-processed</code> .	<code>camel-processed</code>	String
initialDelay (consumer)	Sets the initialDelay before the consumer will start polling. Default is 1000ms	1000	long
persistentTimestampCollection (consumer)	If the QueryType uses a persistent timestamp, this sets the name of the collection within the DB to store the timestamp.	<code>camel-timestamps</code>	String
persistentTimestampObject (consumer)	If the QueryType uses a persistent timestamp, this is the ID of the object in the collection to store the timestamp.	<code>camel-timestamp</code>	String

Name	Description	Default	Type
query (consumer)	Additional query parameters (in JSON) that are used to configure the query used for finding files in the GridFsConsumer		String
queryStrategy (consumer)	Sets the QueryStrategy that is used for polling for new files. Default is Timestamp	Timestamp	QueryStrategy
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
operation (producer)	Sets the operation this endpoint will execute against GridRS.		String
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

228.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.component.mongodb-gridfs.enabled	Enable mongodb-gridfs component	true	Boolean
camel.component.mongodb-gridfs.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

228.4. CONFIGURATION OF DATABASE IN SPRING XML

The following Spring XML creates a bean defining the connection to a MongoDB instance.

■

```
<beans xmlns="http://www.springframework.org/schema/beans"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://www.springframework.org/schema/beans
http://www.springframework.org/schema/beans/spring-beans.xsd">
  <bean id="mongoBean" class="com.mongodb.Mongo">
    <constructor-arg name="host" value="{mongodb.host}" />
    <constructor-arg name="port" value="{mongodb.port}" />
  </bean>
</beans>
```

228.5. SAMPLE ROUTE

The following route defined in Spring XML executes the operation `findOne` on a collection.

Get a file from GridFS

```
<route>
  <from uri="direct:start" />
  <!-- using bean 'mongoBean' defined above -->
  <to uri="mongodb-gridfs:mongoBean?database={mongodb.database}&operation=findOne" />
  <to uri="direct:result" />
</route>
```

228.6. GRIDFS OPERATIONS - PRODUCER ENDPOINT

228.6.1. count

Returns the total number of file in the collection, returning an Integer as the OUT message body.

```
// from("direct:count").to("mongodb-gridfs?database=tickets&operation=count");
Integer result = template.requestBodyAndHeader("direct:count", "irrelevantBody");
assertTrue("Result is not of type Long", result instanceof Integer);
```

You can provide a filename header to provide a count of files matching that filename.

```
Map<String, Object> headers = new HashMap<String, Object>();
headers.put(Exchange.FILE_NAME, "filename.txt");
Integer count = template.requestBodyAndHeaders("direct:count", query, headers);
```

228.6.2. listAll

Returns an Reader that lists all the filenames and their IDs in a tab separated stream.

```
// from("direct:listAll").to("mongodb-gridfs?database=tickets&operation=listAll");
Reader result = template.requestBodyAndHeader("direct:listAll", "irrelevantBody");

filename1.txt 1252314321
filename2.txt 2897651254
```

228.6.3. findOne

Finds a file in the GridFS system and sets the body to an InputStream of the content. Also provides the metadata has headers. It uses Exchange.FILE_NAME from the incoming headers to determine the file to find.

```
// from("direct:findOne").to("mongodb-gridfs?database=tickets&operation=findOne");
Map<String, Object> headers = new HashMap<String, Object>();
headers.put(Exchange.FILE_NAME, "filename.txt");
InputStream result = template.requestBodyAndHeaders("direct:findOne", "irrelevantBody", headers);
```

228.6.4. create

Creates a new file in the GridFs database. It uses the Exchange.FILE_NAME from the incoming headers for the name and the body contents (as an InputStream) as the content.

```
// from("direct:create").to("mongodb-gridfs?database=tickets&operation=create");
Map<String, Object> headers = new HashMap<String, Object>();
headers.put(Exchange.FILE_NAME, "filename.txt");
InputStream stream = ... the data for the file ...
template.requestBodyAndHeaders("direct:create", stream, headers);
```

228.6.5. remove

Removes a file from the GridFS database.

```
// from("direct:remove").to("mongodb-gridfs?database=tickets&operation=remove");
Map<String, Object> headers = new HashMap<String, Object>();
headers.put(Exchange.FILE_NAME, "filename.txt");
template.requestBodyAndHeaders("direct:remove", "", headers);
```

228.7. GRIDFS CONSUMER

CHAPTER 229. MONGODB COMPONENT

Available as of Camel version 2.19

Note: Camel MongoDB3 component Use the Mongo Driver for Java 3.4. If your are looking for previews versions look the Camel MongoDB component

According to Wikipedia: "NoSQL is a movement promoting a loosely defined class of non-relational data stores that break with a long history of relational databases and ACID guarantees." NoSQL solutions have grown in popularity in the last few years, and major extremely-used sites and services such as Facebook, LinkedIn, Twitter, etc. are known to use them extensively to achieve scalability and agility.

Basically, NoSQL solutions differ from traditional RDBMS (Relational Database Management Systems) in that they don't use SQL as their query language and generally don't offer ACID-like transactional behaviour nor relational data. Instead, they are designed around the concept of flexible data structures and schemas (meaning that the traditional concept of a database table with a fixed schema is dropped), extreme scalability on commodity hardware and blazing-fast processing.

MongoDB is a very popular NoSQL solution and the camel-mongodb component integrates Camel with MongoDB allowing you to interact with MongoDB collections both as a producer (performing operations on the collection) and as a consumer (consuming documents from a MongoDB collection).

MongoDB revolves around the concepts of documents (not as is office documents, but rather hierarchical data defined in JSON/BSON) and collections. This component page will assume you are familiar with them. Otherwise, visit <http://www.mongodb.org/>.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-mongodb3</artifactId>
  <version>x.y.z</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

229.1. URI FORMAT

```
mongodb3:connectionBean?
database=databaseName&collection=collectionName&operation=operationName[&moreOptions...]
```

229.2. MONGODB OPTIONS

The MongoDB component has no options.

The MongoDB endpoint is configured using URI syntax:

```
mongodb3:connectionBean
```

with the following path and query parameters:

229.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
connectionBean	Required Name of com.mongodb.Mongo to use.		String

229.2.2. Query Parameters (19 parameters):

Name	Description	Default	Type
collection (common)	Sets the name of the MongoDB collection to bind to this endpoint		String
collectionIndex (common)	Sets the collection index (JSON FORMAT : field1 : order1, field2 : order2)		String
createCollection (common)	Create collection during initialisation if it doesn't exist. Default is true.	true	boolean
database (common)	Sets the name of the MongoDB database to target		String
operation (common)	Sets the operation this endpoint will execute against MongoDB. For possible values, see <code>MongoDbOperation</code> .		<code>MongoDbOperation</code>
outputType (common)	Convert the output of the producer to the selected type : <code>DocumentList</code> <code>Document</code> or <code>Mongolterable</code> . <code>DocumentList</code> or <code>Mongolterable</code> applies to <code>findAll</code> and <code>aggregate</code> . <code>Document</code> applies to all other operations.		<code>MongoDbOutputType</code>
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer)	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		<code>ExceptionHandler</code>
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		<code>ExchangePattern</code>

Name	Description	Default	Type
cursorRegenerationDelay (advanced)	MongoDB tailable cursors will block until new data arrives. If no new data is inserted, after some time the cursor will be automatically freed and closed by the MongoDB server. The client is expected to regenerate the cursor if needed. This value specifies the time to wait before attempting to fetch a new cursor, and if the attempt fails, how long before the next attempt is made. Default value is 1000ms.	1000	long
dynamicity (advanced)	Sets whether this endpoint will attempt to dynamically resolve the target database and collection from the incoming Exchange properties. Can be used to override at runtime the database and collection specified on the otherwise static endpoint URI. It is disabled by default to boost performance. Enabling it will take a minimal performance hit.	false	boolean
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
writeResultAsHeader (advanced)	In write operations, it determines whether instead of returning WriteResult as the body of the OUT message, we transfer the IN message to the OUT and attach the WriteResult as a header.	false	boolean
persistentId (tail)	One tail tracking collection can host many trackers for several tailable consumers. To keep them separate, each tracker should have its own unique persistentId.		String
persistentTailTracking (tail)	Enable persistent tail tracking, which is a mechanism to keep track of the last consumed message across system restarts. The next time the system is up, the endpoint will recover the cursor from the point where it last stopped slurping records.	false	boolean
tailTrackCollection (tail)	Collection where tail tracking information will be persisted. If not specified, <code>MongoDbTailTrackingConfig#DEFAULT_COLLECTION</code> will be used by default.		String

Name	Description	Default	Type
tailTrackDb (tail)	Indicates what database the tail tracking mechanism will persist to. If not specified, the current database will be picked by default. Dynamicity will not be taken into account even if enabled, i.e. the tail tracking database will not vary past endpoint initialisation.		String
tailTrackField (tail)	Field where the last tracked value will be placed. If not specified, <code>MongoDbTailTrackingConfig#DEFAULT_FIELD</code> will be used by default.		String
tailTrackIncreasingField (tail)	Correlation field in the incoming record which is of increasing nature and will be used to position the tailing cursor every time it is generated. The cursor will be (re)created with a query of type: <code>tailTrackIncreasingField lastValue</code> (possibly recovered from persistent tail tracking). Can be of type Integer, Date, String, etc. NOTE: No support for dot notation at the current time, so the field should be at the top level of the document.		String

229.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.component.mongodb3.enabled	Enable mongodb3 component	true	Boolean
camel.component.mongodb3.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

Note on options of MoongODB component

writeConcern Remove in camel 2.19. See Mongo client options [Section 229.4, "Configuration of database in Spring XML"](#). Set the WriteConcern for write operations on MongoDB using the standard ones. Resolved from the fields of the WriteConcern class by calling the link `WriteConcern.valueOf(String)` method.

readPreference Remove in camel 2.19. See Mongo client options [Section 229.4, "Configuration of database in Spring XML"](#). Sets a MongoDB ReadPreference on the Mongo connection. Read preferences set directly on the connection will be overridden by this setting. The link

`com.mongodb.ReadPreferencevalueOf(String)` utility method is used to resolve the passed `readPreference` value. Some examples for the possible values are `nearest` primary or `secondary` etc.

229.4. CONFIGURATION OF DATABASE IN SPRING XML

The following Spring XML creates a bean defining the connection to a MongoDB instance.

Since `mongo java driver 3`, the `WriteConcern` and `readPreference` options are not dynamically modifiable. They are defined in the `mongoClient` object

```
<beans xmlns="http://www.springframework.org/schema/beans"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xmlns:context="http://www.springframework.org/schema/context"
xmlns:mongo="http://www.springframework.org/schema/data/mongo"
xsi:schemaLocation="http://www.springframework.org/schema/context
http://www.springframework.org/schema/context/spring-context.xsd
http://www.springframework.org/schema/data/mongo
http://www.springframework.org/schema/data/mongo/spring-mongo.xsd
http://www.springframework.org/schema/beans
http://www.springframework.org/schema/beans/spring-beans.xsd">

  <mongo:mongo-client id="mongoBean" host="${mongo.url}" port="${mongo.port}"
credentials="${mongo.user}:${mongo.pass}@${mongo.dbname}">
    <mongo:client-options write-concern="NORMAL" />
  </mongo:mongo-client>
</beans>
```

229.5. SAMPLE ROUTE

The following route defined in Spring XML executes the operation `dbStats` on a collection.

Get DB stats for specified collection

```
<route>
  <from uri="direct:start" />
  <!-- using bean 'mongoBean' defined above -->
  <to uri="mongodb3:mongoBean?
database=${mongodb.database}&collection=${mongodb.collection}&operation=getDbStats"
/>
  <to uri="direct:result" />
</route>
```

229.6. MONGODB OPERATIONS - PRODUCER ENDPOINTS

229.6.1. Query operations

229.6.1.1. `findById`

This operation retrieves only one element from the collection whose `_id` field matches the content of the IN message body. The incoming object can be anything that has an equivalent to a **Bson** type. See <http://bsonspec.org//specification> and <http://www.mongodb.org/display/DOCS/Java+Types>.

```
from("direct:findById")
  .to("mongodb3:myDb?database=flights&collection=tickets&operation=findById")
  .to("mock:resultFindById");
```

TIP

Supports optional parameters. This operation supports specifying a fields filter. See [Specifying optional parameters](#).

229.6.1.2. findOneByQuery

Use this operation to retrieve just one element (the first) from the collection that matches a MongoDB query. **The query object is extracted CamelMongoDbCriteria header.** if the CamelMongoDbCriteria header is null the query object is extracted message body, i.e. it should be of type **Bson** or convertible to **Bson**. It can be a JSON String or a Hashmap. See [#Type conversions](#) for more info. you can use the Filters class from MongoDB Driver.

Example with no query (returns any object of the collection):

```
from("direct:findOneByQuery")
  .to("mongodb3:myDb?database=flights&collection=tickets&operation=findOneByQuery")
  .to("mock:resultFindByQuery");
```

Example with a query (returns one matching result):

```
from("direct:findOneByQuery")
  .setHeader(MongoDbConstants.CRITERIA, Filters.eq("name", "Raul Kripalani"))
  .to("mongodb3:myDb?database=flights&collection=tickets&operation=findOneByQuery")
  .to("mock:resultFindByQuery");
```

TIP

Supports optional parameters. This operation supports specifying a fields projection and/or a sort clause. See [Specifying optional parameters](#).

229.6.1.3. findAll

The **findAll** operation returns all documents matching a query, or none at all, in which case all documents contained in the collection are returned. **The query object is extracted CamelMongoDbCriteria header.** if the CamelMongoDbCriteria header is null the query object is extracted message body, i.e. it should be of type **Bson** or convertible to **Bson**. It can be a JSON String or a Hashmap. See [#Type conversions](#) for more info.

Example with no query (returns all object in the collection):

```
from("direct:findAll")
  .to("mongodb3:myDb?database=flights&collection=tickets&operation=findAll")
  .to("mock:resultFindAll");
```

Example with a query (returns all matching results):

```
from("direct:findAll")
  .setHeader(MongoDbConstants.CRITERIA, Filters.eq("name", "Raul Kripalani"))
```

```
.to("mongodb3:myDb?database=flights&collection=tickets&operation=findAll")
.to("mock:resultFindAll");
```

Paging and efficient retrieval is supported via the following headers:

Header key	Quick constant	Description (extracted from MongoDB API doc)	Expected type
CamelMongoDbNumToSkip	MongoDbConstants.NUM_TO_SKIP	Discards a given number of elements at the beginning of the cursor.	int/Integer
CamelMongoDbLimit	MongoDbConstants.LIMIT	Limits the number of elements returned.	int/Integer
CamelMongoDbBatchSize	MongoDbConstants.BATCH_SIZE	Limits the number of elements returned in one batch. A cursor typically fetches a batch of result objects and store them locally. If batchSize is positive, it represents the size of each batch of objects retrieved. It can be adjusted to optimize performance and limit data transfer. If batchSize is negative, it will limit of number objects returned, that fit within the max batch size limit (usually 4MB), and cursor will be closed. For example if batchSize is -10, then the server will return a maximum of 10 documents and as many as can fit in 4MB, then close the cursor. Note that this feature is different from limit() in that documents must fit within a maximum size, and it removes the need to send a request to close the cursor server-side. The batch size can be changed even after a cursor is iterated, in which case the setting will apply on the next batch retrieval.	int/Integer

Example with option outputType=Mongolterable and batch size :

```
from("direct:findAll")
.setHeader(MongoDbConstants.BATCH_SIZE).constant(10)
.setHeader(MongoDbConstants.CRITERIA, Filters.eq("name", "Raul Kripalani"))
.to("mongodb3:myDb?
database=flights&collection=tickets&operation=findAll&outputType=Mongolterable")
.to("mock:resultFindAll");
```

The **findAll** operation will also return the following OUT headers to enable you to iterate through result pages if you are using paging:

Header key	Quick constant	Description (extracted from MongoDB API doc)	Data type
Camel MongoDBResultTotalSize	MongoDbConstants.RESULT_TOTAL_SIZE	Number of objects matching the query. This does not take limit/skip into consideration.	int/Integer
Camel MongoDBResultPageSize	MongoDbConstants.RESULT_PAGE_SIZE	Number of objects matching the query. This does not take limit/skip into consideration.	int/Integer

TIP

Supports optional parameters. This operation supports specifying a fields projection and/or a sort clause. See [Specifying optional parameters](#).

229.6.1.4. count

Returns the total number of objects in a collection, returning a Long as the OUT message body. The following example will count the number of records in the "dynamicCollectionName" collection. Notice how dynamicity is enabled, and as a result, the operation will not run against the "notableScientists" collection, but against the "dynamicCollectionName" collection.

```
// from("direct:count").to("mongodb3:myDb?
database=tickets&collection=flights&operation=count&dynamicity=true");
Long result = template.requestBodyAndHeader("direct:count", "irrelevantBody",
MongoDbConstants.COLLECTION, "dynamicCollectionName");
assertTrue("Result is not of type Long", result instanceof Long);
```

You can provide a query **The query object is extracted CamelMongoDbCriteria header.** if the CamelMongoDbCriteria header is null the query object is extracted message body, i.e. it should be of type **Bson** or convertible to **Bson**., and operation will return the amount of documents matching this criteria.

```
Document query = ...
Long count = template.requestBodyAndHeader("direct:count", query,
MongoDbConstants.COLLECTION, "dynamicCollectionName");
```

229.6.1.5. Specifying a fields filter (projection)

Query operations will, by default, return the matching objects in their entirety (with all their fields). If your

documents are large and you only require retrieving a subset of their fields, you can specify a field filter in all query operations, simply by setting the relevant **Bson** (or type convertible to **Bson**, such as a JSON String, Map, etc.) on the **CamelMongoDbFieldsProjection** header, constant shortcut: **MongoDbConstants.FIELDS_PROJECTION**.

Here is an example that uses MongoDB's **Projections** to simplify the creation of Bson. It retrieves all fields except **_id** and **boringField**:

```
// route: from("direct:findAll").to("mongodb3:myDb?
database=flights&collection=tickets&operation=findAll")
Bson fieldProjection = Projection.exclude("_id", "boringField");
Object result = template.requestBodyAndHeader("direct:findAll", ObjectUtils.NULL,
MongoDbConstants.FIELDS_PROJECTION, fieldProjection);
```

Here is an example that uses MongoDB's **Projections** to simplify the creation of Bson. It retrieves all fields except **_id** and **boringField**:

```
// route: from("direct:findAll").to("mongodb3:myDb?
database=flights&collection=tickets&operation=findAll")
Bson fieldProjection = Projection.exclude("_id", "boringField");
Object result = template.requestBodyAndHeader("direct:findAll", ObjectUtils.NULL,
MongoDbConstants.FIELDS_PROJECTION, fieldProjection);
```

229.6.1.6. Specifying a sort clause

There is often a requirement to fetch the min/max record from a collection based on sorting by a particular field that uses MongoDB's **Sorts** to simplify the creation of Bson. It retrieves all fields except **_id** and **boringField**:

```
// route: from("direct:findAll").to("mongodb3:myDb?
database=flights&collection=tickets&operation=findAll")
Bson sorts = Sorts.descending("_id");
Object result = template.requestBodyAndHeader("direct:findAll", ObjectUtils.NULL,
MongoDbConstants.SORT_BY, sorts);
```

In a Camel route the SORT_BY header can be used with the findOneByQuery operation to achieve the same result. If the FIELDS_PROJECTION header is also specified the operation will return a single field/value pair that can be passed directly to another component (for example, a parameterized MyBatis SELECT query). This example demonstrates fetching the temporally newest document from a collection and reducing the result to a single field, based on the **documentTimestamp** field:

```
.from("direct:someTriggeringEvent")
.setHeader(MongoDbConstants.SORT_BY).constant(Sorts.descending("documentTimestamp"))
.setHeader(MongoDbConstants.FIELDS_PROJECTION).constant(Projection.include("documentTime
stamp"))
.setBody().constant("{}")
.to("mongodb3:myDb?database=local&collection=myDemoCollection&operation=findOneByQuery")
.to("direct:aMyBatisParameterizedSelect")
;
```

229.6.2. Create/update operations

229.6.2.1. insert

Inserts a new object into the MongoDB collection, taken from the IN message body. Type conversion is attempted to turn it into **Document** or a **List**.

Two modes are supported: single insert and multiple insert. For multiple insert, the endpoint will expect a List, Array or Collections of objects of any type, as long as they are - or can be converted to - **Document**. Example:

```
from("direct:insert")
.to("mongodb3:myDb?database=flights&collection=tickets&operation=insert");
```

The operation will return a **WriteResult**, and depending on the **WriteConcern** or the value of the **invokeGetLastError** option, **getLastError()** would have been called already or not. If you want to access the ultimate result of the write operation, you need to retrieve the **CommandResult** by calling **getLastError()** or **getCachedLastError()** on the **WriteResult**. Then you can verify the result by calling **CommandResult.ok()**, **CommandResult.getErrorMessage()** and/or **CommandResult.getException()**.

Note that the new object's **_id** must be unique in the collection. If you don't specify the value, MongoDB will automatically generate one for you. But if you do specify it and it is not unique, the insert operation will fail (and for Camel to notice, you will need to enable **invokeGetLastError** or set a **WriteConcern** that waits for the write result).

This is not a limitation of the component, but it is how things work in MongoDB for higher throughput. If you are using a custom **_id**, you are expected to ensure at the application level that it is unique (and this is a good practice too).

OID(s) of the inserted record(s) is stored in the message header under **CamelMongoOid** key (**MongoDbConstants.OID** constant). The value stored is **org.bson.types.ObjectId** for single insert or **java.util.List<org.bson.types.ObjectId>** if multiple records have been inserted.

In MongoDB Java Driver 3.x the **insertOne** and **insertMany** operation return void. The Camel insert operation return the Document or List of Documents inserted. Note that each Documents are Updated by a new OID if need.

229.6.2.2. save

The save operation is equivalent to an *upsert* (UPdate, inSERT) operation, where the record will be updated, and if it doesn't exist, it will be inserted, all in one atomic operation. MongoDB will perform the matching based on the **_id** field.

Beware that in case of an update, the object is replaced entirely and the usage of MongoDB's **\$modifiers** is not permitted. Therefore, if you want to manipulate the object if it already exists, you have two options:

1. perform a query to retrieve the entire object first along with all its fields (may not be efficient), alter it inside Camel and then save it.
2. use the update operation with **\$modifiers**, which will execute the update at the server-side instead. You can enable the upsert flag, in which case if an insert is required, MongoDB will apply the **\$modifiers** to the filter query object and insert the result.

If the document to be saved does not contain the **_id** attribute, the operation will be an insert, and the new **_id** created will be placed in the **CamelMongoOid** header.

For example:

```
from("direct:insert")
  .to("mongodb3:myDb?database=flights&collection=tickets&operation=save");
```

229.6.2.3. update

Update one or multiple records on the collection. Requires a filter query and a update rules.

You can define the filter using `MongoDBConstants.CRITERIA` header as **Bson** and define the update rules as **Bson** in Body.

NOTE

Update after enrich. While defining the filter by using `MongoDBConstants.CRITERIA` header as **Bson** to query mongodb before you do update, you should notice you need to remove it from the resulting camel exchange during aggregation if you use enrich pattern with a aggregation strategy and then apply mongodb update. If you don't remove this header during aggregation and/or redefine `MongoDBConstants.CRITERIA` header before sending camel exchange to mongodb producer endpoint, you may end up with invalid camel exchange payload while updating mongodb.

The second way Require a `List<Bson>` as the IN message body containing exactly 2 elements:

- Element 1 (index 0) ⇒ filter query ⇒ determines what objects will be affected, same as a typical query object
- Element 2 (index 1) ⇒ update rules ⇒ how matched objects will be updated. All [modifier operations](#) from MongoDB are supported.

NOTE

Multiupdates. By default, MongoDB will only update 1 object even if multiple objects match the filter query. To instruct MongoDB to update **all** matching records, set the `CamelMongoDbMultiUpdate` IN message header to **true**.

A header with key `CamelMongoDbRecordsAffected` will be returned (`MongoDBConstants.RECORDS_AFFECTED` constant) with the number of records updated (copied from `WriteResult.getN()`).

Supports the following IN message headers:

Header key	Quick constant	Description (extracted from MongoDB API doc)	Expected type
Camel MongoDBMultiUpdate	MongoDbConstants.MULTIUPDATE	If the update should be applied to all objects matching. See http://www.mongodb.org/display/DOCS/Atomic+Operations	boolean/Boolean
Camel MongoDBUpsert	MongoDbConstants.UPSERT	If the database should create the element if it does not exist	boolean/Boolean

For example, the following will update **all** records whose filterField field equals true by setting the value of the "scientist" field to "Darwin":

```
// route: from("direct:update").to("mongodb3:myDb?
database=science&collection=notableScientists&operation=update");
Bson filterField = Filters.eq("filterField", true);
String updateObj = Updates.set("scientist", "Darwin");
Object result = template.requestBodyAndHeader("direct:update", new Bson[] {filterField,
Document.parse(updateObj)}, MongoClientConstants.MULTIUPDATE, true);
```

```
// route: from("direct:update").to("mongodb3:myDb?
database=science&collection=notableScientists&operation=update");
Maps<String, Object> headers = new HashMap<>(2);
```

```
headers.add(MongoDbConstants.MULTIUPDATE, true);
headers.add(MongoDbConstants.FIELDS_FILTER, Filters.eq("filterField", true));
String updateObj = Updates.set("scientist", "Darwin");
Object result = template.requestBodyAndHeaders("direct:update", updateObj, headers);
```

```
// route: from("direct:update").to("mongodb3:myDb?
database=science&collection=notableScientists&operation=update");
String updateObj = "[{"filterField": true}, {"$set", {"scientist", "Darwin"}}]";
Object result = template.requestBodyAndHeader("direct:update", updateObj,
MongoDbConstants.MULTIUPDATE, true);
```

229.6.3. Delete operations

229.6.3.1. remove

Remove matching records from the collection. The IN message body will act as the removal filter query, and is expected to be of type **DBObject** or a type convertible to it.

The following example will remove all objects whose field 'conditionField' equals true, in the science database, notableScientists collection:

```
// route: from("direct:remove").to("mongodb3:myDb?
database=science&collection=notableScientists&operation=remove");
Bson conditionField = Filters.eq("conditionField", true);
Object result = template.requestBody("direct:remove", conditionField);
```

A header with key **CamelMongoDbRecordsAffected** is returned (**MongoDbConstants.RECORDS_AFFECTED** constant) with type **int**, containing the number of records deleted (copied from **WriteResult.getN()**).

229.6.4. Bulk Write Operations

229.6.4.1. bulkWrite

Available as of Camel 2.21

Performs write operations in bulk with controls for order of execution. Requires a **List<WriteModel<Document>>** as the IN message body containing commands for insert, update, and delete operations.

The following example will insert a new scientist "Pierre Curie", update record with id "5" by setting the value of the "scientist" field to "Marie Curie" and delete record with id "3":

```
// route: from("direct:bulkWrite").to("mongodb:myDb?
database=science&collection=notableScientists&operation=bulkWrite");
List<WriteModel<Document>> bulkOperations = Arrays.asList(
    new InsertOneModel<>(new Document("scientist", "Pierre Curie")),
    new UpdateOneModel<>(new Document("_id", "5"),
        new Document("$set", new Document("scientist", "Marie Curie"))),
    new DeleteOneModel<>(new Document("_id", "3")));

BulkWriteResult result = template.requestBody("direct:bulkWrite", bulkOperations,
BulkWriteResult.class);
```

By default, operations are executed in order and interrupted on the first write error without processing any remaining write operations in the list. To instruct MongoDB to continue to process remaining write operations in the list, set the **CamelMongoDbBulkOrdered** IN message header to **false**. Unordered operations are executed in parallel and this behavior is not guaranteed.

Header key	Quick constant	Description (extracted from MongoDB API doc)	Expected type
CamelMongoDbBulkOrdered	MongoDbConstants.BULK_ORDERED	Perform an ordered or unordered operation execution. Defaults to true.	boolean/Boolean

229.6.5. Other operations

229.6.5.1. aggregate

Perform an aggregation with the given pipeline contained in the body. **Aggregations could be long and heavy operations. Use with care.**

```
// route: from("direct:aggregate").to("mongodb3:myDb?
database=science&collection=notableScientists&operation=aggregate");
List<Bson> aggregate = Arrays.asList(match(or(eq("scientist", "Darwin"), eq("scientist",
group("$scientist", sum("count", 1)));
from("direct:aggregate")
.setBody().constant(aggregate)
.to("mongodb3:myDb?database=science&collection=notableScientists&operation=aggregate")
.to("mock:resultAggregate");
```

Supports the following IN message headers:

Header key	Quick constant	Description (extracted from MongoDB API doc)	Expected type
CamelMongoDbBatchSize	MongoDbConstants.BATCH_SIZE	Sets the number of documents to return per batch.	int/Integer
CamelMongoDbAllowDiskUse	MongoDbConstants.ALLOW_DISK_USE	Enable aggregation pipeline stages to write data to temporary files.	boolean/Boolean

By default a List of all results is returned. This can be heavy on memory depending on the size of the results. A safer alternative is to set your `outputType=Mongolterable`. The next Processor will see an iterable in the message body allowing it to step through the results one by one. Thus setting a batch size and returning an iterable allows for efficient retrieval and processing of the result.

You can also "stream" the documents returned from the server into your route by including `outputType=DBCursor` (Camel 2.21+) as an endpoint option which may prove simpler than setting the above headers. This hands your Exchange the DBCursor from the Mongo driver, just as if you were executing the `aggregate()` within the Mongo shell, allowing your route to iterate over the results. By default and without this option, this component will load the documents from the driver's cursor into a List and return this to your route - which may result in a large number of in-memory objects. Remember, with a DBCursor do not ask for the number of documents matched - see the MongoDB documentation site for details.

Example with option `outputType=Mongolterable` and batch size:

```
// route: from("direct:aggregate").to("mongodb3:myDb?
database=science&collection=notableScientists&operation=aggregate&outputType=Mongolterable");
List<Bson> aggregate = Arrays.asList(match(or(eq("scientist", "Darwin"), eq("scientist",
    group("$scientist", sum("count", 1))));
from("direct:aggregate")
    .setHeader(MongoDbConstants.BATCH_SIZE).constant(10)
    .setBody().constant(aggregate)
```

```
.to("mongodb3:myDb?
database=science&collection=notableScientists&operation=aggregate&outputType=Mongolterable")
.split(body())
.streaming()
.to("mock:resultAggregate");
```

Note that calling `.split(body())` is enough to send the entries down the route one-by-one, however it would still load all the entries into memory first. Calling `.streaming()` is thus required to load data into memory by batches.

229.6.5.2. getDbStats

Equivalent of running the `db.stats()` command in the MongoDB shell, which displays useful statistic figures about the database.

For example:

```
> db.stats();
{
  "db" : "test",
  "collections" : 7,
  "objects" : 719,
  "avgObjSize" : 59.73296244784423,
  "dataSize" : 42948,
  "storageSize" : 1000058880,
  "numExtents" : 9,
  "indexes" : 4,
  "indexSize" : 32704,
  "fileSize" : 1275068416,
  "nsSizeMB" : 16,
  "ok" : 1
}
```

Usage example:

```
// from("direct:getDbStats").to("mongodb3:myDb?
database=flights&collection=tickets&operation=getDbStats");
Object result = template.requestBody("direct:getDbStats", "irrelevantBody");
assertTrue("Result is not of type Document", result instanceof Document);
```

The operation will return a data structure similar to the one displayed in the shell, in the form of a **Document** in the OUT message body.

229.6.5.3. getColStats

Equivalent of running the `db.collection.stats()` command in the MongoDB shell, which displays useful statistic figures about the collection.

For example:

```
> db.camelTest.stats();
{
  "ns" : "test.camelTest",
  "count" : 100,
  "size" : 5792,
  "avgObjSize" : 57.92,
```

```

"storageSize" : 20480,
"numExtents" : 2,
"nindexes" : 1,
"lastExtentSize" : 16384,
"paddingFactor" : 1,
"flags" : 1,
"totalIndexSize" : 8176,
"indexSizes" : {
  "_id_" : 8176
},
"ok" : 1
}

```

Usage example:

```

// from("direct:getColStats").to("mongodb3:myDb?
database=flights&collection=tickets&operation=getColStats");
Object result = template.requestBody("direct:getColStats", "irrelevantBody");
assertTrue("Result is not of type Document", result instanceof Document);

```

The operation will return a data structure similar to the one displayed in the shell, in the form of a **Document** in the OUT message body.

229.6.5.4. command

Run the body as a command on database. Usefull for admin operation as getting host informations, replication or sharding status.

Collection parameter is not use for this operation.

```

// route: from("command").to("mongodb3:myDb?database=science&operation=command");
DBObject commandBody = new BasicDBObject("hostInfo", "1");
Object result = template.requestBody("direct:command", commandBody);

```

229.6.6. Dynamic operations

An Exchange can override the endpoint's fixed operation by setting the **CamelMongoDbOperation** header, defined by the **MongoDbConstants.OPERATION_HEADER** constant.

The values supported are determined by the MongoDbOperation enumeration and match the accepted values for the **operation** parameter on the endpoint URI.

For example:

```

// from("direct:insert").to("mongodb3:myDb?database=flights&collection=tickets&operation=insert");
Object result = template.requestBodyAndHeader("direct:insert", "irrelevantBody",
MongoDbConstants.OPERATION_HEADER, "count");
assertTrue("Result is not of type Long", result instanceof Long);

```

229.7. TAILABLE CURSOR CONSUMER

MongoDB offers a mechanism to instantaneously consume ongoing data from a collection, by keeping the cursor open just like the **tail -f** command of *nix systems. This mechanism is significantly more efficient than a scheduled poll, due to the fact that the server pushes new data to the client as it

becomes available, rather than making the client ping back at scheduled intervals to fetch new data. It also reduces otherwise redundant network traffic.

There is only one requisite to use tailable cursors: the collection must be a "capped collection", meaning that it will only hold N objects, and when the limit is reached, MongoDB flushes old objects in the same order they were originally inserted. For more information, please refer to:

<http://www.mongodb.org/display/DOCS/Tailable+Cursors>.

The Camel MongoDB component implements a tailable cursor consumer, making this feature available for you to use in your Camel routes. As new objects are inserted, MongoDB will push them as **Document** in natural order to your tailable cursor consumer, who will transform them to an Exchange and will trigger your route logic.

229.8. HOW THE TAILABLE CURSOR CONSUMER WORKS

To turn a cursor into a tailable cursor, a few special flags are to be signalled to MongoDB when first generating the cursor. Once created, the cursor will then stay open and will block upon calling the **MongoCursor.next()** method until new data arrives. However, the MongoDB server reserves itself the right to kill your cursor if new data doesn't appear after an indeterminate period. If you are interested to continue consuming new data, you have to regenerate the cursor. And to do so, you will have to remember the position where you left off or else you will start consuming from the top again.

The Camel MongoDB tailable cursor consumer takes care of all these tasks for you. You will just need to provide the key to some field in your data of increasing nature, which will act as a marker to position your cursor every time it is regenerated, e.g. a timestamp, a sequential ID, etc. It can be of any datatype supported by MongoDB. Date, Strings and Integers are found to work well. We call this mechanism "tail tracking" in the context of this component.

The consumer will remember the last value of this field and whenever the cursor is to be regenerated, it will run the query with a filter like: **increasingField > lastValue**, so that only unread data is consumed.

Setting the increasing field: Set the key of the increasing field on the endpoint URI **tailTrackingIncreasingField** option. In Camel 2.10, it must be a top-level field in your data, as nested navigation for this field is not yet supported. That is, the "timestamp" field is okay, but "nested.timestamp" will not work. Please open a ticket in the Camel JIRA if you do require support for nested increasing fields.

Cursor regeneration delay: One thing to note is that if new data is not already available upon initialisation, MongoDB will kill the cursor instantly. Since we don't want to overwhelm the server in this case, a **cursorRegenerationDelay** option has been introduced (with a default value of 1000ms.), which you can modify to suit your needs.

An example:

```
from("mongodb3:myDb?
database=flights&collection=cancellations&tailTrackIncreasingField=departureTime")
    .id("tailableCursorConsumer1")
    .autoStartup(false)
    .to("mock:test");
```

The above route will consume from the "flights.cancellations" capped collection, using "departureTime" as the increasing field, with a default regeneration cursor delay of 1000ms.

229.9. PERSISTENT TAIL TRACKING

Standard tail tracking is volatile and the last value is only kept in memory. However, in practice you will need to restart your Camel container every now and then, but your last value would then be lost and your tailable cursor consumer would start consuming from the top again, very likely sending duplicate records into your route.

To overcome this situation, you can enable the **persistent tail tracking** feature to keep track of the last consumed increasing value in a special collection inside your MongoDB database too. When the consumer initialises again, it will restore the last tracked value and continue as if nothing happened.

The last read value is persisted on two occasions: every time the cursor is regenerated and when the consumer shuts down. We may consider persisting at regular intervals too in the future (flush every 5 seconds) for added robustness if the demand is there. To request this feature, please open a ticket in the Camel JIRA.

229.10. ENABLING PERSISTENT TAIL TRACKING

To enable this function, set at least the following options on the endpoint URI:

- **persistentTailTracking** option to **true**
- **persistentId** option to a unique identifier for this consumer, so that the same collection can be reused across many consumers

Additionally, you can set the **tailTrackDb**, **tailTrackCollection** and **tailTrackField** options to customise where the runtime information will be stored. Refer to the endpoint options table at the top of this page for descriptions of each option.

For example, the following route will consume from the "flights.cancellations" capped collection, using "departureTime" as the increasing field, with a default regeneration cursor delay of 1000ms, with persistent tail tracking turned on, and persisting under the "cancellationsTracker" id on the "flights.camelTailTracking", storing the last processed value under the "lastTrackingValue" field (**camelTailTracking** and **lastTrackingValue** are defaults).

```
from("mongodb3:myDb?
database=flights&collection=cancellations&tailTrackIncreasingField=departureTime&persistentTailTrack
ng=true" +
"&persistentId=cancellationsTracker")
.id("tailableCursorConsumer2")
.autoStartup(false)
.to("mock:test");
```

Below is another example identical to the one above, but where the persistent tail tracking runtime information will be stored under the "trackers.camelTrackers" collection, in the "lastProcessedDepartureTime" field:

```
from("mongodb3:myDb?
database=flights&collection=cancellations&tailTrackIncreasingField=departureTime&persistentTailTrack
ng=true" +
"&persistentId=cancellationsTracker&tailTrackDb=trackers&tailTrackCollection=camelTrackers" +
"&tailTrackField=lastProcessedDepartureTime")
.id("tailableCursorConsumer3")
.autoStartup(false)
.to("mock:test");
```

229.11. TYPE CONVERSIONS

The **MongoDbBasicConverters** type converter included with the camel-mongodb component provides the following conversions:

Name	From type	To type	How?
fromMapToDocument	Map	Document	constructs a new Document via the new Document(Map m) constructor.
fromDocumentToMap	Document	Map	Document already implements Map .
fromStringToDocument	String	Document	uses com.mongodb.Document.parse(String s) .
fromAnyObjectToDocument	Object	Document	uses the Jackson library to convert the object to a Map , which is in turn used to initialise a new Document .
fromStringToList	String	List<Bson>	uses org.bson.codecs.configuration.CodecRegistries to convert to BsonArray then to List<Bson> .

This type converter is auto-discovered, so you don't need to configure anything manually.

CHAPTER 230. MQTT COMPONENT

Available as of Camel version 2.10

The **mqtt:** component is used for communicating with [MQTT](#) compliant message brokers, like [Apache ActiveMQ](#) or [Mosquitto](#)

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-mqtt</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

230.1. URI FORMAT

```
mqtt://name[?options]
```

Where **name** is the name you want to assign the component.

230.2. OPTIONS

The MQTT component supports 4 options, which are listed below.

Name	Description	Default	Type
host (common)	The URI of the MQTT broker to connect too - this component also supports SSL - e.g. <code>ssl://127.0.0.1:8883</code>		String
userName (security)	Username to be used for authentication against the MQTT broker		String
password (security)	Password to be used for authentication against the MQTT broker		String
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The MQTT endpoint is configured using URI syntax:

```
mqtt:name
```

with the following path and query parameters:

230.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
name	Required A logical name to use which is not the topic name.		String

230.2.2. Query Parameters (39 parameters):

Name	Description	Default	Type
blockingExecutor (common)	SSL connections perform blocking operations against internal thread pool unless you call the <code>setBlockingExecutor</code> method to configure that executor they will use instead.		Executor
byDefaultRetain (common)	The default retain policy to be used on messages sent to the MQTT broker	false	boolean
cleanSession (common)	Set to false if you want the MQTT server to persist topic subscriptions and ack positions across client sessions. Defaults to true.	false	boolean
clientId (common)	Use to set the client Id of the session. This is what an MQTT server uses to identify a session where <code>setCleanSession(false)</code> ; is being used. The id must be 23 characters or less. Defaults to auto generated id (based on your socket address, port and timestamp).		String
connectAttempts Max (common)	The maximum number of reconnect attempts before an error is reported back to the client on the first attempt by the client to connect to a server. Set to -1 to use unlimited attempts. Defaults to -1.	-1	long
connectWaitInSec onds (common)	Delay in seconds the Component will wait for a connection to be established to the MQTT broker	10	int
disconnectWaitIn Seconds (common)	The number of seconds the Component will wait for a valid disconnect on <code>stop()</code> from the MQTT broker	5	int
dispatchQueue (common)	A <code>HawtDispatch</code> dispatch queue is used to synchronize access to the connection. If an explicit queue is not configured via the <code>setDispatchQueue</code> method, then a new queue will be created for the connection. Setting an explicit queue might be handy if you want multiple connection to share the same queue for synchronization.		DispatchQueue

Name	Description	Default	Type
host (common)	The URI of the MQTT broker to connect too - this component also supports SSL - e.g. <code>ssl://127.0.0.1:8883</code>	<code>tcp://127.0.0.1:1883</code>	URI
keepAlive (common)	Configures the Keep Alive timer in seconds. Defines the maximum time interval between messages received from a client. It enables the server to detect that the network connection to a client has dropped, without having to wait for the long TCP/IP timeout.		short
localAddress (common)	The local InetAddress and port to use		URI
maxReadRate (common)	Sets the maximum bytes per second that this transport will receive data at. This setting throttles reads so that the rate is not exceeded. Defaults to 0 which disables throttling.		int
maxWriteRate (common)	Sets the maximum bytes per second that this transport will send data at. This setting throttles writes so that the rate is not exceeded. Defaults to 0 which disables throttling.		int
mqttQosProperty Name (common)	The property name to look for on an Exchange for an individual published message. If this is set (one of <code>AtMostOnce</code> , <code>AtLeastOnce</code> or <code>ExactlyOnce</code>) - then that QoS will be set on the message sent to the MQTT message broker.	MQTT Qos	String
mqttRetainProperty Name (common)	The property name to look for on an Exchange for an individual published message. If this is set (expects a Boolean value) - then the retain property will be set on the message sent to the MQTT message broker.	MQTT Retain	String
mqttTopicProperty Name (common)	These a properties that are looked for in an Exchange - to publish to	MQTT TopicProperty Name	String
publishTopicName (common)	The default Topic to publish messages on	<code>camel/mqtt/test</code>	String
qualityOfService (common)	Quality of service level to use for topics.	<code>AtLeastOnce</code>	String
receiveBufferSize (common)	Sets the size of the internal socket receive buffer. Defaults to 65536 (64k)	65536	int

Name	Description	Default	Type
reconnectAttemptsMax (common)	The maximum number of reconnect attempts before an error is reported back to the client after a server connection had previously been established. Set to -1 to use unlimited attempts. Defaults to -1.	-1	long
reconnectBackoffMultiplier (common)	The Exponential backoff be used between reconnect attempts. Set to 1 to disable exponential backoff. Defaults to 2.	2.0	double
reconnectDelay (common)	How long to wait in ms before the first reconnect attempt. Defaults to 10.	10	long
reconnectDelayMax (common)	The maximum amount of time in ms to wait between reconnect attempts. Defaults to 30,000.	30000	long
sendBufferSize (common)	Sets the size of the internal socket send buffer. Defaults to 65536 (64k)	65536	int
sendWaitInSeconds (common)	The maximum time the Component will wait for a receipt from the MQTT broker to acknowledge a published message before throwing an exception	5	int
sslContext (common)	To configure security using SSLContext configuration		SSLContext
subscribeTopicName (common)	Deprecated These are set on the Endpoint - together with properties inherited from MQTT		String
subscribeTopicNames (common)	A comma-delimited list of Topics to subscribe to for messages. Note that each item of this list can contain MQTT wildcards (and/or #), in order to subscribe to topics matching a certain pattern within a hierarchy. For example, is a wildcard for all topics at a level within the hierarchy, so if a broker has topics topics/one and topics/two, then topics/ can be used to subscribe to both. A caveat to consider here is that if the broker adds topics/three, the route would also begin to receive messages from that topic.		String
trafficClass (common)	Sets traffic class or type-of-service octet in the IP header for packets sent from the transport. Defaults to 8 which means the traffic should be optimized for throughput.	8	int
version (common)	Set to 3.1.1 to use MQTT version 3.1.1. Otherwise defaults to the 3.1 protocol version.	3.1	String

Name	Description	Default	Type
willMessage (common)	The Will message to send. Defaults to a zero length message.		String
willQos (common)	Sets the quality of service to use for the Will message. Defaults to AT_MOST_ONCE.	AtMost Once	QoS
willRetain (common)	Set to true if you want the Will to be published with the retain option.		QoS
willTopic (common)	If set the server will publish the client's Will message to the specified topics if the client has an unexpected disconnection.		String
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer)	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		<code>ExceptionHandler</code>
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		<code>ExchangePattern</code>
lazySessionCreation (producer)	Sessions can be lazily created to avoid exceptions, if the remote server is not up and running when the Camel producer is started.	true	boolean
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

230.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 5 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.mqtt.enabled</code>	Enable mqtt component	true	Boolean
<code>camel.component.mqtt.host</code>	The URI of the MQTT broker to connect too - this component also supports SSL - e.g. <code>ssl://127.0.0.1:8883</code>		String
<code>camel.component.mqtt.password</code>	Password to be used for authentication against the MQTT broker		String
<code>camel.component.mqtt.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.component.mqtt.user-name</code>	Username to be used for authentication against the MQTT broker		String

230.4. SAMPLES

Sending messages:

```
from("direct:foo").to("mqtt:cheese?publishTopicName=test.mqtt.topic");
```

Consuming messages:

```
from("mqtt:bar?subscribeTopicName=test.mqtt.topic").transform(body().convertToString()).to("mock:result")
```

230.5. ENDPOINTS

Camel supports the Message Endpoint pattern using the [Endpoint](#) interface. Endpoints are usually created by a Component and Endpoints are usually referred to in the DSL via their URIs.

From an Endpoint you can use the following methods

- `createProducer()` will create a [Producer](#) for sending message exchanges to the endpoint
- `createConsumer()` implements the Event Driven Consumer pattern for consuming message exchanges from the endpoint via a [Processor](#) when creating a [Consumer](#)
- `createPollingConsumer()` implements the Polling Consumer pattern for consuming message exchanges from the endpoint via a [PollingConsumer](#)

230.6. SEE ALSO

- [Configuring Camel](#)

- Message Endpoint pattern
- URIs
- Writing Components

CHAPTER 231. MSV COMPONENT

Available as of Camel version 1.1

The MSV component performs XML validation of the message body using the [MSV Library](#) and any of the supported XML schema languages, such as [XML Schema](#) or [RelaxNG XML Syntax](#).

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-msv</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

Note that the [Jing](#) component also supports [RelaxNG Compact Syntax](#)

231.1. URI FORMAT

```
msv:someLocalOrRemoteResource[?options]
```

Where **someLocalOrRemoteResource** is some URL to a local resource on the classpath or a full URL to a remote resource or resource on the file system. For example

```
msv:org/foo/bar.rng
msv:file:../foo/bar.rng
msv:http://acme.com/cheese.rng
```

You can append query options to the URI in the following format, **?option=value&option=value&...**

231.2. OPTIONS

The MSV component supports 3 options, which are listed below.

Name	Description	Default	Type
schemaFactory (advanced)	To use the javax.xml.validation.SchemaFactory.		SchemaFactory
resourceResolverFactory (advanced)	To use a custom LSResourceResolver which depends on a dynamic endpoint resource URI		ValidatorResourceResolverFactory
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The MSV endpoint is configured using URI syntax:

msv:resourceUri

with the following path and query parameters:

231.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
resourceUri	Required URL to a local resource on the classpath, or a reference to lookup a bean in the Registry, or a full URL to a remote resource or resource on the file system which contains the XSD to validate against.		String

231.2.2. Query Parameters (11 parameters):

Name	Description	Default	Type
failOnNullBody (producer)	Whether to fail if no body exists.	true	boolean
failOnNullHeader (producer)	Whether to fail if no header exists when validating against a header.	true	boolean
headerName (producer)	To validate against a header instead of the message body.		String
errorHandler (advanced)	To use a custom <code>org.apache.camel.processor.validation.ValidatorErrorHandler</code> . The default error handler captures the errors and throws an exception.		ValidatorErrorHandler
resourceResolver (advanced)	To use a custom <code>LSResourceResolver</code> . Do not use together with <code>resourceResolverFactory</code>		LSResourceResolver
resourceResolverFactory (advanced)	To use a custom <code>LSResourceResolver</code> which depends on a dynamic endpoint resource URI. The default resource resolver factory returns a resource resolver which can read files from the class path and file system. Do not use together with <code>resourceResolver</code> .		ValidatorResourceResolverFactory
schemaFactory (advanced)	To use a custom <code>javax.xml.validation.SchemaFactory</code>		SchemaFactory

Name	Description	Default	Type
schemaLanguage (advanced)	Configures the W3C XML Schema Namespace URI.	http://www.w3.org/2001/XMLSchema	String
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
useDom (advanced)	Whether DOMSource/DOMResult or SaxSource/SaxResult should be used by the validator.	false	boolean
useSharedSchema (advanced)	Whether the Schema instance should be shared or not. This option is introduced to work around a JDK 1.6.x bug. Xerces should not have this issue.	true	boolean

231.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 4 options, which are listed below.

Name	Description	Default	Type
camel.component.msv.enabled	Enable msv component	true	Boolean
camel.component.msv.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
camel.component.msv.resource-resolver-factory	To use a custom LSResourceResolver which depends on a dynamic endpoint resource URI. The option is a <code>org.apache.camel.component.validator.ValidatorResourceResolverFactory</code> type.		String
camel.component.msv.schema-factory	To use the <code>javax.xml.validation.SchemaFactory</code> . The option is a <code>javax.xml.validation.SchemaFactory</code> type.		String

231.4. EXAMPLE

The following [example](#) shows how to configure a route from endpoint **direct:start** which then goes to one of two endpoints, either **mock:valid** or **mock:invalid** based on whether or not the XML matches the given [RelaxNG XML Schema](#) (which is supplied on the classpath).

231.5. SEE ALSO

- [Endpoint](#)
- [Getting Started](#)

CHAPTER 232. MUSTACHE COMPONENT

Available as of Camel version 2.12

The **mustache**: component allows for processing a message using a [Mustache](#) template. This can be ideal when using Templating to generate responses for requests.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
<groupId>org.apache.camel</groupId>
<artifactId>camel-mustache</artifactId>
<version>x.x.x</version> <!-- use the same version as your Camel core version -->
</dependency>
```

232.1. URI FORMAT

```
mustache:templateName[?options]
```

Where **templateName** is the classpath-local URI of the template to invoke; or the complete URL of the remote template (eg: [file://folder/myfile.mustache](#)).

You can append query options to the URI in the following format, **?option=value&option=value&...**

232.2. OPTIONS

The Mustache component supports 4 options, which are listed below.

Name	Description	Default	Type
allowContextMap All (producer)	Sets whether the context map should allow access to all details. By default only the message body and headers can be accessed. This option can be enabled for full access to the current Exchange and CamelContext. Doing so imposes a potential security risk as this opens access to the full power of CamelContext API.	false	boolean
allowTemplateFromHeader (producer)	Whether to allow to use resource template from header or not (default false). Enabling this option has security ramifications. For example, if the header contains untrusted or user derived content, this can ultimately impact on the confidentiality and integrity of your end application, so use this option with caution.	false	boolean
mustacheFactory (advanced)	To use a custom MustacheFactory		MustacheFactory

Name	Description	Default	Type
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Mustache endpoint is configured using URI syntax:

```
mustache:resourceUri
```

with the following path and query parameters:

232.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
resourceUri	Required Path to the resource. You can prefix with: classpath, file, http, ref, or bean. classpath, file and http loads the resource using these protocols (classpath is default). ref will lookup the resource in the registry. bean will call a method on a bean to be used as the resource. For bean you can specify the method name after dot, eg bean:myBean.myMethod.		String

232.2.2. Query Parameters (7 parameters):

Name	Description	Default	Type
allowContextMapAll (producer)	Sets whether the context map should allow access to all details. By default only the message body and headers can be accessed. This option can be enabled for full access to the current Exchange and CamelContext. Doing so imposes a potential security risk as this opens access to the full power of CamelContext API.	false	boolean
allowTemplateFromHeader (producer)	Whether to allow to use resource template from header or not (default false). Enabling this option has security ramifications. For example, if the header contains untrusted or user derived content, this can ultimately impact on the confidentiality and integrity of your end application, so use this option with caution.	false	boolean

Name	Description	Default	Type
contentCache (producer)	Sets whether to use resource content cache or not	false	boolean
encoding (producer)	Character encoding of the resource content.		String
endDelimiter (producer)	Characters used to mark template code end.	}}	String
startDelimiter (producer)	Characters used to mark template code beginning.	{{	String
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

232.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 3 options, which are listed below.

Name	Description	Default	Type
camel.component. .mustache.enabled	Enable mustache component	true	Boolean
camel.component. .mustache.mustache-factory	To use a custom MustacheFactory. The option is a com.github.mustachejava.MustacheFactory type.		String
camel.component. .mustache.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

232.4. MUSTACHE CONTEXT

Camel will provide exchange information in the Mustache context (just a **Map**). The **Exchange** is transferred as:

key	value
exchange	The Exchange itself.

key	value
exchange.properties	The Exchange properties.
headers	The headers of the In message.
camelContext	The Camel Context.
request	The In message.
body	The In message body.
response	The Out message (only for InOut message exchange pattern).

232.5. DYNAMIC TEMPLATES

Camel provides two headers by which you can define a different resource location for a template or the template content itself. If any of these headers is set then Camel uses this over the endpoint configured resource. This allows you to provide a dynamic template at runtime.

Header	Type	Description	Support Version
MustacheConstants.MUSTACHE_RESOURCE_URI	String	A URI for the template resource to use instead of the endpoint configured.	

Header	Type	Description	Support Version
MustacheConstants.MUSTACHE_TEMPLATE	String	The template to use instead of the endpoint configured.	

232.6. SAMPLES

For example you could use something like:

```
from("activemq:My.Queue").
to("mustache:com/acme/MyResponse.mustache");
```

To use a Mustache template to formulate a response for a message for InOut message exchanges (where there is a **JMSReplyTo** header).

If you want to use InOnly and consume the message and send it to another destination you could use:

```
from("activemq:My.Queue").
to("mustache:com/acme/MyResponse.mustache").
to("activemq:Another.Queue");
```

It's possible to specify what template the component should use dynamically via a header, so for example:

```
from("direct:in").
setHeader(MustacheConstants.MUSTACHE_RESOURCE_URI).constant("path/to/my/template.mustache").
to("mustache:dummy?allowTemplateFromHeader=true");
```

WARNING

Enabling the **allowTemplateFromHeader** option has security ramifications. For example, if the header contains untrusted or user derived content, this can ultimately impact on the confidentiality and integrity of your end application, so use this option with caution.

232.7. THE EMAIL SAMPLE

In this sample we want to use Mustache templating for an order confirmation email. The email template is laid out in Mustache as:

```
Dear {{headers.lastName}}, {{headers.firstName}}
```

```
Thanks for the order of {{headers.item}}.
```

```
Regards Camel Riders Bookstore  
{{body}}
```

232.8. SEE ALSO

- [Configuring Camel](#)
- [Component](#)
- [Endpoint](#)
- [Getting Started](#)

CHAPTER 233. MVEL COMPONENT

Available as of Camel version 2.12

The **mvel**: component allows you to process a message using an [MVEL](#) template. This can be ideal when using Templating to generate responses for requests.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-mvel</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

233.1. URI FORMAT

```
mvel:templateName[?options]
```

Where **templateName** is the classpath-local URI of the template to invoke; or the complete URL of the remote template (eg: [file://folder/myfile.mvel](#)).

You can append query options to the URI in the following format, **?option=value&option=value&...**

233.2. OPTIONS

The MVEL component supports 2 options, which are listed below.

Name	Description	Default	Type
allowContextMapAll (producer)	Sets whether the context map should allow access to all details. By default only the message body and headers can be accessed. This option can be enabled for full access to the current Exchange and CamelContext. Doing so imposes a potential security risk as this opens access to the full power of CamelContext API.	false	boolean
allowTemplateFromHeader (producer)	Whether to allow to use resource template from header or not (default false). Enabling this option has security ramifications. For example, if the header contains untrusted or user derived content, this can ultimately impact on the confidentiality and integrity of your end application, so use this option with caution.	false	boolean

The MVEL endpoint is configured using URI syntax:

```
mvel:resourceUri
```

with the following path and query parameters:

233.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
resourceUri	Required Path to the resource. You can prefix with: classpath, file, http, ref, or bean. classpath, file and http loads the resource using these protocols (classpath is default). ref will lookup the resource in the registry. bean will call a method on a bean to be used as the resource. For bean you can specify the method name after dot, eg bean:myBean.myMethod.		String

233.2.2. Query Parameters (5 parameters):

Name	Description	Default	Type
allowContextMapAll (producer)	Sets whether the context map should allow access to all details. By default only the message body and headers can be accessed. This option can be enabled for full access to the current Exchange and CamelContext. Doing so imposes a potential security risk as this opens access to the full power of CamelContext API.	false	boolean
allowTemplateFromHeader (producer)	Whether to allow to use resource template from header or not (default false). Enabling this option has security ramifications. For example, if the header contains untrusted or user derived content, this can ultimately impact on the confidentiality and integrity of your end application, so use this option with caution.	false	boolean
contentCache (producer)	Sets whether to use resource content cache or not	false	boolean
encoding (producer)	Character encoding of the resource content.		String
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

233.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 4 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.mvel.enabled</code>	Enable mvel component	true	Boolean
<code>camel.component.mvel.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.language.mvel.enabled</code>	Enable mvel language	true	Boolean
<code>camel.language.mvel.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks	true	Boolean

233.4. MESSAGE HEADERS

The mvel component sets a couple headers on the message.

Header	Description
Camel MvelResourceUri	The <code>templateName</code> as a String object.

233.5. MVEL CONTEXT

Camel will provide exchange information in the MVEL context (just a **Map**). The **Exchange** is transferred as:

key	value
exchange	The Exchange itself.
exchange.properties	The Exchange properties.
headers	The headers of the In message.

key	value
camelContext	The Camel Context instance.
request	The In message.
in	The In message.
body	The In message body.
out	The Out message (only for InOut message exchange pattern).
response	The Out message (only for InOut message exchange pattern).

233.6. HOT RELOADING

The mvel template resource is, by default, hot reloadable for both file and classpath resources (expanded jar). If you set **contentCache=true**, Camel will only load the resource once, and thus hot reloading is not possible. This scenario can be used in production, when the resource never changes.

233.7. DYNAMIC TEMPLATES

Camel provides two headers by which you can define a different resource location for a template or the template content itself. If any of these headers is set then Camel uses this over the endpoint configured resource. This allows you to provide a dynamic template at runtime.

Header	Type	Description
Camel MvelResourceUri	String	A URI for the template resource to use instead of the endpoint configured.
Camel MvelTemplate	String	The template to use instead of the endpoint configured.

233.8. SAMPLES

For example you could use something like

```
from("activemq:My.Queue").
to("mvel:com/acme/MyResponse.mvel");
```

To use a MVEL template to formulate a response to a message for InOut message exchanges (where there is a **JMSReplyTo** header).

To specify what template the component should use dynamically via a header, so for example:

```
from("direct:in").
  setHeader("CamelMvelResourceUri").constant("path/to/my/template.mvel").
  to("mvel:dummy?allowTemplateFromHeader=true");
```

To specify a template directly as a header the component should use dynamically via a header, so for example:

```
from("direct:in").
  setHeader("CamelMvelTemplate").constant("@{\\"The result is \"+ request.body * 3}\\\" }").
  to("velocity:dummy?allowTemplateFromHeader=true");
```

WARNING

Enabling the **allowTemplateFromHeader** option has security ramifications. For example, if the header contains untrusted or user derived content, this can ultimately impact on the confidentiality and integrity of your end application, so use this option with caution.

233.9. SEE ALSO

- [Configuring Camel](#)
- [Component](#)
- [Endpoint](#)
- [Getting Started](#)

CHAPTER 234. MVEL LANGUAGE

Available as of Camel version 2.0

Camel allows Mvel to be used as an Expression or Predicate the DSL or Xml Configuration.

You could use Mvel to create an Predicate in a Message Filter or as an Expression for a Recipient List

You can use Mvel dot notation to invoke operations. If you for instance have a body that contains a POJO that has a **getFamilyName** method then you can construct the syntax as follows:

```
"request.body.familyName"
// or
"getRequest().getBody().getFamilyName()"
```

234.1. MVEL OPTIONS

The MVEL language supports 1 options, which are listed below.

Name	Default	Java Type	Description
trim	true	Boolean	Whether to trim the value to remove leading and trailing whitespaces and line breaks

234.2. SPRING BOOT AUTO-CONFIGURATION

The component supports 4 options, which are listed below.

Name	Description	Default	Type
camel.component.mvel.enabled	Enable mvel component	true	Boolean
camel.component.mvel.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
camel.language.mvel.enabled	Enable mvel language	true	Boolean
camel.language.mvel.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks	true	Boolean

234.3. VARIABLES

Variable	Type	Description
this	Exchange	the Exchange is the root object
exchange	Exchange	the Exchange object
exception	Throwable	the Exchange exception (if any)
exchangeId	String	the exchange id
fault	Message	the Fault message (if any)
request	Message	the exchange.in message
response	Message	the exchange.out message (if any)
properties	Map	the exchange properties
property(name)	Object	the property by the given name
property(name, type)	Type	the property by the given name as the given type

234.4. SAMPLES

For example you could use Mvel inside a [Message Filter](#) in XML

```
<route>
  <from uri="seda:foo"/>
  <filter>
    <mvel>request.headers.foo == 'bar'</mvel>
    <to uri="seda:bar"/>
  </filter>
</route>
```

And the sample using Java DSL:

```
from("seda:foo").filter().mvel("request.headers.foo == 'bar'").to("seda:bar");
```

234.5. LOADING SCRIPT FROM EXTERNAL RESOURCE

Available as of Camel 2.11

You can externalize the script and have Camel load it from a resource such as **"classpath:"**, **"file:"**, or **"http:"**.

This is done using the following syntax: **"resource:scheme:location"**, eg to refer to a file on the classpath you can do:

```
.setHeader("myHeader").mvel("resource:classpath:script.mvel")
```

234.6. DEPENDENCIES

To use Mvel in your camel routes you need to add the a dependency on **camel-mvel** which implements the Mvel language.

If you use maven you could just add the following to your pom.xml, substituting the version number for the latest & greatest release (see the download page for the latest versions).

```
<dependency>  
  <groupId>org.apache.camel</groupId>  
  <artifactId>camel-mvel</artifactId>  
  <version>x.x.x</version>  
</dependency>
```

CHAPTER 235. MYBATIS COMPONENT

Available as of Camel version 2.7

The **mybatis:** component allows you to query, poll, insert, update and delete data in a relational database using [MyBatis](#).

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-mybatis</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

235.1. URI FORMAT

`mybatis:statementName[?options]`

Where **statementName** is the statement name in the MyBatis XML mapping file which maps to the query, insert, update or delete operation you wish to evaluate.

You can append query options to the URI in the following format, **?option=value&option=value&...**

This component will by default load the MyBatis SqlMapConfig file from the root of the classpath with the expected name of **SqlMapConfig.xml**.

If the file is located in another location, you will need to configure the **configurationUri** option on the **MyBatisComponent** component.

235.2. OPTIONS

The MyBatis component supports 3 options, which are listed below.

Name	Description	Default	Type
sqlSessionFactory (advanced)	To use the SqlSessionFactory		SqlSessionFactory
configurationUri (common)	Location of MyBatis xml configuration file. The default value is: SqlMapConfig.xml loaded from the classpath	SqlMapConfig.xml	String
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The MyBatis endpoint is configured using URI syntax:

mybatis:statement

with the following path and query parameters:

235.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
statement	Required The statement name in the MyBatis XML mapping file which maps to the query, insert, update or delete operation you wish to evaluate.		String

235.2.2. Query Parameters (29 parameters):

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
maxMessagesPerPoll (consumer)	This option is intended to split results returned by the database pool into the batches and deliver them in multiple exchanges. This integer defines the maximum messages to deliver in single exchange. By default, no maximum is set. Can be used to set a limit of e.g. 1000 to avoid when starting up the server that there are thousands of files. Set a value of 0 or negative to disable it.	0	int
onConsume (consumer)	Statement to run after data has been processed in the route		String
routeEmptyResultSet (consumer)	Whether allow empty resultset to be routed to the next hop	false	boolean
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean

Name	Description	Default	Type
transacted (consumer)	Enables or disables transaction. If enabled then if processing an exchange failed then the consumer break out processing any further exchanges to cause a rollback eager	false	boolean
useliterator (consumer)	Process resultset individually or as a list	true	boolean
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
pollStrategy (consumer)	A pluggable org.apache.camel.PollingConsumerPollingStrategy allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		PollingConsumerPollStrategy
processingStrategy (consumer)	To use a custom MyBatisProcessingStrategy		MyBatisProcessingStrategy
executorType (producer)	The executor type to be used while executing statements. simple - executor does nothing special. reuse - executor reuses prepared statements. batch - executor reuses statements and batches updates.	SIMPLE	ExecutorType
inputHeader (producer)	User the header value for input parameters instead of the message body. By default, inputHeader == null and the input parameters are taken from the message body. If outputHeader is set, the value is used and query parameters will be taken from the header instead of the body.		String
outputHeader (producer)	Store the query result in a header instead of the message body. By default, outputHeader == null and the query result is stored in the message body, any existing content in the message body is discarded. If outputHeader is set, the value is used as the name of the header to store the query result and the original message body is preserved. Setting outputHeader will also omit populating the default CamelMyBatisResult header since it would be the same as outputHeader all the time.		String

Name	Description	Default	Type
statementType (producer)	Mandatory to specify for the producer to control which kind of operation to invoke.		StatementType
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.		int
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.		int
delay (scheduler)	Milliseconds before the next poll. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	500	long
greedy (scheduler)	If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	1000	long
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that.	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz2 component	none	ScheduledPollConsumer Scheduler

Name	Description	Default	Type
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz2, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for initialDelay and delay options.	MILLIS ECON DS	TimeUnit
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.	true	boolean

235.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 4 options, which are listed below.

Name	Description	Default	Type
camel.component.mybatis.configuration-uri	Location of MyBatis xml configuration file. The default value is: SqlMapConfig.xml loaded from the classpath	SqlMap pConfi g.xml	String
camel.component.mybatis.enabled	Enable mybatis component	true	Boolean
camel.component.mybatis.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
camel.component.mybatis.sql-session-factory	To use the SqlSessionFactory. The option is a org.apache.ibatis.session.SqlSessionFactory type.		String

235.4. MESSAGE HEADERS

Camel will populate the result message, either IN or OUT with a header with the statement used:

Header	Type	Description
CamelMyBatisStatementName	String	The statementName used (for example: insertAccount).
CamelMyBatisResult	Object	The response returned from MtBatis in any of the operations. For instance an INSERT could return the auto-generated key, or number of rows etc.

235.5. MESSAGE BODY

The response from MyBatis will only be set as the body if it's a **SELECT** statement. That means, for example, for **INSERT** statements Camel will not replace the body. This allows you to continue routing and keep the original body. The response from MyBatis is always stored in the header with the key **CamelMyBatisResult**.

235.6. SAMPLES

For example if you wish to consume beans from a JMS queue and insert them into a database you could do the following:

```
from("activemq:queue:newAccount")
  .to("mybatis:insertAccount?statementType=Insert");
```

Notice we have to specify the **statementType**, as we need to instruct Camel which kind of operation to invoke.

Where **insertAccount** is the MyBatis ID in the SQL mapping file:

```
<!-- Insert example, using the Account parameter class -->
<insert id="insertAccount" parameterType="Account">
  insert into ACCOUNT (
    ACC_ID,
    ACC_FIRST_NAME,
    ACC_LAST_NAME,
    ACC_EMAIL
  )
  values (
    #{id}, #{firstName}, #{lastName}, #{emailAddress}
  )
</insert>
```

235.7. USING STATEMENTTYPE FOR BETTER CONTROL OF MYBATIS

When routing to an MyBatis endpoint you will want more fine grained control so you can control whether the SQL statement to be executed is a **SELECT**, **UPDATE**, **DELETE** or **INSERT** etc. So for instance if we want to route to an MyBatis endpoint in which the IN body contains parameters to a **SELECT**

statement we can do:

In the code above we can invoke the MyBatis statement **selectAccountById** and the IN body should contain the account id we want to retrieve, such as an **Integer** type.

We can do the same for some of the other operations, such as **SelectList**:

And the same for **UPDATE**, where we can send an **Account** object as the IN body to MyBatis:

235.7.1. Using InsertList StatementType

Available as of Camel 2.10

MyBatis allows you to insert multiple rows using its for-each batch driver. To use this, you need to use the `<foreach>` in the mapper XML file. For example as shown below:

Then you can insert multiple rows, by sending a Camel message to the **mybatis** endpoint which uses the **InsertList** statement type, as shown below:

235.7.2. Using UpdateList StatementType

Available as of Camel 2.11

MyBatis allows you to update multiple rows using its for-each batch driver. To use this, you need to use the `<foreach>` in the mapper XML file. For example as shown below:

```
<update id="batchUpdateAccount" parameterType="java.util.Map">
  update ACCOUNT set
  ACC_EMAIL = #{emailAddress}
  where
  ACC_ID in
  <foreach item="Account" collection="list" open="(" close=")" separator=",">
    #{Account.id}
  </foreach>
</update>
```

Then you can update multiple rows, by sending a Camel message to the **mybatis** endpoint which uses the **UpdateList** statement type, as shown below:

```
from("direct:start")
  .to("mybatis:batchUpdateAccount?statementType=UpdateList")
  .to("mock:result");
```

235.7.3. Using DeleteList StatementType

Available as of Camel 2.11

MyBatis allows you to delete multiple rows using its for-each batch driver. To use this, you need to use the `<foreach>` in the mapper XML file. For example as shown below:

```
<delete id="batchDeleteAccountById" parameterType="java.util.List">
  delete from ACCOUNT
  where
  ACC_ID in
```

```

<foreach item="AccountID" collection="list" open="(" close=")" separator=",">
  #{AccountID}
</foreach>
</delete>

```

Then you can delete multiple rows, by sending a Camel message to the mybatis endpoint which uses the DeleteList statement type, as shown below:

```

from("direct:start")
  .to("mybatis:batchDeleteAccount?statementType=DeleteList")
  .to("mock:result");

```

235.7.4. Notice on InsertList, UpdateList and DeleteList StatementTypes

Parameter of any type (List, Map, etc.) can be passed to mybatis and an end user is responsible for handling it as required with the help of [mybatis dynamic queries](#) capabilities.

235.7.5. Scheduled polling example

This component supports scheduled polling and can therefore be used as a Polling Consumer. For example to poll the database every minute:

```

from("mybatis:selectAllAccounts?delay=60000")
  .to("activemq:queue:allAccounts");

```

See "ScheduledPollConsumer Options" on Polling Consumer for more options.

Alternatively you can use another mechanism for triggering the scheduled polls, such as the [Timer](#) or [Quartz](#) components. In the sample below we poll the database, every 30 seconds using the [Timer](#) component and send the data to the JMS queue:

```

from("timer://pollTheDatabase?delay=30000")
  .to("mybatis:selectAllAccounts")
  .to("activemq:queue:allAccounts");

```

And the MyBatis SQL mapping file used:

```

<!-- Select with no parameters using the result map for Account class. -->
<select id="selectAllAccounts" resultMap="AccountResult">
  select * from ACCOUNT
</select>

```

235.7.6. Using onConsume

This component supports executing statements **after** data have been consumed and processed by Camel. This allows you to do post updates in the database. Notice all statements must be **UPDATE** statements. Camel supports executing multiple statements whose names should be separated by commas.

The route below illustrates we execute the **consumeAccount** statement data is processed. This allows us to change the status of the row in the database to processed, so we avoid consuming it twice or more.

And the statements in the sqlmap file:

235.7.7. Participating in transactions

Setting up a transaction manager under camel-mybatis can be a little bit fiddly, as it involves externalising the database configuration outside the standard MyBatis **SqlMapConfig.xml** file.

The first part requires the setup of a **DataSource**. This is typically a pool (either DBCP, or c3p0), which needs to be wrapped in a Spring proxy. This proxy enables non-Spring use of the **DataSource** to participate in Spring transactions (the MyBatis **SqlSessionFactory** does just this).

```
<bean id="dataSource"
class="org.springframework.jdbc.datasource.TransactionAwareDataSourceProxy">
  <constructor-arg>
    <bean class="com.mchange.v2.c3p0.ComboPooledDataSource">
      <property name="driverClass" value="org.postgresql.Driver"/>
      <property name="jdbcUrl" value="jdbc:postgresql://localhost:5432/myDatabase"/>
      <property name="user" value="myUser"/>
      <property name="password" value="myPassword"/>
    </bean>
  </constructor-arg>
</bean>
```

This has the additional benefit of enabling the database configuration to be externalised using property placeholders.

A transaction manager is then configured to manage the outermost **DataSource**:

```
<bean id="txManager"
class="org.springframework.jdbc.datasource.DataSourceTransactionManager">
  <property name="dataSource" ref="dataSource"/>
</bean>
```

A **mybatis-springSqlSessionFactoryBean** then wraps that same **DataSource**:

```
<bean id="sqlSessionFactory" class="org.mybatis.spring.SqlSessionFactoryBean">
  <property name="dataSource" ref="dataSource"/>
  <!-- standard mybatis config file -->
  <property name="configLocation" value="/META-INF/SqlMapConfig.xml"/>
  <!-- externalised mappers -->
  <property name="mapperLocations" value="classpath*:META-INF/mappers/**/*.xml"/>
</bean>
```

The camel-mybatis component is then configured with that factory:

```
<bean id="mybatis" class="org.apache.camel.component.mybatis.MyBatisComponent">
  <property name="sqlSessionFactory" ref="sqlSessionFactory"/>
</bean>
```

Finally, a transaction policy is defined over the top of the transaction manager, which can then be used as usual:

```
<bean id="PROPAGATION_REQUIRED"
class="org.apache.camel.spring.spi.SpringTransactionPolicy">
```

```
<property name="transactionManager" ref="txManager"/>
<property name="propagationBehaviorName" value="PROPAGATION_REQUIRED"/>
</bean>

<camelContext id="my-model-context" xmlns="http://camel.apache.org/schema/spring">
  <route id="insertModel">
    <from uri="direct:insert"/>
    <transacted ref="PROPAGATION_REQUIRED"/>
    <to uri="mybatis:myModel.insert?statementType=Insert"/>
  </route>
</camelContext>
```

CHAPTER 236. MYBATIS BEAN COMPONENT

Available as of Camel version 2.22

The **mybatis-bean**: component allows you to query, insert, update and delete data in a relational database using [MyBatis](#) bean annotations.

This component can **only** be used as a producer. If you want to consume from MyBatis then use the regular **mybatis** component.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-mybatis</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

This component will by default load the MyBatis SqlMapConfig file from the root of the classpath with the expected name of **SqlMapConfig.xml**.

If the file is located in another location, you will need to configure the **configurationUri** option on the **MyBatisComponent** component.

236.1. OPTIONS

The MyBatis Bean component supports 3 options, which are listed below.

Name	Description	Default	Type
sqlSessionFactory (advanced)	To use the SqlSessionFactory		SqlSessionFactory
configurationUri (producer)	Location of MyBatis xml configuration file. The default value is: SqlMapConfig.xml loaded from the classpath	SqlMapConfig.xml	String
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The MyBatis Bean endpoint is configured using URI syntax:

```
mybatis-bean:beanName:methodName
```

with the following path and query parameters:

236.1.1. Path Parameters (2 parameters):

Name	Description	Default	Type
beanName	Required Name of the bean with the MyBatis annotations. This can either be a type alias or a FQN class name.		String
methodName	Required Name of the method on the bean that has the SQL query to be executed.		String

236.1.2. Query Parameters (4 parameters):

Name	Description	Default	Type
executorType (producer)	The executor type to be used while executing statements. simple - executor does nothing special. reuse - executor reuses prepared statements. batch - executor reuses statements and batches updates.	SIMPLE	ExecutorType
inputHeader (producer)	User the header value for input parameters instead of the message body. By default, inputHeader == null and the input parameters are taken from the message body. If outputHeader is set, the value is used and query parameters will be taken from the header instead of the body.		String
outputHeader (producer)	Store the query result in a header instead of the message body. By default, outputHeader == null and the query result is stored in the message body, any existing content in the message body is discarded. If outputHeader is set, the value is used as the name of the header to store the query result and the original message body is preserved. Setting outputHeader will also omit populating the default CamelMyBatisResult header since it would be the same as outputHeader all the time.		String
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

236.2. SPRING BOOT AUTO-CONFIGURATION

The component supports 4 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.mybatis-bean.configuration-uri</code>	Location of MyBatis xml configuration file. The default value is: <code>SqlMapConfig.xml</code> loaded from the classpath	<code>SqlMapConfig.xml</code>	String
<code>camel.component.mybatis-bean.enabled</code>	Whether to enable auto configuration of the mybatis-bean component. This is enabled by default.		Boolean
<code>camel.component.mybatis-bean.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	<code>true</code>	Boolean
<code>camel.component.mybatis-bean.sql-session-factory</code>	To use the <code>SqlSessionFactory</code> . The option is a <code>org.apache.ibatis.session.SqlSessionFactory</code> type.		String

236.3. MESSAGE HEADERS

Camel will populate the result message, either IN or OUT with a header with the statement used:

Header	Type	Description
<code>CamelMyBatisResult</code>	Object	The response returned from MtBatis in any of the operations. For instance a INSERT could return the auto-generated key, or number of rows etc.

236.4. MESSAGE BODY

The response from MyBatis will only be set as the body if it's a **SELECT** statement. That means, for example, for **INSERT** statements Camel will not replace the body. This allows you to continue routing and keep the original body. The response from MyBatis is always stored in the header with the key **CamelMyBatisResult**.

236.5. SAMPLES

For example if you wish to consume beans from a JMS queue and insert them into a database you could do the following:

```
from("activemq:queue:newAccount")
    .to("mybatis-bean:AccountService:insertBeanAccount");
```

Notice we have to specify the bean name and method name, as we need to instruct Camel which kind of operation to invoke.

Where **AccountService** is the type alias for the bean that has the MyBatis bean annotations. You can configure type alias in the SqlMapConfig file:

```
<typeAliases>
  <typeAlias alias="Account" type="org.apache.camel.component.mybatis.Account"/>
  <typeAlias alias="AccountService"
type="org.apache.camel.component.mybatis.bean.AccountService"/>
</typeAliases>
```

On the `AccountService` bean you can declare the MyBatis mappings using annotations as shown:

```
public interface AccountService {

    @Select("select ACC_ID as id, ACC_FIRST_NAME as firstName, ACC_LAST_NAME as
lastName"
+ ", ACC_EMAIL as emailAddress from ACCOUNT where ACC_ID = #{id}")
    Account selectBeanAccountById(@Param("id") int no);

    @Select("select * from ACCOUNT order by ACC_ID")
    @ResultMap("Account.AccountResult")
    List<Account> selectBeanAllAccounts();

    @Insert("insert into ACCOUNT (ACC_ID,ACC_FIRST_NAME,ACC_LAST_NAME,ACC_EMAIL)"
+ " values (#{id}, #{firstName}, #{lastName}, #{emailAddress})")
    void insertBeanAccount(Account account);

}
```

CHAPTER 237. NAGIOS COMPONENT

Available as of Camel version 2.3

The [Nagios](#) component allows you to send passive checks to [Nagios](#).

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-nagios</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

237.1. URI FORMAT

```
nagios://host[:port][?Options]
```

Camel provides two abilities with the [Nagios](#) component. You can send passive check messages by sending a message to its endpoint.

Camel also provides a `EventNotifier` which allows you to send notifications to Nagios.

237.2. OPTIONS

The Nagios component supports 2 options, which are listed below.

Name	Description	Default	Type
configuration (advanced)	To use a shared NagiosConfiguration		NagiosConfiguration
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Nagios endpoint is configured using URI syntax:

```
nagios:host:port
```

with the following path and query parameters:

237.2.1. Path Parameters (2 parameters):

Name	Description	Default	Type
host	Required This is the address of the Nagios host where checks should be send.		String
port	Required The port number of the host.		int

237.2.2. Query Parameters (7 parameters):

Name	Description	Default	Type
connectionTimeout (producer)	Connection timeout in millis.	5000	int
sendSync (producer)	Whether or not to use synchronous when sending a passive check. Setting it to false will allow Camel to continue routing the message and the passive check message will be send asynchronously.	true	boolean
timeout (producer)	Sending timeout in millis.	5000	int
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
encryption (security)	To specify an encryption method.		Encryption
encryptionMethod (security)	Deprecated To specify an encryption method.		NagiosEncryption Method
password (security)	Password to be authenticated when sending checks to Nagios.		String

237.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 10 options, which are listed below.

Name	Description	Default	Type
camel.component.nagios.configuration.connection-timeout	Connection timeout in millis.	5000	Integer

Name	Description	Default	Type
camel.component.nagios.configuration.encryption	To specify an encryption method.		Encryption
camel.component.nagios.configuration.host	This is the address of the Nagios host where checks should be send.		String
camel.component.nagios.configuration.nagios-settings			NagiosSettings
camel.component.nagios.configuration.password	Password to be authenticated when sending checks to Nagios.		String
camel.component.nagios.configuration.port	The port number of the host.		Integer
camel.component.nagios.configuration.timeout	Sending timeout in millis.	5000	Integer
camel.component.nagios.enabled	Enable nagios component	true	Boolean
camel.component.nagios.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
camel.component.nagios.configuration.encryption-method	To specify an encryption method.		NagiosEncryption Method

237.4. SENDING MESSAGE EXAMPLES

You can send a message to Nagios where the message payload contains the message. By default it will be **OK** level and use the CamelContext name as the service name. You can overrule these values using headers as shown above.

For example we send the **Hello Nagios** message to Nagios as follows:

```
template.sendBody("direct:start", "Hello Nagios");

from("direct:start").to("nagios:127.0.0.1:5667?password=secret").to("mock:result");
```

To send a **CRITICAL** message you can send the headers such as:

```
Map headers = new HashMap();
headers.put(NagiosConstants.LEVEL, "CRITICAL");
headers.put(NagiosConstants.HOST_NAME, "myHost");
headers.put(NagiosConstants.SERVICE_NAME, "myService");
template.sendBodyAndHeaders("direct:start", "Hello Nagios", headers);
```

237.5. USING NAGIOSEVENTNOTIFER

The [Nagios](#) component also provides an `EventNotifier` which you can use to send events to Nagios. For example we can enable this from Java as follows:

```
NagiosEventNotifier notifier = new NagiosEventNotifier();
notifier.getConfiguration().setHost("localhost");
notifier.getConfiguration().setPort(5667);
notifier.getConfiguration().setPassword("password");

CamelContext context = ...
context.getManagementStrategy().addEventNotifier(notifier);
return context;
```

In Spring XML its just a matter of defining a Spring bean with the type **EventNotifier** and Camel will pick it up as documented here: [Advanced configuration of CamelContext using Spring](#) .

237.6. SEE ALSO

- [Configuring Camel](#)
- [Component](#)
- [Endpoint](#)
- [Getting Started](#)

CHAPTER 238. NATS COMPONENT

Available as of Camel version 2.17

NATS is a fast and reliable messaging platform.

Maven users will need to add the following dependency to their **pom.xml** for this component.

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-nats</artifactId>
  <!-- use the same version as your Camel core version -->
  <version>x.y.z</version>
</dependency>
```

238.1. URI FORMAT

```
nats:servers[?options]
```

Where **servers** represents the list of NATS servers.

238.2. OPTIONS

The Nats component supports 2 options, which are listed below.

Name	Description	Default	Type
useGlobalSslContext Parameters (security)	Enable usage of global SSL context parameters.	false	boolean
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Nats endpoint is configured using URI syntax:

```
nats:servers
```

with the following path and query parameters:

238.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
------	-------------	---------	------

Name	Description	Default	Type
servers	Required URLs to one or more NAT servers. Use comma to separate URLs when specifying multiple servers.		String

238.2.2. Query Parameters (25 parameters):

Name	Description	Default	Type
connection (common)	Reference an already instantiated connection to Nats server		Connection
connectionTimeout (common)	Timeout for connection attempts. (in milliseconds)	2000	int
flushConnection (common)	Define if we want to flush connection or not	false	boolean
flushTimeout (common)	Set the flush timeout (in milliseconds)	1000	int
maxPingsOut (common)	maximum number of pings have not received a response allowed by the client	2	int
maxReconnectAttempts (common)	Max reconnection attempts	60	int
noEcho (common)	Turn off echo. If supported by the gnatsd version you are connecting to this flag will prevent the server from echoing messages back to the connection if it has subscriptions on the subject being published to.	false	boolean
noRandomizeServers (common)	Whether or not randomizing the order of servers for the connection attempts	false	boolean
pedantic (common)	Whether or not running in pedantic mode (this affects performance)	false	boolean
pingInterval (common)	Ping interval to be aware if connection is still alive (in milliseconds)	120000	int
reconnect (common)	Whether or not using reconnection feature	true	boolean

Name	Description	Default	Type
reconnectTimeWait (common)	Waiting time before attempts reconnection (in milliseconds)	2000	int
requestCleanupInterval (common)	Interval to clean up cancelled/timed out requests.	5000	int
topic (common)	Required The name of topic we want to use		String
verbose (common)	Whether or not running in verbose mode	false	boolean
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
maxMessages (consumer)	Stop receiving messages from a topic we are subscribing to after maxMessages		String
poolSize (consumer)	Consumer pool size	10	int
queueName (consumer)	The Queue name if we are using nats for a queue configuration		String
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
replySubject (producer)	the subject to which subscribers should send response		String
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
secure (security)	Set secure option indicating TLS is required	false	boolean

Name	Description	Default	Type
<code>sslContextParameters</code> (security)	To configure security using <code>SSLContextParameters</code>		<code>SSLContextParameters</code>

238.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 3 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.nats.enabled</code>	Enable nats component	true	Boolean
<code>camel.component.nats.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.component.nats.use-global-ssl-context-parameters</code>	Enable usage of global SSL context parameters.	false	Boolean

238.4. HEADERS

Name	Type	Description
Camel NatsMessage Timestamp	long	The timestamp of a consumed message.

Producer example:

```
from("direct:send").to("nats://localhost:4222?topic=test");
```

In case of using Authorization you can directly specify your credentials in the server URL

```
from("direct:send").to("nats://username:password@localhost:4222?topic=test");
```

or your token

```
from("direct:send").to("nats://token@localhost:4222?topic=test");
```

Consumer example:

```
from("nats://localhost:4222?topic=test&maxMessages=5&queueName=test").to("mock:result");
```

CHAPTER 239. NETTY COMPONENT (DEPRECATED)

Available as of Camel version 2.3

WARNING

This component is deprecated. You should use [Netty4](#).

The **netty** component in Camel is a socket communication component, based on the [Netty](#) project.

Netty is a NIO client server framework which enables quick and easy development of network applications such as protocol servers and clients.

Netty greatly simplifies and streamlines network programming such as TCP and UDP socket server.

This camel component supports both producer and consumer endpoints.

The Netty component has several options and allows fine-grained control of a number of TCP/UDP communication parameters (buffer sizes, keepAlives, tcpNoDelay etc) and facilitates both In-Only and In-Out communication on a Camel route.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-netty</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

239.1. URI FORMAT

The URI scheme for a netty component is as follows

```
netty:tcp://0.0.0.0:99999[?options]
netty:udp://remotehost:99999/[?options]
```

This component supports producer and consumer endpoints for both TCP and UDP.

You can append query options to the URI in the following format, **?option=value&option=value&...**

239.2. OPTIONS

The Netty component supports 4 options, which are listed below.

Name	Description	Default	Type
configuration (advanced)	To use the NettyConfiguration as configuration when creating endpoints.		NettyConfiguration
maximumPoolSize (advanced)	The core pool size for the ordered thread pool, if its in use. The default value is 16.	16	int
useGlobalSslContext Parameters (security)	Enable usage of global SSL context parameters.	false	boolean
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Netty endpoint is configured using URI syntax:

```
netty:protocol:host:port
```

with the following path and query parameters:

239.2.1. Path Parameters (3 parameters):

Name	Description	Default	Type
protocol	Required The protocol to use which can be tcp or udp.		String
host	Required The hostname. For the consumer the hostname is localhost or 0.0.0.0 For the producer the hostname is the remote host to connect to		String
port	Required The host port number		int

239.2.2. Query Parameters (67 parameters):

Name	Description	Default	Type
disconnect (common)	Whether or not to disconnect(close) from Netty Channel right after use. Can be used for both consumer and producer.	false	boolean

Name	Description	Default	Type
keepAlive (common)	Setting to ensure socket is not closed due to inactivity	true	boolean
reuseAddress (common)	Setting to facilitate socket multiplexing	true	boolean
sync (common)	Setting to set endpoint as one-way or request-response	true	boolean
tcpNoDelay (common)	Setting to improve TCP protocol performance	true	boolean
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
broadcast (consumer)	Setting to choose Multicast over UDP	false	boolean
clientMode (consumer)	If the <code>clientMode</code> is true, netty consumer will connect the address as a TCP client.	false	boolean
backlog (consumer)	Allows to configure a backlog for netty consumer (server). Note the backlog is just a best effort depending on the OS. Setting this option to a value such as 200, 500 or 1000, tells the TCP stack how long the accept queue can be. If this option is not configured, then the backlog depends on OS setting.		int
bossCount (consumer)	When netty works on nio mode, it uses default <code>bossCount</code> parameter from Netty, which is 1. User can use this operation to override the default <code>bossCount</code> from Netty	1	int
bossPool (consumer)	To use a explicit <code>org.jboss.netty.channel.socket.nio.BossPool</code> as the boss thread pool. For example to share a thread pool with multiple consumers. By default each consumer has their own boss pool with 1 core thread.		BossPool
channelGroup (consumer)	To use a explicit ChannelGroup.		ChannelGroup

Name	Description	Default	Type
disconnectOnNoReply (consumer)	If sync is enabled then this option dictates NettyConsumer if it should disconnect where there is no reply to send back.	true	boolean
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
maxChannelMemorySize (consumer)	The maximum total size of the queued events per channel when using orderedThreadPoolExecutor. Specify 0 to disable.	10485760	long
maxTotalMemorySize (consumer)	The maximum total size of the queued events for this pool when using orderedThreadPoolExecutor. Specify 0 to disable.	209715200	long
nettyServerBootstrapFactory (consumer)	To use a custom NettyServerBootstrapFactory		NettyServerBootstrapFactory
networkInterface (consumer)	When using UDP then this option can be used to specify a network interface by its name, such as eth0 to join a multicast group.		String
noReplyLogLevel (consumer)	If sync is enabled this option dictates NettyConsumer which logging level to use when logging a there is no reply to send back.	WARN	LoggingLevel
orderedThreadPoolExecutor (consumer)	Whether to use ordered thread pool, to ensure events are processed orderly on the same channel. See details at the netty javadoc of org.jboss.netty.handler.execution.OrderedMemoryAwareThreadPoolExecutor for more details.	true	boolean
serverClosedChannelExceptionCaughtLogLevel (consumer)	If the server (NettyConsumer) catches an java.nio.channels.ClosedChannelException then its logged using this logging level. This is used to avoid logging the closed channel exceptions, as clients can disconnect abruptly and then cause a flood of closed exceptions in the Netty server.	DEBUG	LoggingLevel

Name	Description	Default	Type
serverExceptionCaughtLogLevel (consumer)	If the server (NettyConsumer) catches an exception then its logged using this logging level.	WARN	LogLevel
serverPipelineFactory (consumer)	To use a custom ServerPipelineFactory		ServerPipelineFactory
workerCount (consumer)	When netty works on nio mode, it uses default workerCount parameter from Netty, which is cpu_core_threads2. User can use this operation to override the default workerCount from Netty		int
workerPool (consumer)	To use a explicit org.jboss.netty.channel.socket.nio.WorkerPool as the worker thread pool. For example to share a thread pool with multiple consumers. By default each consumer has their own worker pool with 2 x cpu count core threads.		WorkerPool
connectTimeout (producer)	Time to wait for a socket connection to be available. Value is in millis.	10000	long
requestTimeout (producer)	Allows to use a timeout for the Netty producer when calling a remote server. By default no timeout is in use. The value is in milli seconds, so eg 30000 is 30 seconds. The requestTimeout is using Netty's ReadTimeoutHandler to trigger the timeout.		long
clientPipelineFactory (producer)	To use a custom ClientPipelineFactory		ClientPipelineFactory
lazyChannelCreation (producer)	Channels can be lazily created to avoid exceptions, if the remote server is not up and running when the Camel producer is started.	true	boolean
producerPoolEnabled (producer)	Whether producer pool is enabled or not. Important: Do not turn this off, as the pooling is needed for handling concurrency and reliable request/reply.	true	boolean
producerPoolMaxActive (producer)	Sets the cap on the number of objects that can be allocated by the pool (checked out to clients, or idle awaiting checkout) at a given time. Use a negative value for no limit.	-1	int
producerPoolMaxIdle (producer)	Sets the cap on the number of idle instances in the pool.	100	int

Name	Description	Default	Type
producerPoolMinEvictableIdle (producer)	Sets the minimum amount of time (value in millis) an object may sit idle in the pool before it is eligible for eviction by the idle object evictor.	30000 0	long
producerPoolMinIdle (producer)	Sets the minimum number of instances allowed in the producer pool before the evictor thread (if active) spawns new objects.		int
udpConnectionlessSending (producer)	This option supports connection less udp sending which is a real fire and forget. A connected udp send receive the PortUnreachableException if no one is listen on the receiving port.	false	boolean
useChannelBuffer (producer)	If the useChannelBuffer is true, netty producer will turn the message body into ChannelBuffer before sending it out.	false	boolean
bootstrapConfiguration (advanced)	To use a custom configured NettyServerBootstrapConfiguration for configuring this endpoint.		NettyServerBootstrap Configuration
options (advanced)	Allows to configure additional netty options using option. as prefix. For example option.child.keepAlive=false to set the netty option child.keepAlive=false. See the Netty documentation for possible options that can be used.		Map
receiveBufferSize (advanced)	The TCP/UDP buffer sizes to be used during inbound communication. Size is bytes.	65536	long
receiveBufferSizePredictor (advanced)	Configures the buffer size predictor. See details at Jetty documentation and this mail thread.		int
sendBufferSize (advanced)	The TCP/UDP buffer sizes to be used during outbound communication. Size is bytes.	65536	long
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

Name	Description	Default	Type
transferExchange (advanced)	Only used for TCP. You can transfer the exchange over the wire instead of just the body. The following fields are transferred: In body, Out body, fault body, In headers, Out headers, fault headers, exchange properties, exchange exception. This requires that the objects are serializable. Camel will exclude any non-serializable objects and log it at WARN level.	false	boolean
allowDefaultCodec (codec)	The netty component installs a default codec if both, encoder/decoder is null and textline is false. Setting allowDefaultCodec to false prevents the netty component from installing a default codec as the first element in the filter chain.	true	boolean
autoAppendDelimiter (codec)	Whether or not to auto append missing end delimiter when sending using the textline codec.	true	boolean
decoder (codec)	Deprecated A custom ChannelHandler class that can be used to perform special marshalling of inbound payloads. Must override <code>org.jboss.netty.channel.ChannelUpStreamHandler</code> .		ChannelHandler
decoderMaxLineLength (codec)	The max line length to use for the textline codec.	1024	int
decoders (codec)	A list of decoders to be used. You can use a String which have values separated by comma, and have the values be looked up in the Registry. Just remember to prefix the value with # so Camel knows it should lookup.		String
delimiter (codec)	The delimiter to use for the textline codec. Possible values are LINE and NULL.	LINE	TextLineDelimiter
encoder (codec)	Deprecated A custom ChannelHandler class that can be used to perform special marshalling of outbound payloads. Must override <code>org.jboss.netty.channel.ChannelDownStreamHandler</code> .		ChannelHandler
encoders (codec)	A list of encoders to be used. You can use a String which have values separated by comma, and have the values be looked up in the Registry. Just remember to prefix the value with # so Camel knows it should lookup.		String

Name	Description	Default	Type
encoding (codec)	The encoding (a charset name) to use for the textline codec. If not provided, Camel will use the JVM default Charset.		String
textline (codec)	Only used for TCP. If no codec is specified, you can use this flag to indicate a text line based codec; if not specified or the value is false, then Object Serialization is assumed over TCP.	false	boolean
enabledProtocols (security)	Which protocols to enable when using SSL	TLSv1, TLSv1.1, TLSv1.2	String
keyStoreFile (security)	Client side certificate keystore to be used for encryption		File
keyStoreFormat (security)	Keystore format to be used for payload encryption. Defaults to JKS if not set	JKS	String
keyStoreResource (security)	Client side certificate keystore to be used for encryption. Is loaded by default from classpath, but you can prefix with classpath:, file:, or http: to load the resource from different systems.		String
needClientAuth (security)	Configures whether the server needs client authentication when using SSL.	false	boolean
passphrase (security)	Password setting to use in order to encrypt/decrypt payloads sent using SSH		String
securityProvider (security)	Security provider to be used for payload encryption. Defaults to SunX509 if not set.	SunX509	String
ssl (security)	Setting to specify whether SSL encryption is applied to this endpoint	false	boolean
sslClientCertHeaders (security)	When enabled and in SSL mode, then the Netty consumer will enrich the Camel Message with headers having information about the client certificate such as subject name, issuer name, serial number, and the valid date range.	false	boolean
sslContextParameters (security)	To configure security using SSLContextParameters		SSLContextParameters

Name	Description	Default	Type
sslHandler (security)	Reference to a class that could be used to return an SSL Handler		SslHandler
trustStoreFile (security)	Server side certificate keystore to be used for encryption		File
trustStoreResource (security)	Server side certificate keystore to be used for encryption. Is loaded by default from classpath, but you can prefix with classpath:, file:, or http: to load the resource from different systems.		String

239.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 70 options, which are listed below.

Name	Description	Default	Type
camel.component.netty.configuration.allow-default-codec	The netty component installs a default codec if both, encoder/decoder is null and textline is false. Setting allowDefaultCodec to false prevents the netty component from installing a default codec as the first element in the filter chain.	true	Boolean
camel.component.netty.configuration.auto-append-delimiter	Whether or not to auto append missing end delimiter when sending using the textline codec.	true	Boolean
camel.component.netty.configuration.backlog	Allows to configure a backlog for netty consumer (server). Note the backlog is just a best effort depending on the OS. Setting this option to a value such as 200, 500 or 1000, tells the TCP stack how long the accept queue can be. If this option is not configured, then the backlog depends on OS setting.		Integer
camel.component.netty.configuration.boss-count	When netty works on nio mode, it uses default bossCount parameter from Netty, which is 1. User can use this operation to override the default bossCount from Netty	1	Integer
camel.component.netty.configuration.boss-pool	To use a explicit org.jboss.netty.channel.socket.nio.BossPool as the boss thread pool. For example to share a thread pool with multiple consumers. By default each consumer has their own boss pool with 1 core thread.		BossPool

Name	Description	Default	Type
<code>camel.component.netty.configuration.broadcast</code>	Setting to choose Multicast over UDP	false	Boolean
<code>camel.component.netty.configuration.channel-group</code>	To use a explicit ChannelGroup.		ChannelGroup
<code>camel.component.netty.configuration.client-mode</code>	If the clientMode is true, netty consumer will connect the address as a TCP client.	false	Boolean
<code>camel.component.netty.configuration.client-pipeline-factory</code>	To use a custom ClientPipelineFactory		ClientPipelineFactory
<code>camel.component.netty.configuration.connect-timeout</code>	Time to wait for a socket connection to be available. Value is in millis.	10000	Long
<code>camel.component.netty.configuration.decoder-max-line-length</code>	The max line length to use for the textline codec.	1024	Integer
<code>camel.component.netty.configuration.decoders</code>	A list of decoders to be used. You can use a String which have values separated by comma, and have the values be looked up in the Registry. Just remember to prefix the value with # so Camel knows it should lookup.		List
<code>camel.component.netty.configuration.delimiter</code>	The delimiter to use for the textline codec. Possible values are LINE and NULL.		TextLineDelimiter
<code>camel.component.netty.configuration.disconnect</code>	Whether or not to disconnect(close) from Netty Channel right after use. Can be used for both consumer and producer.	false	Boolean
<code>camel.component.netty.configuration.disconnect-no-reply</code>	If sync is enabled then this option dictates NettyConsumer if it should disconnect where there is no reply to send back.	true	Boolean

Name	Description	Default	Type
<code>camel.component.netty.configuration.enabled-protocols</code>	Which protocols to enable when using SSL	TLSv1, TLSv1.1, TLSv1.2	String
<code>camel.component.netty.configuration.encoders</code>	A list of encoders to be used. You can use a String which have values separated by comma, and have the values be looked up in the Registry. Just remember to prefix the value with # so Camel knows it should lookup.		List
<code>camel.component.netty.configuration.encoding</code>	The encoding (a charset name) to use for the textline codec. If not provided, Camel will use the JVM default Charset.		String
<code>camel.component.netty.configuration.host</code>	The hostname. For the consumer the hostname is localhost or 0.0.0.0 For the producer the hostname is the remote host to connect to		String
<code>camel.component.netty.configuration.keep-alive</code>	Setting to ensure socket is not closed due to inactivity	true	Boolean
<code>camel.component.netty.configuration.key-store-format</code>	Keystore format to be used for payload encryption. Defaults to JKS if not set	JKS	String
<code>camel.component.netty.configuration.key-store-resource</code>	Client side certificate keystore to be used for encryption. Is loaded by default from classpath, but you can prefix with classpath:, file:, or http: to load the resource from different systems.		String
<code>camel.component.netty.configuration.lazy-channel-creation</code>	Channels can be lazily created to avoid exceptions, if the remote server is not up and running when the Camel producer is started.	true	Boolean
<code>camel.component.netty.configuration.max-channel-memory-size</code>	The maximum total size of the queued events per channel when using orderedThreadPoolExecutor. Specify 0 to disable.	10485760	Long

Name	Description	Default	Type
<code>camel.component.netty.configuration.max-total-memory-size</code>	The maximum total size of the queued events for this pool when using <code>orderedThreadPoolExecutor</code> . Specify 0 to disable.	209715200	Long
<code>camel.component.netty.configuration.need-client-auth</code>	Configures whether the server needs client authentication when using SSL.	false	Boolean
<code>camel.component.netty.configuration.netty-server-bootstrap-factory</code>	To use a custom <code>NettyServerBootstrapFactory</code>		<code>NettyServerBootstrapFactory</code>
<code>camel.component.netty.configuration.network-interface</code>	When using UDP then this option can be used to specify a network interface by its name, such as <code>eth0</code> to join a multicast group.		String
<code>camel.component.netty.configuration.no-reply-log-level</code>	If sync is enabled this option dictates <code>NettyConsumer</code> which logging level to use when logging a there is no reply to send back.		<code>LoggingLevel</code>
<code>camel.component.netty.configuration.options</code>	Allows to configure additional netty options using option. as prefix. For example <code>option.child.keepAlive=false</code> to set the netty option <code>child.keepAlive=false</code> . See the Netty documentation for possible options that can be used.		Map
<code>camel.component.netty.configuration.ordered-thread-pool-executor</code>	Whether to use ordered thread pool, to ensure events are processed orderly on the same channel. See details at the netty javadoc of <code>org.jboss.netty.handler.execution.OrderedMemoryAwareThreadPoolExecutor</code> for more details.	true	Boolean
<code>camel.component.netty.configuration.passphrase</code>	Password setting to use in order to encrypt/decrypt payloads sent using SSH		String
<code>camel.component.netty.configuration.port</code>	The host port number		Integer

Name	Description	Default	Type
<code>camel.component.netty.configuration.producer-pool-enabled</code>	Whether producer pool is enabled or not. Important: Do not turn this off, as the pooling is needed for handling concurrency and reliable request/reply.	true	Boolean
<code>camel.component.netty.configuration.producer-pool-max-active</code>	Sets the cap on the number of objects that can be allocated by the pool (checked out to clients, or idle awaiting checkout) at a given time. Use a negative value for no limit.	-1	Integer
<code>camel.component.netty.configuration.producer-pool-max-idle</code>	Sets the cap on the number of idle instances in the pool.	100	Integer
<code>camel.component.netty.configuration.producer-pool-min-evictable-idle</code>	Sets the minimum amount of time (value in millis) an object may sit idle in the pool before it is eligible for eviction by the idle object evictor.	30000 0	Long
<code>camel.component.netty.configuration.producer-pool-min-idle</code>	Sets the minimum number of instances allowed in the producer pool before the evictor thread (if active) spawns new objects.		Integer
<code>camel.component.netty.configuration.protocol</code>	The protocol to use which can be tcp or udp.		String
<code>camel.component.netty.configuration.receive-buffer-size</code>	The TCP/UDP buffer sizes to be used during inbound communication. Size is bytes.	65536	Long
<code>camel.component.netty.configuration.receive-buffer-size-predictor</code>	Configures the buffer size predictor. See details at Jetty documentation and this mail thread.		Integer
<code>camel.component.netty.configuration.request-timeout</code>	Allows to use a timeout for the Netty producer when calling a remote server. By default no timeout is in use. The value is in milli seconds, so eg 30000 is 30 seconds. The requestTimeout is using Netty's ReadTimeoutHandler to trigger the timeout.		Long

Name	Description	Default	Type
<code>camel.component.netty.configuration.reuse-address</code>	Setting to facilitate socket multiplexing	true	Boolean
<code>camel.component.netty.configuration.security-provider</code>	Security provider to be used for payload encryption. Defaults to SunX509 if not set.	SunX509	String
<code>camel.component.netty.configuration.send-buffer-size</code>	The TCP/UDP buffer sizes to be used during outbound communication. Size is bytes.	65536	Long
<code>camel.component.netty.configuration.server-closed-channel-exception-caught-log-level</code>	If the server (NettyConsumer) catches an <code>java.nio.channels.ClosedChannelException</code> then its logged using this logging level. This is used to avoid logging the closed channel exceptions, as clients can disconnect abruptly and then cause a flood of closed exceptions in the Netty server.		LogLevel
<code>camel.component.netty.configuration.server-exception-caught-log-level</code>	If the server (NettyConsumer) catches an exception then its logged using this logging level.		LogLevel
<code>camel.component.netty.configuration.server-pipeline-factory</code>	To use a custom <code>ServerPipelineFactory</code>		<code>ServerPipelineFactory</code>
<code>camel.component.netty.configuration.ssl</code>	Setting to specify whether SSL encryption is applied to this endpoint	false	Boolean
<code>camel.component.netty.configuration.ssl-client-cert-headers</code>	When enabled and in SSL mode, then the Netty consumer will enrich the Camel Message with headers having information about the client certificate such as subject name, issuer name, serial number, and the valid date range.	false	Boolean
<code>camel.component.netty.configuration.ssl-context-parameters</code>	To configure security using <code>SSLContextParameters</code>		<code>SSLContextParameters</code>

Name	Description	Default	Type
<code>camel.component.netty.configuration.ssl-handler</code>	Reference to a class that could be used to return an SSL Handler		SslHandler
<code>camel.component.netty.configuration.sync</code>	Setting to set endpoint as one-way or request-response	true	Boolean
<code>camel.component.netty.configuration.tcp-no-delay</code>	Setting to improve TCP protocol performance	true	Boolean
<code>camel.component.netty.configuration.textline</code>	Only used for TCP. If no codec is specified, you can use this flag to indicate a text line based codec; if not specified or the value is false, then Object Serialization is assumed over TCP.	false	Boolean
<code>camel.component.netty.configuration.transfer-exchange</code>	Only used for TCP. You can transfer the exchange over the wire instead of just the body. The following fields are transferred: In body, Out body, fault body, In headers, Out headers, fault headers, exchange properties, exchange exception. This requires that the objects are serializable. Camel will exclude any non-serializable objects and log it at WARN level.	false	Boolean
<code>camel.component.netty.configuration.trust-store-resource</code>	Server side certificate keystore to be used for encryption. Is loaded by default from classpath, but you can prefix with classpath:, file:, or http: to load the resource from different systems.		String
<code>camel.component.netty.configuration.udp-connectionless-sending</code>	This option supports connection less udp sending which is a real fire and forget. A connected udp send receive the PortUnreachableException if no one is listen on the receiving port.	false	Boolean
<code>camel.component.netty.configuration.use-channel-buffer</code>	If the useChannelBuffer is true, netty producer will turn the message body into ChannelBuffer before sending it out.	false	Boolean
<code>camel.component.netty.configuration.worker-count</code>	When netty works on nio mode, it uses default workerCount parameter from Netty, which is <code>cpu_core_threads2</code> . User can use this operation to override the default workerCount from Netty		Integer

Name	Description	Default	Type
<code>camel.component.netty.configuration.worker-pool</code>	To use a explicit <code>org.jboss.netty.channel.socket.nio.WorkerPool</code> as the worker thread pool. For example to share a thread pool with multiple consumers. By default each consumer has their own worker pool with 2 x cpu count core threads.		WorkerPool
<code>camel.component.netty.enabled</code>	Enable netty component	true	Boolean
<code>camel.component.netty.maximum-pool-size</code>	The core pool size for the ordered thread pool, if its in use. The default value is 16.	16	Integer
<code>camel.component.netty.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.component.netty.use-global-ssl-context-parameters</code>	Enable usage of global SSL context parameters.	false	Boolean
<code>camel.component.netty.configuration.decoder</code>	A custom <code>ChannelHandler</code> class that can be used to perform special marshalling of inbound payloads. Must override <code>org.jboss.netty.channel.ChannelUpStreamHandler</code> .		ChannelHandler
<code>camel.component.netty.configuration.encoder</code>	A custom <code>ChannelHandler</code> class that can be used to perform special marshalling of outbound payloads. Must override <code>org.jboss.netty.channel.ChannelDownStreamHandler</code> .		ChannelHandler
<code>camel.component.netty.configuration.key-store-file</code>	Client side certificate keystore to be used for encryption		File
<code>camel.component.netty.configuration.maximum-pool-size</code>			Integer
<code>camel.component.netty.configuration.trust-store-file</code>	Server side certificate keystore to be used for encryption		File

239.4. REGISTRY BASED OPTIONS

Codec Handlers and SSL Keystores can be enlisted in the Registry, such as in the Spring XML file. The values that could be passed in, are the following:

Name	Description
passphrase	password setting to use in order to encrypt/decrypt payloads sent using SSH
keyStoreFormat	keystore format to be used for payload encryption. Defaults to "JKS" if not set
securityProvider	Security provider to be used for payload encryption. Defaults to "SunX509" if not set.
keyStoreFile	deprecated: Client side certificate keystore to be used for encryption
trustStoreFile	deprecated: Server side certificate keystore to be used for encryption
keyStoreResource	Camel 2.11.1: Client side certificate keystore to be used for encryption. Is loaded by default from classpath, but you can prefix with " classpath: ", " file: ", or " http: " to load the resource from different systems.
trustStoreResource	Camel 2.11.1: Server side certificate keystore to be used for encryption. Is loaded by default from classpath, but you can prefix with " classpath: ", " file: ", or " http: " to load the resource from different systems.
sslHandler	Reference to a class that could be used to return an SSL Handler
encoder	A custom ChannelHandler class that can be used to perform special marshalling of outbound payloads. Must override org.jboss.netty.channel.ChannelDownStreamHandler .
encoders	A list of encoders to be used. You can use a String which have values separated by comma, and have the values be looked up in the Registry. Just remember to prefix the value with # so Camel knows it should lookup.
decoder	A custom ChannelHandler class that can be used to perform special marshalling of inbound payloads. Must override org.jboss.netty.channel.ChannelUpStreamHandler .

Name	Description
decoders	A list of decoders to be used. You can use a String which have values separated by comma, and have the values be looked up in the Registry. Just remember to prefix the value with # so Camel knows it should lookup.

Important: Read below about using non shareable encoders/decoders.

239.4.1. Using non shareable encoders or decoders

If your encoders or decoders is not shareable (eg they have the `@Shareable` class annotation), then your encoder/decoder must implement the **`org.apache.camel.component.netty.ChannelHandlerFactory`** interface, and return a new instance in the **`newChannelHandler`** method. This is to ensure the encoder/decoder can safely be used. If this is not the case, then the Netty component will log a WARN when an endpoint is created.

The Netty component offers a **`org.apache.camel.component.netty.ChannelHandlerFactories`** factory class, that has a number of commonly used methods.

239.5. SENDING MESSAGES TO/FROM A NETTY ENDPOINT

239.5.1. Netty Producer

In Producer mode, the component provides the ability to send payloads to a socket endpoint using either TCP or UDP protocols (with optional SSL support).

The producer mode supports both one-way and request-response based operations.

239.5.2. Netty Consumer

In Consumer mode, the component provides the ability to:

- listen on a specified socket using either TCP or UDP protocols (with optional SSL support),
- receive requests on the socket using text/xml, binary and serialized object based payloads and
- send them along on a route as message exchanges.

The consumer mode supports both one-way and request-response based operations.

239.6. HEADERS

The following headers are filled for the exchanges created by the Netty consumer:

Header key	Class	Description
Netty Constants. NETTY_CHANNEL_HANDLER_CONTEXT / Camel Netty ChannelHandlerContext	org.jboss.netty.channel.ChannelHandlerContext	`ChannelHandlerContext` instance associated with the connection received by netty.
Netty Constants. NETTY_MESSAGE_EVENT / Camel Netty MessageEvent	org.jboss.netty.channel.MessageEvent	`MessageEvent` instance associated with the connection received by netty.
Netty Constants. NETTY_REMOTE_ADDRESS / Camel Netty RemoteAddress	java.net.SocketAddress	Remote address of the incoming socket connection.

Header key	Class	Description
Netty Constants.NETTY_LOCAL_ADDRESS	java.net.SocketAddress	Local address of the incoming socket connection.

239.7. USAGE SAMPLES

239.7.1. A UDP Netty endpoint using Request-Reply and serialized object payload

```
RouteBuilder builder = new RouteBuilder() {
    public void configure() {
        from("netty:udp://0.0.0.0:5155?sync=true")
            .process(new Processor() {
                public void process(Exchange exchange) throws Exception {
                    Poetry poetry = (Poetry) exchange.getIn().getBody();
                    poetry.setPoet("Dr. Sarojini Naidu");
                    exchange.getOut().setBody(poetry);
                }
            })
    }
};
```

239.7.2. A TCP based Netty consumer endpoint using One-way communication

```
RouteBuilder builder = new RouteBuilder() {
    public void configure() {
        from("netty:tcp://0.0.0.0:5150")
            .to("mock:result");
    }
};
```

239.7.3. An SSL/TCP based Netty consumer endpoint using Request-Reply communication

Using the JSSE Configuration Utility

As of Camel 2.9, the Netty component supports SSL/TLS configuration through the [Camel JSSE](#)

Configuration Utility. This utility greatly decreases the amount of component specific code you need to write and is configurable at the endpoint and component levels. The following examples demonstrate how to use the utility with the Netty component.

Programmatic configuration of the component

```

KeyStoreParameters ksp = new KeyStoreParameters();
ksp.setResource("/users/home/server/keystore.jks");
ksp.setPassword("keystorePassword");

KeyManagersParameters kmp = new KeyManagersParameters();
kmp.setKeyStore(ksp);
kmp.setKeyPassword("keyPassword");

SSLContextParameters scp = new SSLContextParameters();
scp.setKeyManagers(kmp);

NettyComponent nettyComponent = getContext().getComponent("netty", NettyComponent.class);
nettyComponent.setSslContextParameters(scp);

```

Spring DSL based configuration of endpoint

```

...
<camel:sslContextParameters
  id="sslContextParameters">
  <camel:keyManagers
    keyPassword="keyPassword">
  <camel:keyStore
    resource="/users/home/server/keystore.jks"
    password="keystorePassword"/>
  </camel:keyManagers>
</camel:sslContextParameters>...
...
<to uri="netty:tcp://0.0.0.0:5150?
sync=true&ssl=true&sslContextParameters=#sslContextParameters"/>
...

```

Using Basic SSL/TLS configuration on the Jetty Component

```

JndiRegistry registry = new JndiRegistry(createJndiContext());
registry.bind("password", "changeit");
registry.bind("ksf", new File("src/test/resources/keystore.jks"));
registry.bind("tsf", new File("src/test/resources/keystore.jks"));

context.createRegistry(registry);
context.addRoutes(new RouteBuilder() {
  public void configure() {
    String netty_ssl_endpoint =
      "netty:tcp://0.0.0.0:5150?sync=true&ssl=true&passphrase=#password"
      + "&keyStoreFile=#ksf&trustStoreFile=#tsf";
    String return_string =
      "When You Go Home, Tell Them Of Us And Say,"
      + "For Your Tomorrow, We Gave Our Today.";

    from(netty_ssl_endpoint)

```

```

        .process(new Processor() {
            public void process(Exchange exchange) throws Exception {
                exchange.getOut().setBody(return_string);
            }
        }
    );
};

```

Getting access to `SSLSession` and the client certificate

Available as of Camel 2.12

You can get access to the `javax.net.ssl.SSLSession` if you eg need to get details about the client certificate. When `ssl=true` then the `Netty` component will store the `SSLSession` as a header on the Camel Message as shown below:

```

SSLSession session = exchange.getIn().getHeader(NettyConstants.NETTY_SSL_SESSION,
SSLSession.class);
// get the first certificate which is client certificate
javax.security.cert.X509Certificate cert = session.getPeerCertificateChain()[0];
Principal principal = cert.getSubjectDN();

```

Remember to set `needClientAuth=true` to authenticate the client, otherwise `SSLSession` cannot access information about the client certificate, and you may get an exception `javax.net.ssl.SSLPeerUnverifiedException: peer not authenticated`. You may also get this exception if the client certificate is expired or not valid etc.

TIP

The option `sslClientCertHeaders` can be set to `true` which then enriches the Camel Message with headers having details about the client certificate. For example the subject name is readily available in the header `CamelNettySSLClientCertSubjectName`.

239.7.4. Using Multiple Codecs

In certain cases it may be necessary to add chains of encoders and decoders to the netty pipeline. To add multiple codecs to a camel netty endpoint the 'encoders' and 'decoders' uri parameters should be used. Like the 'encoder' and 'decoder' parameters they are used to supply references (to lists of `ChannelUpstreamHandlers` and `ChannelDownstreamHandlers`) that should be added to the pipeline. Note that if encoders is specified then the encoder param will be ignored, similarly for decoders and the decoder param.

INFO: Read further above about using non shareable encoders/decoders.

The lists of codecs need to be added to the Camel's registry so they can be resolved when the endpoint is created.

Spring's native collections support can be used to specify the codec lists in an application context

The bean names can then be used in netty endpoint definitions either as a comma separated list or contained in a List e.g.

or via spring.

239.8. CLOSING CHANNEL WHEN COMPLETE

When acting as a server you sometimes want to close the channel when, for example, a client conversion is finished.

You can do this by simply setting the endpoint option **disconnect=true**.

However you can also instruct Camel on a per message basis as follows.

To instruct Camel to close the channel, you should add a header with the key

CamelNettyCloseChannelWhenComplete set to a boolean **true** value.

For instance, the example below will close the channel after it has written the bye message back to the client:

```
from("netty:tcp://0.0.0.0:8080").process(new Processor() {
    public void process(Exchange exchange) throws Exception {
        String body = exchange.getIn().getBody(String.class);
        exchange.getOut().setBody("Bye " + body);
        // some condition which determines if we should close
        if (close) {
            exchange.getOut().setHeader(NettyConstants.NETTY_CLOSE_CHANNEL_WHEN_COMPLETE,
                true);
        }
    }
});
```

239.9. ADDING CUSTOM CHANNEL PIPELINE FACTORIES TO GAIN COMPLETE CONTROL OVER A CREATED PIPELINE

Available as of Camel 2.5

Custom channel pipelines provide complete control to the user over the handler/interceptor chain by inserting custom handler(s), encoder(s) & decoders without having to specify them in the Netty Endpoint URL in a very simple way.

In order to add a custom pipeline, a custom channel pipeline factory must be created and registered with the context via the context registry (JNDIRegistry, or the camel-spring ApplicationContextRegistry etc).

A custom pipeline factory must be constructed as follows

- A Producer linked channel pipeline factory must extend the abstract class **ClientPipelineFactory**.
- A Consumer linked channel pipeline factory must extend the abstract class **ServerPipelineFactory**.
- The classes should override the `getPipeline()` method in order to insert custom handler(s), encoder(s) and decoder(s). Not overriding the `getPipeline()` method creates a pipeline with no handlers, encoders or decoders wired to the pipeline.

The example below shows how ServerChannel Pipeline factory may be created

Using custom pipeline factory

```
public class SampleServerChannelPipelineFactory extends ServerPipelineFactory {
    private int maxLineSize = 1024;

    public ChannelPipeline getPipeline() throws Exception {
```

```

ChannelPipeline channelPipeline = Channels.pipeline();

channelPipeline.addLast("encoder-SD", new StringEncoder(CharsetUtil.UTF_8));
channelPipeline.addLast("decoder-DELIM", new DelimiterBasedFrameDecoder(maxLineSize,
true, Delimiters.lineDelimiter()));
channelPipeline.addLast("decoder-SD", new StringDecoder(CharsetUtil.UTF_8));
// here we add the default Camel ServerChannelHandler for the consumer, to allow Camel to
route the message etc.
channelPipeline.addLast("handler", new ServerChannelHandler(consumer));

return channelPipeline;
}
}

```

The custom channel pipeline factory can then be added to the registry and instantiated/utilized on a camel route in the following way

```

Registry registry = camelContext.getRegistry();
serverPipelineFactory = new TestServerChannelPipelineFactory();
registry.bind("spf", serverPipelineFactory);
context.addRoutes(new RouteBuilder() {
public void configure() {
String netty_ssl_endpoint =
"netty:tcp://0.0.0.0:5150?serverPipelineFactory=#spf"
String return_string =
"When You Go Home, Tell Them Of Us And Say,"
+ "For Your Tomorrow, We Gave Our Today.";

from(netty_ssl_endpoint)
.process(new Processor() {
public void process(Exchange exchange) throws Exception {
exchange.getOut().setBody(return_string);
}
}
});
}
});

```

239.10. REUSING NETTY BOSS AND WORKER THREAD POOLS

Available as of Camel 2.12

Netty has two kind of thread pools: boss and worker. By default each Netty consumer and producer has their private thread pools. If you want to reuse these thread pools among multiple consumers or producers then the thread pools must be created and enlisted in the Registry.

For example using Spring XML we can create a shared worker thread pool using the **NettyWorkerPoolBuilder** with 2 worker threads as shown below:

```

<!-- use the worker pool builder to help create the shared thread pool -->
<bean id="poolBuilder" class="org.apache.camel.component.netty.NettyWorkerPoolBuilder">
  <property name="workerCount" value="2"/>
</bean>

<!-- the shared worker thread pool -->

```

```
<bean id="sharedPool" class="org.jboss.netty.channel.socket.nio.WorkerPool"
      factory-bean="poolBuilder" factory-method="build" destroy-method="shutdown">
</bean>
```

TIP

For boss thread pool there is a **org.apache.camel.component.netty.NettyServerBossPoolBuilder** builder for Netty consumers, and a **org.apache.camel.component.netty.NettyClientBossPoolBuilder** for the Netty producers.

Then in the Camel routes we can refer to this worker pools by configuring the **workerPool** option in the [URI](#) as shown below:

```
<route>
  <from uri="netty:tcp://0.0.0.0:5021?
textline=true&sync=true&workerPool=#sharedPool&orderedThreadPoolExecutor=false"
/>
  <to uri="log:result"/>
  ...
</route>
```

And if we have another route we can refer to the shared worker pool:

```
<route>
  <from uri="netty:tcp://0.0.0.0:5022?
textline=true&sync=true&workerPool=#sharedPool&orderedThreadPoolExecutor=false"
/>
  <to uri="log:result"/>
  ...
</route>
```

i. and so forth.

CHAPTER 240. NETTY HTTP COMPONENT (DEPRECATED)

Available as of Camel version 2.12

The `netty-http` component is an extension to `Netty` component to facilitate HTTP transport with `Netty`.

This camel component supports both producer and consumer endpoints.

WARNING

This component is deprecated. You should use [Netty4 HTTP](#).

INFO: **Stream**. Netty is stream based, which means the input it receives is submitted to Camel as a stream. That means you will only be able to read the content of the stream **once**. If you find a situation where the message body appears to be empty or you need to access the data multiple times (eg: doing multicasting, or redelivery error handling) you should use Stream caching or convert the message body to a **String** which is safe to be re-read multiple times. Notice Netty4 HTTP reads the entire stream into memory using `io.netty.handler.codec.http.HttpObjectAggregator` to build the entire full http message. But the resulting message is still a stream based message which is readable once.

Maven users will need to add the following dependency to their `pom.xml` for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-netty-http</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

240.1. URI FORMAT

The URI scheme for a netty component is as follows

```
netty-http:http://0.0.0.0:8080[?options]
```

You can append query options to the URI in the following format, **?option=value&option=value&...**

INFO: **Query parameters vs endpoint options** You may be wondering how Camel recognizes URI query parameters and endpoint options. For example you might create endpoint URI as follows - **netty-http:http://example.com?myParam=myValue&compression=true**. In this example **myParam** is the HTTP parameter, while **compression** is the Camel endpoint option. The strategy used by Camel in such situations is to resolve available endpoint options and remove them from the URI. It means that for the discussed example, the HTTP request sent by Netty HTTP producer to the endpoint will look as follows - **http://example.com?myParam=myValue**, because **compression** endpoint option will be resolved and removed from the target URL. Keep also in mind that you cannot specify endpoint options using dynamic headers (like **CamelHttpQuery**). Endpoint options can be specified only at the endpoint URI definition level (like **to** or **from** DSL elements).

240.2. HTTP OPTIONS

INFO: **A lot more options. Important:** This component inherits all the options from [Netty](#). So make sure to look at the [Netty](#) documentation as well.

Notice that some options from [Netty](#) is not applicable when using this [Netty HTTP](#) component, such as options related to UDP transport.

The Netty HTTP component supports 7 options, which are listed below.

Name	Description	Default	Type
nettyHttpBinding (advanced)	To use a custom <code>org.apache.camel.component.netty.http.NettyHttpBinding</code> for binding to/from Netty and Camel Message API.		NettyHttpBinding
configuration (common)	To use the <code>NettyConfiguration</code> as configuration when creating endpoints.		NettyHttpConfiguration
headerFilterStrategy (advanced)	To use a custom <code>org.apache.camel.spi.HeaderFilterStrategy</code> to filter headers.		HeaderFilterStrategy
securityConfiguration (security)	Refers to a <code>org.apache.camel.component.netty.http.NettyHttpSecurityConfiguration</code> for configuring secure web resources.		NettyHttpSecurityConfiguration
useGlobalSslContextParameters (security)	Enable usage of global SSL context parameters.	false	boolean
maximumPoolSize (advanced)	The core pool size for the ordered thread pool, if its in use. The default value is 16.	16	int
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Netty HTTP endpoint is configured using URI syntax:

```
netty-http:protocol:host:port/path
```

with the following path and query parameters:

240.2.1. Path Parameters (4 parameters):

Name	Description	Default	Type
protocol	Required The protocol to use which is either http or https		String
host	Required The local hostname such as localhost, or 0.0.0.0 when being a consumer. The remote HTTP server hostname when using producer.		String
port	The host port number		int
path	Resource path		String

240.2.2. Query Parameters (78 parameters):

Name	Description	Default	Type
bridgeEndpoint (common)	If the option is true, the producer will ignore the Exchange.HTTP_URI header, and use the endpoint's URI for request. You may also set the <code>throwExceptionOnFailure</code> to be false to let the producer send all the fault response back. The consumer working in the bridge mode will skip the gzip compression and WWW URL form encoding (by adding the <code>Exchange.SKIP_GZIP_ENCODING</code> and <code>Exchange.SKIP_WWW_FORM_URL ENCODED</code> headers to the consumed exchange).	false	boolean
disconnect (common)	Whether or not to disconnect(close) from Netty Channel right after use. Can be used for both consumer and producer.	false	boolean
keepAlive (common)	Setting to ensure socket is not closed due to inactivity	true	boolean
reuseAddress (common)	Setting to facilitate socket multiplexing	true	boolean
sync (common)	Setting to set endpoint as one-way or request-response	true	boolean
tcpNoDelay (common)	Setting to improve TCP protocol performance	true	boolean

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
matchOnUriPrefix (consumer)	Whether or not Camel should try to find a target consumer by matching the URI prefix if no exact match is found.	false	boolean
send503whenSuspended (consumer)	Whether to send back HTTP status code 503 when the consumer has been suspended. If the option is false then the Netty Acceptor is unbound when the consumer is suspended, so clients cannot connect anymore.	true	boolean
backlog (consumer)	Allows to configure a backlog for netty consumer (server). Note the backlog is just a best effort depending on the OS. Setting this option to a value such as 200, 500 or 1000, tells the TCP stack how long the accept queue can be. If this option is not configured, then the backlog depends on OS setting.		int
bossCount (consumer)	When netty works on nio mode, it uses default bossCount parameter from Netty, which is 1. User can use this operation to override the default bossCount from Netty	1	int
bossPool (consumer)	To use a explicit <code>org.jboss.netty.channel.socket.nio.BossPool</code> as the boss thread pool. For example to share a thread pool with multiple consumers. By default each consumer has their own boss pool with 1 core thread.		BossPool
channelGroup (consumer)	To use a explicit ChannelGroup.		ChannelGroup
chunkedMaxContentLength (consumer)	Value in bytes the max content length per chunked frame received on the Netty HTTP server.	1048576	int
compression (consumer)	Allow using gzip/deflate for compression on the Netty HTTP server if the client supports it from the HTTP headers.	false	boolean

Name	Description	Default	Type
disableStreamCache (consumer)	Determines whether or not the raw input stream from Netty <code>HttpRequest#getContent()</code> is cached or not (Camel will read the stream into a in light-weight memory based Stream caching) cache. By default Camel will cache the Netty input stream to support reading it multiple times to ensure it Camel can retrieve all data from the stream. However you can set this option to true when you for example need to access the raw stream, such as streaming it directly to a file or other persistent store. Mind that if you enable this option, then you cannot read the Netty stream multiple times out of the box, and you would need manually to reset the reader index on the Netty raw stream.	false	boolean
disconnectOnNoReply (consumer)	If sync is enabled then this option dictates NettyConsumer if it should disconnect where there is no reply to send back.	true	boolean
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
httpMethodRestrict (consumer)	To disable HTTP methods on the Netty HTTP consumer. You can specify multiple separated by comma.		String
mapHeaders (consumer)	If this option is enabled, then during binding from Netty to Camel Message then the headers will be mapped as well (eg added as header to the Camel Message as well). You can turn off this option to disable this. The headers can still be accessed from the <code>org.apache.camel.component.netty.http.NettyHttpRequestMessage</code> message with the method <code>getHttpRequest()</code> that returns the Netty HTTP request <code>org.jboss.netty.handler.codec.http.HttpRequest</code> instance.	true	boolean
maxChannelMemorySize (consumer)	The maximum total size of the queued events per channel when using <code>orderedThreadPoolExecutor</code> . Specify 0 to disable.	10485760	long

Name	Description	Default	Type
maxHeaderSize (consumer)	The maximum length of all headers. If the sum of the length of each header exceeds this value, a <code>TooLongFrameException</code> will be raised.	8192	int
maxTotalMemory Size (consumer)	The maximum total size of the queued events for this pool when using <code>orderedThreadPoolExecutor</code> . Specify 0 to disable.	209715200	long
nettyServerBootstrapFactory (consumer)	To use a custom <code>NettyServerBootstrapFactory</code>		<code>NettyServerBootstrapFactory</code>
nettySharedHttpServer (consumer)	To use a shared Netty HTTP server. See <code>Netty HTTP Server Example</code> for more details.		<code>NettySharedHttpServer</code>
noReplyLogLevel (consumer)	If <code>sync</code> is enabled this option dictates <code>NettyConsumer</code> which logging level to use when logging a there is no reply to send back.	WARN	<code>LoggingLevel</code>
orderedThreadPoolExecutor (consumer)	Whether to use ordered thread pool, to ensure events are processed orderly on the same channel. See details at the netty javadoc of <code>org.jboss.netty.handler.execution.OrderedMemoryAwareThreadPoolExecutor</code> for more details.	true	boolean
serverClosedChannelExceptionCaughtLogLevel (consumer)	If the server (<code>NettyConsumer</code>) catches an <code>java.nio.channels.ClosedChannelException</code> then its logged using this logging level. This is used to avoid logging the closed channel exceptions, as clients can disconnect abruptly and then cause a flood of closed exceptions in the Netty server.	DEBUG	<code>LoggingLevel</code>
serverExceptionCaughtLogLevel (consumer)	If the server (<code>NettyConsumer</code>) catches an exception then its logged using this logging level.	WARN	<code>LoggingLevel</code>
serverPipelineFactory (consumer)	To use a custom <code>ServerPipelineFactory</code>		<code>ServerPipelineFactory</code>
traceEnabled (consumer)	Specifies whether to enable HTTP TRACE for this Netty HTTP consumer. By default TRACE is turned off.	false	boolean

Name	Description	Default	Type
urlDecodeHeaders (consumer)	If this option is enabled, then during binding from Netty to Camel Message then the header values will be URL decoded (eg %20 will be a space character. Notice this option is used by the default <code>org.apache.camel.component.netty.http.NettyHttpBinding</code> and therefore if you implement a custom <code>org.apache.camel.component.netty.http.NettyHttpBinding</code> then you would need to decode the headers accordingly to this option.	false	boolean
workerCount (consumer)	When netty works on nio mode, it uses default <code>workerCount</code> parameter from Netty, which is <code>cpu_core_threads2</code> . User can use this operation to override the default <code>workerCount</code> from Netty		int
workerPool (consumer)	To use a explicit <code>org.jboss.netty.channel.socket.nio.WorkerPool</code> as the worker thread pool. For example to share a thread pool with multiple consumers. By default each consumer has their own worker pool with 2 x cpu count core threads.		WorkerPool
connectTimeout (producer)	Time to wait for a socket connection to be available. Value is in millis.	10000	long
requestTimeout (producer)	Allows to use a timeout for the Netty producer when calling a remote server. By default no timeout is in use. The value is in milli seconds, so eg 30000 is 30 seconds. The <code>requestTimeout</code> is using Netty's <code>ReadTimeoutHandler</code> to trigger the timeout.		long
throwExceptionOnFailure (producer)	Option to disable throwing the <code>HttpOperationFailedException</code> in case of failed responses from the remote server. This allows you to get all responses regardless of the HTTP status code.	true	boolean
clientPipelineFactory (producer)	To use a custom <code>ClientPipelineFactory</code>		ClientPipelineFactory
lazyChannelCreation (producer)	Channels can be lazily created to avoid exceptions, if the remote server is not up and running when the Camel producer is started.	true	boolean
okStatusCodeRange (producer)	The status codes which are considered a success response. The values are inclusive. Multiple ranges can be defined, separated by comma, e.g. 200-204,209,301-304. Each range must be a single number or from-to with the dash included. The default range is 200-299	200-299	String

Name	Description	Default	Type
producerPoolEnabled (producer)	Whether producer pool is enabled or not. Important: Do not turn this off, as the pooling is needed for handling concurrency and reliable request/reply.	true	boolean
producerPoolMaxActive (producer)	Sets the cap on the number of objects that can be allocated by the pool (checked out to clients, or idle awaiting checkout) at a given time. Use a negative value for no limit.	-1	int
producerPoolMaxIdle (producer)	Sets the cap on the number of idle instances in the pool.	100	int
producerPoolMinEvictableIdle (producer)	Sets the minimum amount of time (value in millis) an object may sit idle in the pool before it is eligible for eviction by the idle object evictor.	30000 0	long
producerPoolMinIdle (producer)	Sets the minimum number of instances allowed in the producer pool before the evictor thread (if active) spawns new objects.		int
useChannelBuffer (producer)	If the useChannelBuffer is true, netty producer will turn the message body into ChannelBuffer before sending it out.	false	boolean
useRelativePath (producer)	Sets whether to use a relative path in HTTP requests. Some third party backend systems such as IBM Datapower do not support absolute URIs in HTTP POSTs, and setting this option to true can work around this problem.	false	boolean
bootstrapConfiguration (advanced)	To use a custom configured NettyServerBootstrapConfiguration for configuring this endpoint.		NettyServerBootstrapConfiguration
configuration (advanced)	To use a custom configured NettyHttpConfiguration for configuring this endpoint.		NettyHttpConfiguration
headerFilterStrategy (advanced)	To use a custom org.apache.camel.spi.HeaderFilterStrategy to filter headers.		HeaderFilterStrategy
nettyHttpBinding (advanced)	To use a custom org.apache.camel.component.netty.http.NettyHttpBinding for binding to/from Netty and Camel Message API.		NettyHttpBinding

Name	Description	Default	Type
options (advanced)	Allows to configure additional netty options using option. as prefix. For example option.child.keepAlive=false to set the netty option child.keepAlive=false. See the Netty documentation for possible options that can be used.		Map
receiveBufferSize (advanced)	The TCP/UDP buffer sizes to be used during inbound communication. Size is bytes.	65536	long
receiveBufferSize Predictor (advanced)	Configures the buffer size predictor. See details at Jetty documentation and this mail thread.		int
sendBufferSize (advanced)	The TCP/UDP buffer sizes to be used during outbound communication. Size is bytes.	65536	long
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
transferException (advanced)	If enabled and an Exchange failed processing on the consumer side, and if the caused Exception was send back serialized in the response as a application/x-java-serialized-object content type. On the producer side the exception will be deserialized and thrown as is, instead of the <code>HttpOperationFailedException</code> . The caused exception is required to be serialized. This is by default turned off. If you enable this then be aware that Java will deserialize the incoming data from the request to Java and that can be a potential security risk.	false	boolean
transferExchange (advanced)	Only used for TCP. You can transfer the exchange over the wire instead of just the body. The following fields are transferred: In body, Out body, fault body, In headers, Out headers, fault headers, exchange properties, exchange exception. This requires that the objects are serializable. Camel will exclude any non-serializable objects and log it at WARN level.	false	boolean
decoder (codec)	Deprecated To use a single decoder. This options is deprecated use encoders instead.		ChannelHandler
decoders (codec)	A list of decoders to be used. You can use a String which have values separated by comma, and have the values be looked up in the Registry. Just remember to prefix the value with # so Camel knows it should lookup.		String

Name	Description	Default	Type
encoder (codec)	Deprecated To use a single encoder. This options is deprecated use encoders instead.		ChannelHandler
encoders (codec)	A list of encoders to be used. You can use a String which have values separated by comma, and have the values be looked up in the Registry. Just remember to prefix the value with # so Camel knows it should lookup.		String
enabledProtocols (security)	Which protocols to enable when using SSL	TLSv1, TLSv1.1, TLSv1.2	String
keyStoreFile (security)	Client side certificate keystore to be used for encryption		File
keyStoreFormat (security)	Keystore format to be used for payload encryption. Defaults to JKS if not set	JKS	String
keyStoreResource (security)	Client side certificate keystore to be used for encryption. Is loaded by default from classpath, but you can prefix with classpath:, file:, or http: to load the resource from different systems.		String
needClientAuth (security)	Configures whether the server needs client authentication when using SSL.	false	boolean
passphrase (security)	Password setting to use in order to encrypt/decrypt payloads sent using SSH		String
securityConfiguration (security)	Refers to a org.apache.camel.component.netty.http.NettyHttpSecurityConfiguration for configuring secure web resources.		NettyHttpSecurityConfiguration
securityOptions (security)	To configure NettyHttpSecurityConfiguration using key/value pairs from the map		Map
securityProvider (security)	Security provider to be used for payload encryption. Defaults to SunX509 if not set.	SunX509	String
ssl (security)	Setting to specify whether SSL encryption is applied to this endpoint	false	boolean

Name	Description	Default	Type
sslClientCertHeaders (security)	When enabled and in SSL mode, then the Netty consumer will enrich the Camel Message with headers having information about the client certificate such as subject name, issuer name, serial number, and the valid date range.	false	boolean
sslContextParameters (security)	To configure security using SSLContextParameters		SSLContextParameters
sslHandler (security)	Reference to a class that could be used to return an SSL Handler		SslHandler
trustStoreFile (security)	Server side certificate keystore to be used for encryption		File
trustStoreResource (security)	Server side certificate keystore to be used for encryption. Is loaded by default from classpath, but you can prefix with classpath:, file:, or http: to load the resource from different systems.		String

240.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 31 options, which are listed below.

Name	Description	Default	Type
camel.component.netty-http.configuration.allow-default-codec			Boolean
camel.component.netty-http.configuration.bridge-endpoint	If the option is true, the producer will ignore the Exchange.HTTP_URI header, and use the endpoint's URI for request. You may also set the <code>throwExceptionOnFailure</code> to be false to let the producer send all the fault response back. The consumer working in the bridge mode will skip the gzip compression and WWW URL form encoding (by adding the <code>Exchange.SKIP_GZIP_ENCODING</code> and <code>Exchange.SKIP_WWW_FORM_URL_ENCODED</code> headers to the consumed exchange).	false	Boolean

Name	Description	Default	Type
<code>camel.component.netty-http.configuration.chunked-max-content-length</code>	Value in bytes the max content length per chunked frame received on the Netty HTTP server.	1048576	Integer
<code>camel.component.netty-http.configuration.compression</code>	Allow using gzip/deflate for compression on the Netty HTTP server if the client supports it from the HTTP headers.	false	Boolean
<code>camel.component.netty-http.configuration.disable-stream-cache</code>	Determines whether or not the raw input stream from <code>Netty HttpRequest#getContent()</code> is cached or not (Camel will read the stream into a in light-weight memory based Stream caching) cache. By default Camel will cache the Netty input stream to support reading it multiple times to ensure it Camel can retrieve all data from the stream. However you can set this option to true when you for example need to access the raw stream, such as streaming it directly to a file or other persistent store. Mind that if you enable this option, then you cannot read the Netty stream multiple times out of the box, and you would need manually to reset the reader index on the Netty raw stream.	false	Boolean
<code>camel.component.netty-http.configuration.host</code>	The local hostname such as localhost, or 0.0.0.0 when being a consumer. The remote HTTP server hostname when using producer.		String
<code>camel.component.netty-http.configuration.map-headers</code>	If this option is enabled, then during binding from Netty to Camel Message then the headers will be mapped as well (eg added as header to the Camel Message as well). You can turn off this option to disable this. The headers can still be accessed from the <code>org.apache.camel.component.netty.http.NettyHttpMessage</code> message with the method <code>getHttpRequest()</code> that returns the Netty HTTP request <code>org.jboss.netty.handler.codec.http.HttpRequest</code> instance.	true	Boolean
<code>camel.component.netty-http.configuration.match-on-uri-prefix</code>	Whether or not Camel should try to find a target consumer by matching the URI prefix if no exact match is found.	false	Boolean

Name	Description	Default	Type
<code>camel.component.netty-http.configuration.max-header-size</code>	The maximum length of all headers. If the sum of the length of each header exceeds this value, a <code>TooLongFrameException</code> will be raised.	8192	Integer
<code>camel.component.netty-http.configuration.ok-status-code-range</code>	The status codes which are considered a success response. The values are inclusive. Multiple ranges can be defined, separated by comma, e.g. 200-204,209,301-304. Each range must be a single number or from-to with the dash included. The default range is 200-299	200-299	String
<code>camel.component.netty-http.configuration.path</code>	Resource path		String
<code>camel.component.netty-http.configuration.port</code>	The port number. Is default 80 for http and 443 for https.		Integer
<code>camel.component.netty-http.configuration.protocol</code>	The protocol to use which is either http or https		String
<code>camel.component.netty-http.configuration.send503when-suspended</code>	Whether to send back HTTP status code 503 when the consumer has been suspended. If the option is false then the Netty Acceptor is unbound when the consumer is suspended, so clients cannot connect anymore.	true	Boolean
<code>camel.component.netty-http.configuration.throw-exception-on-failure</code>	Option to disable throwing the <code>HttpOperationFailedException</code> in case of failed responses from the remote server. This allows you to get all responses regardless of the HTTP status code.	true	Boolean

Name	Description	Default	Type
<code>camel.component.netty-http.configuration.transfer-exception</code>	If enabled and an Exchange failed processing on the consumer side, and if the caused Exception was send back serialized in the response as a application/x-java-serialized-object content type. On the producer side the exception will be deserialized and thrown as is, instead of the <code>HttpOperationFailedException</code> . The caused exception is required to be serialized. This is by default turned off. If you enable this then be aware that Java will deserialize the incoming data from the request to Java and that can be a potential security risk.	false	Boolean
<code>camel.component.netty-http.configuration.url-decode-headers</code>	If this option is enabled, then during binding from Netty to Camel Message then the header values will be URL decoded (eg %20 will be a space character. Notice this option is used by the default <code>org.apache.camel.component.netty.http.NettyHttpBinding</code> and therefore if you implement a custom <code>org.apache.camel.component.netty.http.NettyHttpBinding</code> then you would need to decode the headers accordingly to this option.	false	Boolean
<code>camel.component.netty-http.configuration.use-relative-path</code>	Sets whether to use a relative path in HTTP requests. Some third party backend systems such as IBM Datapower do not support absolute URIs in HTTP POSTs, and setting this option to true can work around this problem.	false	Boolean
<code>camel.component.netty-http.enabled</code>	Enable netty-http component	true	Boolean
<code>camel.component.netty-http.header-filter-strategy</code>	To use a custom <code>org.apache.camel.spi.HeaderFilterStrategy</code> to filter headers. The option is a <code>org.apache.camel.spi.HeaderFilterStrategy</code> type.		String
<code>camel.component.netty-http.maximum-pool-size</code>	The core pool size for the ordered thread pool, if its in use. The default value is 16.	16	Integer
<code>camel.component.netty-http.netty-http-binding</code>	To use a custom <code>org.apache.camel.component.netty.http.NettyHttpBinding</code> for binding to/from Netty and Camel Message API. The option is a <code>org.apache.camel.component.netty.http.NettyHttpBinding</code> type.		String

Name	Description	Default	Type
<code>camel.component.netty-http.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.component.netty-http.security-configuration.authenticate</code>	Whether to enable authentication <p/> This is by default enabled.		Boolean
<code>camel.component.netty-http.security-configuration.constraint</code>	The supported restricted. <p/> Currently only Basic is supported.		String
<code>camel.component.netty-http.security-configuration.login-denied-logging-level</code>	Sets a logging level to use for logging denied login attempts (incl stacktraces) <p/> This level is by default DEBUG.		LogLevel
<code>camel.component.netty-http.security-configuration.realm</code>	Sets the name of the realm to use.		String
<code>camel.component.netty-http.security-configuration.role-class-name</code>			String
<code>camel.component.netty-http.security-configuration.security-authenticator</code>	Sets the {@link SecurityAuthenticator} to use for authenticating the {@link HttpPrincipal} .		SecurityAuthenticator
<code>camel.component.netty-http.security-configuration.security-constraint</code>	Sets a {@link SecurityConstraint} to use for checking if a web resource is restricted or not <p/> By default this is <code><tt>null</tt></code> , which means all resources is restricted.		SecurityConstraint

Name	Description	Default	Type
<code>camel.component.netty-http.use-global-ssl-context-parameters</code>	Enable usage of global SSL context parameters.	false	Boolean

240.4. MESSAGE HEADERS

The following headers can be used on the producer to control the HTTP request.

Name	Type	Description
Camel HttpMethod	String	Allow to control what HTTP method to use such as GET, POST, TRACE etc. The type can also be a org.jboss.netty.handler.codec.http.HttpMethod instance.
Camel HttpQuery	String	Allows to provide URI query parameters as a String value that overrides the endpoint configuration. Separate multiple parameters using the & sign. For example: foo=bar&beer=yes .
Camel HttpPath	String	Camel 2.13.1/2.12.4: Allows to provide URI context-path and query parameters as a String value that overrides the endpoint configuration. This allows to reuse the same producer for calling same remote http server, but using a dynamic context-path and query parameters.
Content-Type	String	To set the content-type of the HTTP body. For example: text/plain; charset="UTF-8" .
Camel HttpStatusCode	int	Allows to set the HTTP Status code to use. By default 200 is used for success, and 500 for failure.

The following headers is provided as meta-data when a route starts from an [Netty HTTP](#) endpoint:

The description in the table takes offset in a route having: `from("netty-http:http:0.0.0.0:8080/myapp")`
...

Name	Type	Description
Camel HttpMethod	String	The HTTP method used, such as GET, POST, TRACE etc.

Name	Type	Description
Camel HttpUri	String	The URL including protocol, host and port, etc
Camel HttpUri	String	The URI without protocol, host and port, etc
Camel HttpQuery	String	Any query parameters, such as foo=bar&beer=yes
Camel HttpRawQuery	String	Camel 2.13.0: Any query parameters, such as foo=bar&beer=yes . Stored in the raw form, as they arrived to the consumer (i.e. before URL decoding).
Camel HttpPath	String	Additional context-path. This value is empty if the client called the context-path /myapp . If the client calls /myapp/mystuff , then this header value is /mystuff . In other words its the value after the context-path configured on the route endpoint.
Camel HttpCharacterEncoding	String	The charset from the content-type header.
Camel HttpAuthentication	String	If the user was authenticated using HTTP Basic then this header is added with the value Basic .
Content-Type	String	The content type if provided. For example: text/plain; charset="UTF-8" .

240.5. ACCESS TO NETTY TYPES

This component uses the **org.apache.camel.component.netty.http.NettyHttpRequestMessage** as the message implementation on the Exchange. This allows end users to get access to the original Netty request/response instances if needed, as shown below. Mind that the original response may not be accessible at all times.

```
org.jboss.netty.handler.codec.http.HttpRequest request =
exchange.getIn(NettyHttpRequestMessage.class).getHttpRequest();
```

240.6. EXAMPLES

In the route below we use [Netty HTTP](#) as a HTTP server, which returns back a hardcoded "Bye World" message.

```
from("netty-http:http://0.0.0.0:8080/foo")
    .transform().constant("Bye World");
```

And we can call this HTTP server using Camel also, with the ProducerTemplate as shown below:

```
String out = template.requestBody("netty-http:http://0.0.0.0:8080/foo", "Hello World", String.class);
System.out.println(out);
```

And we get back "Bye World" as the output.

240.7. HOW DO I LET NETTY MATCH WILDCARDS

By default [Netty HTTP](#) will only match on exact uri's. But you can instruct Netty to match prefixes. For example

```
from("netty-http:http://0.0.0.0:8123/foo").to("mock:foo");
```

In the route above [Netty HTTP](#) will only match if the uri is an exact match, so it will match if you enter [http://0.0.0.0:8123/foo](#) but not match if you do [http://0.0.0.0:8123/foo/bar](#).

So if you want to enable wildcard matching you do as follows:

```
from("netty-http:http://0.0.0.0:8123/foo?matchOnUriPrefix=true").to("mock:foo");
```

So now Netty matches any endpoints with starts with **foo**.

To match **any** endpoint you can do:

```
from("netty-http:http://0.0.0.0:8123?matchOnUriPrefix=true").to("mock:foo");
```

240.8. USING MULTIPLE ROUTES WITH SAME PORT

In the same CamelContext you can have multiple routes from [Netty HTTP](#) that shares the same port (eg a **org.jboss.netty.bootstrap.ServerBootstrap** instance). Doing this requires a number of bootstrap options to be identical in the routes, as the routes will share the same **org.jboss.netty.bootstrap.ServerBootstrap** instance. The instance will be configured with the options from the first route created.

The options the routes must be identical configured is all the options defined in the **org.apache.camel.component.netty.NettyServerBootstrapConfiguration** configuration class. If you have configured another route with different options, Camel will throw an exception on startup, indicating the options is not identical. To mitigate this ensure all options is identical.

Here is an example with two routes that share the same port.

Two routes sharing the same port

```
from("netty-http:http://0.0.0.0:{{port}}/foo")
```

```
.to("mock:foo")
.transform().constant("Bye World");

from("netty-http:http://0.0.0.0:{{port}}/bar")
.to("mock:bar")
.transform().constant("Bye Camel");
```

And here is an example of a mis configured 2nd route that do not have identical **org.apache.camel.component.netty.NettyServerBootstrapConfiguration** option as the 1st route. This will cause Camel to fail on startup.

Two routes sharing the same port, but the 2nd route is misconfigured and will fail on starting

```
from("netty-http:http://0.0.0.0:{{port}}/foo")
.to("mock:foo")
.transform().constant("Bye World");

// we cannot have a 2nd route on same port with SSL enabled, when the 1st route is NOT
from("netty-http:http://0.0.0.0:{{port}}/bar?ssl=true")
.to("mock:bar")
.transform().constant("Bye Camel");
```

240.8.1. Reusing same server bootstrap configuration with multiple routes

By configuring the common server bootstrap option in an single instance of a **org.apache.camel.component.netty.NettyServerBootstrapConfiguration** type, we can use the **bootstrapConfiguration** option on the [Netty HTTP](#) consumers to refer and reuse the same options across all consumers.

```
<bean id="nettyHttpBootstrapOptions"
class="org.apache.camel.component.netty.NettyServerBootstrapConfiguration">
  <property name="backlog" value="200"/>
  <property name="connectTimeout" value="20000"/>
  <property name="workerCount" value="16"/>
</bean>
```

And in the routes you refer to this option as shown below

```
<route>
  <from uri="netty-http:http://0.0.0.0:{{port}}/foo?
bootstrapConfiguration=#nettyHttpBootstrapOptions"/>
  ...
</route>

<route>
  <from uri="netty-http:http://0.0.0.0:{{port}}/bar?
bootstrapConfiguration=#nettyHttpBootstrapOptions"/>
  ...
</route>

<route>
  <from uri="netty-http:http://0.0.0.0:{{port}}/beer?
```

```
bootstrapConfiguration=#nettyHttpBootstrapOptions"/>
...
</route>
```

240.8.2. Reusing same server bootstrap configuration with multiple routes across multiple bundles in OSGi container

See the Netty HTTP Server Example for more details and example how to do that.

240.9. USING HTTP BASIC AUTHENTICATION

The [Netty HTTP](#) consumer supports HTTP basic authentication by specifying the security realm name to use, as shown below

```
<route>
  <from uri="netty-http:http://0.0.0.0:{{port}}/foo?securityConfiguration.realm=karaf"/>
  ...
</route>
```

The realm name is mandatory to enable basic authentication. By default the JAAS based authenticator is used, which will use the realm name specified (karaf in the example above) and use the JAAS realm and the JAAS `LoginModule`s of this realm for authentication.

End user of Apache Karaf / ServiceMix has a karaf realm out of the box, and hence why the example above would work out of the box in these containers.

240.9.1. Specifying ACL on web resources

The `org.apache.camel.component.netty.http.SecurityConstraint` allows to define constrains on web resources. And the `org.apache.camel.component.netty.http.SecurityConstraintMapping` is provided out of the box, allowing to easily define inclusions and exclusions with roles.

For example as shown below in the XML DSL, we define the constraint bean:

```
<bean id="constraint" class="org.apache.camel.component.netty.http.SecurityConstraintMapping">
  <!-- inclusions defines url -> roles restrictions -->
  <!-- a * should be used for any role accepted (or even no roles) -->
  <property name="inclusions">
    <map>
      <entry key="/*" value="*" />
      <entry key="/admin/*" value="admin" />
      <entry key="/guest/*" value="admin,guest" />
    </map>
  </property>
  <!-- exclusions is used to define public urls, which requires no authentication -->
  <property name="exclusions">
    <set>
      <value>/public/*</value>
    </set>
  </property>
</bean>
```

The constraint above is define so that

- access to /* is restricted and any roles is accepted (also if user has no roles)
- access to /admin/* requires the admin role
- access to /guest/* requires the admin or guest role
- access to /public/* is an exclusion which means no authentication is needed, and is therefore public for everyone without logging in

To use this constraint we just need to refer to the bean id as shown below:

```
<route>
  <from uri="netty-http:http://0.0.0.0:{{port}}/foo?
matchOnUriPrefix=true&securityConfiguration.realm=karaf&securityConfiguration.securityCon
straint=#constraint"/>
  ...
</route>
```

CHAPTER 241. NETTY4 COMPONENT

Available as of Camel version 2.14

The **netty4** component in Camel is a socket communication component, based on the [Netty](#) project version 4.

Netty is a NIO client server framework which enables quick and easy development of networkServerInitializerFactory applications such as protocol servers and clients.

Netty greatly simplifies and streamlines network programming such as TCP and UDP socket server.

This camel component supports both producer and consumer endpoints.

The Netty component has several options and allows fine-grained control of a number of TCP/UDP communication parameters (buffer sizes, keepAlives, tcpNoDelay, etc) and facilitates both In-Only and In-Out communication on a Camel route.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-netty4</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

241.1. URI FORMAT

The URI scheme for a netty component is as follows

```
netty4:tcp://0.0.0.0:99999[?options]
netty4:udp://remotehost:99999/[?options]
```

This component supports producer and consumer endpoints for both TCP and UDP.

You can append query options to the URI in the following format, **?option=value&option=value&...**

241.2. OPTIONS

The Netty4 component supports 6 options, which are listed below.

Name	Description	Default	Type
maximumPoolSize (advanced)	The thread pool size for the EventExecutorGroup if its in use. The default value is 16.	16	int
configuration (advanced)	To use the NettyConfiguration as configuration when creating endpoints.		NettyConfiguration
executorService (advanced)	To use the given EventExecutorGroup.		EventExecutorGroup

Name	Description	Default	Type
useGlobalSslContextParameters (security)	Enable usage of global SSL context parameters.	false	boolean
sslContextParameters (security)	To configure security using SSLContextParameters		SSLContextParameters
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Netty4 endpoint is configured using URI syntax:

```
netty4:protocol:host:port
```

with the following path and query parameters:

241.2.1. Path Parameters (3 parameters):

Name	Description	Default	Type
protocol	Required The protocol to use which can be tcp or udp.		String
host	Required The hostname. For the consumer the hostname is localhost or 0.0.0.0. For the producer the hostname is the remote host to connect to		String
port	Required The host port number		int

241.2.2. Query Parameters (72 parameters):

Name	Description	Default	Type
disconnect (common)	Whether or not to disconnect(close) from Netty Channel right after use. Can be used for both consumer and producer.	false	boolean
keepAlive (common)	Setting to ensure socket is not closed due to inactivity	true	boolean

Name	Description	Default	Type
reuseAddress (common)	Setting to facilitate socket multiplexing	true	boolean
reuseChannel (common)	This option allows producers and consumers (in client mode) to reuse the same Netty Channel for the lifecycle of processing the Exchange. This is useful if you need to call a server multiple times in a Camel route and want to use the same network connection. When using this, the channel is not returned to the connection pool until the Exchange is done; or disconnected if the disconnect option is set to true. The reused Channel is stored on the Exchange as an exchange property with the key <code>NettyConstants#NETTY_CHANNEL</code> which allows you to obtain the channel during routing and use it as well.	false	boolean
sync (common)	Setting to set endpoint as one-way or request-response	true	boolean
tcpNoDelay (common)	Setting to improve TCP protocol performance	true	boolean
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
broadcast (consumer)	Setting to choose Multicast over UDP	false	boolean
clientMode (consumer)	If the clientMode is true, netty consumer will connect the address as a TCP client.	false	boolean
reconnect (consumer)	Used only in clientMode in consumer, the consumer will attempt to reconnect on disconnection if this is enabled	true	boolean
reconnectInterval (consumer)	Used if reconnect and clientMode is enabled. The interval in milli seconds to attempt reconnection	10000	int

Name	Description	Default	Type
backlog (consumer)	Allows to configure a backlog for netty consumer (server). Note the backlog is just a best effort depending on the OS. Setting this option to a value such as 200, 500 or 1000, tells the TCP stack how long the accept queue can be. If this option is not configured, then the backlog depends on OS setting.		int
bossCount (consumer)	When netty works on nio mode, it uses default bossCount parameter from Netty, which is 1. User can use this operation to override the default bossCount from Netty	1	int
bossGroup (consumer)	Set the BossGroup which could be used for handling the new connection of the server side across the NettyEndpoint		EventLoopGroup
disconnectOnNoReply (consumer)	If sync is enabled then this option dictates NettyConsumer if it should disconnect where there is no reply to send back.	true	boolean
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
nettyServerBootstrapFactory (consumer)	To use a custom NettyServerBootstrapFactory		NettyServerBootstrapFactory
networkInterface (consumer)	When using UDP then this option can be used to specify a network interface by its name, such as eth0 to join a multicast group.		String
noReplyLogLevel (consumer)	If sync is enabled this option dictates NettyConsumer which logging level to use when logging a there is no reply to send back.	WARN	LogLevel
serverClosedChannelExceptionCaughtLogLevel (consumer)	If the server (NettyConsumer) catches an java.nio.channels.ClosedChannelException then its logged using this logging level. This is used to avoid logging the closed channel exceptions, as clients can disconnect abruptly and then cause a flood of closed exceptions in the Netty server.	DEBUG	LogLevel

Name	Description	Default	Type
serverExceptionCaughtLogLevel (consumer)	If the server (NettyConsumer) catches an exception then its logged using this logging level.	WARN	LoggingLevel
serverInitializerFactory (consumer)	To use a custom ServerInitializerFactory		ServerInitializerFactory
usingExecutorService (consumer)	Whether to use ordered thread pool, to ensure events are processed orderly on the same channel.	true	boolean
connectTimeout (producer)	Time to wait for a socket connection to be available. Value is in milliseconds.	10000	int
requestTimeout (producer)	Allows to use a timeout for the Netty producer when calling a remote server. By default no timeout is in use. The value is in milli seconds, so eg 30000 is 30 seconds. The requestTimeout is using Netty's ReadTimeoutHandler to trigger the timeout.		long
clientInitializerFactory (producer)	To use a custom ClientInitializerFactory		ClientInitializerFactory
correlationManager (producer)	To use a custom correlation manager to manage how request and reply messages are mapped when using request/reply with the netty producer. This should only be used if you have a way to map requests together with replies such as if there is correlation ids in both the request and reply messages. This can be used if you want to multiplex concurrent messages on the same channel (aka connection) in netty. When doing this you must have a way to correlate the request and reply messages so you can store the right reply on the inflight Camel Exchange before its continued routed. We recommend extending the TimeoutCorrelationManagerSupport when you build custom correlation managers. This provides support for timeout and other complexities you otherwise would need to implement as well. See also the producerPoolEnabled option for more details.		NettyCamelStateCorrelationManager
lazyChannelCreation (producer)	Channels can be lazily created to avoid exceptions, if the remote server is not up and running when the Camel producer is started.	true	boolean

Name	Description	Default	Type
producerPoolEnabled (producer)	Whether producer pool is enabled or not. Important: If you turn this off then a single shared connection is used for the producer, also if you are doing request/reply. That means there is a potential issue with interleaved responses if replies comes back out-of-order. Therefore you need to have a correlation id in both the request and reply messages so you can properly correlate the replies to the Camel callback that is responsible for continue processing the message in Camel. To do this you need to implement <code>NettyCamelStateCorrelationManager</code> as correlation manager and configure it via the <code>correlationManager</code> option. See also the <code>correlationManager</code> option for more details.	true	boolean
producerPoolMaxActive (producer)	Sets the cap on the number of objects that can be allocated by the pool (checked out to clients, or idle awaiting checkout) at a given time. Use a negative value for no limit.	-1	int
producerPoolMaxIdle (producer)	Sets the cap on the number of idle instances in the pool.	100	int
producerPoolMinEvictableIdle (producer)	Sets the minimum amount of time (value in millis) an object may sit idle in the pool before it is eligible for eviction by the idle object evictor.	30000 0	long
producerPoolMinIdle (producer)	Sets the minimum number of instances allowed in the producer pool before the evictor thread (if active) spawns new objects.		int
udpConnectionlessSending (producer)	This option supports connection less udp sending which is a real fire and forget. A connected udp send receive the <code>PortUnreachableException</code> if no one is listen on the receiving port.	false	boolean
useByteBuf (producer)	If the <code>useByteBuf</code> is true, netty producer will turn the message body into <code>ByteBuf</code> before sending it out.	false	boolean
allowSerializedHeaders (advanced)	Only used for TCP when <code>transferExchange</code> is true. When set to true, serializable objects in headers and properties will be added to the exchange. Otherwise Camel will exclude any non-serializable objects and log it at WARN level.	false	boolean
bootstrapConfiguration (advanced)	To use a custom configured <code>NettyServerBootstrapConfiguration</code> for configuring this endpoint.		<code>NettyServerBootstrapConfiguration</code>

Name	Description	Default	Type
channelGroup (advanced)	To use a explicit ChannelGroup.		ChannelGroup
nativeTransport (advanced)	Whether to use native transport instead of NIO. Native transport takes advantage of the host operating system and is only supported on some platforms. You need to add the netty JAR for the host operating system you are using. See more details at: http://netty.io/wiki/native-transports.html	false	boolean
options (advanced)	Allows to configure additional netty options using option. as prefix. For example option.child.keepAlive=false to set the netty option child.keepAlive=false. See the Netty documentation for possible options that can be used.		Map
receiveBufferSize (advanced)	The TCP/UDP buffer sizes to be used during inbound communication. Size is bytes.	65536	int
receiveBufferSize Predictor (advanced)	Configures the buffer size predictor. See details at Jetty documentation and this mail thread.		int
sendBufferSize (advanced)	The TCP/UDP buffer sizes to be used during outbound communication. Size is bytes.	65536	int
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
transferExchange (advanced)	Only used for TCP. You can transfer the exchange over the wire instead of just the body. The following fields are transferred: In body, Out body, fault body, In headers, Out headers, fault headers, exchange properties, exchange exception. This requires that the objects are serializable. Camel will exclude any non-serializable objects and log it at WARN level.	false	boolean
udpByteArrayCodec (advanced)	For UDP only. If enabled the using byte array codec instead of Java serialization protocol.	false	boolean
workerCount (advanced)	When netty works on nio mode, it uses default workerCount parameter from Netty, which is cpu_core_threads x 2. User can use this operation to override the default workerCount from Netty.		int

Name	Description	Default	Type
workerGroup (advanced)	To use a explicit EventLoopGroup as the boss thread pool. For example to share a thread pool with multiple consumers or producers. By default each consumer or producer has their own worker pool with 2 x cpu count core threads.		EventLoopGroup
allowDefaultCodec (codec)	The netty component installs a default codec if both, encoder/decoder is null and textline is false. Setting allowDefaultCodec to false prevents the netty component from installing a default codec as the first element in the filter chain.	true	boolean
autoAppendDelimiter (codec)	Whether or not to auto append missing end delimiter when sending using the textline codec.	true	boolean
decoder (codec)	Deprecated A custom ChannelHandler class that can be used to perform special marshalling of inbound payloads.		ChannelHandler
decoderMaxLength (codec)	The max line length to use for the textline codec.	1024	int
decoders (codec)	A list of decoders to be used. You can use a String which have values separated by comma, and have the values be looked up in the Registry. Just remember to prefix the value with # so Camel knows it should lookup.		String
delimiter (codec)	The delimiter to use for the textline codec. Possible values are LINE and NULL.	LINE	TextLineDelimiter
encoder (codec)	Deprecated A custom ChannelHandler class that can be used to perform special marshalling of outbound payloads.		ChannelHandler
encoders (codec)	A list of encoders to be used. You can use a String which have values separated by comma, and have the values be looked up in the Registry. Just remember to prefix the value with # so Camel knows it should lookup.		String
encoding (codec)	The encoding (a charset name) to use for the textline codec. If not provided, Camel will use the JVM default Charset.		String

Name	Description	Default	Type
textline (codec)	Only used for TCP. If no codec is specified, you can use this flag to indicate a text line based codec; if not specified or the value is false, then Object Serialization is assumed over TCP.	false	boolean
enabledProtocols (security)	Which protocols to enable when using SSL	TLSv1, TLSv1.1, TLSv1.2	String
keyStoreFile (security)	Client side certificate keystore to be used for encryption		File
keyStoreFormat (security)	Keystore format to be used for payload encryption. Defaults to JKS if not set		String
keyStoreResource (security)	Client side certificate keystore to be used for encryption. Is loaded by default from classpath, but you can prefix with classpath:, file:, or http: to load the resource from different systems.		String
needClientAuth (security)	Configures whether the server needs client authentication when using SSL.	false	boolean
passphrase (security)	Password setting to use in order to encrypt/decrypt payloads sent using SSH		String
securityProvider (security)	Security provider to be used for payload encryption. Defaults to SunX509 if not set.		String
ssl (security)	Setting to specify whether SSL encryption is applied to this endpoint	false	boolean
sslClientCertHeaders (security)	When enabled and in SSL mode, then the Netty consumer will enrich the Camel Message with headers having information about the client certificate such as subject name, issuer name, serial number, and the valid date range.	false	boolean
sslContextParameters (security)	To configure security using SSLContextParameters		SSLContextParameters
sslHandler (security)	Reference to a class that could be used to return an SSL Handler		SslHandler
trustStoreFile (security)	Server side certificate keystore to be used for encryption		File

Name	Description	Default	Type
trustStoreResource (security)	Server side certificate keystore to be used for encryption. Is loaded by default from classpath, but you can prefix with classpath:, file:, or http: to load the resource from different systems.		String

241.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 78 options, which are listed below.

Name	Description	Default	Type
camel.component.netty4.configuration.allow-default-codec	The netty component installs a default codec if both, encoder/decoder is null and textline is false. Setting allowDefaultCodec to false prevents the netty component from installing a default codec as the first element in the filter chain.	true	Boolean
camel.component.netty4.configuration.allow-serialized-headers	Only used for TCP when transferExchange is true. When set to true, serializable objects in headers and properties will be added to the exchange. Otherwise Camel will exclude any non-serializable objects and log it at WARN level.	false	Boolean
camel.component.netty4.configuration.auto-append-delimiter	Whether or not to auto append missing end delimiter when sending using the textline codec.	true	Boolean
camel.component.netty4.configuration.backlog	Allows to configure a backlog for netty consumer (server). Note the backlog is just a best effort depending on the OS. Setting this option to a value such as 200, 500 or 1000, tells the TCP stack how long the accept queue can be. If this option is not configured, then the backlog depends on OS setting.		Integer
camel.component.netty4.configuration.boss-count	When netty works on nio mode, it uses default bossCount parameter from Netty, which is 1. User can use this operation to override the default bossCount from Netty	1	Integer
camel.component.netty4.configuration.boss-group	Set the BossGroup which could be used for handling the new connection of the server side across the NettyEndpoint		EventLoopGroup

Name	Description	Default	Type
<code>camel.component.netty4.configuration.broadcast</code>	Setting to choose Multicast over UDP	false	Boolean
<code>camel.component.netty4.configuration.channel-group</code>	To use a explicit ChannelGroup.		ChannelGroup
<code>camel.component.netty4.configuration.client-initializer-factory</code>	To use a custom ClientInitializerFactory		ClientInitializerFactory
<code>camel.component.netty4.configuration.client-mode</code>	If the clientMode is true, netty consumer will connect the address as a TCP client.	false	Boolean
<code>camel.component.netty4.configuration.connect-timeout</code>	Time to wait for a socket connection to be available. Value is in milliseconds.	10000	Integer
<code>camel.component.netty4.configuration.correlation-manager</code>	To use a custom correlation manager to manage how request and reply messages are mapped when using request/reply with the netty producer. This should only be used if you have a way to map requests together with replies such as if there is correlation ids in both the request and reply messages. This can be used if you want to multiplex concurrent messages on the same channel (aka connection) in netty. When doing this you must have a way to correlate the request and reply messages so you can store the right reply on the inflight Camel Exchange before its continued routed. We recommend extending the TimeoutCorrelationManagerSupport when you build custom correlation managers. This provides support for timeout and other complexities you otherwise would need to implement as well. See also the producerPoolEnabled option for more details.		NettyCamelStateCorrelationManager
<code>camel.component.netty4.configuration.decoder-max-line-length</code>	The max line length to use for the textline codec.	1024	Integer

Name	Description	Default	Type
<code>camel.component.netty4.configuration.decoders</code>	A list of decoders to be used. You can use a String which have values separated by comma, and have the values be looked up in the Registry. Just remember to prefix the value with # so Camel knows it should lookup.		List
<code>camel.component.netty4.configuration.delimiter</code>	The delimiter to use for the textline codec. Possible values are LINE and NULL.		TextLineDelimiter
<code>camel.component.netty4.configuration.disconnect</code>	Whether or not to disconnect(close) from Netty Channel right after use. Can be used for both consumer and producer.	false	Boolean
<code>camel.component.netty4.configuration.disconnect-on-no-reply</code>	If sync is enabled then this option dictates NettyConsumer if it should disconnect where there is no reply to send back.	true	Boolean
<code>camel.component.netty4.configuration.enabled-protocols</code>	Which protocols to enable when using SSL	TLSv1, TLSv1.1, TLSv1.2	String
<code>camel.component.netty4.configuration.encoders</code>	A list of encoders to be used. You can use a String which have values separated by comma, and have the values be looked up in the Registry. Just remember to prefix the value with # so Camel knows it should lookup.		List
<code>camel.component.netty4.configuration.encoding</code>	The encoding (a charset name) to use for the textline codec. If not provided, Camel will use the JVM default Charset.		String
<code>camel.component.netty4.configuration.host</code>	The hostname. For the consumer the hostname is localhost or 0.0.0.0. For the producer the hostname is the remote host to connect to		String
<code>camel.component.netty4.configuration.keep-alive</code>	Setting to ensure socket is not closed due to inactivity	true	Boolean
<code>camel.component.netty4.configuration.key-store-format</code>	Keystore format to be used for payload encryption. Defaults to JKS if not set		String

Name	Description	Default	Type
<code>camel.component.netty4.configuration.key-store-resource</code>	Client side certificate keystore to be used for encryption. Is loaded by default from classpath, but you can prefix with classpath:, file:, or http: to load the resource from different systems.		String
<code>camel.component.netty4.configuration.lazy-channel-creation</code>	Channels can be lazily created to avoid exceptions, if the remote server is not up and running when the Camel producer is started.	true	Boolean
<code>camel.component.netty4.configuration.native-transport</code>	Whether to use native transport instead of NIO. Native transport takes advantage of the host operating system and is only supported on some platforms. You need to add the netty JAR for the host operating system you are using. See more details at: http://netty.io/wiki/native-transports.html	false	Boolean
<code>camel.component.netty4.configuration.need-client-auth</code>	Configures whether the server needs client authentication when using SSL.	false	Boolean
<code>camel.component.netty4.configuration.netty-server-bootstrap-factory</code>	To use a custom NettyServerBootstrapFactory		NettyServerBootstrapFactory
<code>camel.component.netty4.configuration.network-interface</code>	When using UDP then this option can be used to specify a network interface by its name, such as eth0 to join a multicast group.		String
<code>camel.component.netty4.configuration.no-reply-log-level</code>	If sync is enabled this option dictates NettyConsumer which logging level to use when logging a there is no reply to send back.		LogLevel
<code>camel.component.netty4.configuration.options</code>	Allows to configure additional netty options using option. as prefix. For example option.child.keepAlive=false to set the netty option child.keepAlive=false. See the Netty documentation for possible options that can be used.		Map
<code>camel.component.netty4.configuration.passphrase</code>	Password setting to use in order to encrypt/decrypt payloads sent using SSH		String

Name	Description	Default	Type
<code>camel.component.netty4.configuration.port</code>	The host port number		Integer
<code>camel.component.netty4.configuration.producer-pool-enabled</code>	Whether producer pool is enabled or not. Important: If you turn this off then a single shared connection is used for the producer, also if you are doing request/reply. That means there is a potential issue with interleaved responses if replies comes back out-of-order. Therefore you need to have a correlation id in both the request and reply messages so you can properly correlate the replies to the Camel callback that is responsible for continue processing the message in Camel. To do this you need to implement <code>NettyCamelStateCorrelationManager</code> as correlation manager and configure it via the <code>correlationManager</code> option. See also the <code>correlationManager</code> option for more details.	true	Boolean
<code>camel.component.netty4.configuration.producer-pool-max-active</code>	Sets the cap on the number of objects that can be allocated by the pool (checked out to clients, or idle awaiting checkout) at a given time. Use a negative value for no limit.	-1	Integer
<code>camel.component.netty4.configuration.producer-pool-max-idle</code>	Sets the cap on the number of idle instances in the pool.	100	Integer
<code>camel.component.netty4.configuration.producer-pool-min-evictable-idle</code>	Sets the minimum amount of time (value in millis) an object may sit idle in the pool before it is eligible for eviction by the idle object evictor.	30000 0	Long
<code>camel.component.netty4.configuration.producer-pool-min-idle</code>	Sets the minimum number of instances allowed in the producer pool before the evictor thread (if active) spawns new objects.		Integer
<code>camel.component.netty4.configuration.protocol</code>	The protocol to use which can be tcp or udp.		String
<code>camel.component.netty4.configuration.receive-buffer-size</code>	The TCP/UDP buffer sizes to be used during inbound communication. Size is bytes.	65536	Integer

Name	Description	Default	Type
<code>camel.component.netty4.configuration.receive-buffer-size-predictor</code>	Configures the buffer size predictor. See details at Jetty documentation and this mail thread.		Integer
<code>camel.component.netty4.configuration.reconnect</code>	Used only in clientMode in consumer, the consumer will attempt to reconnect on disconnection if this is enabled	true	Boolean
<code>camel.component.netty4.configuration.reconnect-interval</code>	Used if reconnect and clientMode is enabled. The interval in milli seconds to attempt reconnection	10000	Integer
<code>camel.component.netty4.configuration.request-timeout</code>	Allows to use a timeout for the Netty producer when calling a remote server. By default no timeout is in use. The value is in milli seconds, so eg 30000 is 30 seconds. The requestTimeout is using Netty's ReadTimeoutHandler to trigger the timeout.		Long
<code>camel.component.netty4.configuration.reuse-address</code>	Setting to facilitate socket multiplexing	true	Boolean
<code>camel.component.netty4.configuration.reuse-channel</code>	This option allows producers and consumers (in client mode) to reuse the same Netty Channel for the lifecycle of processing the Exchange. This is useful if you need to call a server multiple times in a Camel route and want to use the same network connection. When using this, the channel is not returned to the connection pool until the Exchange is done; or disconnected if the disconnect option is set to true. The reused Channel is stored on the Exchange as an exchange property with the key <code>NettyConstants#NETTY_CHANNEL</code> which allows you to obtain the channel during routing and use it as well.	false	Boolean
<code>camel.component.netty4.configuration.security-provider</code>	Security provider to be used for payload encryption. Defaults to SunX509 if not set.		String

Name	Description	Default	Type
<code>camel.component.netty4.configuration.send-buffer-size</code>	The TCP/UDP buffer sizes to be used during outbound communication. Size is bytes.	65536	Integer
<code>camel.component.netty4.configuration.server-closed-channel-exception-caught-log-level</code>	If the server (NettyConsumer) catches an <code>java.nio.channels.ClosedChannelException</code> then its logged using this logging level. This is used to avoid logging the closed channel exceptions, as clients can disconnect abruptly and then cause a flood of closed exceptions in the Netty server.		LogLevel
<code>camel.component.netty4.configuration.server-exception-caught-log-level</code>	If the server (NettyConsumer) catches an exception then its logged using this logging level.		LogLevel
<code>camel.component.netty4.configuration.server-initializer-factory</code>	To use a custom <code>ServerInitializerFactory</code>		<code>ServerInitializerFactory</code>
<code>camel.component.netty4.configuration.ssl</code>	Setting to specify whether SSL encryption is applied to this endpoint	false	Boolean
<code>camel.component.netty4.configuration.ssl-client-cert-headers</code>	When enabled and in SSL mode, then the Netty consumer will enrich the Camel Message with headers having information about the client certificate such as subject name, issuer name, serial number, and the valid date range.	false	Boolean
<code>camel.component.netty4.configuration.ssl-context-parameters</code>	To configure security using <code>SSLContextParameters</code>		<code>SSLContextParameters</code>
<code>camel.component.netty4.configuration.ssl-handler</code>	Reference to a class that could be used to return an SSL Handler		<code>SslHandler</code>
<code>camel.component.netty4.configuration.sync</code>	Setting to set endpoint as one-way or request-response	true	Boolean

Name	Description	Default	Type
<code>camel.component.netty4.configuration.tcp-no-delay</code>	Setting to improve TCP protocol performance	true	Boolean
<code>camel.component.netty4.configuration.textline</code>	Only used for TCP. If no codec is specified, you can use this flag to indicate a text line based codec; if not specified or the value is false, then Object Serialization is assumed over TCP.	false	Boolean
<code>camel.component.netty4.configuration.transfer-exchange</code>	Only used for TCP. You can transfer the exchange over the wire instead of just the body. The following fields are transferred: In body, Out body, fault body, In headers, Out headers, fault headers, exchange properties, exchange exception. This requires that the objects are serializable. Camel will exclude any non-serializable objects and log it at WARN level.	false	Boolean
<code>camel.component.netty4.configuration.trust-store-resource</code>	Server side certificate keystore to be used for encryption. Is loaded by default from classpath, but you can prefix with classpath:, file:, or http: to load the resource from different systems.		String
<code>camel.component.netty4.configuration.udp-byte-array-codec</code>	For UDP only. If enabled the using byte array codec instead of Java serialization protocol.	false	Boolean
<code>camel.component.netty4.configuration.udp-connectionless-sending</code>	This option supports connection less udp sending which is a real fire and forget. A connected udp send receive the PortUnreachableException if no one is listen on the receiving port.	false	Boolean
<code>camel.component.netty4.configuration.use-byte-buf</code>	If the useByteBuf is true, netty producer will turn the message body into ByteBuf before sending it out.	false	Boolean
<code>camel.component.netty4.configuration.using-executor-service</code>	Whether to use ordered thread pool, to ensure events are processed orderly on the same channel.	true	Boolean
<code>camel.component.netty4.configuration.worker-count</code>	When netty works on nio mode, it uses default workerCount parameter from Netty, which is <code>cpu_core_threads x 2</code> . User can use this operation to override the default workerCount from Netty.		Integer

Name	Description	Default	Type
<code>camel.component.netty4.configuration.worker-group</code>	To use a explicit EventLoopGroup as the boss thread pool. For example to share a thread pool with multiple consumers or producers. By default each consumer or producer has their own worker pool with 2 x cpu count core threads.		EventLoopGroup
<code>camel.component.netty4.enabled</code>	Enable netty4 component	true	Boolean
<code>camel.component.netty4.executor-service</code>	To use the given EventExecutorGroup. The option is a <code>io.netty.util.concurrent.EventExecutorGroup</code> type.		String
<code>camel.component.netty4.maximum-pool-size</code>	The thread pool size for the EventExecutorGroup if its in use. The default value is 16.	16	Integer
<code>camel.component.netty4.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.component.netty4.ssl-context-parameters</code>	To configure security using SSLContextParameters. The option is a <code>org.apache.camel.util.jsse.SSLContextParameters</code> type.		String
<code>camel.component.netty4.use-global-ssl-context-parameters</code>	Enable usage of global SSL context parameters.	false	Boolean
<code>camel.component.netty4.configuration.client-pipeline-factory</code>	@deprecated use <code>#setClientInitializerFactory</code>		ClientInitializerFactory
<code>camel.component.netty4.configuration.decoder</code>	A custom ChannelHandler class that can be used to perform special marshalling of inbound payloads.		ChannelHandler
<code>camel.component.netty4.configuration.encoder</code>	A custom ChannelHandler class that can be used to perform special marshalling of outbound payloads.		ChannelHandler

Name	Description	Default	Type
<code>camel.component.netty4.configuration.key-store-file</code>	Client side certificate keystore to be used for encryption		File
<code>camel.component.netty4.configuration.server-pipeline-factory</code>	@deprecated use <code>#setServerInitializerFactory</code>		ServerInitializerFactory
<code>camel.component.netty4.configuration.trust-store-file</code>	Server side certificate keystore to be used for encryption		File

241.4. REGISTRY BASED OPTIONS

Codec Handlers and SSL Keystores can be enlisted in the Registry, such as in the Spring XML file. The values that could be passed in, are the following:

Name	Description
<code>passphrase</code>	password setting to use in order to encrypt/decrypt payloads sent using SSH
<code>keyStoreFormat</code>	keystore format to be used for payload encryption. Defaults to "JKS" if not set
<code>securityProvider</code>	Security provider to be used for payload encryption. Defaults to "SunX509" if not set.
<code>keyStoreFile</code>	deprecated: Client side certificate keystore to be used for encryption
<code>trustStoreFile</code>	deprecated: Server side certificate keystore to be used for encryption

Name	Description
keyStoreResource	Camel 2.11.1: Client side certificate keystore to be used for encryption. Is loaded by default from classpath, but you can prefix with " classpath: ", " file: ", or " http: " to load the resource from different systems.
trustStoreResource	Camel 2.11.1: Server side certificate keystore to be used for encryption. Is loaded by default from classpath, but you can prefix with " classpath: ", " file: ", or " http: " to load the resource from different systems.
sslHandler	Reference to a class that could be used to return an SSL Handler
encoder	A custom ChannelHandler class that can be used to perform special marshalling of outbound payloads. Must override <code>io.netty.channel.ChannelInboundHandlerAdapter</code> .
encoders	A list of encoders to be used. You can use a String which have values separated by comma, and have the values be looked up in the Registry. Just remember to prefix the value with # so Camel knows it should lookup.
decoder	A custom ChannelHandler class that can be used to perform special marshalling of inbound payloads. Must override <code>io.netty.channel.ChannelOutboundHandlerAdapter</code> .
decoders	A list of decoders to be used. You can use a String which have values separated by comma, and have the values be looked up in the Registry. Just remember to prefix the value with # so Camel knows it should lookup.

**NOTE**

Read below about using non shareable encoders/decoders.

241.4.1. Using non shareable encoders or decoders

If your encoders or decoders are not shareable (e.g. they don't have the `@Shareable` class annotation), then your encoder/decoder must implement the **`org.apache.camel.component.netty.ChannelHandlerFactory`** interface, and return a new instance in the **`newChannelHandler`** method. This is to ensure the encoder/decoder can safely be used. If this is not the case, then the Netty component will log a WARN when an endpoint is created.

The Netty component offers a **`org.apache.camel.component.netty.ChannelHandlerFactories`** factory class, that has a number of commonly used methods.

241.5. SENDING MESSAGES TO/FROM A NETTY ENDPOINT

241.5.1. Netty Producer

In Producer mode, the component provides the ability to send payloads to a socket endpoint using either TCP or UDP protocols (with optional SSL support).

The producer mode supports both one-way and request-response based operations.

241.5.2. Netty Consumer

In Consumer mode, the component provides the ability to:

- listen on a specified socket using either TCP or UDP protocols (with optional SSL support),
- receive requests on the socket using text/xml, binary and serialized object based payloads and
- send them along on a route as message exchanges.

The consumer mode supports both one-way and request-response based operations.

241.6. EXAMPLES

241.6.1. A UDP Netty endpoint using Request-Reply and serialized object payload

```
RouteBuilder builder = new RouteBuilder() {
    public void configure() {
        from("netty4:udp://0.0.0.0:5155?sync=true")
            .process(new Processor() {
                public void process(Exchange exchange) throws Exception {
                    Poetry poetry = (Poetry) exchange.getIn().getBody();
                    poetry.setPoet("Dr. Sarojini Naidu");
                    exchange.getOut().setBody(poetry);
                }
            })
    }
};
```

241.6.2. A TCP based Netty consumer endpoint using One-way communication

```
RouteBuilder builder = new RouteBuilder() {
    public void configure() {
        from("netty4:tcp://0.0.0.0:5150")
            .to("mock:result");
    }
};
```

241.6.3. An SSL/TCP based Netty consumer endpoint using Request-Reply communication

Using the JSSE Configuration Utility

As of Camel 2.9, the Netty component supports SSL/TLS configuration through the [Camel JSSE Configuration Utility](#). This utility greatly decreases the amount of component specific code you need to write and is configurable at the endpoint and component levels. The following examples demonstrate how to use the utility with the Netty component.

Programmatic configuration of the component

```

KeyStoreParameters ksp = new KeyStoreParameters();
ksp.setResource("/users/home/server/keystore.jks");
ksp.setPassword("keystorePassword");

KeyManagersParameters kmp = new KeyManagersParameters();
kmp.setKeyStore(ksp);
kmp.setKeyPassword("keyPassword");

SSLContextParameters scp = new SSLContextParameters();
scp.setKeyManagers(kmp);

NettyComponent nettyComponent = getContext().getComponent("netty4", NettyComponent.class);
nettyComponent.setSslContextParameters(scp);

```

Spring DSL based configuration of endpoint

```

...
<camel:sslContextParameters
  id="sslContextParameters">
  <camel:keyManagers
    keyPassword="keyPassword">
    <camel:keyStore
      resource="/users/home/server/keystore.jks"
      password="keystorePassword"/>
    </camel:keyManagers>
  </camel:sslContextParameters>...
...
<to uri="netty4:tcp://0.0.0.0:5150?
sync=true&ssl=true&sslContextParameters=#sslContextParameters"/>
...

```

[[Netty4-UsingBasicSSL/TLSconfigurationontheJettyComponent]] Using Basic SSL/TLS configuration on the Jetty Component

```

JndiRegistry registry = new JndiRegistry(createJndiContext());
registry.bind("password", "changeit");
registry.bind("ksf", new File("src/test/resources/keystore.jks"));
registry.bind("tsf", new File("src/test/resources/keystore.jks"));

context.createRegistry(registry);
context.addRoutes(new RouteBuilder() {
  public void configure() {
    String netty_ssl_endpoint =
      "netty4:tcp://0.0.0.0:5150?sync=true&ssl=true&passphrase=#password"
      + "&keyStoreFile=#ksf&trustStoreFile=#tsf";
    String return_string =
      "When You Go Home, Tell Them Of Us And Say,"
      + "For Your Tomorrow, We Gave Our Today.";

    from(netty_ssl_endpoint)
      .process(new Processor() {
        public void process(Exchange exchange) throws Exception {
          exchange.getOut().setBody(return_string);
        }
      })
  }
});

```

```

    }
  }
});

```

Getting access to `SSLSession` and the client certificate

You can get access to the `javax.net.ssl.SSLSession` if you eg need to get details about the client certificate. When `ssl=true` then the `Netty4` component will store the `SSLSession` as a header on the Camel Message as shown below:

```

SSLSession session = exchange.getIn().getHeader(NettyConstants.NETTY_SSL_SESSION,
SSLSession.class);
// get the first certificate which is client certificate
javax.security.cert.X509Certificate cert = session.getPeerCertificateChain()[0];
Principal principal = cert.getSubjectDN();

```

Remember to set `needClientAuth=true` to authenticate the client, otherwise `SSLSession` cannot access information about the client certificate, and you may get an exception `javax.net.ssl.SSLPeerUnverifiedException: peer not authenticated`. You may also get this exception if the client certificate is expired or not valid etc.

TIP

The option `sslClientCertHeaders` can be set to `true` which then enriches the Camel Message with headers having details about the client certificate. For example the subject name is readily available in the header `CamelNettySSLClientCertSubjectName`.

241.6.4. Using Multiple Codecs

In certain cases it may be necessary to add chains of encoders and decoders to the netty pipeline. To add multiple codecs to a camel netty endpoint the 'encoders' and 'decoders' uri parameters should be used. Like the 'encoder' and 'decoder' parameters they are used to supply references (lists of `ChannelUpstreamHandlers` and `ChannelDownstreamHandlers`) that should be added to the pipeline. Note that if encoders is specified then the encoder param will be ignored, similarly for decoders and the decoder param.

NOTE

Read further above about using non shareable encoders/decoders.

The lists of codecs need to be added to the Camel's registry so they can be resolved when the endpoint is created.

```

ChannelHandlerFactory lengthDecoder =
ChannelHandlerFactories.newLengthFieldBasedFrameDecoder(1048576, 0, 4, 0, 4);

StringDecoder stringDecoder = new StringDecoder();
registry.bind("length-decoder", lengthDecoder);
registry.bind("string-decoder", stringDecoder);

LengthFieldPrepender lengthEncoder = new LengthFieldPrepender(4);
StringEncoder stringEncoder = new StringEncoder();
registry.bind("length-encoder", lengthEncoder);
registry.bind("string-encoder", stringEncoder);

```

```
List<ChannelHandler> decoders = new ArrayList<ChannelHandler>();
decoders.add(lengthDecoder);
decoders.add(stringDecoder);
```

```
List<ChannelHandler> encoders = new ArrayList<ChannelHandler>();
encoders.add(lengthEncoder);
encoders.add(stringEncoder);
```

```
registry.bind("encoders", encoders);
registry.bind("decoders", decoders);
```

Spring's native collections support can be used to specify the codec lists in an application context

```
<util:list id="decoders" list-class="java.util.LinkedList">
  <bean class="org.apache.camel.component.netty4.ChannelHandlerFactories" factory-
method="newLengthFieldBasedFrameDecoder">
    <constructor-arg value="1048576"/>
    <constructor-arg value="0"/>
    <constructor-arg value="4"/>
    <constructor-arg value="0"/>
    <constructor-arg value="4"/>
  </bean>
  <bean class="io.netty.handler.codec.string.StringDecoder"/>
</util:list>

<util:list id="encoders" list-class="java.util.LinkedList">
  <bean class="io.netty.handler.codec.LengthFieldPrepender">
    <constructor-arg value="4"/>
  </bean>
  <bean class="io.netty.handler.codec.string.StringEncoder"/>
</util:list>

<bean id="length-encoder" class="io.netty.handler.codec.LengthFieldPrepender">
  <constructor-arg value="4"/>
</bean>
<bean id="string-encoder" class="io.netty.handler.codec.string.StringEncoder"/>

<bean id="length-decoder" class="org.apache.camel.component.netty4.ChannelHandlerFactories"
factory-method="newLengthFieldBasedFrameDecoder">
  <constructor-arg value="1048576"/>
  <constructor-arg value="0"/>
  <constructor-arg value="4"/>
  <constructor-arg value="0"/>
  <constructor-arg value="4"/>
</bean>
<bean id="string-decoder" class="io.netty.handler.codec.string.StringDecoder"/>
```

The bean names can then be used in netty endpoint definitions either as a comma separated list or contained in a List e.g.

```
from("direct:multiple-codec").to("netty4:tcp://0.0.0.0:{{port}}?encoders=#encoders&sync=false");

from("netty4:tcp://0.0.0.0:{{port}}?decoders=#length-decoder,#string-
decoder&sync=false").to("mock:multiple-codec");
```

or via XML.

```
<camelContext id="multiple-netty-codecs-context" xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="direct:multiple-codec"/>
    <to uri="netty4:tcp://0.0.0.0:5150?encoders=#encoders&sync=false"/>
  </route>
  <route>
    <from uri="netty4:tcp://0.0.0.0:5150?decoders=#length-decoder,#string-
decoder&sync=false"/>
    <to uri="mock:multiple-codec"/>
  </route>
</camelContext>
```

241.7. CLOSING CHANNEL WHEN COMPLETE

When acting as a server you sometimes want to close the channel when, for example, a client conversion is finished.

You can do this by simply setting the endpoint option **disconnect=true**.

However you can also instruct Camel on a per message basis as follows.

To instruct Camel to close the channel, you should add a header with the key

CamelNettyCloseChannelWhenComplete set to a boolean **true** value.

For instance, the example below will close the channel after it has written the bye message back to the client:

```
from("netty4:tcp://0.0.0.0:8080").process(new Processor() {
  public void process(Exchange exchange) throws Exception {
    String body = exchange.getIn().getBody(String.class);
    exchange.getOut().setBody("Bye " + body);
    // some condition which determines if we should close
    if (close) {

exchange.getOut().setHeader(NettyConstants.NETTY_CLOSE_CHANNEL_WHEN_COMPLETE,
true);
    }
  }
});
```

Adding custom channel pipeline factories to gain complete control over a created pipeline

241.8. CUSTOM PIPELINE

Custom channel pipelines provide complete control to the user over the handler/interceptor chain by inserting custom handler(s), encoder(s) & decoder(s) without having to specify them in the Netty Endpoint URL in a very simple way.

In order to add a custom pipeline, a custom channel pipeline factory must be created and registered with the context via the context registry (JNDIRegistry, or the camel-spring ApplicationContextRegistry etc).

A custom pipeline factory must be constructed as follows

- A Producer linked channel pipeline factory must extend the abstract class **ClientPipelineFactory**.

- A Consumer linked channel pipeline factory must extend the abstract class **ServerInitializerFactory**.
- The classes should override the `initChannel()` method in order to insert custom handler(s), encoder(s) and decoder(s). Not overriding the **initChannel()** method creates a pipeline with no handlers, encoders or decoders wired to the pipeline.

The example below shows how `ServerInitializerFactory` factory may be created

241.8.1. Using custom pipeline factory

```
public class SampleServerInitializerFactory extends ServerInitializerFactory {
    private int maxLineSize = 1024;

    protected void initChannel(Channel ch) throws Exception {
        ChannelPipeline channelPipeline = ch.pipeline();

        channelPipeline.addLast("encoder-SD", new StringEncoder(CharsetUtil.UTF_8));
        channelPipeline.addLast("decoder-DELIM", new DelimiterBasedFrameDecoder(maxLineSize,
true, Delimiters.lineDelimiter()));
        channelPipeline.addLast("decoder-SD", new StringDecoder(CharsetUtil.UTF_8));
        // here we add the default Camel ServerChannelHandler for the consumer, to allow Camel to
route the message etc.
        channelPipeline.addLast("handler", new ServerChannelHandler(consumer));
    }
}
```

The custom channel pipeline factory can then be added to the registry and instantiated/utilized on a camel route in the following way

```
Registry registry = camelContext.getRegistry();
ServerInitializerFactory factory = new TestServerInitializerFactory();
registry.bind("spf", factory);
context.addRoutes(new RouteBuilder() {
    public void configure() {
        String netty_ssl_endpoint =
            "netty4:tcp://0.0.0.0:5150?serverInitializerFactory=#spf"
        String return_string =
            "When You Go Home, Tell Them Of Us And Say,"
            + "For Your Tomorrow, We Gave Our Today.";

        from(netty_ssl_endpoint)
            .process(new Processor() {
                public void process(Exchange exchange) throws Exception {
                    exchange.getOut().setBody(return_string);
                }
            })
    }
});
```

241.9. REUSING NETTY BOSS AND WORKER THREAD POOLS

Netty has two kind of thread pools: boss and worker. By default each Netty consumer and producer has their private thread pools. If you want to reuse these thread pools among multiple consumers or producers then the thread pools must be created and enlisted in the Registry.

For example using Spring XML we can create a shared worker thread pool using the **NettyWorkerPoolBuilder** with 2 worker threads as shown below:

```
<!-- use the worker pool builder to help create the shared thread pool -->
<bean id="poolBuilder" class="org.apache.camel.component.netty.NettyWorkerPoolBuilder">
  <property name="workerCount" value="2"/>
</bean>

<!-- the shared worker thread pool -->
<bean id="sharedPool" class="org.jboss.netty.channel.socket.nio.WorkerPool"
  factory-bean="poolBuilder" factory-method="build" destroy-method="shutdown">
</bean>
```

TIP

For boss thread pool there is a **org.apache.camel.component.netty4.NettyServerBossPoolBuilder** builder for Netty consumers, and a **org.apache.camel.component.netty4.NettyClientBossPoolBuilder** for the Netty producers.

Then in the Camel routes we can refer to this worker pools by configuring the **workerPool** option in the [URI](#) as shown below:

```
<route>
  <from uri="netty4:tcp://0.0.0.0:5021?
textline=true&sync=true&workerPool=#sharedPool&usingExecutorService=false"/>
  <to uri="log:result"/>
  ...
</route>
```

And if we have another route we can refer to the shared worker pool:

```
<route>
  <from uri="netty4:tcp://0.0.0.0:5022?
textline=true&sync=true&workerPool=#sharedPool&usingExecutorService=false"/>
  <to uri="log:result"/>
  ...
</route>
```

and so forth.

241.10. MULTIPLEXING CONCURRENT MESSAGES OVER A SINGLE CONNECTION WITH REQUEST/REPLY

When using Netty for request/reply messaging via the netty producer then by default each message is sent via a non-shared connection (pooled). This ensures that replies are automatic being able to map to the correct request thread for further routing in Camel. In other words correlation between request/reply messages happens out-of-the-box because the replies comes back on the same

connection that was used for sending the request; and this connection is not shared with others. When the response comes back, the connection is returned back to the connection pool, where it can be reused by others.

However if you want to multiplex concurrent request/responses on a single shared connection, then you need to turn off the connection pooling by setting **producerPoolEnabled=false**. Now this means there is a potential issue with interleaved responses if replies comes back out-of-order. Therefore you need to have a correlation id in both the request and reply messages so you can properly correlate the replies to the Camel callback that is responsible for continue processing the message in Camel. To do this you need to implement **NettyCamelStateCorrelationManager** as correlation manager and configure it via the **correlationManager=#myManager** option.

NOTE

We recommend extending the **TimeoutCorrelationManagerSupport** when you build custom correlation managers. This provides support for timeout and other complexities you otherwise would need to implement as well.

You can find an example with the Apache Camel source code in the examples directory under the **camel-example-netty-custom-correlation** directory.

241.11. SEE ALSO

- [Netty HTTP](#)
- [MINA](#)

CHAPTER 242. NETTY4 HTTP COMPONENT

Available as of Camel version 2.14

The **netty4-http** component is an extension to [Netty4](#) component to facilitate HTTP transport with [Netty4](#).

This camel component supports both producer and consumer endpoints.

INFO: **Stream**. Netty is stream based, which means the input it receives is submitted to Camel as a stream. That means you will only be able to read the content of the stream **once**. If you find a situation where the message body appears to be empty or you need to access the data multiple times (eg: doing multicasting, or redelivery error handling) you should use Stream caching or convert the message body to a **String** which is safe to be re-read multiple times. Notice Netty4 HTTP reads the entire stream into memory using **io.netty.handler.codec.http.HttpObjectAggregator** to build the entire full http message. But the resulting message is still a stream based message which is readable once.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-netty4-http</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

INFO: **InputStream**. If the **InputStream** is used as the message body and you want to write or read a large data stream (for example, > 2 GB), you must use streaming support by setting the **disableStreamCache** parameter to **true**.

Example 1: Uploading a large data stream to the server

```
// Upload a large data stream to the server
from("direct:upstream-call")
  .bean(Helper.class, "prepareStream")
  .to("netty-http:http://localhost:{{port}}/upstream?disableStreamCache=true")
  .log("get ${body}");

// Read a large data stream from the client
from("netty-http:http://0.0.0.0:{{port}}/upstream?disableStreamCache=true")
  .bean(Helper.class, "processStream")
  .to("mock:stream-size");
```

Example 2: Downloading a large data stream from the server

```
// Download a large data stream from the server
from("direct:download-call")
  .to("netty-http:http://localhost:{{port}}/downstream?disableStreamCache=true")
  .bean(Helper.class, "asyncProcessStream")
  .log("get ${body}");

// Write a large data stream to the client
from("netty-http:http://0.0.0.0:{{port}}/downstream?disableStreamCache=true")
  .bean(Helper.class, "prepareStream");
```

In the download example, you must read from the **InputStream** in the other thread to avoid blocking the underlying stream handler (see **asyncProcessStream**).

```
public static void processStream(Exchange exchange) throws Exception {
    InputStream is = exchange.getIn().getBody(InputStream.class);

    byte[] buffer = new byte[1024];
    long read = 0;
    long total = 0;
    while ((read = is.read(buffer, 0, buffer.length)) != -1) {
        total += read;
    }

    exchange.getIn().setBody(new Long(total));
}

public static CompletableFuture<Void> asyncProcessStream(Exchange exchange) {
    return CompletableFuture.runAsync(() -> {
        try {
            processStream(exchange);
        } catch (Exception e) {
            exchange.setException(e);
        }
    });
}
```

242.1. URI FORMAT

The URI scheme for a netty component is as follows

```
netty4-http:http://0.0.0.0:8080[?options]
```

You can append query options to the URI in the following format, **?option=value&option=value&...**

INFO: Query parameters vs endpoint options You may be wondering how Camel recognizes URI query parameters and endpoint options. For example you might create endpoint URI as follows - **netty4-http:http://example.com?myParam=myValue&compression=true** . In this example **myParam** is the HTTP parameter, while **compression** is the Camel endpoint option. The strategy used by Camel in such situations is to resolve available endpoint options and remove them from the URI. It means that for the discussed example, the HTTP request sent by Netty HTTP producer to the endpoint will look as follows - **http://example.com?myParam=myValue** , because **compression** endpoint option will be resolved and removed from the target URL. Keep also in mind that you cannot specify endpoint options using dynamic headers (like **CamelHttpQuery**). Endpoint options can be specified only at the endpoint URI definition level (like **to** or **from** DSL elements).

242.2. HTTP OPTIONS

INFO: A lot more options. Important: This component inherits all the options from [Netty4](#). So make sure to look at the [Netty4](#) documentation as well.

Notice that some options from [Netty4](#) is not applicable when using this Netty4 HTTP component, such as options related to UDP transport.

The Netty4 HTTP component supports 9 options, which are listed below.

Name	Description	Default	Type
nettyHttpBinding (advanced)	To use a custom <code>org.apache.camel.component.netty4.http.NettyHttpBinding</code> for binding to/from Netty and Camel Message API.		NettyHttpBinding
configuration (common)	To use the <code>NettyConfiguration</code> as configuration when creating endpoints.		NettyHttpConfiguration
headerFilterStrategy (advanced)	To use a custom <code>org.apache.camel.spi.HeaderFilterStrategy</code> to filter headers.		HeaderFilterStrategy
securityConfiguration (security)	Refers to a <code>org.apache.camel.component.netty4.http.NettyHttpSecurityConfiguration</code> for configuring secure web resources.		NettyHttpSecurityConfiguration
useGlobalSslContextParameters (security)	Enable usage of global SSL context parameters.	false	boolean
maximumPoolSize (advanced)	The thread pool size for the <code>EventExecutorGroup</code> if its in use. The default value is 16.	16	int
executorService (advanced)	To use the given <code>EventExecutorGroup</code> .		EventExecutorGroup
sslContextParameters (security)	To configure security using <code>SSLContextParameters</code>		SSLContextParameters
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Netty4 HTTP endpoint is configured using URI syntax:

```
netty4-http:protocol:host:port/path
```

with the following path and query parameters:

242.2.1. Path Parameters (4 parameters):

Name	Description	Default	Type
protocol	Required The protocol to use which is either http or https		String
host	Required The local hostname such as localhost, or 0.0.0.0 when being a consumer. The remote HTTP server hostname when using producer.		String
port	The host port number		int
path	Resource path		String

242.2.2. Query Parameters (79 parameters):

Name	Description	Default	Type
bridgeEndpoint (common)	If the option is true, the producer will ignore the Exchange.HTTP_URI header, and use the endpoint's URI for request. You may also set the <code>throwExceptionOnFailure</code> to be false to let the producer send all the fault response back. The consumer working in the bridge mode will skip the gzip compression and WWW URL form encoding (by adding the <code>Exchange.SKIP_GZIP_ENCODING</code> and <code>Exchange.SKIP_WWW_FORM_URL ENCODED</code> headers to the consumed exchange).	false	boolean
disconnect (common)	Whether or not to disconnect(close) from Netty Channel right after use. Can be used for both consumer and producer.	false	boolean
keepAlive (common)	Setting to ensure socket is not closed due to inactivity	true	boolean
reuseAddress (common)	Setting to facilitate socket multiplexing	true	boolean

Name	Description	Default	Type
reuseChannel (common)	This option allows producers and consumers (in client mode) to reuse the same Netty Channel for the lifecycle of processing the Exchange. This is useful if you need to call a server multiple times in a Camel route and want to use the same network connection. When using this, the channel is not returned to the connection pool until the Exchange is done; or disconnected if the disconnect option is set to true. The reused Channel is stored on the Exchange as an exchange property with the key <code>NettyConstants#NETTY_CHANNEL</code> which allows you to obtain the channel during routing and use it as well.	false	boolean
sync (common)	Setting to set endpoint as one-way or request-response	true	boolean
tcpNoDelay (common)	Setting to improve TCP protocol performance	true	boolean
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
matchOnUriPrefix (consumer)	Whether or not Camel should try to find a target consumer by matching the URI prefix if no exact match is found.	false	boolean
send503whenSuspended (consumer)	Whether to send back HTTP status code 503 when the consumer has been suspended. If the option is false then the Netty Acceptor is unbound when the consumer is suspended, so clients cannot connect anymore.	true	boolean
backlog (consumer)	Allows to configure a backlog for netty consumer (server). Note the backlog is just a best effort depending on the OS. Setting this option to a value such as 200, 500 or 1000, tells the TCP stack how long the accept queue can be. If this option is not configured, then the backlog depends on OS setting.		int

Name	Description	Default	Type
bossCount (consumer)	When netty works on nio mode, it uses default bossCount parameter from Netty, which is 1. User can use this operation to override the default bossCount from Netty	1	int
bossGroup (consumer)	Set the BossGroup which could be used for handling the new connection of the server side across the NettyEndpoint		EventLoopGroup
chunkedMaxContentLength (consumer)	Value in bytes the max content length per chunked frame received on the Netty HTTP server.	1048576	int
compression (consumer)	Allow using gzip/deflate for compression on the Netty HTTP server if the client supports it from the HTTP headers.	false	boolean
disconnectOnNoReply (consumer)	If sync is enabled then this option dictates NettyConsumer if it should disconnect where there is no reply to send back.	true	boolean
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
httpMethodRestrict (consumer)	To disable HTTP methods on the Netty HTTP consumer. You can specify multiple separated by comma.		String
mapHeaders (consumer)	If this option is enabled, then during binding from Netty to Camel Message then the headers will be mapped as well (eg added as header to the Camel Message as well). You can turn off this option to disable this. The headers can still be accessed from the <code>org.apache.camel.component.netty.http.NettyHttpRequestMessage</code> message with the method <code>getHttpRequest()</code> that returns the Netty HTTP request <code>io.netty.handler.codec.http.HttpRequest</code> instance.	true	boolean

Name	Description	Default	Type
maxHeaderSize (consumer)	The maximum length of all headers. If the sum of the length of each header exceeds this value, a <code>io.netty.handler.codec.TooLongFrameException</code> will be raised.	8192	int
nettyServerBootstrapFactory (consumer)	To use a custom <code>NettyServerBootstrapFactory</code>		<code>NettyServerBootstrapFactory</code>
nettySharedHttpServer (consumer)	To use a shared Netty HTTP server. See <code>Netty HTTP Server Example</code> for more details.		<code>NettySharedHttpServer</code>
noReplyLogLevel (consumer)	If <code>sync</code> is enabled this option dictates <code>NettyConsumer</code> which logging level to use when logging a there is no reply to send back.	WARN	<code>LogLevel</code>
serverClosedChannelExceptionCaughtLogLevel (consumer)	If the server (<code>NettyConsumer</code>) catches an <code>java.nio.channels.ClosedChannelException</code> then its logged using this logging level. This is used to avoid logging the closed channel exceptions, as clients can disconnect abruptly and then cause a flood of closed exceptions in the Netty server.	DEBUG	<code>LogLevel</code>
serverExceptionCaughtLogLevel (consumer)	If the server (<code>NettyConsumer</code>) catches an exception then its logged using this logging level.	WARN	<code>LogLevel</code>
serverInitializerFactory (consumer)	To use a custom <code>ServerInitializerFactory</code>		<code>ServerInitializerFactory</code>
traceEnabled (consumer)	Specifies whether to enable HTTP TRACE for this Netty HTTP consumer. By default TRACE is turned off.	false	boolean
urlDecodeHeaders (consumer)	If this option is enabled, then during binding from Netty to Camel Message then the header values will be URL decoded (eg <code>%20</code> will be a space character. Notice this option is used by the default <code>org.apache.camel.component.netty.http.NettyHttpBinding</code> and therefore if you implement a custom <code>org.apache.camel.component.netty4.http.NettyHttpBinding</code> then you would need to decode the headers accordingly to this option.	false	boolean
usingExecutorService (consumer)	Whether to use ordered thread pool, to ensure events are processed orderly on the same channel.	true	boolean

Name	Description	Default	Type
connectTimeout (producer)	Time to wait for a socket connection to be available. Value is in milliseconds.	10000	int
cookieHandler (producer)	Configure a cookie handler to maintain a HTTP session		CookieHandler
requestTimeout (producer)	Allows to use a timeout for the Netty producer when calling a remote server. By default no timeout is in use. The value is in milli seconds, so eg 30000 is 30 seconds. The requestTimeout is using Netty's ReadTimeoutHandler to trigger the timeout.		long
throwExceptionOnFailure (producer)	Option to disable throwing the <code>HttpOperationFailedException</code> in case of failed responses from the remote server. This allows you to get all responses regardless of the HTTP status code.	true	boolean
clientInitializerFactory (producer)	To use a custom <code>ClientInitializerFactory</code>		ClientInitializerFactory
lazyChannelCreation (producer)	Channels can be lazily created to avoid exceptions, if the remote server is not up and running when the Camel producer is started.	true	boolean
okStatusCodeRange (producer)	The status codes which are considered a success response. The values are inclusive. Multiple ranges can be defined, separated by comma, e.g. 200-204,209,301-304. Each range must be a single number or from-to with the dash included. The default range is 200-299	200-299	String
producerPoolEnabled (producer)	Whether producer pool is enabled or not. Important: If you turn this off then a single shared connection is used for the producer, also if you are doing request/reply. That means there is a potential issue with interleaved responses if replies comes back out-of-order. Therefore you need to have a correlation id in both the request and reply messages so you can properly correlate the replies to the Camel callback that is responsible for continue processing the message in Camel. To do this you need to implement <code>NettyCamelStateCorrelationManager</code> as correlation manager and configure it via the <code>correlationManager</code> option. See also the <code>correlationManager</code> option for more details.	true	boolean

Name	Description	Default	Type
producerPoolMaxActive (producer)	Sets the cap on the number of objects that can be allocated by the pool (checked out to clients, or idle awaiting checkout) at a given time. Use a negative value for no limit.	-1	int
producerPoolMaxIdle (producer)	Sets the cap on the number of idle instances in the pool.	100	int
producerPoolMinEvictableIdle (producer)	Sets the minimum amount of time (value in millis) an object may sit idle in the pool before it is eligible for eviction by the idle object evictor.	30000 0	long
producerPoolMinIdle (producer)	Sets the minimum number of instances allowed in the producer pool before the evictor thread (if active) spawns new objects.		int
useRelativePath (producer)	Sets whether to use a relative path in HTTP requests.	false	boolean
allowSerializedHeaders (advanced)	Only used for TCP when transferExchange is true. When set to true, serializable objects in headers and properties will be added to the exchange. Otherwise Camel will exclude any non-serializable objects and log it at WARN level.	false	boolean
bootstrapConfiguration (advanced)	To use a custom configured NettyServerBootstrapConfiguration for configuring this endpoint.		NettyServerBootstrapConfiguration
channelGroup (advanced)	To use a explicit ChannelGroup.		ChannelGroup
configuration (advanced)	To use a custom configured NettyHttpConfiguration for configuring this endpoint.		NettyHttpConfiguration

Name	Description	Default	Type
disableStreamCache (advanced)	Determines whether or not the raw input stream from <code>Netty HttpRequest#getContent()</code> or <code>HttpResponse#getContent()</code> is cached or not (Camel will read the stream into a in light-weight memory based Stream caching) cache. By default Camel will cache the Netty input stream to support reading it multiple times to ensure it Camel can retrieve all data from the stream. However you can set this option to true when you for example need to access the raw stream, such as streaming it directly to a file or other persistent store. Mind that if you enable this option, then you cannot read the Netty stream multiple times out of the box, and you would need manually to reset the reader index on the Netty raw stream. Also Netty will auto-close the Netty stream when the Netty HTTP server/HTTP client is done processing, which means that if the asynchronous routing engine is in use then any asynchronous thread that may continue routing the <code>org.apache.camel.Exchange</code> may not be able to read the Netty stream, because Netty has closed it.	false	boolean
headerFilterStrategy (advanced)	To use a custom <code>org.apache.camel.spi.HeaderFilterStrategy</code> to filter headers.		HeaderFilterStrategy
nativeTransport (advanced)	Whether to use native transport instead of NIO. Native transport takes advantage of the host operating system and is only supported on some platforms. You need to add the netty JAR for the host operating system you are using. See more details at: http://netty.io/wiki/native-transport.html	false	boolean
nettyHttpBinding (advanced)	To use a custom <code>org.apache.camel.component.netty4.http.NettyHttpBinding</code> for binding to/from Netty and Camel Message API.		NettyHttpBinding
options (advanced)	Allows to configure additional netty options using option. as prefix. For example <code>option.child.keepAlive=false</code> to set the netty option <code>child.keepAlive=false</code> . See the Netty documentation for possible options that can be used.		Map
receiveBufferSize (advanced)	The TCP/UDP buffer sizes to be used during inbound communication. Size is bytes.	65536	int

Name	Description	Default	Type
receiveBufferSizePredictor (advanced)	Configures the buffer size predictor. See details at Jetty documentation and this mail thread.		int
sendBufferSize (advanced)	The TCP/UDP buffer sizes to be used during outbound communication. Size is bytes.	65536	int
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
transferException (advanced)	If enabled and an Exchange failed processing on the consumer side, and if the caused Exception was send back serialized in the response as a application/x-java-serialized-object content type. On the producer side the exception will be deserialized and thrown as is, instead of the <code>HttpOperationFailedException</code> . The caused exception is required to be serialized. This is by default turned off. If you enable this then be aware that Java will deserialize the incoming data from the request to Java and that can be a potential security risk.	false	boolean
transferExchange (advanced)	Only used for TCP. You can transfer the exchange over the wire instead of just the body. The following fields are transferred: In body, Out body, fault body, In headers, Out headers, fault headers, exchange properties, exchange exception. This requires that the objects are serializable. Camel will exclude any non-serializable objects and log it at WARN level.	false	boolean
workerCount (advanced)	When netty works on nio mode, it uses default workerCount parameter from Netty, which is <code>cpu_core_threads x 2</code> . User can use this operation to override the default workerCount from Netty.		int
workerGroup (advanced)	To use a explicit EventLoopGroup as the boss thread pool. For example to share a thread pool with multiple consumers or producers. By default each consumer or producer has their own worker pool with <code>2 x cpu count core threads</code> .		EventLoopGroup
decoder (codec)	Deprecated To use a single decoder. This options is deprecated use encoders instead.		ChannelHandler

Name	Description	Default	Type
decoders (codec)	A list of decoders to be used. You can use a String which have values separated by comma, and have the values be looked up in the Registry. Just remember to prefix the value with # so Camel knows it should lookup.		String
encoder (codec)	Deprecated To use a single encoder. This options is deprecated use encoders instead.		ChannelHandler
encoders (codec)	A list of encoders to be used. You can use a String which have values separated by comma, and have the values be looked up in the Registry. Just remember to prefix the value with # so Camel knows it should lookup.		String
enabledProtocols (security)	Which protocols to enable when using SSL	TLSv1, TLSv1.1, TLSv1.2	String
keyStoreFile (security)	Client side certificate keystore to be used for encryption		File
keyStoreFormat (security)	Keystore format to be used for payload encryption. Defaults to JKS if not set		String
keyStoreResource (security)	Client side certificate keystore to be used for encryption. Is loaded by default from classpath, but you can prefix with classpath:, file:, or http: to load the resource from different systems.		String
needClientAuth (security)	Configures whether the server needs client authentication when using SSL.	false	boolean
passphrase (security)	Password setting to use in order to encrypt/decrypt payloads sent using SSH		String
securityConfiguration (security)	Refers to a org.apache.camel.component.netty4.http.NettyHttpSecurityConfiguration for configuring secure web resources.		NettyHttpSecurityConfiguration
securityOptions (security)	To configure NettyHttpSecurityConfiguration using key/value pairs from the map		Map
securityProvider (security)	Security provider to be used for payload encryption. Defaults to SunX509 if not set.		String

Name	Description	Default	Type
ssl (security)	Setting to specify whether SSL encryption is applied to this endpoint	false	boolean
sslClientCertHeaders (security)	When enabled and in SSL mode, then the Netty consumer will enrich the Camel Message with headers having information about the client certificate such as subject name, issuer name, serial number, and the valid date range.	false	boolean
sslContextParameters (security)	To configure security using SSLContextParameters		SSLContextParameters
sslHandler (security)	Reference to a class that could be used to return an SSL Handler		SslHandler
trustStoreFile (security)	Server side certificate keystore to be used for encryption		File
trustStoreResource (security)	Server side certificate keystore to be used for encryption. Is loaded by default from classpath, but you can prefix with classpath:, file:, or http: to load the resource from different systems.		String

242.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 33 options, which are listed below.

Name	Description	Default	Type
camel.component.netty4-http.configuration.allow-default-codec			Boolean
camel.component.netty4-http.configuration.bridge-endpoint	If the option is true, the producer will ignore the Exchange.HTTP_URI header, and use the endpoint's URI for request. You may also set the <code>throwExceptionOnFailure</code> to be false to let the producer send all the fault response back. The consumer working in the bridge mode will skip the gzip compression and WWW URL form encoding (by adding the <code>Exchange.SKIP_GZIP_ENCODING</code> and <code>Exchange.SKIP_WWW_FORM_URL_ENCODED</code> headers to the consumed exchange).	false	Boolean

Name	Description	Default	Type
<code>camel.component.netty4-http.configuration.chunked-max-content-length</code>	Value in bytes the max content length per chunked frame received on the Netty HTTP server.	1048576	Integer
<code>camel.component.netty4-http.configuration.compression</code>	Allow using gzip/deflate for compression on the Netty HTTP server if the client supports it from the HTTP headers.	false	Boolean
<code>camel.component.netty4-http.configuration.disable-stream-cache</code>	Determines whether or not the raw input stream from <code>Netty HttpRequest#getContent()</code> or <code>HttpResponse#getContent()</code> is cached or not (Camel will read the stream into a in light-weight memory based Stream caching) cache. By default Camel will cache the Netty input stream to support reading it multiple times to ensure it Camel can retrieve all data from the stream. However you can set this option to true when you for example need to access the raw stream, such as streaming it directly to a file or other persistent store. Mind that if you enable this option, then you cannot read the Netty stream multiple times out of the box, and you would need manually to reset the reader index on the Netty raw stream. Also Netty will auto-close the Netty stream when the Netty HTTP server/HTTP client is done processing, which means that if the asynchronous routing engine is in use then any asynchronous thread that may continue routing the <code>org.apache.camel.Exchange</code> may not be able to read the Netty stream, because Netty has closed it.	false	Boolean
<code>camel.component.netty4-http.configuration.host</code>	The local hostname such as localhost, or 0.0.0.0 when being a consumer. The remote HTTP server hostname when using producer.		String
<code>camel.component.netty4-http.configuration.map-headers</code>	If this option is enabled, then during binding from Netty to Camel Message then the headers will be mapped as well (eg added as header to the Camel Message as well). You can turn off this option to disable this. The headers can still be accessed from the <code>org.apache.camel.component.netty.http.NettyHttpMessage</code> message with the method <code>getHttpRequest()</code> that returns the Netty HTTP request <code>io.netty.handler.codec.http.HttpRequest</code> instance.	true	Boolean

Name	Description	Default	Type
<code>camel.component.netty4-http.configuration.match-on-uri-prefix</code>	Whether or not Camel should try to find a target consumer by matching the URI prefix if no exact match is found.	false	Boolean
<code>camel.component.netty4-http.configuration.max-header-size</code>	The maximum length of all headers. If the sum of the length of each header exceeds this value, a <code>io.netty.handler.codec.TooLongFrameException</code> will be raised.	8192	Integer
<code>camel.component.netty4-http.configuration.ok-status-code-range</code>	The status codes which are considered a success response. The values are inclusive. Multiple ranges can be defined, separated by comma, e.g. 200-204,209,301-304. Each range must be a single number or from-to with the dash included. The default range is 200-299	200-299	String
<code>camel.component.netty4-http.configuration.path</code>	Resource path		String
<code>camel.component.netty4-http.configuration.port</code>	The port number. Is default 80 for http and 443 for https.		Integer
<code>camel.component.netty4-http.configuration.protocol</code>	The protocol to use which is either http or https		String
<code>camel.component.netty4-http.configuration.send503when-suspended</code>	Whether to send back HTTP status code 503 when the consumer has been suspended. If the option is false then the Netty Acceptor is unbound when the consumer is suspended, so clients cannot connect anymore.	true	Boolean
<code>camel.component.netty4-http.configuration.throw-exception-on-failure</code>	Option to disable throwing the <code>HttpOperationFailedException</code> in case of failed responses from the remote server. This allows you to get all responses regardless of the HTTP status code.	true	Boolean

Name	Description	Default	Type
<code>camel.component.netty4-http.configuration.transfer-exception</code>	If enabled and an Exchange failed processing on the consumer side, and if the caused Exception was send back serialized in the response as a application/x-java-serialized-object content type. On the producer side the exception will be deserialized and thrown as is, instead of the <code>HttpOperationFailedException</code> . The caused exception is required to be serialized. This is by default turned off. If you enable this then be aware that Java will deserialize the incoming data from the request to Java and that can be a potential security risk.	false	Boolean
<code>camel.component.netty4-http.configuration.url-decode-headers</code>	If this option is enabled, then during binding from Netty to Camel Message then the header values will be URL decoded (eg %20 will be a space character. Notice this option is used by the default <code>org.apache.camel.component.netty.http.NettyHttpBinding</code> and therefore if you implement a custom <code>org.apache.camel.component.netty4.http.NettyHttpBinding</code> then you would need to decode the headers accordingly to this option.	false	Boolean
<code>camel.component.netty4-http.configuration.use-relative-path</code>	Sets whether to use a relative path in HTTP requests.	false	Boolean
<code>camel.component.netty4-http.enabled</code>	Enable netty4-http component	true	Boolean
<code>camel.component.netty4-http.executor-service</code>	To use the given <code>EventExecutorGroup</code> . The option is a <code>io.netty.util.concurrent.EventExecutorGroup</code> type.		String
<code>camel.component.netty4-http.header-filter-strategy</code>	To use a custom <code>org.apache.camel.spi.HeaderFilterStrategy</code> to filter headers. The option is a <code>org.apache.camel.spi.HeaderFilterStrategy</code> type.		String
<code>camel.component.netty4-http.maximum-pool-size</code>	The thread pool size for the <code>EventExecutorGroup</code> if its in use. The default value is 16.	16	Integer

Name	Description	Default	Type
<code>camel.component.netty4-http.netty-http-binding</code>	To use a custom <code>org.apache.camel.component.netty4.http.NettyHttpBinding</code> for binding to/from Netty and Camel Message API. The option is a <code>org.apache.camel.component.netty4.http.NettyHttpBinding</code> type.		String
<code>camel.component.netty4-http.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.component.netty4-http.security-configuration.authenticate</code>	Whether to enable authentication <p>This is by default enabled.</p>		Boolean
<code>camel.component.netty4-http.security-configuration.constraint</code>	The supported restricted. <p>Currently only Basic is supported.</p>		String
<code>camel.component.netty4-http.security-configuration.login-denied-logging-level</code>	Sets a logging level to use for logging denied login attempts (incl stacktraces) <p>This level is by default DEBUG.</p>		LogLevel
<code>camel.component.netty4-http.security-configuration.realm</code>	Sets the name of the realm to use.		String
<code>camel.component.netty4-http.security-configuration.role-class-name</code>			String

Name	Description	Default	Type
<code>camel.component.netty4-http.security-configuration.security-authenticator</code>	Sets the {@link SecurityAuthenticator} to use for authenticating the {@link HttpPrincipal} .		SecurityAuthenticator
<code>camel.component.netty4-http.security-configuration.security-constraint</code>	Sets a {@link SecurityConstraint} to use for checking if a web resource is restricted or not <p/> By default this is <tt>null</tt>, which means all resources is restricted.		SecurityConstraint
<code>camel.component.netty4-http.ssl-context-parameters</code>	To configure security using SSLContextParameters. The option is a <code>org.apache.camel.util.jsse.SSLContextParameters</code> type.		String
<code>camel.component.netty4-http.use-global-ssl-context-parameters</code>	Enable usage of global SSL context parameters.	false	Boolean

242.4. MESSAGE HEADERS

The following headers can be used on the producer to control the HTTP request.

Name	Type	Description
Camel HttpMethod	String	Allow to control what HTTP method to use such as GET, POST, TRACE etc. The type can also be a <code>io.netty.handler.codec.http.HttpMethod</code> instance.
Camel HttpQuery	String	Allows to provide URI query parameters as a String value that overrides the endpoint configuration. Separate multiple parameters using the & sign. For example: foo=bar&beer=yes .
Camel HttpPath	String	Allows to provide URI context-path and query parameters as a String value that overrides the endpoint configuration. This allows to reuse the same producer for calling same remote http server, but using a dynamic context-path and query parameters.
Content-Type	String	To set the content-type of the HTTP body. For example: text/plain; charset="UTF-8" .

Name	Type	Description
Camel HttpResponseCode	int	Allows to set the HTTP Status code to use. By default 200 is used for success, and 500 for failure.

The following headers is provided as meta-data when a route starts from an Netty4 HTTP endpoint:

The description in the table takes offset in a route having: **from("netty4-http:http:0.0.0.0:8080/myapp")**

...

Name	Type	Description
Camel HttpMethod	String	The HTTP method used, such as GET, POST, TRACE etc.
Camel HttpUrl	String	The URL including protocol, host and port, etc: http://0.0.0.0:8080/myapp
Camel HttpUri	String	The URI without protocol, host and port, etc: /myapp
Camel HttpQuery	String	Any query parameters, such as foo=bar&beer=yes
Camel HttpRawQuery	String	Any query parameters, such as foo=bar&beer=yes . Stored in the raw form, as they arrived to the consumer (i.e. before URL decoding).
Camel HttpPath	String	Additional context-path. This value is empty if the client called the context-path /myapp . If the client calls /myapp/mystuff , then this header value is /mystuff . In other words its the value after the context-path configured on the route endpoint.
Camel HttpCharacterEncoding	String	The charset from the content-type header.

Name	Type	Description
Camel HttpAuthentication	String	If the user was authenticated using HTTP Basic then this header is added with the value Basic .
Content-Type	String	The content type if provided. For example: text/plain; charset="UTF-8" .

242.5. ACCESS TO NETTY TYPES

This component uses the **org.apache.camel.component.netty4.http.NettyHttpRequestMessage** as the message implementation on the Exchange. This allows end users to get access to the original Netty request/response instances if needed, as shown below. Mind that the original response may not be accessible at all times.

```
io.netty.handler.codec.http.HttpRequest request =
exchange.getIn(NettyHttpRequestMessage.class).getHttpRequest();
```

242.6. EXAMPLES

In the route below we use Netty4 HTTP as a HTTP server, which returns back a hardcoded "Bye World" message.

```
from("netty4-http:http://0.0.0.0:8080/foo")
.transform().constant("Bye World");
```

And we can call this HTTP server using Camel also, with the ProducerTemplate as shown below:

```
String out = template.requestBody("netty4-http:http://0.0.0.0:8080/foo", "Hello World", String.class);
System.out.println(out);
```

And we get back "Bye World" as the output.

242.7. HOW DO I LET NETTY MATCH WILDCARDS

By default Netty4 HTTP will only match on exact uri's. But you can instruct Netty to match prefixes. For example

```
from("netty4-http:http://0.0.0.0:8123/foo").to("mock:foo");
```

In the route above Netty4 HTTP will only match if the uri is an exact match, so it will match if you enter <http://0.0.0.0:8123/foo> but not match if you do <http://0.0.0.0:8123/foo/bar>.

So if you want to enable wildcard matching you do as follows:

```
from("netty4-http:http://0.0.0.0:8123/foo?matchOnUriPrefix=true").to("mock:foo");
```

So now Netty matches any endpoints with starts with **foo**.

To match **any** endpoint you can do:

```
from("netty4-http:http://0.0.0.0:8123?matchOnUriPrefix=true").to("mock:foo");
```

242.8. USING MULTIPLE ROUTES WITH SAME PORT

In the same CamelContext you can have multiple routes from Netty4 HTTP that shares the same port (eg a **io.netty.bootstrap.ServerBootstrap** instance). Doing this requires a number of bootstrap options to be identical in the routes, as the routes will share the same **io.netty.bootstrap.ServerBootstrap** instance. The instance will be configured with the options from the first route created.

The options the routes must be identical configured is all the options defined in the **org.apache.camel.component.netty4.NettyServerBootstrapConfiguration** configuration class. If you have configured another route with different options, Camel will throw an exception on startup, indicating the options is not identical. To mitigate this ensure all options is identical.

Here is an example with two routes that share the same port.

Two routes sharing the same port

```
from("netty4-http:http://0.0.0.0:{{port}}/foo")
    .to("mock:foo")
    .transform().constant("Bye World");

from("netty4-http:http://0.0.0.0:{{port}}/bar")
    .to("mock:bar")
    .transform().constant("Bye Camel");
```

And here is an example of a mis configured 2nd route that do not have identical **org.apache.camel.component.netty4.NettyServerBootstrapConfiguration** option as the 1st route. This will cause Camel to fail on startup.

Two routes sharing the same port, but the 2nd route is misconfigured and will fail on starting

```
from("netty4-http:http://0.0.0.0:{{port}}/foo")
    .to("mock:foo")
    .transform().constant("Bye World");

// we cannot have a 2nd route on same port with SSL enabled, when the 1st route is NOT
from("netty4-http:http://0.0.0.0:{{port}}/bar?ssl=true")
    .to("mock:bar")
    .transform().constant("Bye Camel");
```

242.8.1. Reusing same server bootstrap configuration with multiple routes

By configuring the common server bootstrap option in an single instance of a **org.apache.camel.component.netty4.NettyServerBootstrapConfiguration** type, we can use the **bootstrapConfiguration** option on the Netty4 HTTP consumers to refer and reuse the same options across all consumers.

```
<bean id="nettyHttpBootstrapOptions"
    class="org.apache.camel.component.netty4.NettyServerBootstrapConfiguration">
```

```

<property name="backlog" value="200"/>
<property name="connectionTimeout" value="20000"/>
<property name="workerCount" value="16"/>
</bean>

```

And in the routes you refer to this option as shown below

```

<route>
  <from uri="netty4-http:http://0.0.0.0:{{port}}/foo?
bootstrapConfiguration=#nettyHttpBootstrapOptions"/>
  ...
</route>

<route>
  <from uri="netty4-http:http://0.0.0.0:{{port}}/bar?
bootstrapConfiguration=#nettyHttpBootstrapOptions"/>
  ...
</route>

<route>
  <from uri="netty4-http:http://0.0.0.0:{{port}}/beer?
bootstrapConfiguration=#nettyHttpBootstrapOptions"/>
  ...
</route>

```

242.8.2. Reusing same server bootstrap configuration with multiple routes across multiple bundles in OSGi container

See the Netty HTTP Server Example for more details and example how to do that.

242.9. USING HTTP BASIC AUTHENTICATION

The Netty HTTP consumer supports HTTP basic authentication by specifying the security realm name to use, as shown below

```

<route>
  <from uri="netty4-http:http://0.0.0.0:{{port}}/foo?securityConfiguration.realm=karaf"/>
  ...
</route>

```

The realm name is mandatory to enable basic authentication. By default the JAAS based authenticator is used, which will use the realm name specified (karaf in the example above) and use the JAAS realm and the JAAS `LoginModule`s of this realm for authentication.

End user of Apache Karaf / ServiceMix has a karaf realm out of the box, and hence why the example above would work out of the box in these containers.

242.9.1. Specifying ACL on web resources

The `org.apache.camel.component.netty4.http.SecurityConstraint` allows to define constrains on web resources. And the `org.apache.camel.component.netty.http.SecurityConstraintMapping` is provided out of the box, allowing to easily define inclusions and exclusions with roles.

For example as shown below in the XML DSL, we define the constraint bean:

```

<bean id="constraint" class="org.apache.camel.component.netty4.http.SecurityConstraintMapping">
  <!-- inclusions defines url -> roles restrictions -->
  <!-- a * should be used for any role accepted (or even no roles) -->
  <property name="inclusions">
    <map>
      <entry key="/*" value="*" />
      <entry key="/admin/*" value="admin" />
      <entry key="/guest/*" value="admin,guest" />
    </map>
  </property>
  <!-- exclusions is used to define public urls, which requires no authentication -->
  <property name="exclusions">
    <set>
      <value>/public/*</value>
    </set>
  </property>
</bean>

```

The constraint above is define so that

- access to /* is restricted and any roles is accepted (also if user has no roles)
- access to /admin/* requires the admin role
- access to /guest/* requires the admin or guest role
- access to /public/* is an exclusion which means no authentication is needed, and is therefore public for everyone without logging in

To use this constraint we just need to refer to the bean id as shown below:

```

<route>
  <from uri="netty4-http:http://0.0.0.0:{{port}}/foo?
  matchOnUriPrefix=true&amp;securityConfiguration.realm=karaf&amp;securityConfiguration.securityCon
  straint=#constraint"/>
  ...
</route>

```

CHAPTER 243. NSQ COMPONENT

Available as of Camel version 2.23

Available as of Camel version 2.23

NSQ is a realtime distributed messaging platform.

Maven users will need to add the following dependency to their **pom.xml** for this component.

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-nsq</artifactId>
  <!-- use the same version as your Camel core version -->
  <version>x.y.z</version>
</dependency>
```

243.1. URI FORMAT

```
nsq:servers[?options]
```

Where **servers** represents the list of NSQ servers - nsqlookupd servers in the case of a consumer and nsqd servers in the case of a producer.

243.2. OPTIONS

The NSQ component supports 2 options, which are listed below.

Name	Description	Default	Type
useGlobalSslContext Parameters (security)	Enable usage of global SSL context parameters.	false	boolean
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The NSQ endpoint is configured using URI syntax:

```
nsq:servers
```

with the following path and query parameters:

243.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
servers	Required The hostnames of one or more nsqlookupd servers (consumer) or nsqd servers (producer).		String

243.2.2. Query Parameters (16 parameters):

Name	Description	Default	Type
topic (common)	Required The name of topic we want to use		String
userAgent (common)	A String to identify the kind of client		String
autoFinish (consumer)	Automatically finish the NSQ message when it is retrieved from the queue and before the Exchange is processed.	true	Boolean
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which means any exceptions occurred while the consumer is trying to pick up incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
channel (consumer)	The name of channel we want to use		String
lookupInterval (consumer)	The lookup retry interval	5000	long
lookupServerPort (consumer)	The port of the nsqdlookupd server	4161	int
messageTimeout (consumer)	The NSQ message timeout for a consumer.	-1	long
poolSize (consumer)	Consumer pool size	10	int
requeueInterval (consumer)	The requeue interval	-1	long

Name	Description	Default	Type
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
port (producer)	The port of the nsqd server	4150	int
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
secure (security)	Set secure option indicating TLS is required	false	boolean
sslContextParameters (security)	To configure security using SSLContextParameters		SSLContextParameters

243.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 3 options, which are listed below.

Name	Description	Default	Type
camel.component.nsq.enabled	Whether to enable auto configuration of the nsq component. This is enabled by default.		Boolean
camel.component.nsq.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
camel.component.nsq.use-global-ssl-context-parameters	Enable usage of global SSL context parameters.	false	Boolean

CHAPTER 244. OGNL LANGUAGE

Available as of Camel version 1.1

Camel allows [OGNL](#) to be used as an Expression or Predicate the DSL or Xml Configuration.

You could use OGNL to create an Predicate in a Message Filter or as an Expression for a Recipient List

You can use OGNL dot notation to invoke operations. If you for instance have a body that contains a POJO that has a **getFamilyName** method then you can construct the syntax as follows:

```
"request.body.familyName"
// or
"getRequest().getBody().getFamilyName()"
```

244.1. OGNL OPTIONS

The OGNL language supports 1 options, which are listed below.

Name	Default	Java Type	Description
trim	true	Boolean	Whether to trim the value to remove leading and trailing whitespaces and line breaks

244.2. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.language.ognl.enabled	Enable ognl language	true	Boolean
camel.language.ognl.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks	true	Boolean

244.3. VARIABLES

Variable	Type	Description
this	Exchange	the Exchange is the root object
exchange	Exchange	the Exchange object

Variable	Type	Description
exception	Throwable	the Exchange exception (if any)
exchangeId	String	the exchange id
fault	Message	the Fault message (if any)
request	Message	the exchange.in message
response	Message	the exchange.out message (if any)
properties	Map	the exchange properties
property(name)	Object	the property by the given name
property(name, type)	Type	the property by the given name as the given type

244.4. SAMPLES

For example you could use OGNL inside a [Message Filter](#) in XML

```
<route>
  <from uri="seda:foo"/>
  <filter>
    <ognl>request.headers.foo == 'bar'</ognl>
    <to uri="seda:bar"/>
  </filter>
</route>
```

And the sample using Java DSL:

```
from("seda:foo").filter().ognl("request.headers.foo == 'bar']").to("seda:bar");
```

244.5. LOADING SCRIPT FROM EXTERNAL RESOURCE

Available as of Camel 2.11

You can externalize the script and have Camel load it from a resource such as **"classpath:"**, **"file:"**, or

"http:".

This is done using the following syntax: **"resource:scheme:location"**, eg to refer to a file on the classpath you can do:

```
.setHeader("myHeader").ognl("resource:classpath:myognl.txt")
```

244.6. DEPENDENCIES

To use OGNL in your camel routes you need to add the a dependency on **camel-ognl** which implements the OGNL language.

If you use maven you could just add the following to your pom.xml, substituting the version number for the latest & greatest release (see the download page for the latest versions).

```
<dependency>  
  <groupId>org.apache.camel</groupId>  
  <artifactId>camel-ognl</artifactId>  
  <version>x.x.x</version>  
</dependency>
```

Otherwise, you'll also need [OGNL](#)

CHAPTER 245. OLINGO2 COMPONENT

Available as of Camel version 2.14

The Olingo2 component utilizes [Apache Olingo](#) version 2.0 APIs to interact with OData 2.0 compliant services. A number of popular commercial and enterprise vendors and products support the OData protocol. A sample list of supporting products can be found on the OData [website](#).

The Olingo2 component supports reading feeds, delta feeds, entities, simple and complex properties, links, counts, using custom and OData system query parameters. It supports updating entities, properties, and association links. It also supports submitting queries and change requests as a single OData batch operation.

The component supports configuring HTTP connection parameters and headers for OData service connection. This allows configuring use of SSL, OAuth2.0, etc. as required by the target OData service.

Maven users will need to add the following dependency to their pom.xml for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-olingo2</artifactId>
  <version>${camel-version}</version>
</dependency>
```

245.1. URI FORMAT

```
olingo2://endpoint/<resource-path>?[options]
```

245.2. OLINGO2 OPTIONS

The Olingo2 component supports 3 options, which are listed below.

Name	Description	Default	Type
configuration (common)	To use the shared configuration		Olingo2Configurat ion
useGlobalSslCont ext Parameters (security)	Enable usage of global SSL context parameters.	false	boolean
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Olingo2 endpoint is configured using URI syntax:

```
olingo2:apiName/methodName
```

with the following path and query parameters:

245.2.1. Path Parameters (2 parameters):

Name	Description	Default	Type
apiName	Required What kind of operation to perform		Olingo2ApiName
methodName	Required What sub operation to use for the selected operation		String

245.2.2. Query Parameters (14 parameters):

Name	Description	Default	Type
connectTimeout (common)	HTTP connection creation timeout in milliseconds, defaults to 30,000 (30 seconds)	30000	int
contentType (common)	Content-Type header value can be used to specify JSON or XML message format, defaults to application/json;charset=utf-8	application/json;charset=utf-8	String
httpAsyncClientBuilder (common)	Custom HTTP async client builder for more complex HTTP client configuration, overrides connectionTimeout, socketTimeout, proxy and sslContext. Note that a socketTimeout MUST be specified in the builder, otherwise OData requests could block indefinitely		HttpAsyncClientBuilder
httpClientBuilder (common)	Custom HTTP client builder for more complex HTTP client configuration, overrides connectionTimeout, socketTimeout, proxy and sslContext. Note that a socketTimeout MUST be specified in the builder, otherwise OData requests could block indefinitely		HttpClientBuilder
httpHeaders (common)	Custom HTTP headers to inject into every request, this could include OAuth tokens, etc.		Map
inBody (common)	Sets the name of a parameter to be passed in the exchange In Body		String
proxy (common)	HTTP proxy server configuration		HttpHost
serviceUri (common)	Target OData service base URI, e.g. http://services.odata.org/OData/OData.svc		String

Name	Description	Default	Type
socketTimeout (common)	HTTP request timeout in milliseconds, defaults to 30,000 (30 seconds)	30000	int
sslContextParameters (common)	To configure security using SSLContextParameters		SSLContextParameters
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

245.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 14 options, which are listed below.

Name	Description	Default	Type
camel.component. .olingo2.configuration. api-name	What kind of operation to perform		Olingo2ApiName
camel.component. .olingo2.configuration. connection. connect-timeout	HTTP connection creation timeout in milliseconds, defaults to 30,000 (30 seconds)	30000	Integer

Name	Description	Default	Type
<code>camel.component.olingo2.configuration.content-type</code>	Content-Type header value can be used to specify JSON or XML message format, defaults to application/json;charset=utf-8	application/json;charset=utf-8	String
<code>camel.component.olingo2.configuration.http-async-client-builder</code>	Custom HTTP async client builder for more complex HTTP client configuration, overrides connectionTimeout, socketTimeout, proxy and sslContext. Note that a socketTimeout MUST be specified in the builder, otherwise OData requests could block indefinitely		HttpAsyncClientBuilder
<code>camel.component.olingo2.configuration.http-client-builder</code>	Custom HTTP client builder for more complex HTTP client configuration, overrides connectionTimeout, socketTimeout, proxy and sslContext. Note that a socketTimeout MUST be specified in the builder, otherwise OData requests could block indefinitely		HttpClientBuilder
<code>camel.component.olingo2.configuration.http-headers</code>	Custom HTTP headers to inject into every request, this could include OAuth tokens, etc.		Map
<code>camel.component.olingo2.configuration.method-name</code>	What sub operation to use for the selected operation		String
<code>camel.component.olingo2.configuration.proxy</code>	HTTP proxy server configuration		HttpHost
<code>camel.component.olingo2.configuration.service-uri</code>	Target OData service base URI, e.g. http://services.odata.org/OData/OData.svc		String
<code>camel.component.olingo2.configuration.socket-timeout</code>	HTTP request timeout in milliseconds, defaults to 30,000 (30 seconds)	30000	Integer
<code>camel.component.olingo2.configuration.ssl-context-parameters</code>	To configure security using SSLContextParameters		SSLContextParameters
<code>camel.component.olingo2.enabled</code>	Enable olingo2 component	true	Boolean

Name	Description	Default	Type
<code>camel.component.olingo2.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.component.olingo2.use-global-ssl-context-parameters</code>	Enable usage of global SSL context parameters.	false	Boolean

245.4. PRODUCER ENDPOINTS

Producer endpoints can use endpoint names and options listed next. Producer endpoints can also use a special option **inBody** that in turn should contain the name of the endpoint option whose value will be contained in the Camel Exchange In message. The **inBody** option defaults to **data** for endpoints that take that option.

245.5. ENDPOINT OPTIONS

Any of the endpoint options can be provided in either the endpoint URI, or dynamically in a message header. The message header name must be of the format **CamelOlingo2.<option>**. Note that the **inBody** option overrides message header, i.e. the endpoint option **inBody=option** would override a **CamelOlingo2.option** header. In addition, query parameters can be specified.

Name	Type	Description
data	Object	Data with appropriate type used to create or modify the OData resource
keyPredicate	String	Key predicate to create a parameterized OData resource endpoint. Useful for create/update operations where the key predicate value is dynamically provided in a header
queryParams	<code>java.util.Map<String,String></code>	OData system options and custom query options. For more information see OData 2.0 URI Conventions
resourcePath	String	OData resource path, may or may not contain key predicate
endpointHttpHeaders	<code>java.util.Map<String,String></code>	Dynamic HTTP Headers to be sent to the endpoint

Name	Type	Description
responseHttpHeaders	java.util.Map<String, String>	Dynamic HTTP Response Headers from the endpoint

Note that the resourcePath option can either be specified in the URI as a part of the URI path, as an endpoint option `?resourcePath=<resource-path>` or as a header value `CamelOlingo2.resourcePath`. The OData entity key predicate can either be a part of the resource path, e.g. `Manufacturers('1')`, where `'_1'` is the key predicate, or be specified separately with resource path `Manufacturers` and keyPredicate option `'1'`.

Endpoint	Options	HTTP Method	Result Body Type
batch	data, endpointHttpHeaders	POST with multipart/mixed batch request	java.util.List<org.apache.camel.component.oringo2.api.batch.Olingo2BatchResponse>
create	data, resourcePath, endpointHttpHeaders	POST	org.apache.oringo.odata2.api.ep.entry.ODataEntry for new entries org.apache.oringo.odata2.api.commons.HttpStatusCodes for other OData resources
delete	resourcePath, endpointHttpHeaders	DELETE	org.apache.oringo.odata2.api.commons.HttpStatusCodes
merge	data, resourcePath, endpointHttpHeaders	MERGE	org.apache.oringo.odata2.api.commons.HttpStatusCodes

Endpoint	Options	HTTP Method	Result Body Type
patch	data, resourcePath, endpointHttpHeaders	PATCH	org.apache.olingo.odata2.api.commons.HttpStatusCodes
read	queryParams, resourcePath, endpointHttpHeaders	GET	Depends on OData resource being queried as described next
update	data, resourcePath, endpointHttpHeaders	PUT	org.apache.olingo.odata2.api.commons.HttpStatusCodes

245.6. ENDPOINT HTTP HEADERS (SINCE 2.20)

The component level configuration property **httpHeaders** supplies static HTTP header information. However, some systems requires dynamic header information to be passed to and received from the endpoint. A sample use case would be systems that require dynamic security tokens. The **endpointHttpHeaders** and **responseHttpHeaders** endpoint properties provides this capability. Set headers that need to be passed to the endpoint in the **CamelOlingo2.endpointHttpHeaders** property and the response headers will be returned in a **CamelOlingo2.responseHttpHeaders** property. Both properties are of the type **java.util.Map<String, String>**.

245.7. ODATA RESOURCE TYPE MAPPING

The result of **read** endpoint and data type of **data** option depends on the OData resource being queried, created or modified.

OData Resource Type	Resource URI from resourcePath and keyPredicate	In or Out Body Type
Entity data model	\$metadata	org.apache.olingo.odata2.api.edm.Edm
Service document	/	org.apache.olingo.odata2.api.servicedocument.ServiceDocument
OData feed	<entity-set>	org.apache.olingo.odata2.api.ep.feed.ODataFeed
OData entry	<entity-set> (<key-predicate>)	org.apache.olingo.odata2.api.ep.entry.ODataEntry for Out body (response) java.util.Map<String, Object> for In body (request)
Simple property	<entity-set> (<key-predicate>)/<simple-property>	Appropriate Java data type as described by Olingo EdmProperty
Simple property value	<entity-set> (<key-predicate>)/<simple-property>/\$value	Appropriate Java data type as described by Olingo EdmProperty

OData Resource Type	Resource URI from resourcePath and keyPredicate	In or Out Body Type
Complex property	<entity-set> (<key-predicate>)/<complex-property>	java.util.Map<String, Object>
Zero or one association link	<entity-set> (<key-predicate>)/\$link/<one-to-one-entity-set-property>	String for response java.util.Map<String, Object> with key property names and values for request
Zero or many association links	<entity-set> (<key-predicate>)/\$links/<one-to-many-entity-set-property>	java.util.List<String> for response java.util.List<java.util.Map<String, Object>> containing list of key property names and values for request
Count	<resource-uri>/\$count	java.lang.Long

245.8. CONSUMER ENDPOINTS

Only the **read** endpoint can be used as a consumer endpoint. Consumer endpoints can use [Scheduled Poll Consumer Options](#) with a **consumer.** prefix to schedule endpoint invocation. By default consumer endpoints that return an array or collection will generate one exchange per element, and their routes will be executed once for each exchange. This behavior can be disabled by setting the endpoint property `consumer.splitResult=false`.

245.9. MESSAGE HEADERS

Any URI option can be provided in a message header for producer endpoints with a **CamelOlingo2.** prefix.

245.10. MESSAGE BODY

All result message bodies utilize objects provided by the underlying [Apache Olingo 2.0 API](#) used by the Olingo2Component. Producer endpoints can specify the option name for incoming message body in the **inBody** endpoint URI parameter. For endpoints that return an array or collection, a consumer endpoint will map every element to distinct messages, unless `consumer.splitResult` is set to **false**.

245.11. USE CASES

The following route reads top 5 entries from the Manufacturer feed ordered by ascending Name property.

```
from("direct:...")
  .setHeader("CamelOlingo2.$top", "5");
  .to("olingo2://read/Manufacturers?orderBy=Name%20asc");
```

The following route reads Manufacturer entry using the key property value in incoming **id** header.

```
from("direct:...")
  .setHeader("CamelOlingo2.keyPredicate", header("id"))
  .to("olingo2://read/Manufacturers");
```

The following route creates Manufacturer entry using the `java.util.Map<String, Object>` in body message.

```
from("direct:...")
  .to("olingo2://create/Manufacturers");
```

The following route polls Manufacturer [delta feed](#) every 30 seconds. The bean **blah** updates the bean **paramsBean** to add an updated **!deltatoken** property with the value returned in the **ODataDeltaFeed** result. Since the initial delta token is not known, the consumer endpoint will produce

an **ODataFeed** value the first time, and **ODataDeltaFeed** on subsequent polls.

```
from("olingo2://read/Manufacturers?  
queryParams=#paramsBean&consumer.timeUnit=SECONDS&consumer.delay=30")  
  .to("bean:blah");
```

CHAPTER 246. OLINGO4 COMPONENT

Available as of Camel version 2.19

The Olingo4 component utilizes [Apache Olingo](#) version 4.0 APIs to interact with OData 4.0 compliant service. Since version 4.0 OData is OASIS standard and number of popular open source and commercial vendors and products support this protocol. A sample list of supporting products can be found on the OData [website](#).

The Olingo4 component supports reading entity sets, entities, simple and complex properties, counts, using custom and OData system query parameters. It supports updating entities and properties. It also supports submitting queries and change requests as a single OData batch operation.

The component supports configuring HTTP connection parameters and headers for OData service connection. This allows configuring use of SSL, OAuth2.0, etc. as required by the target OData service.

Maven users will need to add the following dependency to their pom.xml for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-olingo4</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

246.1. URI FORMAT

```
olingo4://endpoint/<resource-path>?[options]
```

246.2. OLINGO4 OPTIONS

The Olingo4 component supports 3 options, which are listed below.

Name	Description	Default	Type
configuration (common)	To use the shared configuration		Olingo4Configuraton
useGlobalSslContext Parameters (security)	Enable usage of global SSL context parameters.	false	boolean
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Olingo4 endpoint is configured using URI syntax:

```
olingo4:apiName/methodName
```

with the following path and query parameters:

246.2.1. Path Parameters (2 parameters):

Name	Description	Default	Type
apiName	Required What kind of operation to perform		Olingo4ApiName
methodName	Required What sub operation to use for the selected operation		String

246.2.2. Query Parameters (14 parameters):

Name	Description	Default	Type
connectTimeout (common)	HTTP connection creation timeout in milliseconds, defaults to 30,000 (30 seconds)	30000	int
contentType (common)	Content-Type header value can be used to specify JSON or XML message format, defaults to application/json;charset=utf-8	application/json;charset=utf-8	String
httpAsyncClientBuilder (common)	Custom HTTP async client builder for more complex HTTP client configuration, overrides connectionTimeout, socketTimeout, proxy and sslContext. Note that a socketTimeout MUST be specified in the builder, otherwise OData requests could block indefinitely		HttpAsyncClientBuilder
httpClientBuilder (common)	Custom HTTP client builder for more complex HTTP client configuration, overrides connectionTimeout, socketTimeout, proxy and sslContext. Note that a socketTimeout MUST be specified in the builder, otherwise OData requests could block indefinitely		HttpClientBuilder
httpHeaders (common)	Custom HTTP headers to inject into every request, this could include OAuth tokens, etc.		Map
inBody (common)	Sets the name of a parameter to be passed in the exchange In Body		String
proxy (common)	HTTP proxy server configuration		HttpHost

Name	Description	Default	Type
serviceUri (common)	Target OData service base URI, e.g. http://services.odata.org/OData/OData.svc		String
socketTimeout (common)	HTTP request timeout in milliseconds, defaults to 30,000 (30 seconds)	30000	int
sslContextParameters (common)	To configure security using SSLContextParameters		SSLContextParameters
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

246.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 14 options, which are listed below.

Name	Description	Default	Type
camel.component.olingo4.configuration.api-name	What kind of operation to perform		Olingo4ApiName
camel.component.olingo4.configuration.connection.timeout	HTTP connection creation timeout in milliseconds, defaults to 30,000 (30 seconds)	30000	Integer

Name	Description	Default	Type
<code>camel.component.olingo4.configuration.content-type</code>	Content-Type header value can be used to specify JSON or XML message format, defaults to application/json;charset=utf-8	application/json;charset=utf-8	String
<code>camel.component.olingo4.configuration.http-async-client-builder</code>	Custom HTTP async client builder for more complex HTTP client configuration, overrides connectionTimeout, socketTimeout, proxy and sslContext. Note that a socketTimeout MUST be specified in the builder, otherwise OData requests could block indefinitely		HttpAsyncClientBuilder
<code>camel.component.olingo4.configuration.http-client-builder</code>	Custom HTTP client builder for more complex HTTP client configuration, overrides connectionTimeout, socketTimeout, proxy and sslContext. Note that a socketTimeout MUST be specified in the builder, otherwise OData requests could block indefinitely		HttpClientBuilder
<code>camel.component.olingo4.configuration.http-headers</code>	Custom HTTP headers to inject into every request, this could include OAuth tokens, etc.		Map
<code>camel.component.olingo4.configuration.method-name</code>	What sub operation to use for the selected operation		String
<code>camel.component.olingo4.configuration.proxy</code>	HTTP proxy server configuration		HttpHost
<code>camel.component.olingo4.configuration.service-uri</code>	Target OData service base URI, e.g. http://services.odata.org/OData/OData.svc		String
<code>camel.component.olingo4.configuration.socket-timeout</code>	HTTP request timeout in milliseconds, defaults to 30,000 (30 seconds)	30000	Integer
<code>camel.component.olingo4.configuration.ssl-context-parameters</code>	To configure security using SSLContextParameters		SSLContextParameters
<code>camel.component.olingo4.enabled</code>	Enable olingo4 component	true	Boolean

Name	Description	Default	Type
<code>camel.component.olingo4.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.component.olingo4.use-global-ssl-context-parameters</code>	Enable usage of global SSL context parameters.	false	Boolean

246.4. PRODUCER ENDPOINTS

Producer endpoints can use endpoint names and options listed next. Producer endpoints can also use a special option **inBody** that in turn should contain the name of the endpoint option whose value will be contained in the Camel Exchange In message. The **inBody** option defaults to **data** for endpoints that take that option.

Any of the endpoint options can be provided in either the endpoint URI, or dynamically in a message header. The message header name must be of the format **CamelOlingo4.<option>**. Note that the **inBody** option overrides message header, i.e. the endpoint option **inBody=option** would override a **CamelOlingo4.option** header. In addition, query parameters can be specified

Note that the `resourcePath` option can either be specified in the URI as a part of the URI path, as an endpoint option `?resourcePath=<resource-path>` or as a header value `CamelOlingo4.resourcePath`. The OData entity key predicate can either be a part of the resource path, e.g. `Manufacturers('1')`, where `'_1'` is the key predicate, or be specified separately with resource path `Manufacturers` and keyPredicate option `'1'`.

Endpoint	Options	HTTP Method	Result Body Type
batch	data, endpointHttpHeaders	POST with multipart/mixed batch request	<code>java.util.List<org.apache.camel.component.olingo4.api.batch.Olingo4BatchResponse></code>
create	data, resourcePath, endpointHttpHeaders	POST	<code>org.apache.olingoclient.api.domain.ClientEntity</code> for new entries <code>org.apache.olingocommons.api.http.HttpStatus</code> for other OData resources

Endpoint	Options	HTTP Method	Result Body Type
delete	resourcePath, endpointHttpHeaders	DELETE	org.apache.olingo.commons.api.http.HttpStatusCode
merge	data, resourcePath, endpointHttpHeaders	MERGE	org.apache.olingo.commons.api.http.HttpStatusCode
patch	data, resourcePath, endpointHttpHeaders	PATCH	org.apache.olingo.commons.api.http.HttpStatusCode
read	queryParams, resourcePath, endpointHttpHeaders	GET	Depends on OData resource being queried as described next
update	data, resourcePath, endpointHttpHeaders	PUT	org.apache.olingo.commons.api.http.HttpStatusCode

246.5. ENDPOINT HTTP HEADERS (SINCE CAMEL 2.20)

The component level configuration property **httpHeaders** supplies static HTTP header information. However, some systems requires dynamic header information to be passed to and received from the endpoint. A sample use case would be systems that require dynamic security tokens. The **endpointHttpHeaders** and **responseHttpHeaders** endpoint properties provides this capability. Set

headers that need to be passed to the endpoint in the **CamelOlingo4.endpointHttpHeaders** property and the response headers will be returned in a **CamelOlingo4.responseHttpHeaders** property. Both properties are of the type **java.util.Map<String, String>**.

246.6. ODATA RESOURCE TYPE MAPPING

The result of **read** endpoint and data type of **data** option depends on the OData resource being queried, created or modified.

OData Resource Type	Resource URI from resourcePath and keyPredicate	In or Out Body Type
Entity data model	\$metadata	org.apache.olingo.commons.api.edm.Edm
Service document	/	org.apache.olingo.client.api.domain.ClientServiceDocument
OData entity set	<entity-set>	org.apache.olingo.client.api.domain.ClientEntitySet
OData entity	<entity-set> (<key-predicate>)	org.apache.olingo.client.api.domain.ClientEntity for Out body (response) java.util.Map<String, Object> for In body (request)
Simple property	<entity-set> (<key-predicate>)/<simple-property>	org.apache.olingo.client.api.domain.ClientPrimitiveValue

OData Resource Type	Resource URI from resourcePath and keyPredicate	In or Out Body Type
Simple property value	<entity-set> (<key-predicate>)/<simple-property>/\$value	org.apache.olingo.client.api.domain.ClientPrimitiveValue
Complex property	<entity-set> (<key-predicate>)/<complex-property>	org.apache.olingo.client.api.domain.ClientComplexValue
Count	<resource-uri>/\$count	java.lang.Long

246.7. CONSUMER ENDPOINTS

Only the **read** endpoint can be used as a consumer endpoint. Consumer endpoints can use [Scheduled Poll Consumer Options](#) with a **consumer.** prefix to schedule endpoint invocation. By default consumer endpoints that return an array or collection will generate one exchange per element, and their routes will be executed once for each exchange. This behavior can be disabled by setting the endpoint property **consumer.splitResult=false**.

246.8. MESSAGE HEADERS

Any URI option can be provided in a message header for producer endpoints with a **CamelOlingo4.** prefix.

246.9. MESSAGE BODY

All result message bodies utilize objects provided by the underlying [Apache Olingo 4.0 API](#) used by the `Olingo4Component`. Producer endpoints can specify the option name for incoming message body in the **inBody** endpoint URI parameter. For endpoints that return an array or collection, a consumer endpoint will map every element to distinct messages, unless **consumer.splitResult** is set to **false**.

246.10. USE CASES

The following route reads top 5 entries from the People entity ordered by ascending FirstName property.

```
from("direct:...")
  .setHeader("CamelOlingo4.$top", "5");
  .to("olingo4://read/People?orderBy=FirstName%20asc");
```

The following route reads Airports entity using the key property value in incoming **id** header.

```
from("direct:...")
  .setHeader("CamelOlingo4.keyPredicate", header("id"))
  .to("olingo4://read/Airports");
```

The following route creates People entity using the **ClientEntity** in body message.

```
from("direct:...")
  .to("olingo4://create/People");
```

CHAPTER 247. OPENSIFT COMPONENT (DEPRECATED)

Available as of Camel version 2.14

The **openshift** component is a component for managing your [OpenShift](#) applications.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-openshift</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

247.1. URI FORMAT

```
openshift:clientId[?options]
```

You can append query options to the URI in the following format, **?option=value&option=value&...**

247.2. OPTIONS

The OpenShift component supports 5 options, which are listed below.

Name	Description	Default	Type
username (security)	The username to login to openshift server.		String
password (security)	The password for login to openshift server.		String
domain (common)	Domain name. If not specified then the default domain is used.		String
server (common)	Url to the openshift server. If not specified then the default value from the local openshift configuration file <code>./openshift/express.conf</code> is used. And if that fails as well then <code>openshift.redhat.com</code> is used.		String
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The OpenShift endpoint is configured using URI syntax:

```
openshift:clientId
```

with the following path and query parameters:

247.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
clientId	Required The client id		String

247.2.2. Query Parameters (26 parameters):

Name	Description	Default	Type
domain (common)	Domain name. If not specified then the default domain is used.		String
password (common)	Required The password for login to openshift server.		String
server (common)	Url to the openshift server. If not specified then the default value from the local openshift configuration file <code>/.openshift/express.conf</code> is used. And if that fails as well then <code>openshift.redhat.com</code> is used.		String
username (common)	Required The username to login to openshift server.		String
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean
exceptionHandler (consumer)	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler

Name	Description	Default	Type
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
pollStrategy (consumer)	A pluggable <code>org.apache.camel.PollingConsumerPollingStrategy</code> allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		PollingConsumerPollStrategy
application (producer)	The application name to start, stop, restart, or get the state.		String
mode (producer)	Whether to output the message body as a pojo or json. For pojo the message is a List type.		String
operation (producer)	The operation to perform which can be: list, start, stop, restart, and state. The list operation returns information about all the applications in json format. The state operation returns the state such as: started, stopped etc. The other operations does not return any value.		String
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the <code>backoffMultiplier</code> should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the <code>backoffMultiplier</code> should kick-in.		int
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then <code>backoffIdleThreshold</code> and/or <code>backoffErrorThreshold</code> must also be configured.		int
delay (scheduler)	Milliseconds before the next poll. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	500	long

Name	Description	Default	Type
greedy (scheduler)	If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	1000	long
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that.	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz2 component	none	ScheduledPollConsumer Scheduler
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz2, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for initialDelay and delay options.	MILLIS ECON DS	TimeUnit
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.	true	boolean

247.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 6 options, which are listed below.

Name	Description	Default	Type
camel.component.openshift.domain	Domain name. If not specified then the default domain is used.		String

Name	Description	Default	Type
<code>camel.component.openshift.enabled</code>	Enable openshift component	true	Boolean
<code>camel.component.openshift.password</code>	The password for login to openshift server.		String
<code>camel.component.openshift.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.component.openshift.server</code>	Url to the openshift server. If not specified then the default value from the local openshift configuration file <code>/.openshift/express.conf</code> is used. And if that fails as well then <code>openshift.redhat.com</code> is used.		String
<code>camel.component.openshift.username</code>	The username to login to openshift server.		String

247.4. EXAMPLES

247.4.1. Listing all applications

```
// sending route
from("direct:apps")
  .to("openshift:myClient?username=foo&password=secret&operation=list");
  .to("log:apps");
```

In this case the information about all the applications is returned as pojo. If you want a json response, then set `mode=json`.

247.4.2. Stopping an application

```
// stopping the foobar application
from("direct:control")
  .to("openshift:myClient?username=foo&password=secret&operation=stop&application=foobar");
```

In the example above we stop the application named foobar.

Polling for gear state changes

The consumer is used for polling state changes in gears. Such as when a new gear is added/removed/ or its lifecycle is changed, eg started, or stopped etc.

```
// trigger when state changes on our gears
from("openshift:myClient?username=foo&password=secret&delay=30s")
  .log("Event ${header.CamelOpenShiftEventType} on application ${body.name} changed state to
    ${header.CamelOpenShiftEventNewState}");
```

When the consumer emits an Exchange then the body contains the **com.openshift.client.IApplication** as the message body. And the following headers is included.

Header	May be null	Description
Camel OpenShiftEventType	No	The type of the event which can be one of: added, removed or changed.
Camel OpenShiftEventOldState	Yes	The old state, when the event type is changed.
Camel OpenShiftEventNewState	No	The new state, for any of the event types

- [Getting Started](#)

CHAPTER 248. OPENSIFT BUILD CONFIG COMPONENT

Available as of Camel version 2.17

The **OpenShift Build Config** component is one of [Kubernetes Components](#) which provides a producer to execute kubernetes build config operations.

248.1. COMPONENT OPTIONS

The Openshift Build Config component has no options.

248.2. ENDPOINT OPTIONS

The Openshift Build Config endpoint is configured using URI syntax:

```
openshift-build-configs:masterUrl
```

with the following path and query parameters:

248.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
masterUrl	Required Kubernetes Master url		String

248.2.2. Query Parameters (20 parameters):

Name	Description	Default	Type
apiVersion (producer)	The Kubernetes API Version to use		String
dnsDomain (producer)	The dns domain, used for ServiceCall EIP		String
kubernetesClient (producer)	Default KubernetesClient to use if provided		KubernetesClient
operation (producer)	Producer operation to do on Kubernetes		String
portName (producer)	The port name, used for ServiceCall EIP		String
portProtocol (producer)	The port protocol, used for ServiceCall EIP	tcp	String

Name	Description	Default	Type
connectionTimeout (advanced)	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
caCertData (security)	The CA Cert Data		String
caCertFile (security)	The CA Cert File		String
clientCertData (security)	The Client Cert Data		String
clientCertFile (security)	The Client Cert File		String
clientKeyAlgo (security)	The Key Algorithm used by the client		String
clientKeyData (security)	The Client Key data		String
clientKeyFile (security)	The Client Key file		String
clientKeyPassphrase (security)	The Client Key Passphrase		String
oauthToken (security)	The Auth Token		String
password (security)	Password to connect to Kubernetes		String
trustCerts (security)	Define if the certs we used are trusted anyway or not		Boolean
username (security)	Username to connect to Kubernetes		String

CHAPTER 249. OPENSIFT BUILDS COMPONENT

Available as of Camel version 2.17

The **Kubernetes Builds** component is one of [Kubernetes Components](#) which provides a producer to execute kubernetes build operations.

249.1. COMPONENT OPTIONS

The Openshift Builds component has no options.

249.2. ENDPOINT OPTIONS

The Openshift Builds endpoint is configured using URI syntax:

```
openshift-builds:masterUrl
```

with the following path and query parameters:

249.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
masterUrl	Required Kubernetes Master url		String

249.2.2. Query Parameters (20 parameters):

Name	Description	Default	Type
apiVersion (producer)	The Kubernetes API Version to use		String
dnsDomain (producer)	The dns domain, used for ServiceCall EIP		String
kubernetesClient (producer)	Default KubernetesClient to use if provided		KubernetesClient
operation (producer)	Producer operation to do on Kubernetes		String
portName (producer)	The port name, used for ServiceCall EIP		String
portProtocol (producer)	The port protocol, used for ServiceCall EIP	tcp	String

Name	Description	Default	Type
connectionTimeout (advanced)	Connection timeout in milliseconds to use when making requests to the Kubernetes API server.		Integer
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
caCertData (security)	The CA Cert Data		String
caCertFile (security)	The CA Cert File		String
clientCertData (security)	The Client Cert Data		String
clientCertFile (security)	The Client Cert File		String
clientKeyAlgo (security)	The Key Algorithm used by the client		String
clientKeyData (security)	The Client Key data		String
clientKeyFile (security)	The Client Key file		String
clientKeyPassphrase (security)	The Client Key Passphrase		String
oauthToken (security)	The Auth Token		String
password (security)	Password to connect to Kubernetes		String
trustCerts (security)	Define if the certs we used are trusted anyway or not		Boolean
username (security)	Username to connect to Kubernetes		String

249.3. OPENSTACK COMPONENT

Available as of Camel 2.19

The **openstack** component is a component for managing your [OpenStack](#) applications.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-openstack</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

OpenStack service	Camel Component	Description
OpenStack Cinder	openstack-cinder	Component to maintain OpenStack cinder.
OpenStack Glance	openstack-glance	Component to maintain OpenStack glance.
OpenStack Keystone	openstack-keystone	Component to maintain OpenStack keystone.
OpenStack Neutron	openstack-neutron	Component to maintain OpenStack neutron.
OpenStack Nova	openstack-nova	Component to maintain OpenStack nova.
OpenStack Swift	openstack-swift	Component to maintain OpenStack swift.

CHAPTER 250. OPENSTACK CINDER COMPONENT

Available as of Camel version 2.19

The openstack-cinder component allows messages to be sent to an OpenStack block storage services.

250.1. DEPENDENCIES

Maven users will need to add the following dependency to their pom.xml.

pom.xml

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-openstack</artifactId>
  <version>${camel-version}</version>
</dependency>
```

where `${camel-version}` must be replaced by the actual version of Camel.

250.2. URI FORMAT

```
openstack-cinder://hosturl[?options]
```

You can append query options to the URI in the following format `?options=value&option2=value&...`

250.3. URI OPTIONS

The OpenStack Cinder component has no options.

The OpenStack Cinder endpoint is configured using URI syntax:

```
openstack-cinder:host
```

with the following path and query parameters:

250.3.1. Path Parameters (1 parameters):

Name	Description	Default	Type
host	Required OpenStack host url		String

250.3.2. Query Parameters (9 parameters):

Name	Description	Default	Type
apiVersion (producer)	OpenStack API version	V3	String
config (producer)	OpenStack configuration		Config
domain (producer)	Authentication domain	default	String
operation (producer)	The operation to do		String
password (producer)	Required OpenStack password		String
project (producer)	Required The project ID		String
subsystem (producer)	Required OpenStack Cinder subsystem		String
username (producer)	Required OpenStack username		String
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

250.4. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.component.openstack-cinder.enabled	Enable openstack-cinder component	true	Boolean
camel.component.openstack-cinder.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

250.5. USAGE

You can use following settings for each subsystem:

250.6. VOLUMES

250.6.1. Operations you can perform with the Volume producer

Operation	Description
create	Create new volume.
get	Get the volume.
getAll	Get all volumes.
getAllTypes	Get volume types.
update	Update the volume.
delete	Delete the volume.

250.6.2. Message headers evaluated by the Volume producer

Header	Type	Description
operation	String	The operation to perform.
ID	String	ID of the volume.
name	String	The volume name.
description	String	Volume description.
size	Integer	Size of volume.
volumeType	String	Volume type.
imageRef	String	ID of image.
snapshotId	String	ID of snapshot.

Header	Type	Description
isBootable	Boolean	Is bootable.

If you need more precise volume settings you can create new object of the type `org.openstack4j.model.storage.block.Volume` and send in the message body.

250.7. SNAPSHOTS

250.7.1. Operations you can perform with the Snapshot producer

Operation	Description
create	Create new snapshot.
get	Get the snapshot.
getAll	Get all snapshots.
update	Get update the snapshot.
delete	Delete the snapshot.

250.7.2. Message headers evaluated by the Snapshot producer

Header	Type	Description
operation	String	The operation to perform.
ID	String	ID of the server.
name	String	The server name.
description	String	The snapshot description.
VolumeID	String	The Volume ID.
force	Boolean	Force.

If you need more precise server settings you can create new object of the type `org.openstack4j.model.storage.block.VolumeSnapshot` and send in the message body.

250.8. SEE ALSO

- [Configuring Camel](#)
- [Component](#)
- [Endpoint](#)
- [Getting Started](#)
- [openstack Component](#)

CHAPTER 251. OPENSTACK GLANCE COMPONENT

Available as of Camel version 2.19

The openstack-glance component allows messages to be sent to an OpenStack image services.

251.1. DEPENDENCIES

Maven users will need to add the following dependency to their pom.xml.

pom.xml

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-openstack</artifactId>
  <version>${camel-version}</version>
</dependency>
```

where **`${camel-version}`** must be replaced by the actual version of Camel.

251.2. URI FORMAT

```
openstack-glance://hosturl[?options]
```

You can append query options to the URI in the following format **`?options=value&option2=value&...`**

251.3. URI OPTIONS

The OpenStack Glance component has no options.

The OpenStack Glance endpoint is configured using URI syntax:

```
openstack-glance:host
```

with the following path and query parameters:

251.3.1. Path Parameters (1 parameters):

Name	Description	Default	Type
host	Required OpenStack host url		String

251.3.2. Query Parameters (8 parameters):

Name	Description	Default	Type
apiVersion (producer)	OpenStack API version	V3	String
config (producer)	OpenStack configuration		Config
domain (producer)	Authentication domain	default	String
operation (producer)	The operation to do		String
password (producer)	Required OpenStack password		String
project (producer)	Required The project ID		String
username (producer)	Required OpenStack username		String
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

251.4. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.component.openstack-glance.enabled	Enable openstack-glance component	true	Boolean
camel.component.openstack-glance.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

251.5. USAGE

Operation	Description
reserve	Reserve image.
create	Create new image.
update	Update image.
upload	Upload image.
get	Get the image.
getAll	Get all image.
delete	Delete the image.

251.5.1. Message headers evaluated by the Glance producer

Header	Type	Description
operation	String	The operation to perform.
ID	String	ID of the flavor.
name	String	The flavor name.
diskFormat	org.openstack4j.model.image.DiskFormat	The number of flavor VCPU.
containerFormat	org.openstack4j.model.image.ContainerFormat	Size of RAM.
owner	String	Image owner.
isPublic	Boolean	Is public.

Header	Type	Description
minRam	Long	Minimum ram.
minDisk	Long	Minimum disk.
size	Long	Size.
checksum	String	Checksum.
properties	Map	Image properties.

251.6. SEE ALSO

CHAPTER 252. OPENSTACK KEYSTONE COMPONENT

Available as of Camel version 2.19

The openstack-keystone component allows messages to be sent to an OpenStack identity services.

The openstack-keystone component supports only Identity API v3!

252.1. DEPENDENCIES

Maven users will need to add the following dependency to their pom.xml.

pom.xml

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-openstack</artifactId>
  <version>${camel-version}</version>
</dependency>
```

where `${camel-version}` must be replaced by the actual version of Camel.

252.2. URI FORMAT

```
openstack-keystone://hosturl[?options]
```

You can append query options to the URI in the following format `?options=value&option2=value&...`

252.3. URI OPTIONS

The OpenStack Keystone component has no options.

The OpenStack Keystone endpoint is configured using URI syntax:

```
openstack-keystone:host
```

with the following path and query parameters:

252.3.1. Path Parameters (1 parameters):

Name	Description	Default	Type
host	Required OpenStack host url		String

252.3.2. Query Parameters (8 parameters):

Name	Description	Default	Type
config (producer)	OpenStack configuration		Config
domain (producer)	Authentication domain	default	String
operation (producer)	The operation to do		String
password (producer)	Required OpenStack password		String
project (producer)	Required The project ID		String
subsystem (producer)	Required OpenStack Keystone subsystem		String
username (producer)	Required OpenStack username		String
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

252.4. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.component.openstack-keystone.enabled	Enable openstack-keystone component	true	Boolean
camel.component.openstack-keystone.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

252.5. USAGE

You can use following settings for each subsystem:

252.6. DOMAINS

252.6.1. Operations you can perform with the Domain producer

Operation	Description
create	Create new domain.
get	Get the domain.
getAll	Get all domains.
update	Update the domain.
delete	Delete the domain.

252.6.2. Message headers evaluated by the Domain producer

Header	Type	Description
operation	String	The operation to perform.
ID	String	ID of the domain.
name	String	The domain name.
description	String	Domain description.

If you need more precise domain settings you can create new object of the type `org.openstack4j.model.identity.v3.Domain` and send in the message body.

252.7. GROUPS

252.7.1. Operations you can perform with the Group producer

Operation	Description
create	Create new group.
get	Get the group.
getAll	Get all groups.

Operation	Description
update	Update the group.
delete	Delete the group.
addUserToGroup	Add the user to the group.
checkUserGroup	Check whether is the user in the group.
removeUserFromGroup	Remove the user from the group.

252.7.2. Message headers evaluated by the Group producer

Header	Type	Description
operation	String	The operation to perform.
groupId	String	ID of the group.
name	String	The group name.
userId	String	ID of the user.
domainId	String	ID of the domain.
description	String	Group description.

If you need more precise group settings you can create new object of the type `org.openstack4j.model.identity.v3.Group` and send in the message body.

252.8. PROJECTS

252.8.1. Operations you can perform with the Project producer

Operation	Description
create	Create new project.

Operation	Description
get	Get the project.
getAll	Get all projects.
update	Update the project.
delete	Delete the project.

252.8.2. Message headers evaluated by the Project producer

Header	Type	Description
operation	String	The operation to perform.
ID	String	ID of the project.
name	String	The project name.
description	String	Project description.
domainId	String	ID of the domain.
parentId	String	The parent project ID.

If you need more precise project settings you can create new object of the type `org.openstack4j.model.identity.v3.Project` and send in the message body.

252.9. REGIONS

252.9.1. Operations you can perform with the Region producer

Operation	Description
create	Create new region.
get	Get the region.
getAll	Get all regions.

Operation	Description
update	Update the region.
delete	Delete the region.

252.9.2. Message headers evaluated by the Region producer

Header	Type	Description
operation	String	The operation to perform.
ID	String	ID of the region.
description	String	Region description.

If you need more precise region settings you can create new object of the type `org.openstack4j.model.identity.v3.Region` and send in the message body.

252.10. USERS

252.10.1. Operations you can perform with the User producer

Operation	Description
create	Create new user.
get	Get the user.
getAll	Get all users.
update	Update the user.
delete	Delete the user.

252.10.2. Message headers evaluated by the User producer

Header	Type	Description
operation	String	The operation to perform.

Header	Type	Description
ID	String	ID of the user.
name	String	The user name.
description	String	User description.
domainid	String	ID of the domain.
password	String	User's password.
email	String	User's email.

If you need more precise user settings you can create new object of the type `org.openstack4j.model.identity.v3.User` and send in the message body.

252.11. SEE ALSO

- [Configuring Camel](#)

CHAPTER 253. OPENSTACK NEUTRON COMPONENT

Available as of Camel version 2.19

The openstack-neutron component allows messages to be sent to an OpenStack network services.

253.1. DEPENDENCIES

Maven users will need to add the following dependency to their pom.xml.

pom.xml

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-openstack</artifactId>
  <version>${camel-version}</version>
</dependency>
```

where `${camel-version}` must be replaced by the actual version of Camel.

253.2. URI FORMAT

```
openstack-neutron://hosturl[?options]
```

You can append query options to the URI in the following format `?options=value&option2=value&...`

253.3. URI OPTIONS

The OpenStack Neutron component has no options.

The OpenStack Neutron endpoint is configured using URI syntax:

```
openstack-neutron:host
```

with the following path and query parameters:

253.3.1. Path Parameters (1 parameters):

Name	Description	Default	Type
host	Required OpenStack host url		String

253.3.2. Query Parameters (9 parameters):

Name	Description	Default	Type
apiVersion (producer)	OpenStack API version	V3	String
config (producer)	OpenStack configuration		Config
domain (producer)	Authentication domain	default	String
operation (producer)	The operation to do		String
password (producer)	Required OpenStack password		String
project (producer)	Required The project ID		String
subsystem (producer)	Required OpenStack Neutron subsystem		String
username (producer)	Required OpenStack username		String
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

253.4. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.component.openstack-neutron.enabled	Enable openstack-neutron component	true	Boolean
camel.component.openstack-neutron.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

253.5. USAGE

You can use following settings for each subsystem:

253.6. NETWORKS

253.6.1. Operations you can perform with the Network producer

Operation	Description
create	Create new network.
get	Get the network.
getAll	Get all networks.
delete	Delete the network.

253.6.2. Message headers evaluated by the Network producer

Header	Type	Description
operation	String	The operation to perform.
ID	String	ID of the network.
name	String	The network name.
tenantId	String	Tenant ID.
adminStateUp	Boolean	AdminStateUp header.
networkType	org.openstack4j.model.network.NetworkType	Network type.
physicalNetwork	String	Physical network.

Header	Type	Description
segmentId	String	Segment ID.
isShared	Boolean	Is shared.
isRouterExternal	Boolean	Is router external.

If you need more precise network settings you can create new object of the type `org.openstack4j.model.network.Network` and send in the message body.

253.7. SUBNETS

253.7.1. Operations you can perform with the Subnet producer

Operation	Description
create	Create new subnet.
get	Get the subnet.
getAll	Get all subnets.
delete	Delete the subnet.
action	Perform an action on the subnet.

253.7.2. Message headers evaluated by the Subnet producer

Header	Type	Description
operation	String	The operation to perform.
ID	String	ID of the subnet.
name	String	The subnet name.
networkId	String	Network ID.

Header	Type	Description
enableDHCP	Boolean	Enable DHCP.
gateway	String	Gateway.

If you need more precise subnet settings you can create new object of the type `org.openstack4j.model.network.Subnet` and send in the message body.

253.8. PORTS

253.8.1. Operations you can perform with the Port producer

Operation	Description
create	Create new port.
get	Get the port.
getAll	Get all ports.
update	Update the port.
delete	Delete the port.

253.8.2. Message headers evaluated by the Port producer

Header	Type	Description
operation	String	The operation to perform.
name	String	The port name.
networkId	String	Network ID.
tenantId	String	Tenant ID.

Header	Type	Description
deviceId	String	Device ID.
macAddresses	String	MAC address.

253.9. ROUTERS

253.9.1. Operations you can perform with the Router producer

Operation	Description
create	Create new router.
get	Get the router.
getAll	Get all routers.
update	Update the router.
delete	Delete the router.
attachInterface	Attach an interface.
detachInterface	Detach an interface.

253.9.2. Message headers evaluated by the Port producer

Header	Type	Description
operation	String	The operation to perform.
name	String	The router name.
routerId	String	Router ID.
subnetId	String	Subnet ID.
portId	String	Port ID.

Header	Type	Description
interfaceType	org.openstack4j.model.network.AttachInterfaceType	Interface type.
tenantId	String	Tenant ID.

- [openstack Component](#)

CHAPTER 254. OPENSTACK NOVA COMPONENT

Available as of Camel version 2.19

The openstack-nova component allows messages to be sent to an OpenStack compute services.

254.1. DEPENDENCIES

Maven users will need to add the following dependency to their pom.xml.

pom.xml

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-openstack</artifactId>
  <version>${camel-version}</version>
</dependency>
```

where **`${camel-version}`** must be replaced by the actual version of Camel.

254.2. URI FORMAT

```
openstack-nova://hosturl[?options]
```

You can append query options to the URI in the following format **`?options=value&option2=value&...`**

254.3. URI OPTIONS

The OpenStack Nova component has no options.

The OpenStack Nova endpoint is configured using URI syntax:

```
openstack-nova:host
```

with the following path and query parameters:

254.3.1. Path Parameters (1 parameters):

Name	Description	Default	Type
host	Required OpenStack host url		String

254.3.2. Query Parameters (9 parameters):

Name	Description	Default	Type
apiVersion (producer)	OpenStack API version	V3	String
config (producer)	OpenStack configuration		Config
domain (producer)	Authentication domain	default	String
operation (producer)	The operation to do		String
password (producer)	Required OpenStack password		String
project (producer)	Required The project ID		String
subsystem (producer)	Required OpenStack Nova subsystem		String
username (producer)	Required OpenStack username		String
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

254.4. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.component.openstack-nova.enabled	Enable openstack-nova component	true	Boolean
camel.component.openstack-nova.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

254.5. USAGE

You can use following settings for each subsystem:

254.6. FLAVORS

254.6.1. Operations you can perform with the Flavor producer

Operation	Description
create	Create new flavor.
get	Get the flavor.
getAll	Get all flavors.
delete	Delete the flavor.

254.6.2. Message headers evaluated by the Flavor producer

Header	Type	Description
operation	String	The operation to perform.
ID	String	ID of the flavor.
name	String	The flavor name.
VCPU	Integer	The number of flavor VCPU.
ram	Integer	Size of RAM.
disk	Integer	Size of disk.
swap	Integer	Size of swap.
rxtxFactor	Integer	Rxtx Factor.

If you need more precise flavor settings you can create new object of the type `org.openstack4j.model.compute.Flavor` and send in the message body.

254.7. SERVERS

254.7.1. Operations you can perform with the Server producer

Operation	Description
create	Create new server.
createSnapshot	Create snapshot of the server.
get	Get the server.
getAll	Get all servers.
delete	Delete the server.
action	Perform an action on the server.

254.7.2. Message headers evaluated by the Server producer

Header	Type	Description
operation	String	The operation to perform.
ID	String	ID of the server.
name	String	The server name.
Image Id	String	The Image ID.
Flavor Id	String	The ID of flavor which will be used.
KeypairName	String	The Keypair name.
NetworkId	String	The network ID.
Admin Password	String	Admin password of the new server.

Header	Type	Description
action	org.openstack4j.model.compute.Action	An action to perform.

If you need more precise server settings you can create new object of the type `org.openstack4j.model.compute.ServerCreate` and send in the message body.

254.8. KEYPAIRS

254.8.1. Operations you can perform with the Keypair producer

Operation	Description
create	Create new keypair.
get	Get the keypair.
getAll	Get all keypairs.
delete	Delete the keypair.

254.8.2. Message headers evaluated by the Keypair producer

Header	Type	Description
operation	String	The operation to perform.
name	String	The keypair name.

254.9. SEE ALSO

- [Configuring Camel](#)
- [Component](#)
- [Endpoint](#)
- [Getting Started](#)

- [openstack Component](#)

CHAPTER 255. OPENSTACK SWIFT COMPONENT

Available as of Camel version 2.19

The openstack-swift component allows messages to be sent to an OpenStack object storage services.

255.1. DEPENDENCIES

Maven users will need to add the following dependency to their pom.xml.

pom.xml

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-openstack</artifactId>
  <version>${camel-version}</version>
</dependency>
```

where `${camel-version}` must be replaced by the actual version of Camel.

255.2. URI FORMAT

```
openstack-swift://hosturl[?options]
```

You can append query options to the URI in the following format `?options=value&option2=value&...`

255.3. URI OPTIONS

The OpenStack Swift component has no options.

The OpenStack Swift endpoint is configured using URI syntax:

```
openstack-swift:host
```

with the following path and query parameters:

255.3.1. Path Parameters (1 parameters):

Name	Description	Default	Type
host	Required OpenStack host url		String

255.3.2. Query Parameters (9 parameters):

Name	Description	Default	Type
apiVersion (producer)	OpenStack API version	V3	String
config (producer)	OpenStack configuration		Config
domain (producer)	Authentication domain	default	String
operation (producer)	The operation to do		String
password (producer)	Required OpenStack password		String
project (producer)	Required The project ID		String
subsystem (producer)	Required OpenStack Swift subsystem		String
username (producer)	Required OpenStack username		String
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

255.4. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.component.openstack-swift.enabled	Enable openstack-swift component	true	Boolean
camel.component.openstack-swift.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

255.5. USAGE

You can use following settings for each subsystem:

255.6. CONTAINERS

255.6.1. Operations you can perform with the Container producer

Operation	Description
create	Create new container.
get	Get the container.
getAll	Get all containers.
update	Update the container.
delete	Delete the container.
getMetadata	Get metadata.
createUpdateMetadata	Create/update metadata.
deleteMetadata	Delete metadata.

255.6.2. Message headers evaluated by the Volume producer

Header	Type	Description
operation	String	The operation to perform.
name	String	The container name.
X-Container-Meta-	Map	Container metadata prefix.
X-Versions-Location	String	Versions location.
X-Container-Read	String	ACL - container read.
X-Container-Write	String	ACL - container write.
limit	Integer	List options - limit.

Header	Type	Description
marker	String	List options - marker.
end_marker	String	List options - end marker.
delimiter	Character	List options - delimiter.
path	String	List options - path.

If you need more precise container settings you can create new object of the type `org.openstack4j.model.storage.object.options.CreateUpdateContainerOptions` (in case of create or update operation) or `org.openstack4j.model.storage.object.options.ContainerListOptions` for listing containers and send in the message body.

255.7. OBJECTS

255.7.1. Operations you can perform with the Object producer

Operation	Description
create	Create new object.
get	Get the object.
getAll	Get all objects.
update	Get update the object.
delete	Delete the object.
getMetadata	Get metadata.
createUpdateMetadata	Create/update metadata.

255.7.2. Message headers evaluated by the Object producer

Header	Type	Description
operation	String	The operation to perform.

Header	Type	Description
containerName	String	The container name.
objectName	String	The object name.

CHAPTER 256. OPENTRACING COMPONENT

Available as of Camel 2.19

IMPORTANT

Starting with Camel 2.21, it will be necessary to use an OpenTracing complaint tracer that is compatible with OpenTracing Java API version 0.31 or higher.

The camel-opentracing component is used for tracing and timing incoming and outgoing Camel messages using [OpenTracing](#).

Events (spans) are captured for incoming and outgoing messages being sent to/from Camel.

See the [OpenTracing](#) website for a list of supported tracers.

256.1. CONFIGURATION

The configuration properties for the OpenTracing tracer are:

Option	Default	Description
excludePatterns		Sets exclude pattern(s) that will disable tracing for Camel messages that matches the pattern. The content is a Set<String> where the key is a pattern. The pattern uses the rules from Intercept.
encoding	false	Sets whether the header keys need to be encoded (connector specific) or not. The value is a boolean. Dashes need for instances to be encoded for JMS property keys.

There are three ways in which an OpenTracing tracer can be configured to provide distributed tracing for a Camel application:

256.1.1. Explicit

Include the **camel-opentracing** component in your POM, along with any specific dependencies associated with the chosen OpenTracing compliant Tracer.

To explicitly configure OpenTracing support, instantiate the **OpenTracingTracer** and initialize the camel context. You can optionally specify a **Tracer**, or alternatively it can be implicitly discovered using the **Registry** or **ServiceLoader**.

```
OpenTracingTracer ottracer = new OpenTracingTracer();
// By default it uses a Noop Tracer, but you can override it with a specific OpenTracing
// implementation.
ottracer.setTracer(...);
// And then initialize the context
ottracer.init(camelContext);
```

To use OpenTracingTracer in XML, all you need to do is to define the OpenTracing tracer beans. Camel will automatically discover and use them.

```

<bean id="tracer" class="..."/>
<bean id="ottracer" class="org.apache.camel.opentracing.OpenTracingTracer">
  <property name="tracer" ref="tracer"/>
</bean>

```

256.2. SPRING BOOT

If you are using Spring Boot then you can add the **camel-opentracing-starter** dependency, and turn on OpenTracing by annotating the main class with **@CamelOpenTracing**.

The **Tracer** will be implicitly obtained from the camel context's **Registry**, or the **ServiceLoader**, unless a **Tracer** bean has been defined by the application.

256.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.opentracing.encoding	Activate or deactivate dash encoding in headers (required by JMS) for messaging		Boolean
camel.opentracing.exclude-patterns	Sets exclude pattern(s) that will disable tracing for Camel messages that matches the pattern.		Set

256.4. JAVA AGENT

The third approach is to use a Java Agent to automatically configure the OpenTracing support.

Include the **camel-opentracing** component in your POM, along with any specific dependencies associated with the chosen OpenTracing compliant Tracer.

The OpenTracing Java Agent is associated with the following dependency:

```

<dependency>
  <groupId>io.opentracing.contrib</groupId>
  <artifactId>opentracing-agent</artifactId>
</dependency>

```

The **Tracer** used will be implicitly loaded from the camel context **Registry** or using the **ServiceLoader**.

How this agent is used will be specific to how you execute your application. *Service2* in the [camel-example-opentracing](#) downloads the agent into a local folder and then uses the **exec-maven-plugin** to launch the service with the **-javaagent** command line option.

256.5. EXAMPLE

You can find an example demonstrating the three ways to configure OpenTracing here: [camel-example-opentracing](#)

CHAPTER 257. OPTAPLANNER COMPONENT

Available as of Camel version 2.13

The **optaplanner** component solves the planning problem contained in a message with [OptaPlanner](#). For example: feed it an unsolved Vehicle Routing problem and it solves it.

The component supports consumer as BestSolutionChangedEvent listener and producer for processing Solution and ProblemFactChange

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-optaplanner</artifactId>
  <version>x.x.x</version><!-- use the same version as your Camel core version -->
</dependency>
```

257.1. URI FORMAT

```
optaplanner:solverConfig[?options]
```

The **solverConfig** is the classpath-local URI of the solverConfig, for example **/org/foo/barSolverConfig.xml**.

You can append query options to the URI in the following format, **?option=value&option=value&...**

257.2. OPTAPLANNER OPTIONS

The OptaPlanner component has no options.

The OptaPlanner endpoint is configured using URI syntax:

```
optaplanner:configFile
```

with the following path and query parameters:

257.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
configFile	Required Specifies the location to the solver file		String

257.2.2. Query Parameters (7 parameters):

Name	Description	Default	Type
solverId (common)	Specifies the solverId to user for the solver instance key	DEFAULT_SOLVER	String
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
async (producer)	Specifies to perform operations in async mode	false	boolean
threadPoolSize (producer)	Specifies the thread pool size to use when async is true	10	int
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

257.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.component.optaplanner.enabled	Enable optaplanner component	true	Boolean

Name	Description	Default	Type
<code>camel.component.optaplanner.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

257.4. MESSAGE HEADERS

Name	Default Value	Type	Context	Description
Camel OptaPlannerSolverId	null	String	Shared	Specifies the solverId to use
Camel OptaPlannerIs Async	PUT	String	Producer	Specify whether to use another thread for submitting Solution instances rather than blocking the current thread.

257.5. MESSAGE BODY

Camel takes the planning problem for the IN body, solves it and returns it on the OUT body. (since v 2.16) The IN body object supports the following use cases:

- If the body is instance of Solution, then it will be solved using the solver identified by solverId and either synchronously or asynchronously.
- If the body is instance of ProblemFactChange, then it will trigger addProblemFactChange. If the processing is asynchronously, then it will wait till isEveryProblemFactChangeProcessed before returning result.
- If the body is none of the above types, then the producer will return the best result from the solver identified by solverId

257.6. TERMINATION

The solving will take as long as specified in the **solverConfig**.

```
<solver>
...
<termination>
  <!-- Terminate after 10 seconds, unless it's not feasible by then yet -->
  <terminationCompositionStyle>AND</terminationCompositionStyle>
  <secondsSpentLimit>10</secondsSpentLimit>
  <bestScoreLimit>-1hard/0soft</bestScoreLimit>
```

```
</termination>  
...  
<solver>
```

257.6.1. Samples

Solve an planning problem that's on the ActiveMQ queue with OptaPlanner:

```
from("activemq:My.Queue").  
  .to("optaplanner:/org/foo/barSolverConfig.xml");
```

Expose OptaPlanner as a REST service:

```
from("cxfrs:bean:rsServer?bindingStyle=SimpleConsumer")  
  .to("optaplanner:/org/foo/barSolverConfig.xml");
```

257.7. SEE ALSO

- [Configuring Camel](#)
- [Component](#)
- [Endpoint](#)
- [Getting Started](#)

CHAPTER 258. PAHO COMPONENT

Available as of Camel version 2.16

Paho component provides connector for the MQTT messaging protocol using the [Eclipse Paho](#) library. Paho is one of the most popular MQTT libraries, so if you would like to integrate it with your Java project - Camel Paho connector is a way to go.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-paho</artifactId>
  <version>x.y.z</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

Keep in mind that Paho artifacts are not hosted in the Maven Central, so you need to add Eclipse Paho repository to your POM xml file:

```
<repositories>
  <repository>
    <id>eclipse-paho</id>
    <url>https://repo.eclipse.org/content/repositories/paho-releases</url>
    <snapshots>
      <enabled>>false</enabled>
    </snapshots>
  </repository>
</repositories>
```

258.1. URI FORMAT

```
paho:topic[?options]
```

Where **topic** is the name of the topic.

258.2. OPTIONS

The Paho component supports 4 options, which are listed below.

Name	Description	Default	Type
brokerUrl (common)	The URL of the MQTT broker.		String
clientId (common)	MQTT client identifier.		String
connectOptions (advanced)	Client connection options		MqttConnectOptions

Name	Description	Default	Type
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Paho endpoint is configured using URI syntax:

```
paho:topic
```

with the following path and query parameters:

258.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
topic	Required Name of the topic		String

258.2.2. Query Parameters (15 parameters):

Name	Description	Default	Type
autoReconnect (common)	Client will automatically attempt to reconnect to the server if the connection is lost	true	boolean
brokerUrl (common)	The URL of the MQTT broker.	tcp://localhost:1883	String
clientId (common)	MQTT client identifier.		String
connectOptions (common)	Client connection options		MqttConnectOptions
filePersistenceDirectory (common)	Base directory used by the file persistence provider.		String
password (common)	Password to be used for authentication against the MQTT broker		String
persistence (common)	Client persistence to be used - memory or file.	MEMORY	PahoPersistence

Name	Description	Default	Type
qos (common)	Client quality of service level (0-2).	2	int
resolveMqttConnectOptions (common)	Define if you don't want to resolve the MQTT Connect Options from registry	true	boolean
retained (common)	Retain option	false	boolean
userName (common)	Username to be used for authentication against the MQTT broker		String
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer)	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		<code>ExceptionHandler</code>
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		<code>ExchangePattern</code>
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

258.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 5 options, which are listed below.

Name	Description	Default	Type
camel.component.paho.broker-url	The URL of the MQTT broker.		String

Name	Description	Default	Type
<code>camel.component.paho.client-id</code>	MQTT client identifier.		String
<code>camel.component.paho.connect-options</code>	Client connection options. The option is a <code>org.eclipse.paho.client.mqttv3.MqttConnectOptions</code> type.		String
<code>camel.component.paho.enabled</code>	Enable paho component	true	Boolean
<code>camel.component.paho.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

258.4. HEADERS

The following headers are recognized by the Paho component:

Header	Java constant	Endpoint type	Value type	Description
Camel MqttTopic	<code>PahoConstants.MQTT_TOPIC</code>	Consumer	String	The name of the topic
Camel PahoOverrideTopic	<code>PahoConstants.CAMEL_Paho_OVERRIDE_TOPIC</code>	Producer	String	Name of topic to override and send to instead of topic specified on endpoint

258.5. DEFAULT PAYLOAD TYPE

By default Camel Paho component operates on the binary payloads extracted out of (or put into) the MQTT message:

```
// Receive payload
byte[] payload = (byte[]) consumerTemplate.receiveBody("paho:topic");
```

```
// Send payload  
byte[] payload = "message".getBytes();  
producerTemplate.sendBody("paho:topic", payload);
```

But of course Camel build-in [type conversion API](#) can perform the automatic data type transformations for you. In the example below Camel automatically converts binary payload into **String** (and conversely):

```
// Receive payload  
String payload = consumerTemplate.receiveBody("paho:topic", String.class);  
  
// Send payload  
String payload = "message";  
producerTemplate.sendBody("paho:topic", payload);
```

258.6. SAMPLES

For example the following snippet reads messages from the MQTT broker installed on the same host as the Camel router:

```
from("paho:some/queue")  
    .to("mock:test");
```

While the snippet below sends message to the MQTT broker:

```
from("direct:test")  
    .to("paho:some/target/queue");
```

For example this is how to read messages from the remote MQTT broker:

```
from("paho:some/queue?brokerUrl=tcp://iot.eclipse.org:1883")  
    .to("mock:test");
```

And here we override the default topic and set to a dynamic topic

```
from("direct:test")  
    .setHeader(PahoConstants.CAMEL_PAHO_OVERRIDE_TOPIC, simple("${header.customerId}"))  
    .to("paho:some/target/queue");
```

CHAPTER 259. OSGI PAX LOGGING COMPONENT

Available as of Camel version 2.6

The **paxlogging** component can be used in an OSGi environment to receive [PaxLogging](#) events and process them.

259.1. DEPENDENCIES

Maven users need to add the following dependency to their **pom.xml**

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-paxlogging</artifactId>
  <version>${camel-version}</version>
</dependency>
```

where **\${camel-version}** must be replaced by the actual version of Camel (2.6.0 or higher).

259.2. URI FORMAT

```
paxlogging:appender[?options]
```

where **appender** is the name of the pax appender that need to be configured in the PaxLogging service configuration.

259.3. URI OPTIONS

The OSGi PAX Logging component supports 2 options, which are listed below.

Name	Description	Default	Type
bundleContext (consumer)	The OSGi BundleContext is automatic injected by Camel		BundleContext
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The OSGi PAX Logging endpoint is configured using URI syntax:

```
paxlogging:appender
```

with the following path and query parameters:

259.3.1. Path Parameters (1 parameters):

Name	Description	Default	Type
appender	Required Appender is the name of the pax appender that need to be configured in the PaxLogging service configuration.		String

259.3.2. Query Parameters (4 parameters):

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

259.4. MESSAGE BODY

The **in** message body will be set to the received PaxLoggingEvent.

259.5. EXAMPLE USAGE

```
<route>
  <from uri="paxlogging:camel"/>
  <to uri="stream:out"/>
</route>
```

Configuration:

```
log4j.rootLogger=INFO, out, osgi:VmLogAppender, osgi:camel
```

CHAPTER 260. PDF COMPONENT

Available as of Camel version 2.16

The **PDF**: components provides the ability to create, modify or extract content from PDF documents. This component uses [Apache PDFBox](#) as underlying library to work with PDF documents.

In order to use the PDF component, Maven users will need to add the following dependency to their **pom.xml**:

pom.xml

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-pdf</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

260.1. URI FORMAT

The PDF component only supports producer endpoints.

```
pdf:operation[?options]
```

260.2. OPTIONS

The PDF component has no options.

The PDF endpoint is configured using URI syntax:

```
pdf:operation
```

with the following path and query parameters:

260.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
operation	Required Operation type		PdfOperation

260.2.2. Query Parameters (9 parameters):

Name	Description	Default	Type
font (producer)	Font	Helvetica	PDFont

Name	Description	Default	Type
fontSize (producer)	Font size in pixels	14	float
marginBottom (producer)	Margin bottom in pixels	20	int
marginLeft (producer)	Margin left in pixels	20	int
marginRight (producer)	Margin right in pixels	40	int
marginTop (producer)	Margin top in pixels	20	int
pageSize (producer)	Page size	A4	PDRectangle
textProcessingFactory (producer)	Text processing to use. autoFormatting: Text is getting sliced by words, then max amount of words that fits in the line will be written into pdf document. With this strategy all words that doesn't fit in the line will be moved to the new line. lineTermination: Builds set of classes for line-termination writing strategy. Text getting sliced by line termination symbol and then it will be written regardless it fits in the line or not.	lineTermination	TextProcessingFactory
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

260.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.component.pdf.enabled	Enable pdf component	true	Boolean
camel.component.pdf.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

260.4. HEADERS

Header	Description
pdf-document	Mandatory header for append operation and ignored in all other operations. Expected type is PDDocument . Stores PDF document which will be used for append operation.
protection-policy	Expected type is https://pdfbox.apache.org/docs/1.8.10/javadocs/org/apache/pdfbox/pdmodel/encryption/ProtectionPolicy.html [ProtectionPolicy]. If specified then PDF document will be encrypted with it.
decryption-material	Expected type is https://pdfbox.apache.org/docs/1.8.10/javadocs/org/apache/pdfbox/pdmodel/encryption/DecryptionMaterial.html [DecryptionMaterial]. Mandatory header if PDF document is encrypted.

--

CHAPTER 261. POSTGRESSQL EVENT COMPONENT

Available as of Camel version 2.15

This is a component for Apache Camel which allows for Producing/Consuming PostgreSQL events related to the LISTEN/NOTIFY commands added since PostgreSQL 8.3.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-pgevent</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

URI format

The pgevent component uses the following two styles of endpoint URI notation:

```
pgevent:datasource[?parameters]
pgevent://host:port/database/channel[?parameters]
```

You can append query options to the URI in the following format, **?option=value&option=value&...**

261.1. OPTIONS

The PostgreSQL Event component has no options.

The PostgreSQL Event endpoint is configured using URI syntax:

```
pgevent:host:port/database/channel
```

with the following path and query parameters:

261.1.1. Path Parameters (4 parameters):

Name	Description	Default	Type
host	To connect using hostname and port to the database.	localhost	String
port	To connect using hostname and port to the database.	5432	Integer
database	Required The database name		String
channel	Required The channel name		String

261.1.2. Query Parameters (7 parameters):

Name	Description	Default	Type
datasource (common)	To connect using the given <code>javax.sql.DataSource</code> instead of using hostname and port.		<code>DataSource</code>
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer)	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		<code>ExceptionHandler</code>
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		<code>ExchangePattern</code>
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
pass (security)	Password for login		String
user (security)	Username for login	postgres	String

261.2. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.component.pgevent.enabled	Enable pgevent component	true	Boolean
camel.component.pgevent.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

CHAPTER 262. PGP DATAFORMAT

Available as of Camel version 2.9

The PGP Data Format integrates the Java Cryptographic Extension into Camel, allowing simple and flexible encryption and decryption of messages using Camel's familiar marshal and unmarshal formatting mechanism. It assumes marshalling to mean encryption to cyphertext and unmarshalling to mean decryption back to the original plaintext. This data format implements only symmetric (shared-key) encryption and decryption.

262.1. PGPDATAFORMAT OPTIONS

The PGP dataformat supports 15 options, which are listed below.

Name	Default	Java Type	Description
keyUserId		String	The user ID of the key in the PGP keyring used during encryption. Can also be only a part of a user ID. For example, if the user ID is Test User then you can use the part Test User or to address the user ID.
signatureKeyId		String	User ID of the key in the PGP keyring used for signing (during encryption) or signature verification (during decryption). During the signature verification process the specified User ID restricts the public keys from the public keyring which can be used for the verification. If no User ID is specified for the signature verification then any public key in the public keyring can be used for the verification. Can also be only a part of a user ID. For example, if the user ID is Test User then you can use the part Test User or to address the User ID.
password		String	Password used when opening the private key (not used for encryption).
signaturePassword		String	Password used when opening the private key used for signing (during encryption).
keyFileName		String	Filename of the keyring; must be accessible as a classpath resource (but you can specify a location in the file system by using the file: prefix).
signatureKeyFileName		String	Filename of the keyring to use for signing (during encryption) or for signature verification (during decryption); must be accessible as a classpath resource (but you can specify a location in the file system by using the file: prefix).
signatureKeyRing		String	Keyring used for signing/verifying as byte array. You can not set the signatureKeyFileName and signatureKeyRing at the same time.

Name	Default	Java Type	Description
<code>armored</code>	<code>false</code>	Boolean	This option will cause PGP to base64 encode the encrypted text, making it available for copy/paste, etc.
<code>integrity</code>	<code>true</code>	Boolean	Adds an integrity check/sign into the encryption file. The default value is true.
<code>provider</code>		String	Java Cryptography Extension (JCE) provider, default is Bouncy Castle (BC). Alternatively you can use, for example, the IAIC JCE provider; in this case the provider must be registered beforehand and the Bouncy Castle provider must not be registered beforehand. The Sun JCE provider does not work.
<code>algorithm</code>		Integer	Symmetric key encryption algorithm; possible values are defined in <code>org.bouncycastle.bcpkg.SymmetricKeyAlgorithmTags</code> ; for example 2 (= TRIPLE DES), 3 (= CAST5), 4 (= BLOWFISH), 6 (= DES), 7 (= AES_128). Only relevant for encrypting.
<code>compressionAlgorithm</code>		Integer	Compression algorithm; possible values are defined in <code>org.bouncycastle.bcpkg.CompressionAlgorithmTags</code> ; for example 0 (= UNCOMPRESSED), 1 (= ZIP), 2 (= ZLIB), 3 (= BZIP2). Only relevant for encrypting.
<code>hashAlgorithm</code>		Integer	Signature hash algorithm; possible values are defined in <code>org.bouncycastle.bcpkg.HashAlgorithmTags</code> ; for example 2 (= SHA1), 8 (= SHA256), 9 (= SHA384), 10 (= SHA512), 11 (= SHA224). Only relevant for signing.
<code>signatureVerificationOption</code>		String	Controls the behavior for verifying the signature during unmarshaling. There are 4 values possible: <code>optional</code> : The PGP message may or may not contain signatures; if it does contain signatures, then a signature verification is executed. <code>required</code> : The PGP message must contain at least one signature; if this is not the case an exception (<code>PGPException</code>) is thrown. A signature verification is executed. <code>ignore</code> : Contained signatures in the PGP message are ignored; no signature verification is executed. <code>no_signature_allowed</code> : The PGP message must not contain a signature; otherwise an exception (<code>PGPException</code>) is thrown.
<code>contentTypeHeader</code>	<code>false</code>	Boolean	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example <code>application/xml</code> for data formats marshalling to XML, or <code>application/json</code> for data formats marshalling to JSon etc.

262.2. PGPDATAFORMAT MESSAGE HEADERS

You can override the PGPDataFormat options by applying below headers into message dynamically.

Name	Type	Description
Camel PGPDataFormatKeyFileName	String	Since Camel 2.11.0; filename of the keyring; will override existing setting directly on the PGPDataFormat.
Camel PGPDataFormatEncryptionKeyRing	byte[]	Since Camel 2.12.1; the encryption keyring; will override existing setting directly on the PGPDataFormat.
Camel PGPDataFormatKeyUserId	String	Since Camel 2.11.0; the User ID of the key in the PGP keyring; will override existing setting directly on the PGPDataFormat.
Camel PGPDataFormatKeyUserIds	List<String>	Since camel 2.12.2; the User IDs of the key in the PGP keyring; will override existing setting directly on the PGPDataFormat.
Camel PGPDataFormatKeyPassword	String	Since Camel 2.11.0; password used when opening the private key; will override existing setting directly on the PGPDataFormat.
Camel PGPDataFormatSignatureKeyFileName	String	Since Camel 2.11.0; filename of the signature keyring; will override existing setting directly on the PGPDataFormat.

Name	Type	Description
Camel PGPDataFormatSignatureKeyRing	byte[]	Since Camel 2.12.1; the signature keyring; will override existing setting directly on the PGPDataFormat.
Camel PGPDataFormatSignatureKeyUserid	String	Since Camel 2.11.0; the User ID of the signature key in the PGP keyring; will override existing setting directly on the PGPDataFormat.
Camel PGPDataFormatSignatureKeyUserids	List<String>	Since Camel 2.12.3; the User IDs of the signature keys in the PGP keyring; will override existing setting directly on the PGPDataFormat.
Camel PGPDataFormatSignatureKeyPassword	String	Since Camel 2.11.0; password used when opening the signature private key; will override existing setting directly on the PGPDataFormat.
Camel PGPDataFormatEncryptionAlgorithm	int	Since Camel 2.12.2; symmetric key encryption algorithm; will override existing setting directly on the PGPDataFormat.
Camel PGPDataFormatSignatureHashAlgorithm	int	Since Camel 2.12.2; signature hash algorithm; will override existing setting directly on the PGPDataFormat.

Name	Type	Description
Camel PGPDataFormatCompressionAlgorithm	int	Since Camel 2.12.2; compression algorithm; will override existing setting directly on the PGPDataFormat.
Camel PGPDataFormatNumberOfEncryptionKeys	Integer	Since *Camel 2.12.3; *number of public keys used for encrypting the symmetric key, set by PGPDataFormat during encryption process
Camel PGPDataFormatNumberOfSigningKeys	Integer	Since *Camel 2.12.3; *number of private keys used for creating signatures, set by PGPDataFormat during signing process

262.3. ENCRYPTING WITH PGPDATAFORMAT

The following sample uses the popular PGP format for encrypting/decrypting files using the [Bouncy Castle Java libraries](#):

The following sample performs signing + encryption, and then signature verification + decryption. It uses the same keyring for both signing and encryption, but you can obviously use different keys:

Or using Spring:

262.3.1. To work with the previous example you need the following

- A public keyring file which contains the public keys used to encrypt the data
- A private keyring file which contains the keys used to decrypt the data
- The keyring password

262.3.2. Managing your keyring

To manage the keyring, I use the command line tools, I find this to be the simplest approach in managing the keys. There are also Java libraries available from <http://www.bouncycastle.org/java.html> if you would prefer to do it that way.

Install the command line utilities on linux

```
apt-get install gnupg
```

Create your keyring, entering a secure password

```
gpg --gen-key
```

If you need to import someone else's public key so that you can encrypt a file for them.

```
gpg --import <filename.key
```

The following files should now exist and can be used to run the example

```
ls -l ~/.gnupg/pubring.gpg ~/.gnupg/secring.gpg
```

[[Crypto-PGPDecrypting/VerifyingofMessagesEncrypted/SignedbyDifferentPrivate/PublicKeys]] PGP
Decrypting/Verifying of Messages Encrypted/Signed by Different # Private/Public Keys

Since **Camel 2.12.2**.

A PGP Data Formater can decrypt/verify messages which have been encrypted by different public keys or signed by different private keys. Just, provide the corresponding private keys in the secret keyring, the corresponding public keys in the public keyring, and the passphrases in the passphrase accessor.

```
Map<String, String> userId2Passphrase = new HashMap<String, String>(2);
// add passphrases of several private keys whose corresponding public keys have been used to
// encrypt the messages
userId2Passphrase.put("UserIdOfKey1", "passphrase1"); // you must specify the exact User ID!
userId2Passphrase.put("UserIdOfKey2", "passphrase2");
PGPPassphraseAccessor passphraseAccessor = new
PGPPassphraseAccessorDefault(userId2Passphrase);

PGPDataFormat pgpVerifyAndDecrypt = new PGPDataFormat();
pgpVerifyAndDecrypt.setPassphraseAccessor(passphraseAccessor);
// the method getSecKeyRing() provides the secret keyring as byte array containing the private keys
pgpVerifyAndDecrypt.setEncryptionKeyRing(getSecKeyRing()); // alternatively you can use
// setKeyFileName(keyfileName)
// the method getPublicKeyRing() provides the public keyring as byte array containing the public keys
pgpVerifyAndDecrypt.setSignatureKeyRing((getPublicKeyRing())); // alternatively you can use
// setSignatureKeyFileName(signatureKeyfileName)
// it is not necessary to specify the encryption or signer User Id

from("direct:start")
    ...
    .unmarshal(pgpVerifyAndDecrypt) // can decrypt/verify messages encrypted/signed by different
    private/public keys
    ...
```

- The functionality is especially useful to support the key exchange. If you want to exchange the private key for decrypting you can accept for a period of time messages which are either encrypted with the old or new corresponding public key. Or if the sender wants to exchange his signer private key, you can accept for a period of time, the old or new signer key.

- Technical background: The PGP encrypted data contains a Key ID of the public key which was used to encrypt the data. This Key ID can be used to locate the private key in the secret keyring to decrypt the data. The same mechanism is also used to locate the public key for verifying a signature. Therefore you no longer must specify User IDs for the unmarshaling.

262.4. RESTRICTING THE SIGNER IDENTITIES DURING PGP SIGNATURE VERIFICATION

Since **Camel 2.12.3**.

If you verify a signature you not only want to verify the correctness of the signature but you also want check that the signature comes from a certain identity or a specific set of identities. Therefore it is possible to restrict the number of public keys from the public keyring which can be used for the verification of a signature.

Signature User IDs

```
// specify the User IDs of the expected signer identities
List<String> expectedSigUserIds = new ArrayList<String>();
expectedSigUserIds.add("Trusted company1");
expectedSigUserIds.add("Trusted company2");

PGPDataFormat pgpVerifyWithSpecificKeysAndDecrypt = new PGPDataFormat();
pgpVerifyWithSpecificKeysAndDecrypt.setPassword("my password"); // for decrypting with private
key
pgpVerifyWithSpecificKeysAndDecrypt.setKeyFileName(keyfileName);
pgpVerifyWithSpecificKeysAndDecrypt.setSignatureKeyFileName(signatureKeyfileName);
pgpVerifyWithSpecificKeysAndDecrypt.setSignatureKeyUserids(expectedSigUserIds); // if you have
only one signer identity then you can also use setSignatureKeyUserid("expected Signer")

from("direct:start")
...
.unmarshal(pgpVerifyWithSpecificKeysAndDecrypt)
...
```

- If the PGP content has several signatures the verification is successful as soon as one signature can be verified.
- If you do not want to restrict the signer identities for verification then do not specify the signature key User IDs. In this case all public keys in the public keyring are taken into account.

262.5. SEVERAL SIGNATURES IN ONE PGP DATA FORMAT

Since **Camel 2.12.3**.

The PGP specification allows that one PGP data format can contain several signatures from different keys. Since Camel 2.13.3 it is possible to create such kind of PGP content via specifying signature User IDs which relate to several private keys in the secret keyring.

Several Signatures

```
PGPDataFormat pgpSignAndEncryptSeveralSignerKeys = new PGPDataFormat();
pgpSignAndEncryptSeveralSignerKeys.setKeyUserid(keyUserid); // for encrypting, you can also use
setKeyUserids if you want to encrypt with several keys
```

```
pgpSignAndEncryptSeveralSignerKeys.setKeyFileName(keyfileName);
pgpSignAndEncryptSeveralSignerKeys.setSignatureKeyFileName(signatureKeyfileName);
pgpSignAndEncryptSeveralSignerKeys.setSignaturePassword("sdude"); // here we assume that all
private keys have the same password, if this is not the case then you can use
setPassphraseAccessor
```

```
List<String> signerUserIds = new ArrayList<String>();
signerUserIds.add("company old key");
signerUserIds.add("company new key");
pgpSignAndEncryptSeveralSignerKeys.setSignatureKeyUserids(signerUserIds);
```

```
from("direct:start")
    ...
    .marshal(pgpSignAndEncryptSeveralSignerKeys)
    ...
```

262.6. SUPPORT OF SUB-KEYS AND KEY FLAGS IN PGP DATA FORMAT MARSHALER

Since *Camel 2.12.3.

*An [OpenPGP V4 key](#) can have a primary key and sub-keys. The usage of the keys is indicated by the so called [Key Flags](#). For example, you can have a primary key with two sub-keys; the primary key shall only be used for certifying other keys (Key Flag 0x01), the first sub-key shall only be used for signing (Key Flag 0x02), and the second sub-key shall only be used for encryption (Key Flag 0x04 or 0x08). The PGP Data Format marshaler takes into account these Key Flags of the primary key and sub-keys in order to determine the right key for signing and encryption. This is necessary because the primary key and its sub-keys have the same User IDs.

262.7. SUPPORT OF CUSTOM KEY ACCESSORS

Since *Camel 2.13.0.

*You can implement custom key accessors for encryption/signing. The above `PGPDataFormat` class selects in a certain predefined way the keys which should be used for signing/encryption or verifying/decryption. If you have special requirements how your keys should be selected you should use the `PGPKeyAccessDataFormat` class instead and implement the interfaces [PGPPublicKeyAccessor](#) and [PGPSecretKeyAccessor](#) as beans. There are default implementations [DefaultPGPPublicKeyAccessor](#) and [DefaultPGPSecretKeyAccessor](#) which cache the keys, so that not every time the keyring is parsed when the processor is called.

`PGPKeyAccessDataFormat` has the same options as `PGPDataFormat` except `password`, `keyFileName`, `encryptionKeyRing`, `signaturePassword`, `signatureKeyFileName`, and `signatureKeyRing`.

262.8. DEPENDENCIES

To use the PGP dataformat in your camel routes you need to add the following dependency to your pom.

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-crypto</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

262.9. SEE ALSO

- Data Format

- <http://www.bouncycastle.org/java.html>

CHAPTER 263. PROPERTIES COMPONENT

Available as of Camel version 2.3

263.1. URI FORMAT

```
properties:key[?options]
```

Where **key** is the key for the property to lookup

263.2. OPTIONS

The Properties component supports 17 options, which are listed below.

Name	Description	Default	Type
locations (common)	A list of locations to load properties. This option will override any default locations and only use the locations from this option.		List
location (common)	A list of locations to load properties. You can use comma to separate multiple locations. This option will override any default locations and only use the locations from this option.		String
encoding (common)	Encoding to use when loading properties file from the file system or classpath. If no encoding has been set, then the properties files is loaded using ISO-8859-1 encoding (latin-1) as documented by <code>java.util.Properties#load(java.io.InputStream)</code>		String
propertiesResolver (common)	To use a custom PropertiesResolver		PropertiesResolver
propertiesParser (common)	To use a custom PropertiesParser		PropertiesParser
cache (common)	Whether or not to cache loaded properties. The default value is true.	true	boolean
propertyPrefix (advanced)	Optional prefix prepended to property names before resolution.		String
propertySuffix (advanced)	Optional suffix appended to property names before resolution.		String

Name	Description	Default	Type
fallbackToUnaugmentedProperty (advanced)	If true, first attempt resolution of property name augmented with <code>propertyPrefix</code> and <code>propertySuffix</code> before falling back the plain property name specified. If false, only the augmented property name is searched.	true	boolean
defaultFallbackEnabled (common)	If false, the component does not attempt to find a default for the key by looking after the colon separator.	true	boolean
ignoreMissingLocation (common)	Whether to silently ignore if a location cannot be located, such as a properties file not found.	false	boolean
prefixToken (advanced)	Sets the value of the prefix token used to identify properties to replace. Setting a value of null restores the default token (link <code>DEFAULT_PREFIX_TOKEN</code>).	<code>{{</code>	String
suffixToken (advanced)	Sets the value of the suffix token used to identify properties to replace. Setting a value of null restores the default token (link <code>DEFAULT_SUFFIX_TOKEN</code>).	<code>}}</code>	String
initialProperties (advanced)	Sets initial properties which will be used before any locations are resolved.		Properties
overrideProperties (advanced)	Sets a special list of override properties that take precedence and will use first, if a property exist.		Properties
systemPropertiesMode (common)	Sets the system property mode.	2	int
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Properties endpoint is configured using URI syntax:

```
properties:key
```

with the following path and query parameters:

263.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
key	Required Property key to use as placeholder		String

263.2.2. Query Parameters (6 parameters):

Name	Description	Default	Type
ignoreMissingLocation (common)	Whether to silently ignore if a location cannot be located, such as a properties file not found.	false	boolean
locations (common)	A list of locations to load properties. You can use comma to separate multiple locations. This option will override any default locations and only use the locations from this option.		String
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN/ERROR level and ignored.	false	boolean
exceptionHandler (consumer)	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN/ERROR level and ignored.		<code>ExceptionHandler</code>
exchangePattern (consumer)	Sets the default exchange pattern when creating an exchange.		<code>ExchangePattern</code>
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

TIP

Resolving property from Java code

You can use the method `resolvePropertyPlaceholders` on the `CamelContext` to resolve a property from any Java code.

263.3. USING PROPERTYPLACEHOLDER

Available as of Camel 2.3

Camel now provides a new **PropertiesComponent** in **camel-core** which allows you to use property placeholders when defining Camel Endpoint URIs.

This works much like you would do if using Spring's **<property-placeholder>** tag. However Spring have a limitation which prevents 3rd party frameworks to leverage Spring property placeholders to the fullest. See more at [How do I use Spring Property Placeholder with Camel XML](#) .

TIP

Bridging Spring and Camel property placeholders

From Camel 2.10 onwards, you can bridge the Spring property placeholder with Camel, see further below for more details.

The property placeholder is generally in use when doing:

- lookup or creating endpoints
- lookup of beans in the Registry
- additional supported in Spring XML (see below in examples)
- using Blueprint PropertyPlaceholder with Camel [Properties](#) component
- using **@PropertyInject** to inject a property in a POJO
- **Camel 2.14.1** Using default value if a property does not exists
- **Camel 2.14.1** Include out of the box functions, to lookup property values from OS environment variables, JVM system properties, or the service idiom.
- **Camel 2.14.1** Using custom functions, which can be plugged into the property component.

263.4. SYNTAX

The syntax to use Camel's property placeholder is to use **{{key}}** for example **{{file.uri}}** where **file.uri** is the property key.

You can use property placeholders in parts of the endpoint URI's which for example you can use placeholders for parameters in the URIs.

From **Camel 2.14.1** onwards you can specify a default value to use if a property with the key does not exists, eg **file.uri:/some/path** where the default value is the text after the colon (eg /some/path).

NOTE

Do not use colon in the property key. The colon is used as a separator token when you are providing a default value, which is supported from **Camel 2.14.1** onwards.

263.5. PROPERTYRESOLVER

Camel provides a pluggable mechanism which allows 3rd part to provide their own resolver to lookup properties. Camel provides a default implementation **org.apache.camel.component.properties.DefaultPropertiesResolver** which is capable of loading

properties from the file system, classpath or Registry. You can prefix the locations with either:

- **ref: Camel 2.4:** to lookup in the Registry
- **file:** to load the from file system
- **classpath:** to load from classpath (this is also the default if no prefix is provided)
- **blueprint: Camel 2.7:** to use a specific OSGi blueprint placeholder service

263.6. DEFINING LOCATION

The **PropertiesResolver** need to know a location(s) where to resolve the properties. You can define 1 to many locations. If you define the location in a single String property you can separate multiple locations with comma such as:

```
pc.setLocation("com/mycompany/myprop.properties,com/mycompany/other.properties");
```

Available as of Camel 2.19.0

You can set which location can be discarded if missing by by setting the **optional** attribute, which is false by default, i.e:

```
pc.setLocations(
    "com/mycompany/override.properties;optional=true"
    "com/mycompany/defaults.properties");
```

263.7. USING SYSTEM AND ENVIRONMENT VARIABLES IN LOCATIONS

Available as of Camel 2.7

The location now supports using placeholders for JVM system properties and OS environments variables.

For example:

```
location=file:${karaf.home}/etc/foo.properties
```

In the location above we defined a location using the file scheme using the JVM system property with key **karaf.home**.

To use an OS environment variable instead you would have to prefix with env:

```
location=file:${env:APP_HOME}/etc/foo.properties
```

Where **APP_HOME** is an OS environment.

You can have multiple placeholders in the same location, such as:

```
location=file:${env:APP_HOME}/etc/${prop.name}.properties
```

#=== Using system and environment variables to configure property prefixes and suffixes

Available as of Camel 2.12.5, 2.13.3, 2.14.0

propertyPrefix, **propertySuffix** configuration properties support using placeholders for JVM system properties and OS environments variables.

For example, if **PropertiesComponent** is configured with the following properties file:

```
dev.endpoint = result1
test.endpoint = result2
```

Then with the following route definition:

```
PropertiesComponent pc = context.getComponent("properties", PropertiesComponent.class);
pc.setPropertyPrefix("${stage}.");
// ...
context.addRoutes(new RouteBuilder() {
    @Override
    public void configure() throws Exception {
        from("direct:start").to("properties:mock:{{endpoint}}");
    }
});
```

it is possible to change the target endpoint by changing system property **stage** either to **dev** (the message will be routed to **mock:result1**) or **test** (the message will be routed to **mock:result2**).

263.8. CONFIGURING IN JAVA DSL

You have to create and register the **PropertiesComponent** under the name **properties** such as:

```
PropertiesComponent pc = new PropertiesComponent();
pc.setLocation("classpath:com/mycompany/myprop.properties");
context.addComponent("properties", pc);
```

263.9. CONFIGURING IN SPRING XML

Spring XML offers two variations to configure. You can define a spring bean as a **PropertiesComponent** which resembles the way done in Java DSL. Or you can use the **<propertyPlaceholder>** tag.

```
<bean id="properties" class="org.apache.camel.component.properties.PropertiesComponent">
    <property name="location" value="classpath:com/mycompany/myprop.properties"/>
</bean>
```

Using the **<propertyPlaceholder>** tag makes the configuration a bit more fresh such as:

```
<camelContext ...>
    <propertyPlaceholder id="properties" location="com/mycompany/myprop.properties"/>
</camelContext>
```

Setting the properties location through the location tag works just fine but sometime you have a number of resources to take into account and starting from **Camel 2.19.0** you can set the properties location with a dedicated **propertiesLocation**:

```

<camelContext ...>
  <propertyPlaceholder id="myPropertyPlaceholder">
    <propertiesLocation
      resolver = "classpath"
      path    = "com/my/company/something/my-properties-1.properties"
      optional = "false"/>
    <propertiesLocation
      resolver = "classpath"
      path    = "com/my/company/something/my-properties-2.properties"
      optional = "false"/>
    <propertiesLocation
      resolver = "file"
      path    = "${karaf.home}/etc/my-override.properties"
      optional = "true"/>
  </propertyPlaceholder>
</camelContext>

```

TIP**Specifying the cache option inside XML**

Camel 2.10 onwards supports specifying a value for the cache option both inside the Spring as well as the Blueprint XML.

263.10. USING A PROPERTIES FROM THE REGISTRY**Available as of Camel 2.4**

For example in OSGi you may want to expose a service which returns the properties as a **java.util.Properties** object.

Then you could setup the [Properties](#) component as follows:

```
<propertyPlaceholder id="properties" location="ref:myProperties"/>
```

Where **myProperties** is the id to use for lookup in the OSGi registry. Notice we use the **ref:** prefix to tell Camel that it should lookup the properties for the Registry.

263.11. EXAMPLES USING PROPERTIES COMPONENT

When using property placeholders in the endpoint URIs you can either use the **properties:** component or define the placeholders directly in the URI. We will show example of both cases, starting with the former.

```

// properties
cool.end=mock:result

// route
from("direct:start").to("properties:{{cool.end}}");

```

You can also use placeholders as a part of the endpoint uri:

```

// properties
cool.foo=result

```

```
// route
from("direct:start").to("properties:mock:{{cool.foo}}");
```

In the example above the to endpoint will be resolved to **mock:result**.

You can also have properties with refer to each other such as:

```
// properties
cool.foo=result
cool.concat=mock:{{cool.foo}}

// route
from("direct:start").to("properties:mock:{{cool.concat}}");
```

Notice how **cool.concat** refer to another property.

The **properties:** component also offers you to override and provide a location in the given uri using the **locations** option:

```
from("direct:start").to("properties:bar.end?locations=com/mycompany/bar.properties");
```

263.12. EXAMPLES

You can also use property placeholders directly in the endpoint uris without having to use **properties:**.

```
// properties
cool.foo=result

// route
from("direct:start").to("mock:{{cool.foo}}");
```

And you can use them in multiple wherever you want them:

```
// properties
cool.start=direct:start
cool.showid=true
cool.result=result

// route
from("{{cool.start}}")
  .to("log:{{cool.start}}?showBodyType=false&showExchangeId={{cool.showid}}")
  .to("mock:{{cool.result}}");
```

You can also your property placeholders when using `ProducerTemplate` for example:

```
template.sendBody("{{cool.start}}", "Hello World");
```

263.13. EXAMPLE WITH SIMPLE LANGUAGE

The [Simple](#) language now also support using property placeholders, for example in the route below:

```
// properties
```

```
cheese.quote=Camel rocks
```

```
// route
from("direct:start")
  .transform().simple("Hi ${body} do you think ${properties:cheese.quote}?");
```

You can also specify the location in the [Simple](#) language for example:

```
// bar.properties
bar.quote=Beer tastes good

// route
from("direct:start")
  .transform().simple("Hi ${body}. ${properties:com/mycompany/bar.properties:bar.quote}.");
```

263.14. ADDITIONAL PROPERTY PLACEHOLDER SUPPORTED IN SPRING XML

The property placeholders is also supported in many of the Camel Spring XML tags such as **<package>**, **<packageScan>**, **<contextScan>**, **<jmxAgent>**, **<endpoint>**, **<routeBuilder>**, **<proxy>** and the others.

The example below has property placeholder in the **<jmxAgent>** tag:

You can also define property placeholders in the various attributes on the **<camelContext>** tag such as **trace** as shown here:

263.15. OVERRIDING A PROPERTY SETTING USING A JVM SYSTEM PROPERTY

Available as of Camel 2.5

It is possible to override a property value at runtime using a JVM System property without the need to restart the application to pick up the change. This may also be accomplished from the command line by creating a JVM System property of the same name as the property it replaces with a new value. An example of this is given below

```
PropertiesComponent pc = context.getComponent("properties", PropertiesComponent.class);
pc.setCache(false);

System.setProperty("cool.end", "mock:override");
System.setProperty("cool.result", "override");

context.addRoutes(new RouteBuilder() {
    @Override
    public void configure() throws Exception {
        from("direct:start").to("properties:cool.end");
        from("direct:foo").to("properties:mock:{{cool.result}}");
    }
});
context.start();

getMockEndpoint("mock:override").expectedMessageCount(2);
```

```

template.sendBody("direct:start", "Hello World");
template.sendBody("direct:foo", "Hello Foo");

System.clearProperty("cool.end");
System.clearProperty("cool.result");

assertMockEndpointsSatisfied();

```

263.16. USING PROPERTY PLACEHOLDERS FOR ANY KIND OF ATTRIBUTE IN THE XML DSL

Available as of Camel 2.7

NOTE

If you use OSGi Blueprint then this only works from **2.11.1** or **2.10.5** onwards.

Previously it was only the **xs:string** type attributes in the XML DSL that support placeholders. For example often a timeout attribute would be a **xs:int** type and thus you cannot set a string value as the placeholder key. This is now possible from Camel 2.7 onwards using a special placeholder namespace.

In the example below we use the **prop** prefix for the namespace <http://camel.apache.org/schema/placeholder> by which we can use the **prop** prefix in the attributes in the XML DSLs. Notice how we use that in the Multicast to indicate that the option **stopOnException** should be the value of the placeholder with the key "stop".

In our properties file we have the value defined as

```
stop=true
```

263.17. USING BLUEPRINT PROPERTY PLACEHOLDER WITH CAMEL ROUTES

Available as of Camel 2.7

Camel supports Blueprint which also offers a property placeholder service. Camel supports convention over configuration, so all you have to do is to define the OSGi Blueprint property placeholder in the XML file as shown below:

```

<blueprint xmlns="http://www.osgi.org/xmlns/blueprint/v1.0.0"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xmlns:cm="http://aries.apache.org/blueprint/xmlns/blueprint-cm/v1.0.0"
  xsi:schemaLocation="
    http://www.osgi.org/xmlns/blueprint/v1.0.0
    https://www.osgi.org/xmlns/blueprint/v1.0.0/blueprint.xsd">

  <!-- OSGi blueprint property placeholder -->
  <cm:property-placeholder id="myblueprint.placeholder" persistent-id="camel.blueprint">
    <!-- list some properties as needed -->
    <cm:default-properties>
      <cm:property name="result" value="mock:result"/>
    </cm:default-properties>

```

```

</cm:property-placeholder>

<camelContext xmlns="http://camel.apache.org/schema/blueprint">
  <!-- in the route we can use {{ }} placeholders which will lookup in blueprint
        as Camel will auto detect the OSGi blueprint property placeholder and use it -->
  <route>
    <from uri="direct:start"/>
    <to uri="mock:foo"/>
    <to uri="{{result}}"/>
  </route>
</camelContext>
</blueprint>

```

263.17.1. Using OSGi blueprint property placeholders in Camel routes

By default Camel detects and uses OSGi blueprint property placeholder service. You can disable this by setting the attribute **useBlueprintPropertyResolver** to false on the **<camelContext>** definition.

263.17.2. About placeholder syntax

Notice how we can use the Camel syntax for placeholders **{{** and **}}** in the Camel route, which will lookup the value from OSGi blueprint.

The blueprint syntax for placeholders is **\${ }**. So outside the **<camelContext>** you must use the **\${ }** syntax. Where as inside **<camelContext>** you must use **{{** and **}}** syntax.

OSGi blueprint allows you to configure the syntax, so you can actually align those if you want.

You can also explicit refer to a specific OSGi blueprint property placeholder by its id. For that you need to use the Camel's **<propertyPlaceholder>** as shown in the example below:

```

<blueprint xmlns="http://www.osgi.org/xmlns/blueprint/v1.0.0"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xmlns:cm="http://aries.apache.org/blueprint/xmlns/blueprint-cm/v1.0.0"
  xsi:schemaLocation="
    http://www.osgi.org/xmlns/blueprint/v1.0.0
    https://www.osgi.org/xmlns/blueprint/v1.0.0/blueprint.xsd">

  <!-- OSGi blueprint property placeholder -->
  <cm:property-placeholder id="myblueprint.placeholder" persistent-id="camel.blueprint">
    <!-- list some properties as needed -->
    <cm:default-properties>
      <cm:property name="prefix.result" value="mock:result"/>
    </cm:default-properties>
  </cm:property-placeholder>

  <camelContext xmlns="http://camel.apache.org/schema/blueprint">
    <!-- using Camel properties component and refer to the blueprint property placeholder by its id --
  >
    <propertyPlaceholder id="properties" location="blueprint:myblueprint.placeholder"
      prefixToken="[[" suffixToken="]"
      propertyPrefix="prefix."/>

    <!-- in the route we can use {{ }} placeholders which will lookup in blueprint -->
    <route>

```

```

    <from uri="direct:start"/>
    <to uri="mock:foo"/>
    <to uri="[[result]]"/>
  </route>
</camelContext>
</blueprint>

```

263.18. EXPLICIT REFERRING TO A OSGI BLUEPRINT PLACEHOLDER IN CAMEL

Notice how we use the **blueprint** scheme to refer to the OSGi blueprint placeholder by its id. This allows you to mix and match, for example you can also have additional schemes in the location. For example to load a file from the classpath you can do:

```
location="blueprint:myblueprint.placeholder,classpath:myproperties.properties"
```

Each location is separated by comma.

263.19. OVERRIDING BLUEPRINT PROPERTY PLACEHOLDERS OUTSIDE CAMELCONTEXT

Available as of Camel 2.10.4

When using Blueprint property placeholder in the Blueprint XML file, you can declare the properties directly in the XML file as shown below:

Notice that we have a **<bean>** which refers to one of the properties. And in the Camel route we refer to the other using the **{{** and **}}** notation.

Now if you want to override these Blueprint properties from an unit test, you can do this as shown below:

To do this we override and implement the **useOverridePropertiesWithConfigAdmin** method. We can then put the properties we want to override on the given props parameter. And the return value **must** be the **persistence-id** of the **<cm:property-placeholder>** tag, which you define in the blueprint XML file.

263.20. USING .CFG OR .PROPERTIES FILE FOR BLUEPRINT PROPERTY PLACEHOLDERS

Available as of Camel 2.10.4

When using Blueprint property placeholder in the Blueprint XML file, you can declare the properties in a **.properties** or **.cfg** file. If you use Apache ServieMix / Karaf then this container has a convention that it loads the properties from a file in the etc directory with the naming **etc/pid.cfg**, where **pid** is the **persistence-id**.

For example in the blueprint XML file we have the **persistence-id="stuff"**, which mean it will load the configuration file as **etc/stuff.cfg**.

Now if you want to unit test this blueprint XML file, then you can override the **loadConfigAdminConfigurationFile** and tell Camel which file to load as shown below:

Notice that this method requires to return a **String[]** with 2 values. The 1st value is the path for the configuration file to load. The 2nd value is the **persistence-id** of the **<cm:property-placeholder>** tag.

The **stuff.cfg** file is just a plain properties file with the property placeholders such as:

```
== this is a comment
greeting=Bye
```

263.21. USING .CFG FILE AND OVERRIDING PROPERTIES FOR BLUEPRINT PROPERTY PLACEHOLDERS

You can do both as well. Here is a complete example. First we have the Blueprint XML file:

And in the unit test class we do as follows:

And the **etc/stuff.cfg** configuration file contains

```
greeting=Bye
echo=Yay
destination=mock:result
```

263.22. BRIDGING SPRING AND CAMEL PROPERTY PLACEHOLDERS

Available as of Camel 2.10

The Spring Framework does not allow 3rd party frameworks such as Apache Camel to seamlessly hook into the Spring property placeholder mechanism. However you can easily bridge Spring and Camel by declaring a Spring bean with the type

org.apache.camel.spring.spi.BridgePropertyPlaceholderConfigurer, which is a Spring **org.springframework.beans.factory.config.PropertyPlaceholderConfigurer** type.

To bridge Spring and Camel you must define a single bean as shown below:

Bridging Spring and Camel property placeholders

You **must not** use the spring `<context:property-placeholder>` namespace at the same time; this is not possible.

After declaring this bean, you can define property placeholders using both the Spring style, and the Camel style within the `<camelContext>` tag as shown below:

Using bridge property placeholders

Notice how the hello bean is using pure Spring property placeholders using the `#{ }` notation. And in the Camel routes we use the Camel placeholder notation with `{{ and }}`.

263.23. CLASHING SPRING PROPERTY PLACEHOLDERS WITH CAMELS SIMPLE LANGUAGE

Take notice when using Spring bridging placeholder then the spring `#{ }` syntax clashes with the [Simple](#) in Camel, and therefore take care. For example:

```
<setHeader headerName="Exchange.FILE_NAME">
  <simple>{{file.rootdir}}/${in.header.CamelFileName}</simple>
</setHeader>
```

clashes with Spring property placeholders, and you should use `$simple{ }` to indicate using the [Simple](#) language in Camel.

```
<setHeader headerName="Exchange.FILE_NAME">
  <simple>{{file.rootdir}}/$simple{in.header.CamelFileName}</simple>
</setHeader>
```

An alternative is to configure the `PropertyPlaceholderConfigurer` with `ignoreUnresolvablePlaceholders` option to `true`.

263.24. OVERRIDING PROPERTIES FROM CAMEL TEST KIT

Available as of Camel 2.10

When Testing with Camel and using the [Properties](#) component, you may want to be able to provide the properties to be used from directly within the unit test source code.

This is now possible from Camel 2.10 onwards, as the Camel test kits, eg `CamelTestSupport` class offers the following methods

- `useOverridePropertiesWithPropertiesComponent`
- `ignoreMissingLocationWithPropertiesComponent`

So for example in your unit test classes, you can override the `useOverridePropertiesWithPropertiesComponent` method and return a `java.util.Properties` that contains the properties which should be preferred to be used.

263.24.1. Providing properties from within unit test source

This can be done from any of the Camel Test kits, such as `camel-test`, `camel-test-spring`, and `camel-test-blueprint`.

The `ignoreMissingLocationWithPropertiesComponent` can be used to instruct Camel to ignore any locations which was not discoverable, for example if you run the unit test, in an environment that does not have access to the location of the properties.

263.25. USING @PROPERTYINJECT

Available as of Camel 2.12

Camel allows to inject property placeholders in POJOs using the `@PropertyInject` annotation which can be set on fields and setter methods.

For example you can use that with `RouteBuilder` classes, such as shown below:

```
public class MyRouteBuilder extends RouteBuilder {

    @PropertyInject("hello")
    private String greeting;

    @Override
    public void configure() throws Exception {
        from("direct:start")
            .transform().constant(greeting)
    }
}
```

```

        .to("${result}");
    }
}

```

Notice we have annotated the greeting field with **@PropertyInject** and define it to use the key **"hello"**. Camel will then lookup the property with this key and inject its value, converted to a String type.

You can also use multiple placeholders and text in the key, for example we can do:

```

@propertyInject("Hello {{name}} how are you?")
private String greeting;

```

This will lookup the placeholder with they key **"name"**.

You can also add a default value if the key does not exists, such as:

```

@propertyInject(value = "myTimeout", defaultValue = "5000")
private int timeout;

```

263.26. USING OUT OF THE BOX FUNCTIONS

Available as of Camel 2.14.1

The [Properties](#) component includes the following functions out of the box

- **env** - A function to lookup the property from OS environment variables
- **sys** - A function to lookup the property from Java JVM system properties
- **service** - A function to lookup the property from OS environment variables using the service naming idiom
- **service.name** - **Camel 2.16.1**: A function to lookup the property from OS environment variables using the service naming idiom returning the hostname part only
- **service.port** - **Camel 2.16.1**: A function to lookup the property from OS environment variables using the service naming idiom returning the port part only

As you can see these functions is intended to make it easy to lookup values from the environment. As they are provided out of the box, they can easily be used as shown below:

```

<camelContext xmlns="http://camel.apache.org/schema/blueprint">

  <route>
    <from uri="direct:start"/>
    <to uri="{env:SOMENAME}"/>
    <to uri="{sys:MyJvmPropertyName}"/>
  </route>
</camelContext>

```

You can use default values as well, so if the property does not exists, you can define a default value as shown below, where the default value is a **log:foo** and **log:bar** value.

```
<camelContext xmlns="http://camel.apache.org/schema/blueprint">
  <route>
    <from uri="direct:start"/>
    <to uri="{env:SOMENAME:log:foo}"/>
    <to uri="{sys:MyJvmPropertyName:log:bar}"/>
  </route>
</camelContext>
```

The service function is for looking up a service which is defined using OS environment variables using the service naming idiom, to refer to a service location using **hostname : port**

- `NAME_SERVICE_HOST`
- `NAME_SERVICE_PORT`

in other words the service uses `_SERVICE_HOST` and `_SERVICE_PORT` as prefix. So if the service is named FOO, then the OS environment variables should be set as

```
export $FOO_SERVICE_HOST=myserver
export $FOO_SERVICE_PORT=8888
```

For example if the FOO service a remote HTTP service, then we can refer to the service in the Camel endpoint uri, and use the [HTTP](#) component to make the HTTP call:

```
<camelContext xmlns="http://camel.apache.org/schema/blueprint">
  <route>
    <from uri="direct:start"/>
    <to uri="http://{service:FOO}/myapp"/>
  </route>
</camelContext>
```

And we can use default values if the service has not been defined, for example to call a service on localhost, maybe for unit testing etc

```
<camelContext xmlns="http://camel.apache.org/schema/blueprint">
  <route>
    <from uri="direct:start"/>
    <to uri="http://{service:FOO:localhost:8080}/myapp"/>
  </route>
</camelContext>
```

263.27. USING CUSTOM FUNCTIONS

Available as of Camel 2.14.1

The [Properties](#) component allow to plugin 3rd party functions which can be used during parsing of the property placeholders. These functions are then able to do custom logic to resolve the placeholders, such as looking up in databases, do custom computations, or whatnot. The name of the function becomes the prefix used in the placeholder. This is best illustrated in the example code below

```
<bean id="beerFunction" class="MyBeerFunction"/>
```

```

<camelContext xmlns="http://camel.apache.org/schema/blueprint">
  <propertyPlaceholder id="properties">
    <propertiesFunction ref="beerFunction"/>
  </propertyPlaceholder>

  <route>
    <from uri="direct:start"/>
    <to uri="{beer:FOO}"/>
    <to uri="{beer:BAR}"/>
  </route>
</camelContext>

```

NOTE

from **camel 2.19.0** the location attribute (on `propertyPlaceholder` tag) is not more mandatory

Here we have a Camel XML route where we have defined the `<propertyPlaceholder>` to use a custom function, which we refer to be the bean id - eg the **beerFunction**. As the beer function uses **"beer"** as its name, then the placeholder syntax can trigger the beer function by starting with **beer:value**.

The implementation of the function is only two methods as shown below:

```

public static final class MyBeerFunction implements PropertiesFunction {

    @Override
    public String getName() {
        return "beer";
    }

    @Override
    public String apply(String remainder) {
        return "mock:" + remainder.toLowerCase();
    }
}

```

The function must implement the **org.apache.camel.component.properties.PropertiesFunction** interface. The method **getName** is the name of the function, eg beer. And the **apply** method is where we implement the custom logic to do. As the sample code is from an unit test, it just returns a value to refer to a mock endpoint.

To register a custom function from Java code is as shown below:

```

PropertiesComponent pc = context.getComponent("properties", PropertiesComponent.class);
pc.addFunction(new MyBeerFunction());

```

CHAPTER 264. PROTOBUF DATAFORMAT

Available as of Camel version 2.2.0

CHAPTER 265. PROTOBUF - PROTOCOL BUFFERS

"Protocol Buffers - Google's data interchange format"

Camel provides a Data Format to serialize between Java and the Protocol Buffer protocol. The project's site details why you may wish to [choose this format over xml](#). Protocol Buffer is language-neutral and platform-neutral, so messages produced by your Camel routes may be consumed by other language implementations.

[API Site](#)

[Protobuf Implementation](#)

[Protobuf Java Tutorial](#)

265.1. PROTOBUF OPTIONS

The Protobuf dataformat supports 3 options, which are listed below.

Name	Default	Java Type	Description
<code>instanceClass</code>		String	Name of class to use when unarmshalling
<code>contentTypeFormat</code>	native	String	Defines a content type format in which protobuf message will be serialized/deserialized from(to) the Java bean. The format can either be native or json for either native protobuf or json fields representation. The default value is native.
<code>contentTypeHeader</code>	false	Boolean	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON etc.

265.2. SPRING BOOT AUTO-CONFIGURATION

The component supports 4 options, which are listed below.

Name	Description	Default	Type
<code>camel.dataformat.protobuf.content-type-format</code>	Defines a content type format in which protobuf message will be serialized/deserialized from(to) the Java bean. The format can either be native or json for either native protobuf or json fields representation. The default value is native.	native	String

Name	Description	Default	Type
<code>camel.dataformat.protobuf.content-type-header</code>	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSon etc.	false	Boolean
<code>camel.dataformat.protobuf.enabled</code>	Enable protobuf dataformat	true	Boolean
<code>camel.dataformat.protobuf.instance-class</code>	Name of class to use when unarmshalling		String

ND

265.3. CONTENT TYPE FORMAT (STARTING FROM CAMEL 2.19)

It's possible to parse JSON message to convert it to the protobuf format and unparse it back using native util converter. To use this option, set `contentTypeFormat` value to 'json' or call `protobuf` with second parameter. If default instance is not specified, always use native protobuf format. The sample code shows below:

```
from("direct:marshal")
  .unmarshal()
  .protobuf("org.apache.camel.dataformat.protobuf.generated.AddressBookProtos$Person", "json")
  .to("mock:reverse");
```

265.4. PROTOBUF OVERVIEW

This quick overview of how to use Protobuf. For more detail see the [complete tutorial](#)

265.5. DEFINING THE PROTO FORMAT

The first step is to define the format for the body of your exchange. This is defined in a `.proto` file as so:

`addressbook.proto`

```
syntax = "proto2";

package org.apache.camel.component.protobuf;

option java_package = "org.apache.camel.component.protobuf";
option java_outer_classname = "AddressBookProtos";

message Person {
```

```

required string name = 1;
required int32 id = 2;
optional string email = 3;

enum PhoneType {
  MOBILE = 0;
  HOME = 1;
  WORK = 2;
}

message PhoneNumber {
  required string number = 1;
  optional PhoneType type = 2 [default = HOME];
}

repeated PhoneNumber phone = 4;
}

message AddressBook {
  repeated Person person = 1;
}

```

265.6. GENERATING JAVA CLASSES

The Protobuf SDK provides a compiler which will generate the Java classes for the format we defined in our .proto file. If your operating system is supporting by [Protobuf Java code generator maven plugin](#) , you can automate protobuf Java code generating by adding following configurations to your pom.xml:

Insert operating system and CPU architecture detection extension inside **<build>** tag of the project pom.xml or set `os.detected.classifier` parameter manually

```

<extensions>
  <extension>
    <groupId>kr.motd.maven</groupId>
    <artifactId>os-maven-plugin</artifactId>
    <version>1.4.1.Final</version>
  </extension>
</extensions>

```

Insert gRPC and protobuf Java code generator plugin **<plugins>** tag of the project pom.xml

```

<plugin>
  <groupId>org.xolstice.maven.plugins</groupId>
  <artifactId>protobuf-maven-plugin</artifactId>
  <version>0.5.0</version>
  <extensions>true</extensions>
  <executions>
    <execution>
      <goals>
        <goal>test-compile</goal>
        <goal>compile</goal>
      </goals>
      <configuration>
        <protocArtifact>com.google.protobuf:protoc:${protobuf-
version}:exe:${os.detected.classifier}</protocArtifact>

```

```

    </configuration>
  </execution>
</executions>
</plugin>

```

You can also run the compiler for any additional supported languages you require manually.

protoc --java_out=. ./proto/addressbook.proto

This will generate a single Java class named AddressBookProtos which contains inner classes for Person and AddressBook. Builders are also implemented for you. The generated classes implement com.google.protobuf.Message which is required by the serialization mechanism. For this reason it important that only these classes are used in the body of your exchanges. Camel will throw an exception on route creation if you attempt to tell the Data Format to use a class that does not implement com.google.protobuf.Message. Use the generated builders to translate the data from any of your existing domain classes.

265.7. JAVA DSL

You can use create the ProtobufDataFormat instance and pass it to Camel DataFormat marshal and unmarshal API like this.

```

ProtobufDataFormat format = new ProtobufDataFormat(Person.getDefaultInstance());

from("direct:in").marshal(format);
from("direct:back").unmarshal(format).to("mock:reverse");

```

Or use the DSL protobuf() passing the unmarshal default instance or default instance class name like this.

```

// You don't need to specify the default instance for protobuf marshaling
from("direct:marshal").marshal().protobuf();
from("direct:unmarshalA").unmarshal()
    .protobuf("org.apache.camel.dataformat.protobuf.generated.AddressBookProtos$Person")
    .to("mock:reverse");

from("direct:unmarshalB").unmarshal().protobuf(Person.getDefaultInstance()).to("mock:reverse");

```

265.8. SPRING DSL

The following example shows how to use Protobuf to unmarshal using Spring configuring the protobuf data type

```

<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="direct:start"/>
    <unmarshal>
      <protobuf
instanceClass="org.apache.camel.dataformat.protobuf.generated.AddressBookProtos$Person" />
    </unmarshal>
    <to uri="mock:result"/>
  </route>
</camelContext>

```

265.9. DEPENDENCIES

To use Protobuf in your camel routes you need to add the a dependency on **camel-protobuf** which implements this data format.

```
<dependency>  
  <groupId>org.apache.camel</groupId>  
  <artifactId>camel-protobuf</artifactId>  
  <version>x.x.x</version>  
  <!-- use the same version as your Camel core version -->  
</dependency>
```

265.10. SEE ALSO

- [Camel gRPC component](#)

CHAPTER 266. PUBNUB COMPONENT

Available as of Camel version 2.19

Camel PubNub component can be used to communicate with the [PubNub](#) data stream network for connected devices. This component uses pubnub [java library](#).

Use cases includes:

- Chat rooms: Sending and receiving messages
- Locations and Connected cars: dispatching taxi cabs
- Smart sensors: Receiving data from a sensor for data visualizations
- Health: Monitoring heart rate from a patient's wearable device
- Multiplayer gamings
- Interactive media: audience-participating voting system

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-pubnub</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

266.1. URI FORMAT

```
pubnub:channel[?options]
```

Where **channel** is the PubNub channel to publish or subscribe to.

266.2. OPTIONS

The PubNub component has no options.

The PubNub endpoint is configured using URI syntax:

```
pubnub:channel
```

with the following path and query parameters:

266.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
		t	

Name	Description	Default	Type
channel	Required The channel used for subscribing/publishing events		String

266.2.2. Query Parameters (14 parameters):

Name	Description	Default	Type
uuid (common)	UUID to be used as a device identifier, a default UUID is generated if not passed.		String
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
withPresence (consumer)	Also subscribe to related presence information	false	boolean
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern

Name	Description	Default	Type
operation (producer)	The operation to perform. PUBLISH: Default. Send a message to all subscribers of a channel. FIRE: allows the client to send a message to BLOCKS Event Handlers. These messages will go directly to any Event Handlers registered on the channel. HERENOW: Obtain information about the current state of a channel including a list of unique user-ids currently subscribed to the channel and the total occupancy count. WHERENOW: Obtain information about the current list of channels to which a uuid is subscribed to. GETSTATE: Used to get key/value pairs specific to a subscriber uuid. State information is supplied as a JSON object of key/value pairs SETSTATE: Used to set key/value pairs specific to a subscriber uuid GETHISTORY: Fetches historical messages of a channel.		String
pubnub (advanced)	Reference to a Pubnub client in the registry.		PubNub
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
authKey (security)	If Access Manager is utilized, client will use this authKey in all restricted requests.		String
cipherKey (security)	If cipher is passed, all communications to/from PubNub will be encrypted.		String
publishKey (security)	The publish key obtained from your PubNub account. Required when publishing messages.		String
secretKey (security)	The secret key used for message signing.		String
secure (security)	Use SSL for secure transmission.	true	boolean
subscribeKey (security)	The subscribe key obtained from your PubNub account. Required when subscribing to channels or listening for presence events		String

266.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.pubnub.enabled</code>	Enable pubnub component	true	Boolean
<code>camel.component.pubnub.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

266.4. MESSAGE HEADERS WHEN SUBSCRIBING

Name	Description
CamelPubNubTimeToken	The Timestamp for the event.
CamelPubNubChannel	The channel for which the message belongs.

266.5. MESSAGE BODY

The message body can contain any JSON serializable data, including: Objects, Arrays, Ints and Strings. Message data should not contain special Java V4 classes or functions as these will not serialize. String content can include any single-byte or multi-byte UTF-8

Object serialization when sending is done automatically. Just pass the full object as the message payload. PubNub will takes care of object serialization.

When receiving the message body utilize objects provided by the PubNub API.

266.6. EXAMPLES

266.6.1. Publishing events

Default operation when producing. The following snippet publish the event generated by PojoBean to the channel `iot`.

```
from("timer:mytimer")
  // generate some data as POJO.
  .bean(PojoBean.class)
  .to("pubnub:iot?publishKey=mypublishKey");
```

266.6.2. Fire events aka BLOCKS Event Handlers

See <https://www.pubnub.com/blocks-catalog/> for all kind of serverless functions that can be invoked. Example of geolocation lookup

■

```

from("timer:geotimer")
  .process(exchange -> exchange.getIn().setBody(new Foo("bar", "TEXT")))
  .to("pubnub:eon-maps-geolocation-input?
operation=fire&publishKey=mysubkey&subscribeKey=mysubkey");

from("pubnub:eon-map-geolocation-output?subscribeKey=mysubkey)
  // geolocation output will be logged here
  .log("${body}");

```

266.6.3. Subscribing to events

The following snippet listens for events on the `iot` channel. If you can add the option `withPresens`, you will also receive channel `Join`, `Leave` asf events.

```

from("pubnub:iot?subscribeKey=mySubscribeKey")
  .log("${body}")
  .to("mock:result");

```

266.6.4. Performing operations

`herenow` : Obtain information about the current state of a channel including a list of unique user-ids currently subscribed to the channel and the total occupancy count of the channel

```

from("direct:control")
  .to("pubnub:myChannel?
publishKey=mysubkey&subscribeKey=mySubscribeKey&operation=herenow")
  .to("mock:result");

```

`wherenow` : Obtain information about the current list of channels to which a `uuid` is subscribed

```

from("direct:control")
  .to("pubnub:myChannel?
publishKey=mysubkey&subscribeKey=mySubscribeKey&operation=wherenow&uuid=spyonme")
  .to("mock:result");

```

`setstate` : Used to set key/value pairs specific to a subscriber `uuid`.

```

from("direct:control")
  .bean(StateGenerator.class)
  .to("pubnub:myChannel?
publishKey=mysubkey&subscribeKey=mySubscribeKey&operation=setstate&uuid=myuuid");

```

`gethistory` : Fetches historical messages of a channel.

```

from("direct:control")
  .to("pubnub:myChannel?
publishKey=mysubkey&subscribeKey=mySubscribeKey&operation=gethistory");

```

There is a couple of examples in test directory that shows some of the PubNub features. They require a PubNub account, from where you can obtain a `publish-` and `subscribe` key.

The example `PubNubSensorExample` already contains a subscribe key provided by PubNub, so this is ready to run without a account. The example illustrates the PubNub component subscribing to a infinite stream of sensor data.

- [RSS](#)

CHAPTER 267. APACHE PULSAR COMPONENT

Available as of Camel version 2.24

Maven users will need to add the following dependency to their **pom.xml** for this component.

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-pulsar</artifactId>
  <!-- use the same version as your Camel core version -->
  <version>x.y.z</version>
</dependency>
```

267.1. URI FORMAT

```
pulsar:[persistent|non-persistent]://tenant/namespace/topic
```

267.2. OPTIONS

The Apache Pulsar component supports 3 options, which are listed below.

Name	Description	Default	Type
autoConfiguration (common)	The pulsar autoconfiguration		AutoConfiguration
pulsarClient (common)	The pulsar client		PulsarClient
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Apache Pulsar endpoint is configured using URI syntax:

```
pulsar:uri
```

with the following path and query parameters:

267.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
topicUri	The Topic's full URI path including type, tenant and namespace		String

267.2.2. Query Parameters (11 parameters):

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
consumerName (consumer)	Name of the consumer when subscription is EXCLUSIVE	sole-consumer	String
consumerNamePrefix (consumer)	Prefix to add to consumer names when a SHARED or FAILOVER subscription is used	cons	String
consumerQueueSize (consumer)	Size of the consumer queue - defaults to 10	10	int
numberOfConsumers (consumer)	Number of consumers - defaults to 1	1	int
subscriptionName (consumer)	Name of the subscription to use	subscription	String
subscriptionType (consumer)	Type of the subscription EXCLUSIVESHAREDFAILOVER, defaults to EXCLUSIVE	EXCLUSIVE	SubscriptionType
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
producerName (producer)	Name of the producer	default-producer	String

Name	Description	Default	Type
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

267.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 3 options, which are listed below.

Name	Description	Default	Type
camel.component.pulsar.enabled	Whether to enable auto configuration of the pulsar component. This is enabled by default.		Boolean
camel.component.pulsar.pulsar-client	The pulsar client. The option is a <code>org.apache.pulsar.client.api.PulsarClient</code> type.		String
camel.component.pulsar.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

CHAPTER 268. QUARTZ COMPONENT (DEPRECATED)

Available as of Camel version 1.0

The **quartz:** component provides a scheduled delivery of messages using the [Quartz Scheduler 1.x](#). Each endpoint represents a different timer (in Quartz terms, a Trigger and JobDetail).

TIP

If you are using Quartz 2.x then from Camel 2.12 onwards there is a [Quartz2](#) component you should use

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-quartz</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

268.1. URI FORMAT

```
quartz://timerName?options
quartz://groupName/timerName?options
quartz://groupName/timerName?cron=expression
quartz://timerName?cron=expression
```

The component uses either a **CronTrigger** or a **SimpleTrigger**. If no cron expression is provided, the component uses a simple trigger. If no **groupName** is provided, the quartz component uses the **Camel** group name.

You can append query options to the URI in the following format, **?option=value&option=value&...**

268.2. OPTIONS

The Quartz component supports 8 options, which are listed below.

Name	Description	Default	Type
factory (advanced)	To use the custom SchedulerFactory which is used to create the Scheduler.		SchedulerFactory
scheduler (advanced)	To use the custom configured Quartz scheduler, instead of creating a new Scheduler.		Scheduler
properties (consumer)	Properties to configure the Quartz scheduler.		Properties

Name	Description	Default	Type
propertiesFile (consumer)	File name of the properties to load from the classpath		String
startDelayedSeconds (scheduler)	Seconds to wait before starting the quartz scheduler.		int
autoStartScheduler (consumer)	Whether or not the scheduler should be auto started. This options is default true	true	boolean
enableJmx (consumer)	Whether to enable Quartz JMX which allows to manage the Quartz scheduler from JMX. This options is default true	true	boolean
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Quartz endpoint is configured using URI syntax:

```
quartz:groupName/timerName
```

with the following path and query parameters:

268.2.1. Path Parameters (2 parameters):

Name	Description	Default	Type
groupName	The quartz group name to use. The combination of group name and timer name should be unique.	Camel	String
timerName	Required The quartz timer name to use. The combination of group name and timer name should be unique.		String

268.2.2. Query Parameters (13 parameters):

Name	Description	Default	Type
------	-------------	---------	------

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
cron (consumer)	Specifies a cron expression to define when to trigger.		String
deleteJob (consumer)	If set to true, then the trigger automatically delete when route stop. Else if set to false, it will remain in scheduler. When set to false, it will also mean user may reuse pre-configured trigger with camel Uri. Just ensure the names match. Notice you cannot have both <code>deleteJob</code> and <code>pauseJob</code> set to true.	true	boolean
fireNow (consumer)	Whether to fire the scheduler asap when its started using the simple trigger (this option does not support cron)	false	boolean
pauseJob (consumer)	If set to true, then the trigger automatically pauses when route stop. Else if set to false, it will remain in scheduler. When set to false, it will also mean user may reuse pre-configured trigger with camel Uri. Just ensure the names match. Notice you cannot have both <code>deleteJob</code> and <code>pauseJob</code> set to true.	false	boolean
startDelayedSeconds (consumer)	Seconds to wait before starting the quartz scheduler.		int
stateful (consumer)	Uses a Quartz StatefulJob instead of the default job.	false	boolean
usingFixedCamelContextName (consumer)	If it is true, JobDataMap uses the CamelContext name directly to reference the CamelContext, if it is false, JobDataMap uses use the CamelContext management name which could be changed during the deploy time.	false	boolean

Name	Description	Default	Type
exceptionHandler (consumer)	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at <code>WARN</code> or <code>ERROR</code> level and ignored.		<code>ExceptionHandler</code>
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		<code>ExchangePattern</code>
jobParameters (advanced)	To configure additional options on the job.		<code>Map</code>
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	<code>false</code>	<code>boolean</code>
triggerParameters (advanced)	To configure additional options on the trigger.		<code>Map</code>

When using a [StatefulJob](#), the [JobDataMap](#) is re-persisted after every execution of the job, thus preserving state for the next execution.

INFO: Running in OSGi and having multiple bundles with quartz routes If you run in OSGi such as Apache ServiceMix, or Apache Karaf, and have multiple bundles with Camel routes that start from [Quartz](#) endpoints, then make sure if you assign an **id** to the `<camelContext>` that this id is unique, as this is required by the **QuartzScheduler** in the OSGi container. If you do not set any **id** on `<camelContext>` then a unique id is auto assigned, and there is no problem.

268.3. CONFIGURING QUARTZ.PROPERTIES FILE

By default Quartz will look for a **quartz.properties** file in the **org/quartz** directory of the classpath. If you are using WAR deployments this means just drop the `quartz.properties` in **WEB-INF/classes/org/quartz**.

However the Camel [Quartz](#) component also allows you to configure properties:

Parameter	Default	Type	Description
properties	<code>null</code>	Properties	Camel 2.4: You can configure a <code>java.util.Properties</code> instance.
propertiesFile	<code>null</code>	String	Camel 2.4: File name of the properties to load from the classpath

To do this you can configure this in Spring XML as follows

```
<bean id="quartz" class="org.apache.camel.component.quartz.QuartzComponent">
  <property name="propertiesFile" value="com/mycompany/myquartz.properties"/>
</bean>
```

268.4. ENABLING QUARTZ SCHEDULER IN JMX

You need to configure the quartz scheduler properties to enable JMX.

That is typically setting the option "**org.quartz.scheduler.jmx.export**" to a **true** value in the configuration file.

From Camel 2.13 onwards Camel will automatic set this option to true, unless explicit disabled.

268.5. STARTING THE QUARTZ SCHEDULER

This is an example:

```
<bean id="quartz" class="org.apache.camel.component.quartz.QuartzComponent">
  <property name="startDelayedSeconds" value="5"/>
</bean>
```

268.6. CLUSTERING

Available as of Camel 2.4

If you use Quartz in clustered mode, e.g. the **JobStore** is clustered. Then from Camel 2.4 onwards the **Quartz** component will **not** pause/remove triggers when a node is being stopped/shutdown. This allows the trigger to keep running on the other nodes in the cluster.

Note: When running in clustered node no checking is done to ensure unique job name/group for endpoints.

268.7. MESSAGE HEADERS

Camel adds the getters from the Quartz Execution Context as header values. The following headers are added:

calendar, **fireTime**, **jobDetail**, **jobInstance**, **jobRuntime**, **mergedJobDataMap**, **nextFireTime**, **previousFireTime**, **refireCount**, **result**, **scheduledFireTime**, **scheduler**, **trigger**, **triggerName**, **triggerGroup**.

The **fireTime** header contains the **java.util.Date** of when the exchange was fired.

268.8. USING CRON TRIGGERS

Quartz supports [Cron-like expressions](#) for specifying timers in a handy format. You can use these expressions in the **cron** URI parameter; though to preserve valid URI encoding we allow + to be used instead of spaces. Quartz provides a [little tutorial](#) on how to use cron expressions.

For example, the following will fire a message every five minutes starting at 12pm (noon) to 6pm on weekdays:

```
from("quartz://myGroup/myTimerName?cron=0+0/5+12-18+?+*+MON-FRI").to("activemq:Totally.Rocks");
```

which is equivalent to using the cron expression

```
0 0/5 12-18 ? * MON-FRI
```

The following table shows the URI character encodings we use to preserve valid URI syntax:

URI Character	Cron character
+	Space

268.9. SPECIFYING TIME ZONE

Available as of Camel 2.8.1

The Quartz Scheduler allows you to configure time zone per trigger. For example to use a timezone of your country, then you can do as follows:

```
quartz://groupName/timerName?cron=0+0/5+12-18+?+*+MON-FRI&trigger.timeZone=Europe/Stockholm
```

The `timeZone` value is the values accepted by **`java.util.TimeZone`**.

In Camel 2.8.0 or older versions you would have to provide your custom **String** to **`java.util.TimeZone`** [Type Converter](#) to be able configure this from the endpoint uri.

From Camel 2.8.1 onwards we have included such a Type Converter in the camel-core.

268.10. SEE ALSO

- [Configuring Camel](#)
- [Component](#)
- [Endpoint](#)
- [Getting Started](#)
- [Quartz2](#)
- [Timer](#)

CHAPTER 269. QUARTZ2 COMPONENT

Available as of Camel version 2.12

The **quartz2**: component provides a scheduled delivery of messages using the [Quartz Scheduler 2.x](#). Each endpoint represents a different timer (in Quartz terms, a Trigger and JobDetail).

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-quartz2</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

NOTE: Quartz 2.x API is not compatible with Quartz 1.x. If you need to remain on old Quartz 1.x, please use the old [Quartz](#) component instead.

269.1. URI FORMAT

```
quartz2://timerName?options
quartz2://groupName/timerName?options
quartz2://groupName/timerName?cron=expression
quartz2://timerName?cron=expression
```

The component uses either a **CronTrigger** or a **SimpleTrigger**. If no cron expression is provided, the component uses a simple trigger. If no **groupName** is provided, the quartz component uses the **Camel** group name.

You can append query options to the URI in the following format, **?option=value&option=value&...**

269.2. OPTIONS

The Quartz2 component supports 11 options, which are listed below.

Name	Description	Default	Type
autoStartScheduler (scheduler)	Whether or not the scheduler should be auto started. This options is default true	true	boolean
startDelayedSeconds (scheduler)	Seconds to wait before starting the quartz scheduler.		int
prefixJobNameWith EndpointId (consumer)	Whether to prefix the quartz job with the endpoint id. This option is default false.	false	boolean

Name	Description	Default	Type
enableJmx (consumer)	Whether to enable Quartz JMX which allows to manage the Quartz scheduler from JMX. This options is default true	true	boolean
properties (consumer)	Properties to configure the Quartz scheduler.		Properties
propertiesFile (consumer)	File name of the properties to load from the classpath		String
prefixInstanceName (consumer)	Whether to prefix the Quartz Scheduler instance name with the CamelContext name. This is enabled by default, to let each CamelContext use its own Quartz scheduler instance by default. You can set this option to false to reuse Quartz scheduler instances between multiple CamelContext's.	true	boolean
interruptJobsOnShutdown (scheduler)	Whether to interrupt jobs on shutdown which forces the scheduler to shutdown quicker and attempt to interrupt any running jobs. If this is enabled then any running jobs can fail due to being interrupted.	false	boolean
schedulerFactory (advanced)	To use the custom SchedulerFactory which is used to create the Scheduler.		SchedulerFactory
scheduler (advanced)	To use the custom configured Quartz scheduler, instead of creating a new Scheduler.		Scheduler
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Quartz2 endpoint is configured using URI syntax:

```
quartz2:groupName/triggerName
```

with the following path and query parameters:

269.2.1. Path Parameters (2 parameters):

Name	Description	Default	Type
groupName	The quartz group name to use. The combination of group name and timer name should be unique.	Camel	String

Name	Description	Default	Type
triggerName	Required The quartz timer name to use. The combination of group name and timer name should be unique.		String

269.2.2. Query Parameters (19 parameters):

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
cron (consumer)	Specifies a cron expression to define when to trigger.		String
deleteJob (consumer)	If set to true, then the trigger automatically delete when route stop. Else if set to false, it will remain in scheduler. When set to false, it will also mean user may reuse pre-configured trigger with camel Uri. Just ensure the names match. Notice you cannot have both <code>deleteJob</code> and <code>pauseJob</code> set to true.	true	boolean
durableJob (consumer)	Whether or not the job should remain stored after it is orphaned (no triggers point to it).	false	boolean
pauseJob (consumer)	If set to true, then the trigger automatically pauses when route stop. Else if set to false, it will remain in scheduler. When set to false, it will also mean user may reuse pre-configured trigger with camel Uri. Just ensure the names match. Notice you cannot have both <code>deleteJob</code> and <code>pauseJob</code> set to true.	false	boolean
recoverableJob (consumer)	Instructs the scheduler whether or not the job should be re-executed if a 'recovery' or 'fail-over' situation is encountered.	false	boolean
stateful (consumer)	Uses a Quartz <code>PersistJobDataAfterExecution</code> and <code>DisallowConcurrentExecution</code> instead of the default job.	false	boolean

Name	Description	Default	Type
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
customCalendar (advanced)	Specifies a custom calendar to avoid specific range of date		Calendar
jobParameters (advanced)	To configure additional options on the job.		Map
prefixJobNameWithEndpointId (advanced)	Whether the job name should be prefixed with endpoint id	false	boolean
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
triggerParameters (advanced)	To configure additional options on the trigger.		Map
usingFixedCamelContextName (advanced)	If it is true, JobDataMap uses the CamelContext name directly to reference the CamelContext, if it is false, JobDataMap uses use the CamelContext management name which could be changed during the deploy time.	false	boolean
autoStartScheduler (scheduler)	Whether or not the scheduler should be auto started.	true	boolean
fireNow (scheduler)	If it is true will fire the trigger when the route is start when using SimpleTrigger.	false	boolean
startDelayedSeconds (scheduler)	Seconds to wait before starting the quartz scheduler.		int
triggerStartDelay (scheduler)	In case of scheduler has already started, we want the trigger start slightly after current time to ensure endpoint is fully started before the job kicks in.	500	long

269.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 12 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.quartz2.auto-start-scheduler</code>	Whether or not the scheduler should be auto started. This options is default true	true	Boolean
<code>camel.component.quartz2.enable-jmx</code>	Whether to enable Quartz JMX which allows to manage the Quartz scheduler from JMX. This options is default true	true	Boolean
<code>camel.component.quartz2.enabled</code>	Enable quartz2 component	true	Boolean
<code>camel.component.quartz2.interrupt-jobs-on-shutdown</code>	Whether to interrupt jobs on shutdown which forces the scheduler to shutdown quicker and attempt to interrupt any running jobs. If this is enabled then any running jobs can fail due to being interrupted.	false	Boolean
<code>camel.component.quartz2.prefix-instance-name</code>	Whether to prefix the Quartz Scheduler instance name with the CamelContext name. This is enabled by default, to let each CamelContext use its own Quartz scheduler instance by default. You can set this option to false to reuse Quartz scheduler instances between multiple CamelContext's.	true	Boolean
<code>camel.component.quartz2.prefix-job-name-with-endpoint-id</code>	Whether to prefix the quartz job with the endpoint id. This option is default false.	false	Boolean
<code>camel.component.quartz2.properties</code>	Properties to configure the Quartz scheduler. The option is a java.util.Properties type.		String
<code>camel.component.quartz2.properties-file</code>	File name of the properties to load from the classpath		String
<code>camel.component.quartz2.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.component.quartz2.scheduler</code>	To use the custom configured Quartz scheduler, instead of creating a new Scheduler. The option is a org.quartz.Scheduler type.		String

Name	Description	Default	Type
<code>camel.component.quartz2.scheduler-factory</code>	To use the custom SchedulerFactory which is used to create the Scheduler. The option is a <code>org.quartz.SchedulerFactory</code> type.		String
<code>camel.component.quartz2.start-delayed-seconds</code>	Seconds to wait before starting the quartz scheduler.		Integer

For example, the following routing rule will fire two timer events to the **mock:results** endpoint:

```
from("quartz2://myGroup/myTimerName?
trigger.repeatInterval=2&trigger.repeatCount=1").routeId("myRoute")
.to("mock:result");
```

When using **stateful=true**, the [JobDataMap](#) is re-persisted after every execution of the job, thus preserving state for the next execution.

INFO: **Running in OSGi and having multiple bundles with quartz routes** If you run in OSGi such as Apache ServiceMix, or Apache Karaf, and have multiple bundles with Camel routes that start from [Quartz2](#) endpoints, then make sure if you assign an **id** to the `<camelContext>` that this id is unique, as this is required by the **QuartzScheduler** in the OSGi container. If you do not set any **id** on `<camelContext>` then a unique id is auto assigned, and there is no problem.

269.4. CONFIGURING QUARTZ.PROPERTIES FILE

By default Quartz will look for a **quartz.properties** file in the **org/quartz** directory of the classpath. If you are using WAR deployments this means just drop the quartz.properties in **WEB-INF/classes/org/quartz**.

However the Camel [Quartz2](#) component also allows you to configure properties:

Parameter	Default	Type	Description
properties	null	Properties	You can configure a java.util.Properties instance.
propertiesFile	null	String	File name of the properties to load from the classpath

To do this you can configure this in Spring XML as follows

```
<bean id="quartz2" class="org.apache.camel.component.quartz2.QuartzComponent">
  <property name="propertiesFile" value="com/mycompany/myquartz.properties"/>
</bean>
```

269.5. ENABLING QUARTZ SCHEDULER IN JMX

You need to configure the quartz scheduler properties to enable JMX.

That is typically setting the option "**org.quartz.scheduler.jmx.export**" to a **true** value in the configuration file.

From Camel 2.13 onwards Camel will automatic set this option to true, unless explicit disabled.

269.6. STARTING THE QUARTZ SCHEDULER

The [Quartz2](#) component offers an option to let the Quartz scheduler be started delayed, or not auto started at all.

This is an example:

```
<bean id="quartz2" class="org.apache.camel.component.quartz2.QuartzComponent">
  <property name="startDelayedSeconds" value="5"/>
</bean>
```

269.7. CLUSTERING

If you use Quartz in clustered mode, e.g. the **JobStore** is clustered. Then the [Quartz2](#) component will **not** pause/remove triggers when a node is being stopped/shutdown. This allows the trigger to keep running on the other nodes in the cluster.

Note: When running in clustered node no checking is done to ensure unique job name/group for endpoints.

269.8. MESSAGE HEADERS

Camel adds the getters from the Quartz Execution Context as header values. The following headers are added:

calendar, **fireTime**, **jobDetail**, **jobInstance**, **jobRunTime**, **mergedJobDataMap**, **nextFireTime**, **previousFireTime**, **refireCount**, **result**, **scheduledFireTime**, **scheduler**, **trigger**, **triggerName**, **triggerGroup**.

The **fireTime** header contains the **java.util.Date** of when the exchange was fired.

269.9. USING CRON TRIGGERS

Quartz supports [Cron-like expressions](#) for specifying timers in a handy format. You can use these expressions in the **cron** URI parameter; though to preserve valid URI encoding we allow + to be used instead of spaces.

For example, the following will fire a message every five minutes starting at 12pm (noon) to 6pm on weekdays:

```
from("quartz2://myGroup/myTimerName?cron=0+0/5+12-18+?+*+MON-FRI")
  .to("activemq:Totally.Rocks");
```

which is equivalent to using the cron expression

```
0 0/5 12-18 ? * MON-FRI
```

The following table shows the URI character encodings we use to preserve valid URI syntax:

URI Character	Cron character
+	Space

269.10. SPECIFYING TIME ZONE

The Quartz Scheduler allows you to configure time zone per trigger. For example to use a timezone of your country, then you can do as follows:

```
quartz2://groupName/timerName?cron=0+0/5+12-18+?+*+MON-FRI&trigger.timeZone=Europe/Stockholm
```

The `timeZone` value is the values accepted by `java.util.TimeZone`.

269.11. USING QUARTZSCHEDULEDPOLLCONSUMERSCHEDULER

The [Quartz2](#) component provides a Polling Consumer scheduler which allows to use cron based scheduling for [Polling Consumer](#) such as the File and FTP consumers.

For example to use a cron based expression to poll for files every 2nd second, then a Camel route can be define simply as:

```
from("file:inbox?scheduler=quartz2&scheduler.cron=0/2+*+*+*+*+*+*+*")
.to("bean:process");
```

Notice we define the `scheduler=quartz2` to instruct Camel to use the [Quartz2](#) based scheduler. Then we use `scheduler.xxx` options to configure the scheduler. The [Quartz2](#) scheduler requires the `cron` option to be set.

The following options is supported:

Param eter	Default	Type	Description
quartz Scheduler	null	org.quartz.Scheduler	To use a custom Quartz scheduler. If none configure then the shared scheduler from the Quartz2 component is used.
cron	null	String	Mandatory: To define the cron expression for triggering the polls.
triggerId	null	String	To specify the trigger id. If none provided then an UUID is generated and used.

Parameter	Default	Type	Description
triggerGroup	QuartzScheduledPolliconsumerScheduler	String	To specify the trigger group.
timeZone	Default	TimeZone	The time zone to use for the CRON trigger.

Important: Remember configuring these options from the endpoint URIs must be prefixed with **scheduler..** For example to configure the trigger id and group:

```
from("file:inbox?scheduler=quartz2&scheduler.cron=0/2+*+*+*+*+?
&scheduler.triggerId=myId&scheduler.triggerGroup=myGroup")
.to("bean:process");
```

There is also a CRON scheduler in Spring, so you can use the following as well:

```
from("file:inbox?scheduler=spring&scheduler.cron=0/2+*+*+*+*+?")
.to("bean:process");
```

CHAPTER 270. QUICKFIX COMPONENT

Available as of Camel version 2.1

The **quickfix** component adapts the [QuickFIX/J](#) FIX engine for using in Camel . This component uses the standard [Financial Interchange \(FIX\) protocol](#) for message transport.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-quickfix</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

270.1. URI FORMAT

```
quickfix:configFile[?sessionId=sessionID&lazyCreateEngine=true|false]
```

The **configFile** is the name of the QuickFIX/J configuration to use for the FIX engine (located as a resource found in your classpath). The optional **sessionId** identifies a specific FIX session. The format of the **sessionId** is:

```
(BeginString):(SenderCompID)[/(SenderSubID)[/(SenderLocationID)]]->(TargetCompID)
[/((TargetSubID)[/(TargetLocationID)]]]
```

The optional **lazyCreateEngine** (Camel 2.12.3+) parameter allows to create QuickFIX/J engine on demand. Value **true** means the engine is started when first message is send or there's consumer configured in route definition. When **false** value is used, the engine is started at the endpoint creation. When this parameter is missing, the value of component's property **lazyCreateEngines** is being used.

Example URIs:

```
quickfix:config.cfg
```

```
quickfix:config.cfg?sessionId=FIX.4.2:MyTradingCompany->SomeExchange
```

```
quickfix:config.cfg?sessionId=FIX.4.2:MyTradingCompany->SomeExchange&lazyCreateEngine=true
```

270.2. ENDPOINTS

FIX sessions are endpoints for the **quickfix** component. An endpoint URI may specify a single session or all sessions managed by a specific QuickFIX/J engine. Typical applications will use only one FIX engine but advanced users may create multiple FIX engines by referencing different configuration files in **quickfix** component endpoint URIs.

When a consumer does not include a session ID in the endpoint URI, it will receive exchanges for all sessions managed by the FIX engine associated with the configuration file specified in the URI. If a producer does not specify a session in the endpoint URI then it must include the session-related fields in the FIX message being sent. If a session is specified in the URI then the component will automatically inject the session-related fields into the FIX message.

270.3. OPTIONS

The QuickFix component supports 6 options, which are listed below.

Name	Description	Default	Type
messageFactory (advanced)	To use the given MessageFactory		MessageFactory
logFactory (advanced)	To use the given LogFactory		LogFactory
messageStoreFactory (advanced)	To use the given MessageStoreFactory		MessageStoreFactory
configurations (common)	To use the given map of pre configured QuickFix configurations mapped to the key		Map
lazyCreateEngines (common)	If set to true, the engines will be created and started when needed (when first message is send)	false	boolean
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The QuickFix endpoint is configured using URI syntax:

```
quickfix:configurationName
```

with the following path and query parameters:

270.3.1. Path Parameters (1 parameters):

Name	Description	Default	Type
configurationName	Required The configFile is the name of the QuickFIX/J configuration to use for the FIX engine (located as a resource found in your classpath).		String

270.3.2. Query Parameters (6 parameters):

Name	Description	Default	Type
lazyCreateEngine (common)	This option allows to create QuickFIX/J engine on demand. Value true means the engine is started when first message is send or there's consumer configured in route definition. When false value is used, the engine is started at the endpoint creation. When this parameter is missing, the value of component's property lazyCreateEngines is being used.	false	boolean
sessionID (common)	The optional sessionID identifies a specific FIX session. The format of the sessionID is: (BeginString): (SenderCompID)/(SenderSubID)/(SenderLocationID)- (TargetCompID)/(TargetSubID)/(TargetLocationID)		SessionID
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

270.4. SPRING BOOT AUTO-CONFIGURATION

The component supports 7 options, which are listed below.

Name	Description	Default	Type
------	-------------	---------	------

Name	Description	Default	Type
<code>camel.component.quickfix.configurations</code>	To use the given map of pre configured QuickFix configurations mapped to the key		Map
<code>camel.component.quickfix.enabled</code>	Enable quickfix component	true	Boolean
<code>camel.component.quickfix.lazy-create-engines</code>	If set to true, the engines will be created and started when needed (when first message is send)	false	Boolean
<code>camel.component.quickfix.log-factory</code>	To use the given LogFactory. The option is a quickfix.LogFactory type.		String
<code>camel.component.quickfix.message-factory</code>	To use the given MessageFactory. The option is a quickfix.MessageFactory type.		String
<code>camel.component.quickfix.message-store-factory</code>	To use the given MessageStoreFactory. The option is a quickfix.MessageStoreFactory type.		String
<code>camel.component.quickfix.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

270.5. EXCHANGE FORMAT

The exchange headers include information to help with exchange filtering, routing and other processing. The following headers are available:

Header Name	Description
EventCategory	One of AppMessageReceived , AppMessageSent , AdminMessageReceived , AdminMessageSent , SessionCreated , SessionLogon , SessionLogoff . See the QuickfixjEventCategory enum.
SessionID	The FIX message SessionID
MessageType	The FIX MsgType tag value

Header Name	Description
DataDictionary	Specifies a data dictionary to used for parsing an incoming message. Can be an instance of a data dictionary or a resource path for a QuickFIX/J data dictionary file

The DataDictionary header is useful if string messages are being received and need to be parsed in a route. QuickFIX/J requires a data dictionary to parse certain types of messages (with repeating groups, for example). By injecting a DataDictionary header in the route after receiving a message string, the FIX engine can properly parse the data.

270.6. QUICKFIX/J CONFIGURATION EXTENSIONS

When using QuickFIX/J directly, one typically writes code to create instances of logging adapters, message stores and communication connectors. The **quickfix** component will automatically create instances of these classes based on information in the configuration file. It also provides defaults for many of the common required settings and adds additional capabilities (like the ability to activate JMX support).

The following sections describe how the **quickfix** component processes the QuickFIX/J configuration. For comprehensive information about QuickFIX/J configuration, see the [QFJ user manual](#).

270.6.1. Communication Connectors

When the component detects an initiator or acceptor session setting in the QuickFIX/J configuration file it will automatically create the corresponding initiator and/or acceptor connector. These settings can be in the default or in a specific session section of the configuration file.

Session Setting	Component Action
ConnectionType=initiator	Create an initiator connector
ConnectionType=acceptor	Create an acceptor connector

The threading model for the QuickFIX/J session connectors can also be specified. These settings affect all sessions in the configuration file and must be placed in the settings default section.

Default/Global Setting	Component Action
ThreadModel=ThreadPeerConnector	Use SocketInitiator or SocketAcceptor (default)
ThreadModel=ThreadPeerSession	Use ThreadedSocketInitiator or ThreadedSocketAcceptor

270.6.2. Logging

The QuickFIX/J logger implementation can be specified by including the following settings in the default section of the configuration file. The **ScreenLog** is the default if none of the following settings are present in the configuration. It's an error to include settings that imply more than one log implementation. The log factory implementation can also be set directly on the Quickfix component. This will override any related values in the QuickFIX/J settings file.

Default/Global Setting	Component Action
ScreenLogShowEvents	Use a ScreenLog
ScreenLogShowIncoming	Use a ScreenLog
ScreenLogShowOutgoing	Use a ScreenLog

Default/Global Setting	Component Action
SLF4J*	Camel 2.6+. Use a SLF4JLog . Any of the SLF4J settings will cause this log to be used.
FileLogPath	Use a FileLog
JdbcDriver	Use a JdbcLog

270.6.3. Message Store

The QuickFIX/J message store implementation can be specified by including the following settings in the default section of the configuration file. The **MemoryStore** is the default if none of the following settings are present in the configuration. It's an error to include settings that imply more than one message store implementation. The message store factory implementation can also be set directly on the Quickfix component. This will override any related values in the QuickFIX/J settings file.

Default/Global Setting	Component Action
JdbcDriver	Use a JdbcStore
FileStorePath	Use a FileStore
SleepycatDatabaseDir	Use a SleepcatStore

270.6.4. Message Factory

A message factory is used to construct domain objects from raw FIX messages. The default message factory is **DefaultMessageFactory**. However, advanced applications may require a custom message factory. This can be set on the QuickFIX/J component.

270.6.5. JMX

Default t/Glob al Settin g	Component Action
UseJ mx	if Y , then enable QuickFIX/J JMX

270.6.6. Other Defaults

The component provides some default settings for what are normally required settings in QuickFIX/J configuration files. **SessionStartTime** and **SessionEndTime** default to "00:00:00", meaning the session will not be automatically started and stopped. The **HeartBtInt** (heartbeat interval) defaults to 30 seconds.

270.6.7. Minimal Initiator Configuration Example

```
[SESSION]
ConnectionType=initiator
BeginString=FIX.4.4
SenderCompID=YOUR_SENDER
TargetCompID=YOUR_TARGET
```

270.7. USING THE INOUT MESSAGE EXCHANGE PATTERN

Camel 2.8+

Although the FIX protocol is event-driven and asynchronous, there are specific pairs of messages that represent a request-reply message exchange. To use an InOut exchange pattern, there should be a single request message and single reply message to the request. Examples include an OrderStatusRequest message and UserRequest.

270.7.1. Implementing InOut Exchanges for Consumers

Add "exchangePattern=InOut" to the QuickFIX/J endpoint URI. The **MessageOrderStatusService** in the example below is a bean with a synchronous service method. The method returns the response to the request (an ExecutionReport in this case) which is then sent back to the requestor session.

```
from("quickfix:examples/inprocess.cfg?sessionID=FIX.4.2:MARKET-
>TRADER&exchangePattern=InOut")

.filter(header(QuickfixjEndpoint.MESSAGE_TYPE_KEY).isEqualTo(MsgType.ORDER_STATUS_REQ
UEST))
.bean(new MarketOrderStatusService());
```

270.7.2. Implementing InOut Exchanges for Producers

For producers, sending a message will block until a reply is received or a timeout occurs. There is no standard way to correlate reply messages in FIX. Therefore, a correlation criteria must be defined for each type of InOut exchange. The correlation criteria and timeout can be specified using **Exchange**

properties.

Description	Key String	Key Constant	Default
Correlation Criteria	"CorrelationCriteria"	QuickfixjProducer.CORRELATION_CRITERIA_KEY	None
Correlation Timeout in Milliseconds	"CorrelationTimeout"	QuickfixjProducer.CORRELATION_TIMEOUT_KEY	1000

The correlation criteria is defined with a **MessagePredicate** object. The following example will treat a FIX ExecutionReport from the specified session where the transaction type is STATUS and the Order ID matches our request. The session ID should be for the *requestor*, the sender and target CompID fields will be reversed when looking for the reply.

```
exchange.setProperty(QuickfixjProducer.CORRELATION_CRITERIA_KEY,
    new MessagePredicate(new SessionID(sessionID), MsgType.EXECUTION_REPORT)
        .withField(ExecTransType.FIELD, Integer.toString(ExecTransType.STATUS))
        .withField(OrderID.FIELD, request.getString(OrderID.FIELD)));
```

270.7.3. Example

The source code contains an example called **RequestReplyExample** that demonstrates the InOut exchanges for a consumer and producer. This example creates a simple HTTP server endpoint that accepts order status requests. The HTTP request is converted to a FIX OrderStatusRequestMessage, is augmented with a correlation criteria, and is then routed to a quickfix endpoint. The response is then converted to a JSON-formatted string and sent back to the HTTP server endpoint to be provided as the web response.

The Spring configuration have changed from Camel 2.9 onwards. See further below for example.

270.8. SPRING CONFIGURATION

Camel 2.6 - 2.8.x

The QuickFIX/J component includes a Spring **FactoryBean** for configuring the session settings within a Spring context. A type converter for QuickFIX/J session ID strings is also included. The following example shows a simple configuration of an acceptor and initiator session with default settings for both sessions.

```
<!-- camel route -->
<camelContext xmlns="http://camel.apache.org/schema/spring" id="quickfixjContext">
  <route>
    <from uri="quickfix:example"/>
    <filter>
      <simple>${in.header.EventCategory} == 'AppMessageReceived'</simple>
      <to uri="log:test"/>
    </filter>
  </route>
```

```

</camelContext>
  <!-- quickfix component -->
<bean id="quickfix" class="org.apache.camel.component.quickfixj.QuickfixjComponent">
<property name="engineSettings">
  <util:map>
    <entry key="quickfix:example" value-ref="quickfixjSettings"/>
  </util:map>
</property>
<property name="messageFactory">
  <bean
class="org.apache.camel.component.quickfixj.QuickfixjSpringTest.CustomMessageFactory"/>
</property>
</bean>
  <!-- quickfix settings -->
<bean id="quickfixjSettings" class="org.apache.camel.component.quickfixj.QuickfixjSettingsFactory">
<property name="defaultSettings">
  <util:map>
    <entry key="SocketConnectProtocol" value="VM_PIPE"/>
    <entry key="SocketAcceptProtocol" value="VM_PIPE"/>
    <entry key="UseDataDictionary" value="N"/>
  </util:map>
</property>
<property name="sessionSettings">
  <util:map>
    <entry key="FIX.4.2:INITIATOR->ACCEPTOR">
      <util:map>
        <entry key="ConnectionType" value="initiator"/>
        <entry key="SocketConnectHost" value="localhost"/>
        <entry key="SocketConnectPort" value="5000"/>
      </util:map>
    </entry>
    <entry key="FIX.4.2:ACCEPTOR->INITIATOR">
      <util:map>
        <entry key="ConnectionType" value="acceptor"/>
        <entry key="SocketAcceptPort" value="5000"/>
      </util:map>
    </entry>
  </util:map>
</property>
</bean>

```

Camel 2.9 onwards

The QuickFIX/J component includes a **QuickfixjConfiguration** class for configuring the session settings. A type converter for QuickFIX/J session ID strings is also included. The following example shows a simple configuration of an acceptor and initiator session with default settings for both sessions.

```

<!-- camel route -->
<camelContext id="quickfixjContext" xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="quickfix:example"/>
    <filter>
      <simple>${in.header.EventCategory} == 'AppMessageReceived'</simple>
      <to uri="log:test"/>
    </filter>
  </route>

```

```

<route>
  <from uri="vm:test"/>
  <to uri="lazyQuickfix:example"/>
</route>
</camelContext>

<!-- quickfix component -->
<bean id="quickfix" class="org.apache.camel.component.quickfixj.QuickfixjComponent">

        </util:map>
      </entry>
    </util:map>
  </property>
</bean>

```

```

        </util:map>
    </entry>
</util:map>
</property>
</bean>

```

270.9. EXCEPTION HANDLING

QuickFIX/J behavior can be modified if certain exceptions are thrown during processing of a message. If a **RejectLogon** exception is thrown while processing an incoming logon administrative message, then the logon will be rejected.

Normally, QuickFIX/J handles the logon process automatically. However, sometimes an outgoing logon message must be modified to include credentials required by a FIX counterparty. If the FIX logon message body is modified when sending a logon message (EventCategory=**AdminMessageSent** the modified message will be sent to the counterparty. It is important that the outgoing logon message is being processed *synchronously*. If it is processed asynchronously (on another thread), the FIX engine will immediately send the unmodified outgoing message when it's callback method returns.

270.10. FIX SEQUENCE NUMBER MANAGEMENT

If an application exception is thrown during *synchronous* exchange processing, this will cause QuickFIX/J to not increment incoming FIX message sequence numbers and will cause a resend of the counterparty message. This FIX protocol behavior is primarily intended to handle *transport* errors rather than application errors. There are risks associated with using this mechanism to handle application errors. The primary risk is that the message will repeatedly cause application errors each time it's re-received. A better solution is to persist the incoming message (database, JMS queue) immediately before processing it. This also allows the application to process messages asynchronously without losing messages when errors occur.

Although it's possible to send messages to a FIX session before it's logged on (the messages will be sent at logon time), it is usually a better practice to wait until the session is logged on. This eliminates the required sequence number resynchronization steps at logon. Waiting for session logon can be done by setting up a route that processes the **SessionLogon** event category and signals the application to start sending messages.

See the FIX protocol specifications and the QuickFIX/J documentation for more details about FIX sequence number management.

270.11. ROUTE EXAMPLES

Several examples are included in the QuickFIX/J component source code (test subdirectories). One of these examples implements a trival trade execution simulation. The example defines an application component that uses the URI scheme "trade-executor".

The following route receives messages for the trade executor session and passes application messages to the trade executor component.

```

from("quickfix:examples/inprocess.cfg?sessionID=FIX.4.2:MARKET->TRADER").
filter(header(QuickfixjEndpoint.EVENT_CATEGORY_KEY).isEqualTo(QuickfixjEventCategory.AppMessageReceived)).
to("trade-executor:market");

```

The trade executor component generates messages that are routed back to the trade session. The session ID must be set in the FIX message itself since no session ID is specified in the endpoint URI.

```
from("trade-executor:market").to("quickfix:examples/inprocess.cfg");
```

The trader session consumes execution report messages from the market and processes them.

```
from("quickfix:examples/inprocess.cfg?sessionID=FIX.4.2:TRADER->MARKET").
filter(header(QuickfixjEndpoint.MESSAGE_TYPE_KEY).isEqualTo(MsgType.EXECUTION_REPORT)).
bean(new MyTradeExecutionProcessor());
```

270.12. QUICKFIX/J COMPONENT PRIOR TO CAMEL 2.5

The **quickfix** component is an implementation of the [QuickFIX/J](#) engine for Java . This engine allows to connect to a FIX server which is used to exchange financial messages according to [FIX protocol](#) standard.

Note: The component can be used to send/receives messages to a FIX server.

270.13. URI FORMAT

```
quickfix-server:config file
quickfix-client:config file
```

Where **config file** is the location (in your classpath) of the quickfix configuration file used to configure the engine at the startup.

Note: Information about parameters available for quickfix can be found on [QuickFIX/J](#) web site.

The quickfix-server endpoint must be used to receive from FIX server FIX messages and quickfix-client endpoint in the case that you want to send messages to a FIX gateway.

270.14. EXCHANGE DATA FORMAT

The QuickFIX/J engine is like CXF component a messaging bus using MINA as protocol layer to create the socket connection with the FIX engine gateway.

When QuickFIX/J engine receives a message, then it create a QuickFix.Message instance which is next received by the camel endpoint. This object is a 'mapping object' created from a FIX message formatted initially as a collection of key value pairs data. You can use this object or you can use the method 'toString' to retrieve the original FIX message.

Note: Alternatively, you can use [camel bindy dataformat](#) to transform the FIX message into your own java POJO

When a message must be send to QuickFix, then you must create a QuickFix.Message instance.

270.15. LAZY CREATING ENGINES

From **Camel 2.12.3** onwards, you can configure the QuickFixComponent to lazy create and start the engines, which then only start these on-demand. For example you can use this when you have multiple Camel applications in a cluster with master/slaves. And want the slaves to be standby.

270.16. SAMPLES

Direction : to FIX gateway

```
<route>
  <from uri="activemq:queue:fix"/>
  <bean ref="fixService" method="createFixMessage"/> // bean method in charge to transform
message into a QuickFix.Message
  <to uri="quickfix-client:META-INF/quickfix/client.cfg"/> // Quickfix engine who will send the FIX
messages to the gateway
</route>
```

Direction : from FIX gateway

```
<route>
  <from uri="quickfix-server:META-INF/quickfix/server.cfg"/> // QuickFix engine who will receive the
message from FIX gateway
  <bean ref="fixService" method="parseFixMessage"/> // bean method parsing the QuickFix.Message
  <to uri="uri="activemq:queue:fix"/>"
</route>
```

270.17. SEE ALSO

- [Configuring Camel](#)
- [Component](#)
- [Endpoint](#)
- [Getting Started](#)

CHAPTER 271. RABBITMQ COMPONENT

Available as of Camel version 2.12

The `rabbitmq` component allows you produce and consume messages from [RabbitMQ](#) instances. Using the RabbitMQ AMQP client, this component offers a pure RabbitMQ approach over the generic [AMQP](#) component.

Maven users will need to add the following dependency to their `pom.xml` for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-rabbitmq</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

271.1. URI FORMAT

The old syntax is **deprecated**:

```
rabbitmq://hostname[:port]/exchangeName?[options]
```

Instead the hostname and port is configured on the component level, or can be provided as uri query parameters instead.

The new syntax is:

```
rabbitmq:exchangeName?[options]
```

Where **hostname** is the hostname of the running rabbitmq instance or cluster. Port is optional and if not specified then defaults to the RabbitMQ client default (5672). The exchange name determines which exchange produced messages will sent to. In the case of consumers, the exchange name determines which exchange the queue will bind to.

271.2. OPTIONS

The RabbitMQ component supports 50 options, which are listed below.

Name	Description	Default	Type
hostname (common)	The hostname of the running RabbitMQ instance or cluster.		String
portNumber (common)	Port number for the host with the running rabbitmq instance or cluster.	5672	int
username (security)	Username in case of authenticated access	guest	String

Name	Description	Default	Type
password (security)	Password for authenticated access	guest	String
vhost (common)	The vhost for the channel	/	String
addresses (common)	If this option is set, camel-rabbitmq will try to create connection based on the setting of option addresses. The addresses value is a string which looks like server1:12345, server2:12345		String
connectionFactory (common)	To use a custom RabbitMQ connection factory. When this option is set, all connection options (connectionTimeout, requestedChannelMax...) set on URI are not used		ConnectionFactory
threadPoolSize (consumer)	The consumer uses a Thread Pool Executor with a fixed number of threads. This setting allows you to set that number of threads.	10	int
autoDetectConnectionFactory (advanced)	Whether to auto-detect looking up RabbitMQ connection factory from the registry. When enabled and a single instance of the connection factory is found then it will be used. An explicit connection factory can be configured on the component or endpoint level which takes precedence.	true	boolean
connectionTimeout (advanced)	Connection timeout	60000	int
requestedChannelMax (advanced)	Connection requested channel max (max number of channels offered)	2047	int
requestedFrameMax (advanced)	Connection requested frame max (max size of frame offered)	0	int
requestedHeartbeat (advanced)	Connection requested heartbeat (heart-beat in seconds offered)	60	int
automaticRecoveryEnabled (advanced)	Enables connection automatic recovery (uses connection implementation that performs automatic recovery when connection shutdown is not initiated by the application)		Boolean
networkRecoveryInterval (advanced)	Network recovery interval in milliseconds (interval used when recovering from network failure)	5000	Integer

Name	Description	Default	Type
topologyRecoveryEnabled (advanced)	Enables connection topology recovery (should topology recovery be performed)		Boolean
prefetchEnabled (consumer)	Enables the quality of service on the RabbitMQConsumer side. You need to specify the option of prefetchSize, prefetchCount, prefetchGlobal at the same time	false	boolean
prefetchSize (consumer)	The maximum amount of content (measured in octets) that the server will deliver, 0 if unlimited. You need to specify the option of prefetchSize, prefetchCount, prefetchGlobal at the same time		int
prefetchCount (consumer)	The maximum number of messages that the server will deliver, 0 if unlimited. You need to specify the option of prefetchSize, prefetchCount, prefetchGlobal at the same time		int
prefetchGlobal (consumer)	If the settings should be applied to the entire channel rather than each consumer You need to specify the option of prefetchSize, prefetchCount, prefetchGlobal at the same time	false	boolean
channelPoolMaxSize (producer)	Get maximum number of opened channel in pool	10	int
channelPoolMaxWait (producer)	Set the maximum number of milliseconds to wait for a channel from the pool	1000	long
requestTimeout (advanced)	Set timeout for waiting for a reply when using the InOut Exchange Pattern (in milliseconds)	20000	long
requestTimeoutCheckerInterval (advanced)	Set requestTimeoutCheckerInterval for inOut exchange	1000	long
transferException (advanced)	When true and an inOut Exchange failed on the consumer side send the caused Exception back in the response	false	boolean
publisherAcknowledgements (producer)	When true, the message will be published with publisher acknowledgements turned on	false	boolean

Name	Description	Default	Type
publisherAcknowledgementsTimeout (producer)	The amount of time in milliseconds to wait for a basic.ack response from RabbitMQ server		long
guaranteedDeliveries (producer)	When true, an exception will be thrown when the message cannot be delivered (basic.return) and the message is marked as mandatory. PublisherAcknowledgement will also be activated in this case. See also publisher acknowledgements - When will messages be confirmed.	false	boolean
mandatory (producer)	This flag tells the server how to react if the message cannot be routed to a queue. If this flag is set, the server will return an unroutable message with a Return method. If this flag is zero, the server silently drops the message. If the header is present rabbitmq.MANDATORY it will override this option.	false	boolean
immediate (producer)	This flag tells the server how to react if the message cannot be routed to a queue consumer immediately. If this flag is set, the server will return an undeliverable message with a Return method. If this flag is zero, the server will queue the message, but with no guarantee that it will ever be consumed. If the header is present rabbitmq.IMMEDIATE it will override this option.	false	boolean
args (advanced)	Specify arguments for configuring the different RabbitMQ concepts, a different prefix is required for each: Exchange: arg.exchange. Queue: arg.queue. Binding: arg.binding. For example to declare a queue with message ttl argument: http://localhost:5672/exchange/queueargs=arg.queue.x-message-ttl=60000		Map
clientProperties (advanced)	Connection client properties (client info used in negotiating with the server)		Map
sslProtocol (security)	Enables SSL on connection, accepted value are true, TLS and 'SSLv3		String
trustManager (security)	Configure SSL trust manager, SSL should be enabled for this option to be effective		TrustManager
autoAck (consumer)	If messages should be auto acknowledged	true	boolean

Name	Description	Default	Type
autoDelete (common)	If it is true, the exchange will be deleted when it is no longer in use	true	boolean
 durable (common)	If we are declaring a durable exchange (the exchange will survive a server restart)	true	boolean
exclusive (common)	Exclusive queues may only be accessed by the current connection, and are deleted when that connection closes.	false	boolean
exclusiveConsumer (consumer)	Request exclusive access to the queue (meaning only this consumer can access the queue). This is useful when you want a long-lived shared queue to be temporarily accessible by just one consumer.	false	boolean
passive (common)	Passive queues depend on the queue already to be available at RabbitMQ.	false	boolean
skipQueueDeclare (common)	If true the producer will not declare and bind a queue. This can be used for directing messages via an existing routing key.	false	boolean
skipQueueBind (common)	If true the queue will not be bound to the exchange after declaring it	false	boolean
skipExchangeDeclare (common)	This can be used if we need to declare the queue but not the exchange	false	boolean
declare (common)	If the option is true, camel declare the exchange and queue name and bind them together. If the option is false, camel won't declare the exchange and queue name on the server.	true	boolean
deadLetterExchange (common)	The name of the dead letter exchange		String
deadLetterQueue (common)	The name of the dead letter queue		String
deadLetterRoutingKey (common)	The routing key for the dead letter exchange		String
deadLetterExchangeType (common)	The type of the dead letter exchange	direct	String

Name	Description	Default	Type
allowNullHeaders (producer)	Allow pass null values to header	false	boolean
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The RabbitMQ endpoint is configured using URI syntax:

```
rabbitmq:exchangeName
```

with the following path and query parameters:

271.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
exchangeName	Required The exchange name determines which exchange produced messages will sent to. In the case of consumers, the exchange name determines which exchange the queue will bind to.		String

271.2.2. Query Parameters (62 parameters):

Name	Description	Default	Type
addresses (common)	If this option is set, camel-rabbitmq will try to create connection based on the setting of option addresses. The addresses value is a string which looks like server1:12345, server2:12345		Address[]
autoDelete (common)	If it is true, the exchange will be deleted when it is no longer in use	true	boolean
connectionFactory (common)	To use a custom RabbitMQ connection factory. When this option is set, all connection options (connectionTimeout, requestedChannelMax...) set on URI are not used		ConnectionFactory
deadLetterExchange (common)	The name of the dead letter exchange		String

Name	Description	Default	Type
deadLetterExchangeType (common)	The type of the dead letter exchange	direct	String
deadLetterQueue (common)	The name of the dead letter queue		String
deadLetterRoutingKey (common)	The routing key for the dead letter exchange		String
declare (common)	If the option is true, camel declare the exchange and queue name and bind them together. If the option is false, camel won't declare the exchange and queue name on the server.	true	boolean
durable (common)	If we are declaring a durable exchange (the exchange will survive a server restart)	true	boolean
exchangeType (common)	The exchange type such as direct or topic.	direct	String
exclusive (common)	Exclusive queues may only be accessed by the current connection, and are deleted when that connection closes.	false	boolean
hostname (common)	The hostname of the running rabbitmq instance or cluster.		String
passive (common)	Passive queues depend on the queue already to be available at RabbitMQ.	false	boolean
portNumber (common)	Port number for the host with the running rabbitmq instance or cluster. Default value is 5672.		int
queue (common)	The queue to receive messages from		String
routingKey (common)	The routing key to use when binding a consumer queue to the exchange. For producer routing keys, you set the header rabbitmq.ROUTING_KEY.		String
skipExchangeDeclare (common)	This can be used if we need to declare the queue but not the exchange	false	boolean
skipQueueBind (common)	If true the queue will not be bound to the exchange after declaring it	false	boolean

Name	Description	Default	Type
skipQueueDeclare (common)	If true the producer will not declare and bind a queue. This can be used for directing messages via an existing routing key.	false	boolean
vhost (common)	The vhost for the channel	/	String
autoAck (consumer)	If messages should be auto acknowledged	true	boolean
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
concurrentConsumers (consumer)	Number of concurrent consumers when consuming from broker. (eg similar as to the same option for the JMS component).	1	int
exclusiveConsumer (consumer)	Request exclusive access to the queue (meaning only this consumer can access the queue). This is useful when you want a long-lived shared queue to be temporarily accessible by just one consumer.	false	boolean
prefetchCount (consumer)	The maximum number of messages that the server will deliver, 0 if unlimited. You need to specify the option of prefetchSize, prefetchCount, prefetchGlobal at the same time		int
prefetchEnabled (consumer)	Enables the quality of service on the RabbitMQConsumer side. You need to specify the option of prefetchSize, prefetchCount, prefetchGlobal at the same time	false	boolean
prefetchGlobal (consumer)	If the settings should be applied to the entire channel rather than each consumer You need to specify the option of prefetchSize, prefetchCount, prefetchGlobal at the same time	false	boolean
prefetchSize (consumer)	The maximum amount of content (measured in octets) that the server will deliver, 0 if unlimited. You need to specify the option of prefetchSize, prefetchCount, prefetchGlobal at the same time		int

Name	Description	Default	Type
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
threadPoolSize (consumer)	The consumer uses a Thread Pool Executor with a fixed number of threads. This setting allows you to set that number of threads.	10	int
allowNullHeaders (producer)	Allow pass null values to header	false	boolean
bridgeEndpoint (producer)	If the bridgeEndpoint is true, the producer will ignore the message header of rabbitmq.EXCHANGE_NAME and rabbitmq.ROUTING_KEY	false	boolean
channelPoolMaxSize (producer)	Get maximum number of opened channel in pool	10	int
channelPoolMaxWait (producer)	Set the maximum number of milliseconds to wait for a channel from the pool	1000	long
guaranteedDeliveries (producer)	When true, an exception will be thrown when the message cannot be delivered (basic.return) and the message is marked as mandatory. PublisherAcknowledgement will also be activated in this case. See also publisher acknowledgements - When will messages be confirmed.	false	boolean
immediate (producer)	This flag tells the server how to react if the message cannot be routed to a queue consumer immediately. If this flag is set, the server will return an undeliverable message with a Return method. If this flag is zero, the server will queue the message, but with no guarantee that it will ever be consumed. If the header is present rabbitmq.IMMEDIATE it will override this option.	false	boolean

Name	Description	Default	Type
mandatory (producer)	This flag tells the server how to react if the message cannot be routed to a queue. If this flag is set, the server will return an unroutable message with a Return method. If this flag is zero, the server silently drops the message. If the header is present <code>rabbitmq.MANDATORY</code> it will override this option.	false	boolean
publisherAcknowledgements (producer)	When true, the message will be published with publisher acknowledgements turned on	false	boolean
publisherAcknowledgementsTimeout (producer)	The amount of time in milliseconds to wait for a <code>basic.ack</code> response from RabbitMQ server		long
args (advanced)	Specify arguments for configuring the different RabbitMQ concepts, a different prefix is required for each: Exchange: <code>arg.exchange</code> . Queue: <code>arg.queue</code> . Binding: <code>arg.binding</code> . For example to declare a queue with message ttl argument: http://localhost:5672/exchange/queueargs=arg.queue.x-message-ttl=60000		Map
automaticRecoveryEnabled (advanced)	Enables connection automatic recovery (uses connection implementation that performs automatic recovery when connection shutdown is not initiated by the application)		Boolean
bindingArgs (advanced)	Deprecated Key/value args for configuring the queue binding parameters when <code>declare=true</code>		Map
clientProperties (advanced)	Connection client properties (client info used in negotiating with the server)		Map
connectionTimeout (advanced)	Connection timeout	60000	int
exchangeArgs (advanced)	Deprecated Key/value args for configuring the exchange parameters when <code>declare=true</code>		Map
exchangeArgsConfigurer (advanced)	Deprecated Set the configurer for setting the exchange args in <code>Channel.exchangeDeclare</code>		ArgsConfigurer
networkRecoveryInterval (advanced)	Network recovery interval in milliseconds (interval used when recovering from network failure)	5000	Integer

Name	Description	Default	Type
queueArgs (advanced)	Deprecated Key/value args for configuring the queue parameters when declare=true		Map
queueArgsConfigurer (advanced)	Deprecated Set the configurer for setting the queue args in Channel.queueDeclare		ArgsConfigurer
requestedChannelMax (advanced)	Connection requested channel max (max number of channels offered)	2047	int
requestedFrameMax (advanced)	Connection requested frame max (max size of frame offered)	0	int
requestedHeartbeat (advanced)	Connection requested heartbeat (heart-beat in seconds offered)	60	int
requestTimeout (advanced)	Set timeout for waiting for a reply when using the InOut Exchange Pattern (in milliseconds)	20000	long
requestTimeoutCheckerInterval (advanced)	Set requestTimeoutCheckerInterval for inOut exchange	1000	long
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
topologyRecoveryEnabled (advanced)	Enables connection topology recovery (should topology recovery be performed)		Boolean
transferException (advanced)	When true and an inOut Exchange failed on the consumer side send the caused Exception back in the response	false	boolean
password (security)	Password for authenticated access	guest	String
sslProtocol (security)	Enables SSL on connection, accepted value are true, TLS and 'SSLv3		String
trustManager (security)	Configure SSL trust manager, SSL should be enabled for this option to be effective		TrustManager
username (security)	Username in case of authenticated access	guest	String

271.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 51 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.rabbitmq.addresses</code>	If this option is set, camel-rabbitmq will try to create connection based on the setting of option addresses. The addresses value is a string which looks like server1:12345, server2:12345		String
<code>camel.component.rabbitmq.allow-null-headers</code>	Allow pass null values to header	false	Boolean
<code>camel.component.rabbitmq.args</code>	Specify arguments for configuring the different RabbitMQ concepts, a different prefix is required for each: Exchange: arg.exchange. Queue: arg.queue. Binding: arg.binding. For example to declare a queue with message ttl argument: http://localhost:5672/exchange/queueargs=arg.queue.x-message-ttl=60000		Map
<code>camel.component.rabbitmq.auto-ack</code>	If messages should be auto acknowledged	true	Boolean
<code>camel.component.rabbitmq.auto-delete</code>	If it is true, the exchange will be deleted when it is no longer in use	true	Boolean
<code>camel.component.rabbitmq.auto-detect-connection-factory</code>	Whether to auto-detect looking up RabbitMQ connection factory from the registry. When enabled and a single instance of the connection factory is found then it will be used. An explicit connection factory can be configured on the component or endpoint level which takes precedence.	true	Boolean
<code>camel.component.rabbitmq.automatic-recovery-enabled</code>	Enables connection automatic recovery (uses connection implementation that performs automatic recovery when connection shutdown is not initiated by the application)		Boolean
<code>camel.component.rabbitmq.channel-pool-max-size</code>	Get maximum number of opened channel in pool	10	Integer
<code>camel.component.rabbitmq.channel-pool-max-wait</code>	Set the maximum number of milliseconds to wait for a channel from the pool	1000	Long

Name	Description	Default	Type
<code>camel.component.rabbitmq.client-properties</code>	Connection client properties (client info used in negotiating with the server)		Map
<code>camel.component.rabbitmq.connection-factory</code>	To use a custom RabbitMQ connection factory. When this option is set, all connection options (connectionTimeout, requestedChannelMax...) set on URI are not used. The option is a <code>com.rabbitmq.client.ConnectionFactory</code> type.		String
<code>camel.component.rabbitmq.connection-timeout</code>	Connection timeout	60000	Integer
<code>camel.component.rabbitmq.dead-letter-exchange</code>	The name of the dead letter exchange		String
<code>camel.component.rabbitmq.dead-letter-exchange-type</code>	The type of the dead letter exchange	direct	String
<code>camel.component.rabbitmq.dead-letter-queue</code>	The name of the dead letter queue		String
<code>camel.component.rabbitmq.dead-letter-routing-key</code>	The routing key for the dead letter exchange		String
<code>camel.component.rabbitmq.declare</code>	If the option is true, camel declare the exchange and queue name and bind them together. If the option is false, camel won't declare the exchange and queue name on the server.	true	Boolean
<code>camel.component.rabbitmq.durable</code>	If we are declaring a durable exchange (the exchange will survive a server restart)	true	Boolean
<code>camel.component.rabbitmq.enabled</code>	Enable rabbitmq component	true	Boolean
<code>camel.component.rabbitmq.exclusive</code>	Exclusive queues may only be accessed by the current connection, and are deleted when that connection closes.	false	Boolean

Name	Description	Default	Type
<code>camel.component.rabbitmq.exclusive-consumer</code>	Request exclusive access to the queue (meaning only this consumer can access the queue). This is useful when you want a long-lived shared queue to be temporarily accessible by just one consumer.	false	Boolean
<code>camel.component.rabbitmq.guaranteed-deliveries</code>	When true, an exception will be thrown when the message cannot be delivered (<code>basic.return</code>) and the message is marked as mandatory. <code>PublisherAcknowledgement</code> will also be activated in this case. See also <code>publisher acknowledgements - When will messages be confirmed</code> .	false	Boolean
<code>camel.component.rabbitmq.hostname</code>	The hostname of the running RabbitMQ instance or cluster.		String
<code>camel.component.rabbitmq.immediate</code>	This flag tells the server how to react if the message cannot be routed to a queue consumer immediately. If this flag is set, the server will return an undeliverable message with a <code>Return</code> method. If this flag is zero, the server will queue the message, but with no guarantee that it will ever be consumed. If the header is present <code>rabbitmq.IMMEDIATE</code> it will override this option.	false	Boolean
<code>camel.component.rabbitmq.mandatory</code>	This flag tells the server how to react if the message cannot be routed to a queue. If this flag is set, the server will return an unroutable message with a <code>Return</code> method. If this flag is zero, the server silently drops the message. If the header is present <code>rabbitmq.MANDATORY</code> it will override this option.	false	Boolean
<code>camel.component.rabbitmq.network-recovery-interval</code>	Network recovery interval in milliseconds (interval used when recovering from network failure)	5000	Integer
<code>camel.component.rabbitmq.passive</code>	Passive queues depend on the queue already to be available at RabbitMQ.	false	Boolean
<code>camel.component.rabbitmq.password</code>	Password for authenticated access	guest	String
<code>camel.component.rabbitmq.port-number</code>	Port number for the host with the running rabbitmq instance or cluster.	5672	Integer

Name	Description	Default	Type
<code>camel.component.rabbitmq.prefetch-count</code>	The maximum number of messages that the server will deliver, 0 if unlimited. You need to specify the option of <code>prefetchSize</code> , <code>prefetchCount</code> , <code>prefetchGlobal</code> at the same time		Integer
<code>camel.component.rabbitmq.prefetch-enabled</code>	Enables the quality of service on the RabbitMQConsumer side. You need to specify the option of <code>prefetchSize</code> , <code>prefetchCount</code> , <code>prefetchGlobal</code> at the same time	false	Boolean
<code>camel.component.rabbitmq.prefetch-global</code>	If the settings should be applied to the entire channel rather than each consumer You need to specify the option of <code>prefetchSize</code> , <code>prefetchCount</code> , <code>prefetchGlobal</code> at the same time	false	Boolean
<code>camel.component.rabbitmq.prefetch-size</code>	The maximum amount of content (measured in octets) that the server will deliver, 0 if unlimited. You need to specify the option of <code>prefetchSize</code> , <code>prefetchCount</code> , <code>prefetchGlobal</code> at the same time		Integer
<code>camel.component.rabbitmq.publisher-acknowledgements</code>	When true, the message will be published with publisher acknowledgements turned on	false	Boolean
<code>camel.component.rabbitmq.publisher-acknowledgements-timeout</code>	The amount of time in milliseconds to wait for a <code>basic.ack</code> response from RabbitMQ server		Long
<code>camel.component.rabbitmq.request-timeout</code>	Set timeout for waiting for a reply when using the InOut Exchange Pattern (in milliseconds)	20000	Long
<code>camel.component.rabbitmq.request-timeout-checker-interval</code>	Set <code>requestTimeoutCheckerInterval</code> for inOut exchange	1000	Long
<code>camel.component.rabbitmq.requested-channel-max</code>	Connection requested channel max (max number of channels offered)	2047	Integer

Name	Description	Default	Type
<code>camel.component.rabbitmq.requested-frame-max</code>	Connection requested frame max (max size of frame offered)	0	Integer
<code>camel.component.rabbitmq.requested-heartbeat</code>	Connection requested heartbeat (heart-beat in seconds offered)	60	Integer
<code>camel.component.rabbitmq.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.component.rabbitmq.skip-exchange-declare</code>	This can be used if we need to declare the queue but not the exchange	false	Boolean
<code>camel.component.rabbitmq.skip-queue-bind</code>	If true the queue will not be bound to the exchange after declaring it	false	Boolean
<code>camel.component.rabbitmq.skip-queue-declare</code>	If true the producer will not declare and bind a queue. This can be used for directing messages via an existing routing key.	false	Boolean
<code>camel.component.rabbitmq.ssl-protocol</code>	Enables SSL on connection, accepted value are true, TLS and 'SSLv3		String
<code>camel.component.rabbitmq.thread-pool-size</code>	The consumer uses a Thread Pool Executor with a fixed number of threads. This setting allows you to set that number of threads.	10	Integer
<code>camel.component.rabbitmq.topology-recovery-enabled</code>	Enables connection topology recovery (should topology recovery be performed)		Boolean
<code>camel.component.rabbitmq.transfer-exception</code>	When true and an inOut Exchange failed on the consumer side send the caused Exception back in the response	false	Boolean
<code>camel.component.rabbitmq.trust-manager</code>	Configure SSL trust manager, SSL should be enabled for this option to be effective. The option is a <code>javax.net.ssl.TrustManager</code> type.		String

Name	Description	Default	Type
<code>camel.component.rabbitmq.username</code>	Username in case of authenticated access	guest	String
<code>camel.component.rabbitmq.vhost</code>	The vhost for the channel	/	String

See <http://www.rabbitmq.com/releases/rabbitmq-java-client/current-javadoc/com/rabbitmq/client/ConnectionFactory.html> and the AMQP specification for more information on connection options.

271.4. USING CONNECTION FACTORY

To connect to RabbitMQ you can setup a **ConnectionFactory** (same as with JMS) with the login details such as:

```
<bean id="rabbitConnectionFactory" class="com.rabbitmq.client.ConnectionFactory">
  <property name="host" value="localhost"/>
  <property name="port" value="5672"/>
  <property name="username" value="camel"/>
  <property name="password" value="bugs bunny"/>
</bean>
```

And then refer to the connection factory in the endpoint uri as shown below:

```
<camelContext>
  <route>
    <from uri="direct:rabbitMQEx2"/>
    <to uri="rabbitmq:ex2?connectionFactory=#rabbitConnectionFactory"/>
  </route>
</camelContext>
```

From Camel 2.21 onwards the **ConnectionFactory** is auto-detected by default, so you can just do

```
<camelContext>
  <route>
    <from uri="direct:rabbitMQEx2"/>
    <to uri="rabbitmq:ex2"/>
  </route>
</camelContext>
```

271.5. MESSAGE HEADERS

The following headers are set on exchanges when consuming messages.

Property	Value
rabbitmq.ROUTING_KEY	The routing key that was used to receive the message, or the routing key that will be used when producing a message
rabbitmq.EXCHANGE_NAME	The exchange the message was received from
rabbitmq.DELIVERY_TAG	The rabbitmq delivery tag of the received message
rabbitmq.REDELIVERY_TAG	Whether the message is a redelivered
rabbitmq.REQUEUE	Camel 2.14.2: This is used by the consumer to control rejection of the message. When the consumer is complete processing the exchange, and if the exchange failed, then the consumer is going to reject the message from the RabbitMQ broker. The value of this header controls this behavior. If the value is false (by default) then the message is discarded/dead-lettered. If the value is true, then the message is re-queued.

The following headers are used by the producer. If these are set on the camel exchange then they will be set on the RabbitMQ message.

Property	Value
rabbitmq.ROUTING_KEY	The routing key that will be used when sending the message
rabbitmq.EXCHANGE_NAME	The exchange the message was received from

Property	Value
rabbitmq.EXCHANGE_OVERRIDE_NAME	Camel 2.21: Used for force sending the message to this exchange instead of the endpoint configured name on the producer
rabbitmq.CONTENT_TYPE	The contentType to set on the RabbitMQ message
rabbitmq.PRIORITY	The priority header to set on the RabbitMQ message
rabbitmq.CORRELATIONID	The correlationId to set on the RabbitMQ message
rabbitmq.MESSAGE_ID	The message id to set on the RabbitMQ message
rabbitmq.DELIVERY_MODE	If the message should be persistent or not
rabbitmq.USERID	The userId to set on the RabbitMQ message
rabbitmq.CLUSTERID	The clusterId to set on the RabbitMQ message
rabbitmq.REPLY_TO	The replyTo to set on the RabbitMQ message

Property	Value
rabbitmq.CONTENT_ENCODING	The contentEncoding to set on the RabbitMQ message
rabbitmq.TYPE	The type to set on the RabbitMQ message
rabbitmq.EXPIRATION	The expiration to set on the RabbitMQ message
rabbitmq.TIMESTAMP	The timestamp to set on the RabbitMQ message
rabbitmq.APP_ID	The appId to set on the RabbitMQ message

Headers are set by the consumer once the message is received. The producer will also set the headers for downstream processors once the exchange has taken place. Any headers set prior to production that the producer sets will be overridden.

271.6. MESSAGE BODY

The component will use the camel exchange in body as the rabbit mq message body. The camel exchange in object must be convertible to a byte array. Otherwise the producer will throw an exception of unsupported body type.

271.7. SAMPLES

To receive messages from a queue that is bound to an exchange A with the routing key B,

```
from("rabbitmq:A?routingKey=B")
```

To receive messages from a queue with a single thread with auto acknowledge disabled.

```
from("rabbitmq:A?routingKey=B&threadPoolSize=1&autoAck=false")
```

To send messages to an exchange called C

```
to("rabbitmq:C")
```

Declaring a headers exchange and queue

```
from("rabbitmq:ex?exchangeType=headers&queue=q&bindingArgs=#bindArgs")
```

and place corresponding **Map<String, Object>** with the id of "bindArgs" in the Registry.

For example declaring a method in spring

```
@Bean(name="bindArgs")
public Map<String, Object> bindArgsBuilder() {
    return Collections.singletonMap("foo", "bar");
}
```

271.7.1. Issue when routing between exchanges (in Camel 2.20.x or older)

If you for example want to route messages from one Rabbit exchange to another as shown in the example below with foo → bar:

```
from("rabbitmq:foo")
    .to("rabbitmq:bar")
```

Then beware that Camel will route the message to itself, eg foo → foo. So why is that? This is because the consumer that receives the message (eg from) provides the message header **rabbitmq.EXCHANGE_NAME** with the name of the exchange, eg **foo**. And when the Camel producer is sending the message to **bar** then the header **rabbitmq.EXCHANGE_NAME** will override this and instead send the message to **foo**.

To avoid this you need to either:

- Remove the header:

```
from("rabbitmq:foo")
    .removeHeader("rabbitmq.EXCHANGE_NAME")
    .to("rabbitmq:bar")
```

- Or turn on **bridgeEndpoint** mode on the producer:

```
from("rabbitmq:foo")
    .to("rabbitmq:bar?bridgeEndpoint=true")
```

From Camel 2.21 onwards this has been improved so you can easily route between exchanges. The header **rabbitmq.EXCHANGE_NAME** is not longer used by the producer to override the destination exchange. Instead a new header **rabbitmq.EXCHANGE_OVERRIDE_NAME** can be used to send to a different exchange. For example to send to cheese exchange you can do

```
from("rabbitmq:foo")
    .setHeader("rabbitmq.EXCHANGE_OVERRIDE_NAME", constant("cheese"))
    .to("rabbitmq:bar")
```

CHAPTER 272. REACTIVE STREAMS COMPONENT

Available as of Camel version 2.19

The **reactive-streams** component allows you to exchange messages with reactive stream processing libraries compatible with the [reactive streams](#) standard.

The component supports backpressure and has been tested using the [reactive streams technology compatibility kit \(TCK\)](#).

The Camel module provides a **reactive-streams** component that allows users to define incoming and outgoing streams within Camel routes, and a direct client API that allows using Camel endpoints directly into any external reactive framework.

Camel uses an internal implementation of the reactive streams *Publisher* and *Subscriber*, so it's not tied to any specific framework. The following reactive frameworks have been used in the integration tests: [Reactor Core 3](#), [RxJava 2](#).

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-reactive-streams</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

272.1. URI FORMAT

```
reactive-streams://stream?[options]
```

Where **stream** is a logical stream name used to bind Camel routes to the external stream processing systems.

272.2. OPTIONS

The Reactive Streams component supports 4 options, which are listed below.

Name	Description	Default	Type
internalEngineConfiguration (advanced)	Configures the internal engine for Reactive Streams.		ReactiveStreamsEngineConfiguration
backpressureStrategy (producer)	The backpressure strategy to use when pushing events to a slow subscriber.	BUFFER	ReactiveStreamsBackpressureStrategy

Name	Description	Default	Type
serviceType (advanced)	Set the type of the underlying reactive streams implementation to use. The implementation is looked up from the registry or using a ServiceLoader, the default implementation is DefaultCamelReactiveStreamsService		String
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Reactive Streams endpoint is configured using URI syntax:

```
reactive-streams:stream
```

with the following path and query parameters:

272.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
stream	Name of the stream channel used by the endpoint to exchange messages.		String

272.2.2. Query Parameters (10 parameters):

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
concurrentConsumers (consumer)	Number of threads used to process exchanges in the Camel route.	1	int

Name	Description	Default	Type
exchangesRefillLowWatermark (consumer)	Set the low watermark of requested exchanges to the active subscription as percentage of the maxInflightExchanges. When the number of pending items from the upstream source is lower than the watermark, new items can be requested to the subscription. If set to 0, the subscriber will request items in batches of maxInflightExchanges, only after all items of the previous batch have been processed. If set to 1, the subscriber can request a new item each time an exchange is processed (chatty). Any intermediate value can be used.	0.25	double
forwardOnComplete (consumer)	Determines if onComplete events should be pushed to the Camel route.	false	boolean
forwardOnError (consumer)	Determines if onError events should be pushed to the Camel route. Exceptions will be set as message body.	false	boolean
maxInflightExchanges (consumer)	Maximum number of exchanges concurrently being processed by Camel. This parameter controls backpressure on the stream. Setting a non-positive value will disable backpressure.	128	Integer
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
backpressureStrategy (producer)	The backpressure strategy to use when pushing events to a slow subscriber.		ReactiveStreamsBackpressureStrategy
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

272.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 7 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.reactive-streams.backpressure-strategy</code>	The backpressure strategy to use when pushing events to a slow subscriber.		ReactiveStreamsBackpressureStrategy
<code>camel.component.reactive-streams.enabled</code>	Enable reactive-streams component	true	Boolean
<code>camel.component.reactive-streams.internal-engine-configuration.thread-pool-max-size</code>	The maximum number of threads used by the reactive streams internal engine.		Integer
<code>camel.component.reactive-streams.internal-engine-configuration.thread-pool-min-size</code>	The minimum number of threads used by the reactive streams internal engine.		Integer
<code>camel.component.reactive-streams.internal-engine-configuration.thread-pool-name</code>	The name of the thread pool used by the reactive streams internal engine.		String
<code>camel.component.reactive-streams.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.component.reactive-streams.service-type</code>	Set the type of the underlying reactive streams implementation to use. The implementation is looked up from the registry or using a ServiceLoader, the default implementation is <code>DefaultCamelReactiveStreamsService</code>		String

272.4. USAGE

The library is aimed to support all the communication modes needed by an application to interact with Camel data:

- **Get** data from Camel routes (In-Only from Camel)

- **Send** data to Camel routes (In-Only towards Camel)
- **Request** a transformation to a Camel route (In-Out towards Camel)
- **Process** data flowing from a Camel route using a reactive processing step (In-Out from Camel)

272.5. GETTING DATA FROM CAMEL

In order to subscribe to data flowing from a Camel route, exchanges should be redirected to a named stream, like in the following snippet:

```
from("timer:clock")
  .setBody().header(Exchange.TIMER_COUNTER)
  .to("reactive-streams:numbers");
```

Routes can also be written using the XML DSL.

In the example, an unbounded stream of numbers is associated to the name **numbers**. The stream can be accessed using the **CamelReactiveStreams** utility class.

```
CamelReactiveStreamsService camel = CamelReactiveStreams.get(context);

// Getting a stream of exchanges
Publisher<Exchange> exchanges = camel.fromStream("numbers");

// Getting a stream of Integers (using Camel standard conversion system)
Publisher<Integer> numbers = camel.fromStream("numbers", Integer.class);
```

The stream can be used easily with any reactive streams compatible library. Here is an example of how to use it with [RxJava 2](#) (although any reactive framework can be used to process events).

```
Flowable.fromPublisher(integers)
  .doOnNext(System.out::println)
  .subscribe();
```

The example prints all numbers generated by Camel into **System.out**.

272.5.1. Getting data from Camel using the direct API

For short Camel routes and for users that prefer defining the whole processing flow using functional constructs of the reactive framework (without using the Camel DSL at all), streams can also be defined using Camel URIs.

```
CamelReactiveStreamsService camel = CamelReactiveStreams.get(context);

// Get a stream from all the files in a directory
Publisher<String> files = camel.from("file:folder", String.class);

// Use the stream in RxJava2
Flowable.fromPublisher(files)
  .doOnNext(System.out::println)
  .subscribe();
```

272.6. SENDING DATA TO CAMEL

When an external library needs to push events into a Camel route, the Reactive Streams endpoint must be set as consumer.

```
from("reactive-streams:elements")
.to("log:INFO");
```

A handle to the **elements** stream can be obtained from the **CamelReactiveStreams** utility class.

```
CamelReactiveStreamsService camel = CamelReactiveStreams.get(context);

Subscriber<String> elements = camel.streamSubscriber("elements", String.class);
```

The subscriber can be used to push events to the Camel route that consumes from the **elements** stream.

Here is an example of how to use it with [RxJava 2](#) (although any reactive framework can be used to publish events).

```
Flowable.interval(1, TimeUnit.SECONDS)
.map(i -> "Item " + i)
.subscribe(elements);
```

String items are generated every second by RxJava in the example and they are pushed into the Camel route defined above.

272.6.1. Sending data to Camel using the direct API

Also in this case, the direct API can be used to obtain a Camel subscriber from an endpoint URI.

```
CamelReactiveStreamsService camel = CamelReactiveStreams.get(context);

// Send two strings to the "seda:queue" endpoint
Flowable.just("hello", "world")
.subscribe(camel.subscriber("seda:queue", String.class));
```

272.7. REQUEST A TRANSFORMATION TO CAMEL

Routes defined in some Camel DSL can be used within a reactive stream framework to perform a specific transformation (the same mechanism can be also used to eg. just send data to a *http* endpoint and continue).

The following snippet shows how RxJava functional code can request the task of loading and marshalling files to Camel.

```
CamelReactiveStreamsService camel = CamelReactiveStreams.get(context);

// Process files starting from their names
Flowable.just(new File("file1.txt"), new File("file2.txt"))
.flatMap(file -> camel.toStream("readAndMarshal", String.class))
```

```
// Camel output will be converted to String
// other steps
.subscribe();
```

In order this to work, a route like the following should be defined in the Camel context:

```
from("reactive-streams:readAndMarshal")
.marshall() // ... other details
```

272.7.1. Request a transformation to Camel using the direct API

An alternative approach consists in using the URI endpoints directly in the reactive flow:

```
CamelReactiveStreamsService camel = CamelReactiveStreams.get(context);

// Process files starting from their names
Flowable.just(new File("file1.txt"), new File("file2.txt"))
.flatMap(file -> camel.to("direct:process", String.class))
// Camel output will be converted to String
// other steps
.subscribe();
```

When using the `to()` method instead of the `toStream`, there is no need to define the route using "reactive-streams:" endpoints (although they are used under the hood).

In this case, the Camel transformation can be just:

```
from("direct:process")
.marshall() // ... other details
```

272.8. PROCESS CAMEL DATA INTO THE REACTIVE FRAMEWORK

While a reactive streams *Publisher* allows exchanging data in a unidirectional way, Camel routes often use a in-out exchange pattern (eg. to define REST endpoints and, in general, where a reply is needed for each request).

In these circumstances, users can add a reactive processing step to the flow, to enhance a Camel route or to define the entire transformation using the reactive framework.

For example, given the following route:

```
from("timer:clock")
.setBody().header(Exchange.TIMER_COUNTER)
.to("direct:reactive")
.log("Continue with Camel route... n=${body}");
```

A reactive processing step can be associated to the "direct:reactive" endpoint:

```
CamelReactiveStreamsService camel = CamelReactiveStreams.get(context);

camel.process("direct:reactive", Integer.class, items ->
    Flowable.fromPublisher(items) // RxJava2
        .map(n -> -n)); // make every number negative
```

Data flowing in the Camel route will be processed by the external reactive framework then continue the processing flow inside Camel.

This mechanism can also be used to define a In-Out exchange in a completely reactive way.

```
CamelReactiveStreamsService camel = CamelReactiveStreams.get(context);

// requires a rest-capable Camel component
camel.process("rest:get:orders", exchange ->
    Flowable.fromPublisher(exchange)
        .flatMap(ex -> allOrders())); // retrieve orders asynchronously
```

See Camel examples ([camel-example-reactive-streams](#)) for details.

272.9. ADVANCED TOPICS

272.9.1. Controlling Backpressure (producer side)

When routing Camel exchanges to an external subscriber, backpressure is handled by an internal buffer that caches exchanges before delivering them. If the subscriber is slower than the exchange rate, the buffer may become too big. In many circumstances this must be avoided.

Considering the following route:

```
from("jms:queue")
    .to("reactive-streams:flow");
```

If the JMS queue contains a high number of messages and the Subscriber associated with the **flow** stream is too slow, messages are dequeued from JMS and appended to the buffer, possibly causing a "out of memory" error. To avoid such problems, a **ThrottlingInflightRoutePolicy** can be set in the route.

```
ThrottlingInflightRoutePolicy policy = new ThrottlingInflightRoutePolicy();
policy.setMaxInflightExchanges(10);

from("jms:queue")
    .routePolicy(policy)
    .to("reactive-streams:flow");
```

The policy limits the maximum number of active exchanges (and so the maximum size of the buffer), keeping it lower than the threshold (**10** in the example). When more than **10** messages are in flight, the route is suspended, waiting for the subscriber to process them.

With this mechanism, the subscriber controls the route suspension/resume automatically, through backpressure. When multiple subscribers are consuming items from the same stream, the slowest one controls the route status automatically.

In other circumstances, eg. when using a **http** consumer, the route suspension makes the http service unavailable, so using the default configuration (no policy, unbounded buffer) should be preferable. Users should try to avoid memory issues by limiting the number of requests to the http service (eg. scaling out).

In contexts where a certain amount of data loss is acceptable, setting a backpressure strategy other than **BUFFER** can be a solution for dealing with fast sources.

```
from("direct:thermostat")  
.to("reactive-streams:flow?backpressureStrategy=LATEST");
```

When the **LATEST** backpressure strategy is used, only the last exchange received from the route is kept by the publisher, while older data is discarded (other options are available).

272.9.2. Controlling Backpressure (consumer side)

When Camel consumes items from a reactive-streams publisher, the maximum number of inflight exchanges can be set as endpoint option.

The subscriber associated with the consumer interacts with the publisher to keep the number of messages in the route lower than the threshold.

An example of backpressure-aware route:

```
from("reactive-streams:numbers?maxInflightExchanges=10")  
.to("direct:endpoint");
```

The number of items that Camel requests to the source publisher (through the reactive streams backpressure mechanism) is always lower than **10**. Messages are processed by a single thread in the Camel side.

The number of concurrent consumers (threads) can also be set as endpoint option (**concurrentConsumers**). When using 1 consumer (the default), the order of items in the source stream is maintained. When this value is increased, items will be processed concurrently by multiple threads (so not preserving the order).

272.10. CAMEL REACTIVE STREAMS STARTER

A starter module is available to spring-boot users. When using the starter, the **CamelReactiveStreamsService** can be directly injected into Spring components.

To use the starter, add the following to your spring boot pom.xml file:

```
<dependency>  
  <groupId>org.apache.camel</groupId>  
  <artifactId>camel-reactive-streams-starter</artifactId>  
  <version>${camel.version}</version> <!-- use the same version as your Camel core version -->  
</dependency>
```

272.11. SEE ALSO

- [Configuring Camel](#)
- [Component](#)
- [Endpoint](#)
- [Getting Started](#)

CHAPTER 273. REACTOR COMPONENT

Available as of Camel version 2.20

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-reactor</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

CHAPTER 274. REF COMPONENT

Available as of Camel version 1.2

The `ref:` component is used for lookup of existing endpoints bound in the Registry.

274.1. URI FORMAT

```
ref:someName[?options]
```

Where **someName** is the name of an endpoint in the Registry (usually, but not always, the Spring registry). If you are using the Spring registry, **someName** would be the bean ID of an endpoint in the Spring registry.

274.2. REF OPTIONS

The Ref component has no options.

The Ref endpoint is configured using URI syntax:

```
ref:name
```

with the following path and query parameters:

274.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
<code>name</code>	Required Name of endpoint to lookup in the registry.		String

274.2.2. Query Parameters (4 parameters):

Name	Description	Default	Type
<code>bridgeErrorHandler</code> (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN/ERROR level and ignored.	false	boolean

Name	Description	Default	Type
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN/ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the default exchange pattern when creating an exchange.		ExchangePattern
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

274.3. RUNTIME LOOKUP

This component can be used when you need dynamic discovery of endpoints in the Registry where you can compute the URI at runtime. Then you can look up the endpoint using the following code:

```
// lookup the endpoint
String myEndpointRef = "bigspenderOrder";
Endpoint endpoint = context.getEndpoint("ref:" + myEndpointRef);

Producer producer = endpoint.createProducer();
Exchange exchange = producer.createExchange();
exchange.getIn().setBody(payloadToSend);
// send the exchange
producer.process(exchange);
```

And you could have a list of endpoints defined in the Registry such as:

```
<camelContext id="camel" xmlns="http://activemq.apache.org/camel/schema/spring">
  <endpoint id="normalOrder" uri="activemq:order.slow"/>
  <endpoint id="bigspenderOrder" uri="activemq:order.high"/>
</camelContext>
```

274.4. SAMPLE

In the sample below we use the **ref:** in the URI to reference the endpoint with the spring ID, **endpoint2:**

You could, of course, have used the **ref** attribute instead:

```
<to ref="endpoint2"/>
```

Which is the more common way to write it.

CHAPTER 275. REST COMPONENT

Available as of Camel version 2.14

The rest component allows to define REST endpoints (consumer) using the Rest DSL and plugin to other Camel components as the REST transport.

From Camel 2.18 onwards the rest component can also be used as a client (producer) to call REST services.

275.1. URI FORMAT

```
rest://method:path[:uriTemplate]?[options]
```

275.2. URI OPTIONS

The REST component supports 4 options, which are listed below.

Name	Description	Default	Type
componentName (common)	The Camel Rest component to use for the REST transport, such as restlet, spark-rest. If no component has been explicit configured, then Camel will lookup if there is a Camel component that integrates with the Rest DSL, or if a <code>org.apache.camel.spi.RestConsumerFactory</code> (consumer) or <code>org.apache.camel.spi.RestProducerFactory</code> (producer) is registered in the registry. If either one is found, then that is being used.		String
apiDoc (producer)	The OpenAPI api doc resource to use. The resource is loaded from classpath by default and must be in JSON format.		String
host (producer)	Host and port of HTTP service to use (override host in OpenAPI schema)		String
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The REST endpoint is configured using URI syntax:

```
rest:method:path:uriTemplate
```

with the following path and query parameters:

275.2.1. Path Parameters (3 parameters):

Name	Description	Default	Type
method	Required HTTP method to use.		String
path	Required The base path		String
uriTemplate	The uri template		String

275.2.2. Query Parameters (15 parameters):

Name	Description	Default	Type
componentName (common)	The Camel Rest component to use for the REST transport, such as restlet, spark-rest. If no component has been explicit configured, then Camel will lookup if there is a Camel component that integrates with the Rest DSL, or if a <code>org.apache.camel.spi.RestConsumerFactory</code> is registered in the registry. If either one is found, then that is being used.		String
consumes (common)	Media type such as: 'text/xml', or 'application/json' this REST service accepts. By default we accept all kinds of types.		String
inType (common)	To declare the incoming POJO binding type as a FQN class name		String
outType (common)	To declare the outgoing POJO binding type as a FQN class name		String
produces (common)	Media type such as: 'text/xml', or 'application/json' this REST service returns.		String
routeld (common)	Name of the route this REST services creates		String
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN/ERROR level and ignored.	false	boolean

Name	Description	Default	Type
description (consumer)	Human description to document this REST service		String
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN/ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the default exchange pattern when creating an exchange.		ExchangePattern
apiDoc (producer)	The OpenAPI api doc resource to use. The resource is loaded from classpath by default and must be in JSon format.		String
bindingMode (producer)	Configures the binding mode for the producer. If set to anything other than 'off' the producer will try to convert the body of the incoming message from inType to the json or xml, and the response from json or xml to outType.		RestBindingMode
host (producer)	Host and port of HTTP service to use (override host in OpenAPI schema)		String
queryParameters (producer)	Query parameters for the HTTP service to call		String
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

275.3. SUPPORTED REST COMPONENTS

The following components support rest consumer (Rest DSL):

- camel-coap
- camel-netty-http
- camel-netty4-http
- camel-jetty
- camel-restlet
- camel-servlet
- camel-spark-rest

- camel-undertow

The following components support rest producer:

- camel-http
- camel-http4
- camel-netty4-http
- camel-jetty
- camel-restlet
- camel-undertow

275.4. PATH AND URITEMPLATE SYNTAX

The path and uriTemplate option is defined using a REST syntax where you define the REST context path using support for parameters.

TIP:If no uriTemplate is configured then path option works the same way. It does not matter if you configure only path or if you configure both options. Though configuring both a path and uriTemplate is a more common practice with REST.

The following is a Camel route using a a path only

```
from("rest:get:hello")
  .transform().constant("Bye World");
```

And the following route uses a parameter which is mapped to a Camel header with the key "me".

```
from("rest:get:hello/{me}")
  .transform().simple("Bye ${header.me}");
```

The following examples have configured a base path as "hello" and then have two REST services configured using uriTemplates.

```
from("rest:get:hello/{me}")
  .transform().simple("Hi ${header.me}");

from("rest:get:hello/french/{me}")
  .transform().simple("Bonjour ${header.me}");
```

275.5. REST PRODUCER EXAMPLES

You can use the rest component to call REST services like any other Camel component.

For example to call a REST service on using **hello/{me}** you can do

```
from("direct:start")
  .to("rest:get:hello/{me}");
```

And then the dynamic value **{me}** is mapped to Camel message with the same name. So to call this REST service you can send an empty message body and a header as shown:

```
template.sendBodyAndHeader("direct:start", null, "me", "Donald Duck");
```

The Rest producer needs to know the hostname and port of the REST service, which you can configure using the host option as shown:

```
from("direct:start")
    .to("rest:get:hello/{me}?host=myserver:8080/foo");
```

Instead of using the host option, you can configure the host on the **restConfiguration** as shown:

```
restConfiguration().host("myserver:8080/foo");

from("direct:start")
    .to("rest:get:hello/{me}");
```

You can use the **producerComponent** to select which Camel component to use as the HTTP client, for example to use http4 you can do:

```
restConfiguration().host("myserver:8080/foo").producerComponent("http4");

from("direct:start")
    .to("rest:");
```

275.6. REST PRODUCER BINDING

The REST producer supports binding using JSON or XML like the rest-dsl does.

For example to use jetty with json binding mode turned on you can configure this in the rest configuration:

```
restConfiguration().component("jetty").host("localhost").port(8080).bindingMode(RestBindingMode.json);

from("direct:start")
    .to("rest:post:user");
```

Then when calling the REST service using rest producer it will automatic bind any POJOs to json before calling the REST service:

```
UserPojo user = new UserPojo();
user.setId(123);
user.setName("Donald Duck");

template.sendBody("direct:start", user);
```

In the example above we send a POJO instance **UserPojo** as the message body. And because we have turned on JSON binding in the rest configuration, then the POJO will be marshalled from POJO to JSON before calling the REST service.

However if you want to also perform binding for the response message (eg what the REST service send back as response) you would need to configure the **outType** option to specify what is the classname of the POJO to unmarshal from JSon to POJO.

For example if the REST service returns a JSon payload that binds to **com.foo.MyResponsePojo** you can configure this as shown:

```
restConfiguration().component("jetty").host("localhost").port(8080).bindingMode(RestBindingMode.json);  
  
from("direct:start")  
  .to("rest:post:user?outType=com.foo.MyResponsePojo");
```

IMPORTANT

You must configure **outType** option if you want POJO binding to happen for the response messages received from calling the REST service.

275.7. MORE EXAMPLES

See Rest DSL which offers more examples and how you can use the Rest DSL to define those in a nicer RESTful way.

There is a **camel-example-servlet-rest-tomcat** example in the Apache Camel distribution, that demonstrates how to use the Rest DSL with SERVLET as transport that can be deployed on Apache Tomcat, or similar web containers.

275.8. SEE ALSO

- Rest DSL
- [SERVLET](#)

PART I. REST OPENAPI COMPONENT

Since Camel 3.1

Only producer is supported

The REST OpenApi* configures rest producers from [OpenApi](#) (Open API) specification document and delegates to a component implementing the *RestProducerFactory* interface. Currently known working components are:

- [http](#)
- [netty-http](#)
- [undertow](#)

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-rest-openapi</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

CHAPTER 276. URI FORMAT

`rest-openapi:[specificationPath#]operationId`

Where **operationId** is the ID of the operation in the OpenApi specification, and **specificationPath** is the path to the specification. If the **specificationPath** is not specified it defaults to **openapi.json**. The lookup mechanism uses Camel's **ResourceHelper** to load the resource, which means that you can use CLASSPATH resources (**classpath:my-specification.json**), files (**file:/some/path.json**), the web (**http://api.example.com/openapi.json**) or reference a bean (**ref:nameOfBean**) or use a method of a bean (**bean:nameOfBean.methodName**) to get the specification resource, falling that OpenApi's own resource loading support.

This component does not act as a HTTP client, it delegates that to another component mentioned above. The lookup mechanism searches for a single component that implements the *RestProducerFactory* interface and uses that. If the CLASSPATH contains more than one, then the property **componentName** should be set to indicate which component to delegate to.

Most of the configuration is taken from the OpenApi specification but the option exists to override those by specifying them on the component or on the endpoint. Typically you would just need to override the **host** or **basePath** if those differ from the specification.

NOTE

The **host** parameter should contain the absolute URI containing scheme, hostname and port number, for instance: **https://api.example.com**

With **componentName** you specify what component is used to perform the requests, this named component needs to be present in the Camel context and implement the required *RestProducerFactory* interface – as do the components listed at the top.

If you do not specify the *componentName* at either component or endpoint level, CLASSPATH is searched for a suitable delegate. There should be only one component present on the CLASSPATH that implements the *RestProducerFactory* interface for this to work.

This component's endpoint URI is lenient which means that in addition to message headers you can specify REST operation's parameters as endpoint parameters, these will be constant for all subsequent invocations so it makes sense to use this feature only for parameters that are indeed constant for all invocations – for example API version in path such as **/api/{version}/users/{id}**.

CHAPTER 277. OPTIONS

The REST OpenApi component supports 10 options, which are listed below.

Name	Description	Default	Type
basePath (producer)	API basePath, for example /v2. Default is unset, if set overrides the value present in OpenApi specification.		String
componentName (producer)	Name of the Camel component that will perform the requests. The component must be present in Camel registry and it must implement RestProducerFactory service provider interface. If not set CLASSPATH is searched for single component that implements RestProducerFactory SPI. Can be overridden in endpoint configuration.		String
consumes (producer)	What payload type this component capable of consuming. Could be one type, like application/json or multiple types as application/json, application/xml; q=0.5 according to the RFC7231. This equates to the value of Accept HTTP header. If set overrides any value found in the OpenApi specification. Can be overridden in endpoint configuration		String
host (producer)	Scheme hostname and port to direct the HTTP requests to in the form of https://hostname:port. Can be configured at the endpoint, component or in the corresponding REST configuration in the Camel Context. If you give this component a name (e.g. petstore) that REST configuration is consulted first, rest-openapi next, and global configuration last. If set overrides any value found in the OpenApi specification, RestConfiguration. Can be overridden in endpoint configuration.		String
produces (producer)	What payload type this component is producing. For example application/json according to the RFC7231. This equates to the value of Content-Type HTTP header. If set overrides any value present in the OpenApi specification. Can be overridden in endpoint configuration.		String

Name	Description	Default	Type
specificationUri (producer)	Path to the OpenApi specification file. The scheme, host base path are taken from this specification, but these can be overridden with properties on the component or endpoint level. If not given the component tries to load openapi.json resource. Note that the host defined on the component and endpoint of this Component should contain the scheme, hostname and optionally the port in the URI syntax (i.e. https://api.example.com:8080). Can be overridden in endpoint configuration.	openapi.json	URI
sslContextParameters (security)	Customize TLS parameters used by the component. If not set defaults to the TLS parameters set in the Camel context		SSLContextParameters
useGlobalSslContextParameters (security)	Enable usage of global SSL context parameters.	false	boolean
basicPropertyBinding (advanced)	Whether the component should use basic property binding (Camel 2.x) or the newer property binding with additional capabilities	false	boolean
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean

The REST OpenApi endpoint is configured using URI syntax:

```
rest-openapi:specificationUri#operationId
```

with the following path and query parameters:

277.1. PATH PARAMETERS (2 PARAMETERS):

Name	Description	Default	Type
specificationUri	Path to the OpenApi specification file. The scheme, host base path are taken from this specification, but these can be overridden with properties on the component or endpoint level. If not given the component tries to load openapi.json resource from the classpath. Note that the host defined on the component and endpoint of this Component should contain the scheme, hostname and optionally the port in the URI syntax (i.e. http://api.example.com:8080). Overrides component configuration. The OpenApi specification can be loaded from different sources by prefixing with file: classpath: http: https:. Support for https is limited to using the JDK installed UrlHandler, and as such it can be cumbersome to setup TLS/SSL certificates for https (such as setting a number of javax.net.ssl JVM system properties). How to do that consult the JDK documentation for UrlHandler.	openapi.json	URI
operationId	Required ID of the operation from the OpenApi specification.		String

277.2. QUERY PARAMETERS (8 PARAMETERS):

Name	Description	Default	Type
basePath (producer)	API basePath, for example /v2. Default is unset, if set overrides the value present in OpenApi specification and in the component configuration.		String
componentName (producer)	Name of the Camel component that will perform the requests. The component must be present in Camel registry and it must implement RestProducerFactory service provider interface. If not set CLASSPATH is searched for single component that implements RestProducerFactory SPI. Overrides component configuration.		String
consumes (producer)	What payload type this component capable of consuming. Could be one type, like application/json or multiple types as application/json, application/xml; q=0.5 according to the RFC7231. This equates to the value of Accept HTTP header. If set overrides any value found in the OpenApi specification and in the component configuration		String

Name	Description	Default	Type
host (producer)	Scheme hostname and port to direct the HTTP requests to in the form of https://hostname:port. Can be configured at the endpoint, component or in the corresponding REST configuration in the Camel Context. If you give this component a name (e.g. petstore) that REST configuration is consulted first, rest-openapi next, and global configuration last. If set overrides any value found in the OpenApi specification, RestConfiguration. Overrides all other configuration.		String
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
produces (producer)	What payload type this component is producing. For example application/json according to the RFC7231. This equates to the value of Content-Type HTTP header. If set overrides any value present in the OpenApi specification. Overrides all other configuration.		String
basicPropertyBinding (advanced)	Whether the endpoint should use basic property binding (Camel 2.x) or the newer property binding with additional capabilities	false	boolean
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

CHAPTER 278. SPRING BOOT AUTO-CONFIGURATION

When using Spring Boot make sure to use the following Maven dependency to have support for auto configuration:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-rest-openapi-starter</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

The component supports 12 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.rest-openapi.base-path</code>	API basePath, for example /v2. Default is unset, if set overrides the value present in OpenApi specification.		String
<code>camel.component.rest-openapi.basic-property-binding</code>	Whether the component should use basic property binding (Camel 2.x) or the newer property binding with additional capabilities	false	Boolean
<code>camel.component.rest-openapi.bridge-error-handler</code>	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	Boolean
<code>camel.component.rest-openapi.component-name</code>	Name of the Camel component that will perform the requests. The component must be present in Camel registry and it must implement <code>RestProducerFactory</code> service provider interface. If not set CLASSPATH is searched for single component that implements <code>RestProducerFactory</code> SPI. Can be overridden in endpoint configuration.		String
<code>camel.component.rest-openapi.consumes</code>	What payload type this component capable of consuming. Could be one type, like <code>application/json</code> or multiple types as <code>application/json, application/xml; q=0.5</code> according to the RFC7231. This equates to the value of Accept HTTP header. If set overrides any value found in the OpenApi specification. Can be overridden in endpoint configuration		String

Name	Description	Default	Type
<code>camel.component.rest-openapi.enabled</code>	Whether to enable auto configuration of the rest-openapi component. This is enabled by default.		Boolean
<code>camel.component.rest-openapi.host</code>	Scheme hostname and port to direct the HTTP requests to in the form of <code>https://hostname:port</code> . Can be configured at the endpoint, component or in the corresponding REST configuration in the Camel Context. If you give this component a name (e.g. petstore) that REST configuration is consulted first, rest-openapi next, and global configuration last. If set overrides any value found in the OpenApi specification, RestConfiguration. Can be overridden in endpoint configuration.		String
<code>camel.component.rest-openapi.lazy-start-producer</code>	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	Boolean
<code>camel.component.rest-openapi.produces</code>	What payload type this component is producing. For example <code>application/json</code> according to the RFC7231. This equates to the value of Content-Type HTTP header. If set overrides any value present in the OpenApi specification. Can be overridden in endpoint configuration.		String
<code>camel.component.rest-openapi.specification-uri</code>	Path to the OpenApi specification file. The scheme, host base path are taken from this specification, but these can be overridden with properties on the component or endpoint level. If not given the component tries to load <code>openapi.json</code> resource. Note that the host defined on the component and endpoint of this Component should contain the scheme, hostname and optionally the port in the URI syntax (i.e. <code>https://api.example.com:8080</code>). Can be overridden in endpoint configuration.		URI
<code>camel.component.rest-openapi.ssl-context-parameters</code>	Customize TLS parameters used by the component. If not set defaults to the TLS parameters set in the Camel context. The option is a <code>org.apache.camel.support.jsse.SSLContextParameters</code> type.		String

Name	Description	Default	Type
<code>camel.component.rest-openapi.use-global-ssl-context-parameters</code>	Enable usage of global SSL context parameters.	false	Boolean

CHAPTER 279. EXAMPLE: PETSTORE

Checkout the example in the **camel-example-rest-openapi** project in the **examples** directory.

For example if you wanted to use the *PetStore* provided REST API simply reference the specification URI and desired operation id from the OpenApi specification or download the specification and store it as **openapi.json** (in the root) of CLASSPATH that way it will be automatically used. Let's use the *Undertow* component to perform all the requests and Camels excellent support for Spring Boot.

Here are our dependencies defined in Maven POM file:

```
<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-undertow-starter</artifactId>
</dependency>

<dependency>
  <groupId>org.apache.camel.springboot</groupId>
  <artifactId>camel-rest-openapi-starter</artifactId>
</dependency>
```

Start by defining the *Undertow* component and the *RestOpenApiComponent*:

```
@Bean
public Component petstore(CamelContext camelContext, UndertowComponent undertow) {
    RestOpenApiComponent petstore = new RestOpenApiComponent(camelContext);
    petstore.setSpecificationUri("https://petstore3.swagger.io/api/v3/openapi.json");
    petstore.setDelegate(undertow);

    return petstore;
}
```

NOTE

Support in Camel for Spring Boot will auto create the **UndertowComponent** Spring bean, and you can configure it using **application.properties** (or **application.yml**) using prefix **camel.component.undertow..** We are defining the **petstore** component here in order to have a named component in the Camel context that we can use to interact with the PetStore REST API, if this is the only **rest-openapi** component used we might configure it in the same manner (using **application.properties**).

Now in our application we can simply use the **ProducerTemplate** to invoke PetStore REST methods:

```
@Autowired
ProducerTemplate template;

String getPetJsonById(int petId) {
    return template.requestBodyAndHeaders("petstore:getPetById", null, "petId", petId);
}
```

CHAPTER 280. REST SWAGGER COMPONENT

Available as of Camel version 2.19

The **rest-swagger** configures rest producers from [Swagger](#) (Open API) specification document and delegates to a component implementing the *RestProducerFactory* interface. Currently known working components are:

- [http](#)
- [http4](#)
- [netty4-http](#)
- [restlet](#)
- [jetty](#)
- [undertow](#)

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-rest-swagger</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

280.1. URI FORMAT

```
rest-swagger:[specificationPath#]operationId
```

Where **operationId** is the ID of the operation in the Swagger specification, and **specificationPath** is the path to the specification. If the **specificationPath** is not specified it defaults to **swagger.json**. The lookup mechanism uses Camels **ResourceHelper** to load the resource, which means that you can use CLASSPATH resources (**classpath:my-specification.json**), files (**file:/some/path.json**), the web (**http://api.example.com/swagger.json**) or reference a bean (**ref:nameOfBean**) or use a method of a bean (**bean:nameOfBean.methodName**) to get the specification resource, falling that Swagger's own resource loading support.

This component does not act as a HTTP client, it delegates that to another component mentioned above. The lookup mechanism searches for a single component that implements the *RestProducerFactory* interface and uses that. If the CLASSPATH contains more than one, then the property **componentName** should be set to indicate which component to delegate to.

Most of the configuration is taken from the Swagger specification but the option exists to override those by specifying them on the component or on the endpoint. Typically you would just need to override the **host** or **basePath** if those differ from the specification.

NOTE

The **host** parameter should contain the absolute URI containing scheme, hostname and port number, for instance: <https://api.example.com>

With **componentName** you specify what component is used to perform the requests, this named component needs to be present in the Camel context and implement the required *RestProducerFactory* interface – as do the components listed at the top.

If you do not specify the *componentName* at either component or endpoint level, CLASSPATH is searched for a suitable delegate. There should be only one component present on the CLASSPATH that implements the *RestProducerFactory* interface for this to work.

This component's endpoint URI is lenient which means that in addition to message headers you can specify REST operation's parameters as endpoint parameters, these will be constant for all subsequent invocations so it makes sense to use this feature only for parameters that are indeed constant for all invocations – for example API version in path such as **/api/7.8/users/{id}**.

280.2. OPTIONS

The REST Swagger component supports 9 options, which are listed below.

Name	Description	Default	Type
basePath (producer)	API basePath, for example /v2. Default is unset, if set overrides the value present in Swagger specification.		String
componentName (producer)	Name of the Camel component that will perform the requests. The component must be present in Camel registry and it must implement RestProducerFactory service provider interface. If not set CLASSPATH is searched for single component that implements RestProducerFactory SPI. Can be overridden in endpoint configuration.		String
consumes (producer)	What payload type this component capable of consuming. Could be one type, like application/json or multiple types as application/json, application/xml; q=0.5 according to the RFC7231. This equates to the value of Accept HTTP header. If set overrides any value found in the Swagger specification. Can be overridden in endpoint configuration		String
host (producer)	Scheme hostname and port to direct the HTTP requests to in the form of https://hostname:port . Can be configured at the endpoint, component or in the corresponding REST configuration in the Camel Context. If you give this component a name (e.g. petstore) that REST configuration is consulted first, rest-swagger next, and global configuration last. If set overrides any value found in the Swagger specification, RestConfiguration. Can be overridden in endpoint configuration.		String

Name	Description	Default	Type
produces (producer)	What payload type this component is producing. For example application/json according to the RFC7231. This equates to the value of Content-Type HTTP header. If set overrides any value present in the Swagger specification. Can be overridden in endpoint configuration.		String
specificationUri (producer)	Path to the Swagger specification file. The scheme, host base path are taken from this specification, but these can be overridden with properties on the component or endpoint level. If not given the component tries to load swagger.json resource. Note that the host defined on the component and endpoint of this Component should contain the scheme, hostname and optionally the port in the URI syntax (i.e. https://api.example.com:8080). Can be overridden in endpoint configuration.	swagger.json	URI
sslContextParameters (security)	Customize TLS parameters used by the component. If not set defaults to the TLS parameters set in the Camel context		SSLContextParameters
useGlobalSslContextParameters (security)	Enable usage of global SSL context parameters.	false	boolean
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The REST Swagger endpoint is configured using URI syntax:

```
rest-swagger:specificationUri#operationId
```

with the following path and query parameters:

280.2.1. Path Parameters (2 parameters):

Name	Description	Default	Type
------	-------------	---------	------

Name	Description	Default	Type
specificationUri	Path to the Swagger specification file. The scheme, host base path are taken from this specification, but these can be overridden with properties on the component or endpoint level. If not given the component tries to load swagger.json resource. Note that the host defined on the component and endpoint of this Component should contain the scheme, hostname and optionally the port in the URI syntax (i.e. https://api.example.com:8080). Overrides component configuration.	swagger.json	URI
operationId	Required ID of the operation from the Swagger specification.		String

280.2.2. Query Parameters (6 parameters):

Name	Description	Default	Type
basePath (producer)	API basePath, for example /v2. Default is unset, if set overrides the value present in Swagger specification and in the component configuration.		String
componentName (producer)	Name of the Camel component that will perform the requests. The component must be present in Camel registry and it must implement RestProducerFactory service provider interface. If not set CLASSPATH is searched for single component that implements RestProducerFactory SPI. Overrides component configuration.		String
consumes (producer)	What payload type this component capable of consuming. Could be one type, like application/json or multiple types as application/json, application/xml; q=0.5 according to the RFC7231. This equates to the value of Accept HTTP header. If set overrides any value found in the Swagger specification and. in the component configuration		String

Name	Description	Default	Type
host (producer)	Scheme hostname and port to direct the HTTP requests to in the form of https://hostname:port . Can be configured at the endpoint, component or in the corresponding REST configuration in the Camel Context. If you give this component a name (e.g. petstore) that REST configuration is consulted first, rest-swagger next, and global configuration last. If set overrides any value found in the Swagger specification, RestConfiguration. Overrides all other configuration.		String
produces (producer)	What payload type this component is producing. For example application/json according to the RFC7231. This equates to the value of Content-Type HTTP header. If set overrides any value present in the Swagger specification. Overrides all other configuration.		String
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

280.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 10 options, which are listed below.

Name	Description	Default	Type
camel.component.rest-swagger.base-path	API basePath, for example /v2. Default is unset, if set overrides the value present in Swagger specification.		String
camel.component.rest-swagger.component-name	Name of the Camel component that will perform the requests. The component must be present in Camel registry and it must implement RestProducerFactory service provider interface. If not set CLASSPATH is searched for single component that implements RestProducerFactory SPI. Can be overridden in endpoint configuration.		String

Name	Description	Default	Type
<code>camel.component.rest-swagger.consumes</code>	What payload type this component capable of consuming. Could be one type, like <code>application/json</code> or multiple types as <code>application/json, application/xml; q=0.5</code> according to the RFC7231. This equates to the value of <code>Accept</code> HTTP header. If set overrides any value found in the Swagger specification. Can be overridden in endpoint configuration		String
<code>camel.component.rest-swagger.enabled</code>	Enable rest-swagger component	true	Boolean
<code>camel.component.rest-swagger.host</code>	Scheme hostname and port to direct the HTTP requests to in the form of <code>https://hostname:port</code> . Can be configured at the endpoint, component or in the corresponding REST configuration in the Camel Context. If you give this component a name (e.g. <code>petstore</code>) that REST configuration is consulted first, <code>rest-swagger</code> next, and global configuration last. If set overrides any value found in the Swagger specification, <code>RestConfiguration</code> . Can be overridden in endpoint configuration.		String
<code>camel.component.rest-swagger.produces</code>	What payload type this component is producing. For example <code>application/json</code> according to the RFC7231. This equates to the value of <code>Content-Type</code> HTTP header. If set overrides any value present in the Swagger specification. Can be overridden in endpoint configuration.		String
<code>camel.component.rest-swagger.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.component.rest-swagger.specification-uri</code>	Path to the Swagger specification file. The scheme, host base path are taken from this specification, but these can be overridden with properties on the component or endpoint level. If not given the component tries to load <code>swagger.json</code> resource. Note that the host defined on the component and endpoint of this Component should contain the scheme, hostname and optionally the port in the URI syntax (i.e. <code>https://api.example.com:8080</code>). Can be overridden in endpoint configuration.		URI

Name	Description	Default	Type
<code>camel.component.rest-swagger.ssl-context-parameters</code>	Customize TLS parameters used by the component. If not set defaults to the TLS parameters set in the Camel context. The option is a <code>org.apache.camel.util.jsse.SSLContextParameters</code> type.		String
<code>camel.component.rest-swagger.use-global-ssl-context-parameters</code>	Enable usage of global SSL context parameters.	false	Boolean

280.4. EXAMPLE: PETSTORE

Checkout the example in the `camel-example-rest-swagger` project in the `examples` directory.

For example if you wanted to use the [PetStore](#) provided REST API simply reference the specification URI and desired operation id from the Swagger specification or download the specification and store it as `swagger.json` (in the root) of CLASSPATH that way it will be automatically used. Let's use the [undertow](#) component to perform all the requests and Camels excellent support for Spring Boot.

Here are our dependencies defined in Maven POM file:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-undertow-starter</artifactId>
</dependency>

<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-rest-swagger-starter</artifactId>
</dependency>
```

Start by defining the `Undertow` component and the `RestSwaggerComponent`:

```
@Bean
public Component petstore(CamelContext camelContext, UndertowComponent undertow) {
    RestSwaggerComponent petstore = new RestSwaggerComponent(camelContext);
    petstore.setSpecificationUri("http://petstore.swagger.io/v2/swagger.json");
    petstore.setDelegate(undertow);

    return petstore;
}
```

NOTE

Support in Camel for Spring Boot will auto create the **UndertowComponent** Spring bean, and you can configure it using **application.properties** (or **application.yml**) using prefix **camel.component.undertow..** We are defining the **petstore** component here in order to have a named component in the Camel context that we can use to interact with the PetStore REST API, if this is the only **rest-swagger** component used we might configure it in the same manner (using **application.properties**).

Now in our application we can simply use the **ProducerTemplate** to invoke PetStore REST methods:

```
@Autowired
ProducerTemplate template;

String getPetJsonById(int petId) {
    return template.requestBodyAndHeaders("petstore:getPetById", null, "petId", petId);
}
```

CHAPTER 281. RESTLET COMPONENT

Available as of Camel version 2.0

The **Restlet** component provides [Restlet](#) based endpoints for consuming and producing RESTful resources.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-restlet</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

281.1. URI FORMAT

```
restlet:restletUrl[?options]
```

Format of restletUrl:

```
protocol://hostname[:port][/resourcePattern]
```

Restlet promotes decoupling of protocol and application concerns. The reference implementation of [Restlet Engine](#) supports a number of protocols. However, we have tested the HTTP protocol only. The default port is port 80. We do not automatically switch default port based on the protocol yet.

You can append query options to the URI in the following format, **?option=value&option=value&...**

INFO: It seems Restlet is case sensitive in understanding headers. For example to use content-type, use Content-Type, and for location use Location and so on.

WARNING

We have received a report about drop in performance in camel-restlet in Camel 2.14.0 and 2.14.1. We have reported this to the Restlet team in [issue 996](#). To remedy the issue then from Camel 2.14.2 onwards you can set synchronous=true as option on the endpoint uris, Or set it on the RestletComponent as a global option so all endpoints inherit this option.

281.2. OPTIONS

The Restlet component supports 23 options, which are listed below.

Name	Description	Default	Type
controllerDaemon (consumer)	Indicates if the controller thread should be a daemon (not blocking JVM exit).		Boolean
controllerSleepTimeMs (consumer)	Time for the controller thread to sleep between each control.		Integer
headerFilterStrategy (filter)	To use a custom <code>org.apache.camel.spi.HeaderFilterStrategy</code> to filter header to and from Camel message.		HeaderFilterStrategy
inboundBufferSize (consumer)	The size of the buffer when reading messages.		Integer
maxConnectionsPerHost (common)	Maximum number of concurrent connections per host (IP address).		Integer
maxThreads (consumer)	Maximum threads that will service requests.		Integer
lowThreads (consumer)	Number of worker threads determining when the connector is considered overloaded.		Integer
maxTotalConnections (common)	Maximum number of concurrent connections in total.		Integer
minThreads (consumer)	Minimum threads waiting to service requests.		Integer
outboundBufferSize (consumer)	The size of the buffer when writing messages.		Integer
persistingConnections (consumer)	Indicates if connections should be kept alive after a call.		Boolean
pipeliningConnections (consumer)	Indicates if pipelining connections are supported.		Boolean
threadMaxIdleTimeMs (consumer)	Time for an idle thread to wait for an operation before being collected.		Integer

Name	Description	Default	Type
useForwardedForHeader (consumer)	Lookup the X-Forwarded-For header supported by popular proxies and caches and uses it to populate the Request.getClientAddresses() method result. This information is only safe for intermediary components within your local network. Other addresses could easily be changed by setting a fake header and should not be trusted for serious security checks.		Boolean
reuseAddress (consumer)	Enable/disable the SO_REUSEADDR socket option. See java.io.ServerSocket#reuseAddress property for additional details.		Boolean
maxQueued (consumer)	Maximum number of calls that can be queued if there aren't any worker thread available to service them. If the value is '0', then no queue is used and calls are rejected if no worker thread is immediately available. If the value is '-1', then an unbounded queue is used and calls are never rejected.		Integer
disableStreamCache (consumer)	Determines whether or not the raw input stream from Restlet is cached or not (Camel will read the stream into a in memory/overflow to file, Stream caching) cache. By default Camel will cache the Restlet input stream to support reading it multiple times to ensure Camel can retrieve all data from the stream. However you can set this option to true when you for example need to access the raw stream, such as streaming it directly to a file or other persistent store. DefaultRestletBinding will copy the request input stream into a stream cache and put it into message body if this option is false to support reading the stream multiple times.	false	boolean
port (consumer)	To configure the port number for the restlet consumer routes. This allows to configure this once to reuse the same port for these consumers.		int
synchronous (producer)	Whether to use synchronous Restlet Client for the producer. Setting this option to true can yield faster performance as it seems the Restlet synchronous Client works better.		Boolean
enabledConverters (advanced)	A list of converters to enable as full class name or simple class name. All the converters automatically registered are enabled if empty or null		List

Name	Description	Default	Type
useGlobalSslContext Parameters (security)	Enable usage of global SSL context parameters.	false	boolean
sslContextParameters (security)	To configure security using SSLContextParameters		SSLContextParameters
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Restlet endpoint is configured using URI syntax:

```
restlet:protocol:host:port/uriPattern
```

with the following path and query parameters:

281.2.1. Path Parameters (4 parameters):

Name	Description	Default	Type
protocol	Required The protocol to use which is http or https		String
host	Required The hostname of the restlet service		String
port	Required The port number of the restlet service	80	int
uriPattern	The resource pattern such as /customer/id		String

281.2.2. Query Parameters (18 parameters):

Name	Description	Default	Type
restletMethod (common)	On a producer endpoint, specifies the request method to use. On a consumer endpoint, specifies that the endpoint consumes only restletMethod requests.	GET	Method

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
restletMethods (consumer)	Specify one or more methods separated by commas (e.g. <code>restletMethods=post,put</code>) to be serviced by a restlet consumer endpoint. If both <code>restletMethod</code> and <code>restletMethods</code> options are specified, the <code>restletMethod</code> setting is ignored. The possible methods are: ALL,CONNECT,DELETE,GET,HEAD,OPTIONS,PATCH,POST,PUT,TRACE		String
disableStreamCache (consumer)	Determines whether or not the raw input stream from Restlet is cached or not (Camel will read the stream into a in memory/overflow to file, Stream caching) cache. By default Camel will cache the Restlet input stream to support reading it multiple times to ensure Camel can retrieve all data from the stream. However you can set this option to true when you for example need to access the raw stream, such as streaming it directly to a file or other persistent store. DefaultRestletBinding will copy the request input stream into a stream cache and put it into message body if this option is false to support reading the stream multiple times.	false	boolean
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
restletUriPatterns (consumer)	Deprecated Specify one ore more URI templates to be serviced by a restlet consumer endpoint, using the <code>#</code> notation to reference a List in the Camel Registry. If a URI pattern has been defined in the endpoint URI, both the URI pattern defined in the endpoint and the <code>restletUriPatterns</code> option will be honored.		List

Name	Description	Default	Type
connectTimeout (producer)	The Client will give up connection if the connection is timeout, 0 for unlimited wait.	30000	int
cookieHandler (producer)	Configure a cookie handler to maintain a HTTP session		CookieHandler
socketTimeout (producer)	The Client socket receive timeout, 0 for unlimited wait.	30000	int
throwExceptionOnFailure (producer)	Whether to throw exception on a producer failure. If this option is false then the http status code is set as a message header which can be checked if it has an error value.	true	boolean
autoCloseStream (producer)	Whether to auto close the stream representation as response from calling a REST service using the restlet producer. If the response is streaming and the option streamRepresentation is enabled then you may want to auto close the InputStream from the streaming response to ensure the input stream is closed when the Camel Exchange is done being routed. However if you need to read the stream outside a Camel route, you may need to not auto close the stream.	false	boolean
streamRepresentation (producer)	Whether to support stream representation as response from calling a REST service using the restlet producer. If the response is streaming then this option can be enabled to use an java.io.InputStream as the message body on the Camel Message body. If using this option you may want to enable the autoCloseStream option as well to ensure the input stream is closed when the Camel Exchange is done being routed. However if you need to read the stream outside a Camel route, you may need to not auto close the stream.	false	boolean
headerFilterStrategy (advanced)	To use a custom HeaderFilterStrategy to filter header to and from Camel message.		HeaderFilterStrategy
restletBinding (advanced)	To use a custom RestletBinding to bind between Restlet and Camel message.		RestletBinding
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

Name	Description	Default	Type
restletRealm (security)	To configure the security realms of restlet as a map.		Map
sslContextParameters (security)	To configure security using SSLContextParameters.		SSLContextParameters

281.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 24 options, which are listed below.

Name	Description	Default	Type
camel.component.restlet.controller-daemon	Indicates if the controller thread should be a daemon (not blocking JVM exit).		Boolean
camel.component.restlet.controller-sleep-time-ms	Time for the controller thread to sleep between each control.		Integer
camel.component.restlet.disable-stream-cache	Determines whether or not the raw input stream from Restlet is cached or not (Camel will read the stream into a in memory/overflow to file, Stream caching) cache. By default Camel will cache the Restlet input stream to support reading it multiple times to ensure Camel can retrieve all data from the stream. However you can set this option to true when you for example need to access the raw stream, such as streaming it directly to a file or other persistent store. DefaultRestletBinding will copy the request input stream into a stream cache and put it into message body if this option is false to support reading the stream multiple times.	false	Boolean
camel.component.restlet.enabled	Enable restlet component	true	Boolean
camel.component.restlet.enabled-converters	A list of converters to enable as full class name or simple class name. All the converters automatically registered are enabled if empty or null		List
camel.component.restlet.header-filter-strategy	To use a custom org.apache.camel.spi.HeaderFilterStrategy to filter header to and from Camel message. The option is a org.apache.camel.spi.HeaderFilterStrategy type.		String

Name	Description	Default	Type
<code>camel.component.restlet.inbound-buffer-size</code>	The size of the buffer when reading messages.		Integer
<code>camel.component.restlet.low-threads</code>	Number of worker threads determining when the connector is considered overloaded.		Integer
<code>camel.component.restlet.max-connections-per-host</code>	Maximum number of concurrent connections per host (IP address).		Integer
<code>camel.component.restlet.max-queued</code>	Maximum number of calls that can be queued if there aren't any worker thread available to service them. If the value is '0', then no queue is used and calls are rejected if no worker thread is immediately available. If the value is '-1', then an unbounded queue is used and calls are never rejected.		Integer
<code>camel.component.restlet.max-threads</code>	Maximum threads that will service requests.		Integer
<code>camel.component.restlet.max-total-connections</code>	Maximum number of concurrent connections in total.		Integer
<code>camel.component.restlet.min-threads</code>	Minimum threads waiting to service requests.		Integer
<code>camel.component.restlet.outbound-buffer-size</code>	The size of the buffer when writing messages.		Integer
<code>camel.component.restlet.persisting-connections</code>	Indicates if connections should be kept alive after a call.		Boolean
<code>camel.component.restlet.pipelining-connections</code>	Indicates if pipelining connections are supported.		Boolean
<code>camel.component.restlet.port</code>	To configure the port number for the restlet consumer routes. This allows to configure this once to reuse the same port for these consumers.		Integer

Name	Description	Default	Type
<code>camel.component.restlet.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.component.restlet.reuse-address</code>	Enable/disable the SO_REUSEADDR socket option. See <code>java.io.ServerSocket#reuseAddress</code> property for additional details.		Boolean
<code>camel.component.restlet.ssl-context-parameters</code>	To configure security using <code>SSLContextParameters</code> . The option is a <code>org.apache.camel.util.jsse.SSLContextParameters</code> type.		String
<code>camel.component.restlet.synchronous</code>	Whether to use synchronous Restlet Client for the producer. Setting this option to true can yield faster performance as it seems the Restlet synchronous Client works better.		Boolean
<code>camel.component.restlet.thread-max-idle-time-ms</code>	Time for an idle thread to wait for an operation before being collected.		Integer
<code>camel.component.restlet.use-forwarded-for-header</code>	Lookup the X-Forwarded-For header supported by popular proxies and caches and uses it to populate the <code>Request.getClientAddresses()</code> method result. This information is only safe for intermediary components within your local network. Other addresses could easily be changed by setting a fake header and should not be trusted for serious security checks.		Boolean
<code>camel.component.restlet.use-global-ssl-context-parameters</code>	Enable usage of global SSL context parameters.	false	Boolean

281.4. MESSAGE HEADERS

Name	Type	Description
------	------	-------------

Name	Type	Description
Content-Type	String	Specifies the content type, which can be set on the OUT message by the application/processor. The value is the content-type of the response message. If this header is not set, the content type is based on the object type of the OUT message body. In Camel 2.3 onward, if the Content-Type header is specified in the Camel IN message, the value of the header determine the content type for the Restlet request message. Otherwise, it is defaulted to "application/x-www-form-urlencoded". Prior to release 2.3, it is not possible to change the request content type default.
Camel AcceptContentType	String	Since Camel 2.9.3, 2.10.0: The HTTP Accept request header.
Camel HttpMethod	String	The HTTP request method. This is set in the IN message header.
Camel HttpQuery	String	The query string of the request URI. It is set on the IN message by DefaultRestletBinding when the restlet component receives a request.
Camel HttpResponseCode	String or Integer	The response code can be set on the OUT message by the application/processor. The value is the response code of the response message. If this header is not set, the response code is set by the restlet runtime engine.
Camel HttpUri	String	The HTTP request URI. This is set in the IN message header.
Camel RestletLogin	String	Login name for basic authentication. It is set on the IN message by the application and gets filtered before the restlet request header by Camel.
Camel RestletPassword	String	Password name for basic authentication. It is set on the IN message by the application and gets filtered before the restlet request header by Camel.
Camel RestletRequest	Request	Camel 2.8: The org.restlet.Request object which holds all request details.

Name	Type	Description
Camel RestletResponse	Response	Camel 2.8: The org.restlet.Response object. You can use this to create responses using the API from Restlet. See examples below.
org.restlet.*		Attributes of a Restlet message that get propagated to Camel IN headers.
cache-control	String or List<CacheDirective>	Camel 2.11: User can set the cache-control with the String value or the List of CacheDirective of Restlet from the camel message header.

281.5. MESSAGE BODY

Camel will store the restlet response from the external server on the OUT body. All headers from the IN message will be copied to the OUT message, so that headers are preserved during routing.

281.6. SAMPLES

281.6.1. Restlet Endpoint with Authentication

The following route starts a **restlet** consumer endpoint that listens for **POST** requests on <http://localhost:8080>. The processor creates a response that echoes the request body and the value of the **id** header.

The **restletRealm** setting in the URI query is used to look up a Realm Map in the registry. If this option is specified, the restlet consumer uses the information to authenticate user logins. Only *authenticated* requests can access the resources. In this sample, we create a Spring application context that serves as a registry. The bean ID of the Realm Map should match the *restletRealmRef*.

The following sample starts a **direct** endpoint that sends requests to the server on <http://localhost:8080> (that is, our restlet consumer endpoint).

That is all we need. We are ready to send a request and try out the restlet component:

The sample client sends a request to the **direct:start-auth** endpoint with the following headers:

- **CamelRestletLogin** (used internally by Camel)
- **CamelRestletPassword** (used internally by Camel)
- **id** (application header)

**NOTE**

org.apache.camel.restlet.auth.login and **org.apache.camel.restlet.auth.password** will not be propagated as Restlet header.

The sample client gets a response like the following:

```
received [<order foo='1'/>] as an order id = 89531
```

281.6.2. Single restlet endpoint to service multiple methods and URI templates (deprecated)

This functionality is **deprecated** so do NOT use!

It is possible to create a single route to service multiple HTTP methods using the **restletMethods** option. This snippet also shows how to retrieve the request method from the header:

In addition to servicing multiple methods, the next snippet shows how to create an endpoint that supports multiple URI templates using the **restletUriPatterns** option. The request URI is available in the header of the IN message as well. If a URI pattern has been defined in the endpoint URI (which is not the case in this sample), both the URI pattern defined in the endpoint and the **restletUriPatterns** option will be honored.

The **restletUriPatterns=#uriTemplates** option references the **List<String>** bean defined in the Spring XML configuration.

```
<util:list id="uriTemplates">
  <value>/users/{username}</value>
  <value>/atom/collection/{id}/component/{cid}</value>
</util:list>
```

281.6.3. Using Restlet API to populate response

Available as of Camel 2.8

You may want to use the **org.restlet.Response** API to populate the response. This gives you full access to the Restlet API and fine grained control of the response. See the route snippet below where we generate the response from an inlined Camel Processor:

Generating response using Restlet Response API

281.6.4. Configuring max threads on component

To configure the max threads options you must do this on the component, such as:

```
<bean id="restlet" class="org.apache.camel.component.restlet.RestletComponent">
  <property name="maxThreads" value="100"/>
</bean>
```

281.6.5. Using the Restlet servlet within a webapp

Available as of Camel 2.8

There are [three possible ways](#) to configure a Restlet application within a servlet container and using the subclassed `SpringServerServlet` enables configuration within Camel by injecting the Restlet Component.

Use of the Restlet servlet within a servlet container enables routes to be configured with relative paths in URIs (removing the restrictions of hard-coded absolute URIs) and for the hosting servlet container to handle incoming requests (rather than have to spawn a separate server process on a new port).

To configure, add the following to your `camel-context.xml`;

```
<camelContext>
  <route id="RS_RestletDemo">
    <from uri="restlet:/demo/{id}" />
    <transform>
      <simple>Request type : ${header.CamelHttpMethod} and ID : ${header.id}</simple>
    </transform>
  </route>
</camelContext>

<bean id="RestletComponent" class="org.restlet.Component" />

<bean id="RestletComponentService"
class="org.apache.camel.component.restlet.RestletComponent">
  <constructor-arg index="0">
    <ref bean="RestletComponent" />
  </constructor-arg>
</bean>
```

And add this to your `web.xml`;

```
<!-- Restlet Servlet -->
<servlet>
  <servlet-name>RestletServlet</servlet-name>
  <servlet-class>org.restlet.ext.spring.SpringServerServlet</servlet-class>
  <init-param>
    <param-name>org.restlet.component</param-name>
    <param-value>RestletComponent</param-value>
  </init-param>
</servlet>

<servlet-mapping>
  <servlet-name>RestletServlet</servlet-name>
  <url-pattern>/rs/*</url-pattern>
</servlet-mapping>
```

You will then be able to access the deployed route at <http://localhost:8080/mywebapp/rs/demo/1234> where;

localhost:8080 is the server and port of your servlet container
mywebapp is the name of your deployed webapp
 Your browser will then show the following content;

```
"Request type : GET and ID : 1234"
```

You will need to add dependency on the Spring extension to restlet which you can do in your Maven pom.xml file:

```
<dependency>
  <groupId>org.restlet.jee</groupId>
  <artifactId>org.restlet.ext.spring</artifactId>
  <version>${restlet-version}</version>
</dependency>
```

And you would need to add dependency on the restlet maven repository as well:

```
<repository>
  <id>maven-restlet</id>
  <name>Public online Restlet repository</name>
  <url>https://maven.restlet.com</url>
</repository>
```

CHAPTER 282. RIBBON COMPONENT

Available as of Camel version 2.18

The ribbon component provides use of Netflix Ribbon for client side load balancing.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-ribbon</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

This component helps applying load balancing feature at the client side when using [ServiceCall EIP](#).

282.1. CONFIGURATION

- **Programmatic**

```
RibbonConfiguration configuration = new RibbonConfiguration();
configuration.addProperties("ServerListRefreshInterval", "250");

RibbonLoadBalancer loadBalancer = new RibbonLoadBalancer(configuration);

from("direct:start")
  .serviceCall()
  .name("myService")
  .loadBalancer(loadBalancer)
  .consulServiceDiscovery()
  .end()
  .to("mock:result");
```

- **Spring Boot**

application.properties

```
camel.cloud.ribbon.properties[ServerListRefreshInterval] = 250
```

routes

```
from("direct:start")
  .serviceCall()
  .name("myService")
  .ribbonLoadBalancer()
  .consulServiceDiscovery()
  .end()
  .to("mock:result");
```

- **XML**

```
<route>
```

```
<from uri="direct:start"/>
<serviceCall name="myService">
  <!-- enable ribbon load balancer -->
  <ribbonLoadBalancer>
    <properties key="ServerListRefreshInterval" value="250"/>
  </ribbonLoadBalancer>
</serviceCall>
</route>
```

282.2. SEE ALSO

- [ServiceCall EIP](#)

CHAPTER 283. RMI COMPONENT

Available as of Camel version 1.0

The `rmi:` component binds Exchanges to the RMI protocol (JRMP).

Since this binding is just using RMI, normal RMI rules still apply regarding what methods can be invoked. This component supports only Exchanges that carry a method invocation from an interface that extends the `Remote` interface. All parameters in the method should be either `Serializable` or `Remote` objects.

Maven users will need to add the following dependency to their `pom.xml` for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-rmi</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

283.1. URI FORMAT

```
rmi://rmi-registry-host:rmi-registry-port/registry-path[?options]
```

For example:

```
rmi://localhost:1099/path/to/service
```

You can append query options to the URI in the following format, `?option=value&option=value&...`

283.2. OPTIONS

The RMI component has no options.

The RMI endpoint is configured using URI syntax:

```
rmi:hostname:port/name
```

with the following path and query parameters:

283.2.1. Path Parameters (3 parameters):

Name	Description	Default	Type
<code>hostname</code>	Hostname of RMI server	localhost	String
<code>name</code>	Required Name to use when binding to RMI server		String
<code>port</code>	Port number of RMI server	1099	int

283.2.2. Query Parameters (6 parameters):

Name	Description	Default	Type
method (common)	You can set the name of the method to invoke.		String
remoteInterfaces (common)	To specific the remote interfaces.		List
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

283.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.component.rmi.enabled	Enable rmi component	true	Boolean
camel.component.rmi.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

283.4. USING

To call out to an existing RMI service registered in an RMI registry, create a route similar to the following:

```
from("pojo:foo").to("rmi://localhost:1099/foo");
```

To bind an existing camel processor or service in an RMI registry, define an RMI endpoint as follows:

```
RmiEndpoint endpoint= (RmiEndpoint) endpoint("rmi://localhost:1099/bar");  
endpoint.setRemoteInterfaces(ISay.class);  
from(endpoint).to("pojo:bar");
```

Note that when binding an RMI consumer endpoint, you must specify the **Remote** interfaces exposed.

In XML DSL you can do as follows from **Camel 2.7** onwards:

```
<camel:route>  
  <from uri="rmi://localhost:37541/helloServiceBean?  
remoteInterfaces=org.apache.camel.example.osgi.HelloService"/>  
  <to uri="bean:helloServiceBean"/>  
</camel:route>
```

- [Endpoint](#)
- [Getting Started](#)

CHAPTER 284. ROUTEBOX COMPONENT (DEPRECATED)

Available as of Camel version 2.6

Routebox subject for change

The **routebox** component enables the creation of specialized endpoints that offer encapsulation and a strategy based indirection service to a collection of camel routes hosted in an automatically created or user injected camel context.

Routebox endpoints are camel endpoints that may be invoked directly on camel routes. The routebox endpoint performs the following key functions

- encapsulation - acts as a blackbox, hosting a collection of camel routes stored in an inner camel context. The inner context is fully under the control of the routebox component and is **JVM bound**.
- strategy based indirection - direct payloads sent to the routebox endpoint along a camel route to specific inner routes based on a user defined internal routing strategy or a dispatch map.
- exchange propagation - forward exchanges modified by the routebox endpoint to the next segment of the camel route.

The routebox component supports both consumer and producer endpoints.

Producer endpoints are of two flavors

- Producers that send or dispatch incoming requests to a external routebox consumer endpoint
- Producers that directly invoke routes in an internal embedded camel context thereby not sending requests to an external consumer.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-routebox</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

284.1. THE NEED FOR A CAMEL ROUTEBOX ENDPOINT

The routebox component is designed to ease integration in complex environments needing

- a large collection of routes and
- involving a wide set of endpoint technologies needing integration in different ways

In such environments, it is often necessary to craft an integration solution by creating a sense of layering among camel routes effectively organizing them into

- Coarse grained or higher level routes - aggregated collection of inner or lower level routes exposed as Routebox endpoints that represent an integration focus area. For example

Focus Area	Coarse grained Route Examples
Department Focus	HR routes, Sales routes etc
Supply chain & B2B Focus	Shipping routes, Fulfillment routes, 3rd party services etc
Technology Focus	Database routes, JMS routes, Scheduled batch routes etc

- Fine grained routes - routes that execute a singular and specific business and/or integration pattern.

Requests sent to Routebox endpoints on coarse grained routes can then delegate requests to inner fine grained routes to achieve a specific integration objective, collect the final inner result, and continue to progress to the next step along the coarse-grained route.

284.2. URI FORMAT

```
routebox:routeboxname[?options]
```

You can append query options to the URI in the following format, **?option=value&option=value&...**

284.3. OPTIONS

The RouteBox component has no options.

The RouteBox endpoint is configured using URI syntax:

```
routebox:routeboxName
```

with the following path and query parameters:

284.3.1. Path Parameters (1 parameters):

Name	Description	Default	Type
<code>routeboxName</code>	Required Logical name for the routebox (eg like a queue name)		String

284.3.2. Query Parameters (17 parameters):

Name	Description	Default	Type
dispatchMap (common)	A string representing a key in the Camel Registry matching an object value of the type HashMap. The HashMap key should contain strings that can be matched against the value set for the exchange header ROUTE_DISPATCH_KEY. The HashMap value should contain inner route consumer URI's to which requests should be directed.		Map
dispatchStrategy (common)	To use a custom RouteboxDispatchStrategy which allows to use custom dispatching instead of the default.		RouteboxDispatchStrategy
forkContext (common)	Whether to fork and create a new inner CamelContext instead of reusing the same CamelContext.	true	boolean
innerProtocol (common)	The Protocol used internally by the Routebox component. Can be Direct or SEDA. The Routebox component currently offers protocols that are JVM bound.	direct	String
queueSize (common)	Create a fixed size queue to receive requests.		int
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
pollInterval (consumer)	The timeout used when polling from seda. When a timeout occurs, the consumer can check whether it is allowed to continue running. Setting a lower value allows the consumer to react more quickly upon shutdown.	1000	long
threads (consumer)	Number of threads to be used by the routebox to receive requests.	20	int
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler

Name	Description	Default	Type
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
connectionTimeout (producer)	Timeout in millis used by the producer when sending a message.	20000	long
sendToConsumer (producer)	Dictates whether a Producer endpoint sends a request to an external routebox consumer. If the setting is false, the Producer creates an embedded inner context and processes requests internally.	true	boolean
innerContext (advanced)	A string representing a key in the Camel Registry matching an object value of the type <code>org.apache.camel.CamelContext</code> . If a <code>CamelContext</code> is not provided by the user a <code>CamelContext</code> is automatically created for deployment of inner routes.		CamelContext
innerProducerTemplate (advanced)	The <code>ProducerTemplate</code> to use by the internal embedded <code>CamelContext</code>		ProducerTemplate
innerRegistry (advanced)	To use a custom registry for the internal embedded <code>CamelContext</code> .		Registry
routeBuilders (advanced)	A string representing a key in the Camel Registry matching an object value of the type <code>List</code> . If the user does not supply an <code>innerContext</code> pre-primed with inner routes, the <code>routeBuilders</code> option must be provided as a non-empty list of <code>RouteBuilders</code> containing inner routes		String
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

284.4. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.component.routebox.enabled	Enable routebox component	true	Boolean

Name	Description	Default	Type
<code>camel.component.routebox.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

284.5. SENDING/RECEIVING MESSAGES TO/FROM THE ROUTEBOX

Before sending requests it is necessary to properly configure the routebox by loading the required URI parameters into the Registry as shown below. In the case of Spring, if the necessary beans are declared correctly, the registry is automatically populated by Camel.

284.5.1. Step 1: Loading inner route details into the Registry

```

@Override
protected JndiRegistry createRegistry() throws Exception {
    JndiRegistry registry = new JndiRegistry(createJndiContext());

    // Wire the routeDefinitions & dispatchStrategy to the outer camelContext where the routebox is
    // declared
    List<RouteBuilder> routes = new ArrayList<RouteBuilder>();
    routes.add(new SimpleRouteBuilder());
    registry.bind("registry", createInnerRegistry());
    registry.bind("routes", routes);

    // Wire a dispatch map to registry
    HashMap<String, String> map = new HashMap<String, String>();
    map.put("addToCatalog", "seda:addToCatalog");
    map.put("findBook", "seda:findBook");
    registry.bind("map", map);

    // Alternatively wiring a dispatch strategy to the registry
    registry.bind("strategy", new SimpleRouteDispatchStrategy());

    return registry;
}

private JndiRegistry createInnerRegistry() throws Exception {
    JndiRegistry innerRegistry = new JndiRegistry(createJndiContext());
    BookCatalog catalogBean = new BookCatalog();
    innerRegistry.bind("library", catalogBean);

    return innerRegistry;
}
...
CamelContext context = new DefaultCamelContext(createRegistry());

```

284.5.2. Step 2: Optionally using a Dispatch Strategy instead of a Dispatch Map

Using a dispatch Strategy involves implementing the interface `org.apache.camel.component.routebox.strategy.RouteboxDispatchStrategy` as shown in the example below.

```
public class SimpleRouteDispatchStrategy implements RouteboxDispatchStrategy {

    /* (non-Javadoc)
     * @see
     org.apache.camel.component.routebox.strategy.RouteboxDispatchStrategy#selectDestinationUri(java.u.
     il.List, org.apache.camel.Exchange)
     */
    public URI selectDestinationUri(List<URI> activeDestinations,
        Exchange exchange) {
        URI dispatchDestination = null;

        String operation = exchange.getIn().getHeader("ROUTE_DISPATCH_KEY", String.class);
        for (URI destination : activeDestinations) {
            if (destination.toASCIIString().equalsIgnoreCase("seda:" + operation)) {
                dispatchDestination = destination;
                break;
            }
        }

        return dispatchDestination;
    }
}
```

284.5.3. Step 2: Launching a routebox consumer

When creating a route consumer, note that the # entries in the routeboxUri are matched to the created inner registry, routebuilder list and dispatchStrategy/dispatchMap in the CamelContext Registry. Note that all routebuilders and associated routes are launched in the routebox created inner context

```
private String routeboxUri = "routebox:multipleRoutes?
innerRegistry=#registry&routeBuilders=#routes&dispatchMap=#map";

public void testRouteboxRequests() throws Exception {
    CamelContext context = createCamelContext();
    template = new DefaultProducerTemplate(context);
    template.start();

    context.addRoutes(new RouteBuilder() {
        public void configure() {
            from(routeboxUri)
                .to("log:Routes operation performed?showAll=true");
        }
    });
    context.start();

    // Now use the ProducerTemplate to send the request to the routebox
    template.requestBodyAndHeader(routeboxUri, book, "ROUTE_DISPATCH_KEY",
"addToCatalog");
}
```

284.5.4. Step 3: Using a routebox producer

When sending requests to the routebox, it is not necessary for producers do not need to know the inner route endpoint URI and they can simply invoke the Routebox URI endpoint with a dispatch strategy or dispatchMap as shown below

It is necessary to set a special exchange Header called **ROUTE_DISPATCH_KEY** (optional for Dispatch Strategy) with a key that matches a key in the dispatch map so that the request can be sent to the correct inner route

```
from("direct:sendToStrategyBasedRoutebox")
  .to("routebox:multipleRoutes?
innerRegistry=#registry&routeBuilders=#routes&dispatchStrategy=#strategy")
  .to("log:Routes operation performed?showAll=true");

from ("direct:sendToMapBasedRoutebox")
  .setHeader("ROUTE_DISPATCH_KEY", constant("addToCatalog"))
  .to("routebox:multipleRoutes?
innerRegistry=#registry&routeBuilders=#routes&dispatchMap=#map")
  .to("log:Routes operation performed?showAll=true");
```

CHAPTER 285. RSS COMPONENT

Available as of Camel version 2.0

The `rss:` component is used for polling RSS feeds. Camel will default poll the feed every 60th seconds.

Maven users will need to add the following dependency to their `pom.xml` for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-rss</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

Note: The component currently only supports polling (consuming) feeds.

NOTE

Camel-rss internally uses a [patched version](#) of [ROME](#) hosted on ServiceMix to solve some OSGi [class loading issues](#).

285.1. URI FORMAT

```
rss:rssUri
```

Where `rssUri` is the URI to the RSS feed to poll.

You can append query options to the URI in the following format, `?option=value&option=value&...`

285.2. OPTIONS

The RSS component has no options.

The RSS endpoint is configured using URI syntax:

```
rss:feedUri
```

with the following path and query parameters:

285.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
<code>feedUri</code>	Required The URI to the feed to poll.		String

285.2.2. Query Parameters (27 parameters):

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
feedHeader (consumer)	Sets whether to add the feed object as a header	true	boolean
filter (consumer)	Sets whether to use filtering or not of the entries.	true	boolean
lastUpdate (consumer)	Sets the timestamp to be used for filtering entries from the atom feeds. This options is only in conjunction with the <code>splitEntries</code> .		Date
password (consumer)	Sets the password to be used for basic authentication when polling from a HTTP feed		String
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean
sortEntries (consumer)	Sets whether to sort entries by published date. Only works when <code>splitEntries = true</code> .	false	boolean
splitEntries (consumer)	Sets whether or not entries should be sent individually or whether the entire feed should be sent as a single message	true	boolean
throttleEntries (consumer)	Sets whether all entries identified in a single feed poll should be delivered immediately. If true, only one entry is processed per <code>consumer.delay</code> . Only applicable when <code>splitEntries = true</code> .	true	boolean
username (consumer)	Sets the username to be used for basic authentication when polling from a HTTP feed		String
exceptionHandler (consumer)	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler

Name	Description	Default	Type
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
pollStrategy (consumer)	A pluggable <code>org.apache.camel.PollingConsumerPollingStrategy</code> allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		PollingConsumerPollStrategy
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the <code>backoffMultiplier</code> should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the <code>backoffMultiplier</code> should kick-in.		int
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then <code>backoffIdleThreshold</code> and/or <code>backoffErrorThreshold</code> must also be configured.		int
delay (scheduler)	Milliseconds before the next poll. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	500	long
greedy (scheduler)	If greedy is enabled, then the <code>ScheduledPollConsumer</code> will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	1000	long
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that.	TRACE	LoggingLevel

Name	Description	Default	Type
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz2 component	none	ScheduledPollConsumerScheduler
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz2, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for initialDelay and delay options.	MILLISECONDS	TimeUnit
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.	true	boolean

285.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 4 options, which are listed below.

Name	Description	Default	Type
camel.component.rss.enabled	Enable rss component	true	Boolean
camel.component.rss.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
camel.dataformat.rss.content-type-header	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON etc.	false	Boolean
camel.dataformat.rss.enabled	Enable rss dataformat	true	Boolean

285.4. EXCHANGE DATA TYPES

Camel initializes the In body on the Exchange with a ROME **SyndFeed**. Depending on the value of the **splitEntries** flag, Camel returns either a **SyndFeed** with one **SyndEntry** or a **java.util.List** of **SyndEntries**.

Option	Value	Behavior
splitEntries	true	A single entry from the current feed is set in the exchange.
splitEntries	false	The entire list of entries from the current feed is set in the exchange.

285.5. MESSAGE HEADERS

Header	Description
CamelRssFeed	The entire SyncFeed object.

285.6. RSS DATAFORMAT

The RSS component ships with an RSS dataformat that can be used to convert between String (as XML) and ROME RSS model objects.

- marshal = from ROME **SyndFeed** to XML **String**
- unmarshal = from XML **String** to ROME **SyndFeed**

A route using the RSS dataformat will look like this: **from("rss:file:src/test/data/rss20.xml?splitEntries=false&consumer.delay=1000").marshal().rss().to("mock:marshal");**

The purpose of this feature is to make it possible to use Camel's built-in expressions for manipulating RSS messages. As shown below, an XPath expression can be used to filter the RSS message. In the following example, only entries with Camel in the title will get through the filter.

```
`from("rss:file:src/test/data/rss20.xml?
splitEntries=true&consumer.delay=100").marshal().rss().filter().xpath("//item/title[contains(.,'Camel')]").to
("mock:result");`
```

TIP

Query parameters If the URL for the RSS feed uses query parameters, this component will resolve them. For example if the feed uses **alt=rss**, then the following example will be resolved:

```
from("rss:http://someserver.com/feeds/posts/default?
alt=rss&splitEntries=false&consumer.delay=1000").to("bean:rss");
```

285.7. FILTERING ENTRIES

You can filter out entries using XPath, as shown in the data format section above. You can also exploit Camel's Bean Integration to implement your own conditions. For instance, a filter equivalent to the XPath example above would be:

```
from("rss:file:src/test/data/rss20.xml?splitEntries=true&consumer.delay=100").  
filter().method("myFilterBean", "titleContainsCamel").to("mock:result");
```

The custom bean for this would be:

```
public static class FilterBean {  
    public boolean titleContainsCamel(@Body SyndFeed feed) {  
        SyndEntry firstEntry = (SyndEntry) feed.getEntries().get(0);  
        return firstEntry.getTitle().contains("Camel");  
    }  
}
```

285.8. SEE ALSO

CHAPTER 286. RSS DATAFORMAT

Available as of Camel version 2.1

The RSS component ships with an RSS dataformat that can be used to convert between String (as XML) and ROME RSS model objects.

- marshal = from ROME **SyndFeed** to XML **String**
- unmarshal = from XML **String** to ROME **SyndFeed**

A route using this would look something like this:

The purpose of this feature is to make it possible to use Camel's lovely built-in expressions for manipulating RSS messages. As shown below, an XPath expression can be used to filter the RSS message:

TIP

Query parameters If the URL for the RSS feed uses query parameters, this component will understand them as well, for example if the feed uses **alt=rss**, then you can for example do **from("rss:http://someserver.com/feeds/posts/default?alt=rss&splitEntries=false&consumer.delay=1000").to("bean:rss");**

286.1. OPTIONS

The RSS dataformat supports 1 options, which are listed below.

Name	Default	Java Type	Description
contentTypeHeader	false	Boolean	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSon etc.

286.2. SPRING BOOT AUTO-CONFIGURATION

The component supports 4 options, which are listed below.

Name	Description	Default	Type
camel.component.rss.enabled	Enable rss component	true	Boolean
camel.component.rss.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

Name	Description	Default	Type
camel.dataformat.rss.content-type-header	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSon etc.	false	Boolean
camel.dataformat.rss.enabled	Enable rss dataformat	true	Boolean

ND

CHAPTER 287. RXJAVA2 COMPONENT

Available as of Camel version 2.22

RxJava2 based back-end for Camel's reactive streams component.

See more details in the camel-streams-component documentation.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-rxjava2</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

CHAPTER 288. SALESFORCE COMPONENT

Available as of Camel version 2.12

This component supports producer and consumer endpoints to communicate with Salesforce using Java DTOs.

There is a companion maven plugin Camel Salesforce Plugin that generates these DTOs (see further below).

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-salesforce</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

NOTE

Developers wishing to contribute to the component are instructed to look at the README.md file on instructions on how to get started and setup your environment for running integration tests.

288.1. AUTHENTICATING TO SALESFORCE

The component supports three OAuth authentication flows:

- [OAuth 2.0 Username-Password Flow](#)
- [OAuth 2.0 Refresh Token Flow](#)
- [OAuth 2.0 JWT Bearer Token Flow](#)

For each of the flow different set of properties needs to be set:

Table 288.1. Properties to set for each authentication flow

Property	Where to find it on Salesforce	Flow
clientId	Connected App, Consumer Key	All flows
clientSecret	Connected App, Consumer Secret	Username-Password, Refresh Token
userName	Salesforce user username	Username-Password, JWT Bearer Token
password	Salesforce user password	Username-Password
refreshToken	From OAuth flow callback	Refresh Token

Property	Where to find it on Salesforce	Flow
keystore	Connected App, Digital Certificate	JWT Bearer Token

The component auto determines what flow you're trying to configure, to be remove ambiguity set the **authenticationType** property.

**NOTE**

Using Username-Password Flow in production is not encouraged.

**NOTE**

The certificate used in JWT Bearer Token Flow can be a selfsigned certificate. The KeyStore holding the certificate and the private key must contain only single certificate-private key entry.

288.2. URI FORMAT

When used as a consumer, receiving streaming events, the URI scheme is:

```
salesforce:topic?options
```

When used as a producer, invoking the Salesforce RSET APIs, the URI scheme is:

```
salesforce:operationName?options
```

You can append query options to the URI in the following format, **?option=value&option=value&...**

288.3. PASSING IN SALESFORCE HEADERS AND FETCHING SALESFORCE RESPONSE HEADERS

With Camel 2.21 there is support to pass [Salesforce headers](#) via inbound message headers, header names that start with **Sforce** or **x-sfdc** on the Camel message will be passed on in the request, and response headers that start with **Sforce** will be present in the outbound message headers.

For example to fetch API limits you can specify:

```
// in your Camel route set the header before Salesforce endpoint
//...
.setHeader("Sforce-Limit-Info", constant("api-usage"))
.to("salesforce:getGlobalObjects")
.to(myProcessor);

// myProcessor will receive `Sforce-Limit-Info` header on the outbound
// message
class MyProcessor implements Processor {
    public void process(Exchange exchange) throws Exception {
        Message in = exchange.getIn();
```

```

String apiLimits = in.getHeader("Sforce-Limit-Info", String.class);
    }
}

```

288.4. SUPPORTED SALESFORCE APIS

The component supports the following Salesforce APIs

Producer endpoints can use the following APIs. Most of the APIs process one record at a time, the Query API can retrieve multiple Records.

288.4.1. Rest API

You can use the following for **operationName**:

- `getVersions` - Gets supported Salesforce REST API versions
- `getResources` - Gets available Salesforce REST Resource endpoints
- `getGlobalObjects` - Gets metadata for all available SObject types
- `getBasicInfo` - Gets basic metadata for a specific SObject type
- `getDescription` - Gets comprehensive metadata for a specific SObject type
- `getSObject` - Gets an SObject using its Salesforce Id
- `createSObject` - Creates an SObject
- `updateSObject` - Updates an SObject using Id
- `deleteSObject` - Deletes an SObject using Id
- `getSObjectWithId` - Gets an SObject using an external (user defined) id field
- `upsertSObject` - Updates or inserts an SObject using an external id
- `deleteSObjectWithId` - Deletes an SObject using an external id
- `query` - Runs a Salesforce SOQL query
- `queryMore` - Retrieves more results (in case of large number of results) using result link returned from the 'query' API
- `search` - Runs a Salesforce SOSL query
- `limits` - fetching organization API usage limits
- `recent` - fetching recent items
- `approval` - submit a record or records (batch) for approval process
- `approvals` - fetch a list of all approval processes
- `composite` - submit up to 25 possibly related REST requests and receive individual responses

- composite-tree - create up to 200 records with parent-child relationships (up to 5 levels) in one go
- composite-batch - submit a composition of requests in batch
- queryAll - Runs a SOQL query. It returns the results that are deleted because of a merge or delete. Also returns the information about archived Task and Event records.
- getBlobField - Retrieves the specified blob field from an individual record.
- apexCall - Executes a user defined APEX REST API call.

For example, the following producer endpoint uses the `upsertSObject` API, with the `sObjectIdName` parameter specifying 'Name' as the external id field. The request message body should be an `SObject` DTO generated using the maven plugin. The response message will either be **null** if an existing record was updated, or **CreateSObjectResult** with an id of the new record, or a list of errors while creating the new object.

```
...to("salesforce:upsertSObject?sObjectIdName=Name")...
```

288.4.2. Rest Bulk API

Producer endpoints can use the following APIs. All Job data formats, i.e. xml, csv, zip/xml, and zip/csv are supported.

The request and response have to be marshalled/unmarshalled by the route. Usually the request will be some stream source like a CSV file, and the response may also be saved to a file to be correlated with the request.

You can use the following for **operationName**:

- createJob - Creates a Salesforce Bulk Job
- getJob - Gets a Job using its Salesforce Id
- closeJob - Closes a Job
- abortJob - Aborts a Job
- createBatch - Submits a Batch within a Bulk Job
- getBatch - Gets a Batch using Id
- getAllBatches - Gets all Batches for a Bulk Job Id
- getRequest - Gets Request data (XML/CSV) for a Batch
- getResults - Gets the results of the Batch when its complete
- createBatchQuery - Creates a Batch from an SOQL query
- getQueryResultIds - Gets a list of Result Ids for a Batch Query
- getQueryResult - Gets results for a Result Id
- getRecentReports - Gets up to 200 of the reports you most recently viewed by sending a GET request to the Report List resource.

- `getReportDescription` - Retrieves the report, report type, and related metadata for a report, either in a tabular or summary or matrix format.
- `executeSyncReport` - Runs a report synchronously with or without changing filters and returns the latest summary data.
- `executeAsyncReport` - Runs an instance of a report asynchronously with or without filters and returns the summary data with or without details.
- `getReportInstances` - Returns a list of instances for a report that you requested to be run asynchronously. Each item in the list is treated as a separate instance of the report.
- `getReportResults`: Contains the results of running a report.

For example, the following producer endpoint uses the `createBatch` API to create a Job Batch. The in message must contain a body that can be converted into an **InputStream** (usually UTF-8 CSV or XML content from a file, etc.) and header fields 'jobId' for the Job and 'contentType' for the Job content type, which can be XML, CSV, ZIP_XML or ZIP_CSV. The put message body will contain **BatchInfo** on success, or throw a **SalesforceException** on error.

```
...to("salesforce:createBatchJob")..
```

288.4.3. Rest Streaming API

Consumer endpoints can use the following syntax for streaming endpoints to receive Salesforce notifications on create/update.

To create and subscribe to a topic

```
from("salesforce:CamelTestTopic?
notifyForFields=ALL&notifyForOperations=ALL&sObjectName=Merchandise__c&updateTopic=true&SO
bjectQuery=SELECT Id, Name FROM Merchandise__c")...
```

To subscribe to an existing topic

```
from("salesforce:CamelTestTopic&sObjectName=Merchandise__c")...
```

288.4.4. Platform events

To emit a platform event use **createObject** operation. And set the message body can be JSON string or **InputStream** with key-value data – in that case **sObjectName** needs to be set to the API name of the event, or a class that extends from **AbstractDTOBase** with the appropriate class name for the event.

For example using a DTO:

```
class Order_Event__e extends AbstractDTOBase {
    @JsonProperty("OrderNumber")
    private String orderNumber;
    // ... other properties and getters/setters
}

from("timer:tick")
    .process(exchange -> {
        final Message in = exchange.getIn();
```

```
String orderNumber = "ORD" + String.valueOf(in.getHeader(Exchange.TIMER_COUNTER));
Order_Event__e event = new Order_Event__e();
event.setOrderNumber(orderNumber);
in.setBody(event);
})
.to("salesforce:createSObject");
```

Or using JSON event data:

```
from("timer:tick")
  .process(exchange -> {
    final Message in = exchange.getIn();
    String orderNumber = "ORD" + String.valueOf(in.getHeader(Exchange.TIMER_COUNTER));
    in.setBody("{\"OrderNumber\":\"" + orderNumber + "\"}");
  })
  .to("salesforce:createSObject?sObjectName=Order_Event__e");
```

To receive platform events use the consumer endpoint with the API name of the platform event prefixed with **event/** (or **/event/**), e.g.: **salesforce:events/Order_Event__e**. Processor consuming from that endpoint will receive either **org.apache.camel.component.salesforce.api.dto.PlatformEvent** object or **org.cometd.bayeux.Message** in the body depending on the **rawPayload** being **false** or **true** respectively.

For example, in the simplest form to consume one event:

```
PlatformEvent event = consumer.receiveBody("salesforce:event/Order_Event__e",
PlatformEvent.class);
```

288.5. EXAMPLES

288.5.1. Uploading a document to a ContentWorkspace

Create the ContentVersion in Java, using a Processor instance:

```
public class ContentProcessor implements Processor {
  public void process(Exchange exchange) throws Exception {
    Message message = exchange.getIn();

    ContentVersion cv = new ContentVersion();
    ContentWorkspace cw = getWorkspace(exchange);
    cv.setFirstPublishLocationId(cw.getId());
    cv.setTitle("test document");
    cv.setPathOnClient("test_doc.html");
    byte[] document = message.getBody(byte[].class);
    ObjectMapper mapper = new ObjectMapper();
    String enc = mapper.convertValue(document, String.class);
    cv.setVersionDataUrl(enc);
    message.setBody(cv);
  }

  protected ContentWorkspace getWorkSpace(Exchange exchange) {
    // Look up the content workspace somehow, maybe use enrich() to add it to a
    // header that can be extracted here
  }
}
```

```

    }
}
}

```

Give the output from the processor to the Salesforce component:

```

from("file:///home/camel/library")
  .to(new ContentProcessor()) // convert bytes from the file into a ContentVersion SObject
  // for the salesforce component
  .to("salesforce:createSObject");

```

288.6. USING SALESFORCE LIMITS API

With **salesforce:limits** operation you can fetch of API limits from Salesforce and then act upon that data received. The result of **salesforce:limits** operation is mapped to **org.apache.camel.component.salesforce.api.dto.Limits** class and can be used in a custom processors or expressions.

For instance, consider that you need to limit the API usage of Salesforce so that 10% of daily API requests is left for other routes. The body of output message contains an instance of **org.apache.camel.component.salesforce.api.dto.Limits** object that can be used in conjunction with Content Based Router and Content Based Router and [Spring Expression Language \(SpEL\)](#) to choose when to perform queries.

Notice how multiplying **1.0** with the integer value held in **body.dailyApiRequests.remaining** makes the expression evaluate as with floating point arithmetic, without it - it would end up making integral division which would result with either **0** (some API limits consumed) or **1** (no API limits consumed).

```

from("direct:querySalesforce")
  .to("salesforce:limits")
  .choice()
  .when(spel("#{1.0 * body.dailyApiRequests.remaining / body.dailyApiRequests.max < 0.1}"))
    .to("salesforce:query?...")
  .otherwise()
    .setBody(constant("Used up Salesforce API limits, leaving 10% for critical routes"))
  .endChoice()

```

288.7. WORKING WITH APPROVALS

All the properties are named exactly the same as in the Salesforce REST API prefixed with **approval..** You can set approval properties by setting **approval.PropertyName** of the Endpoint these will be used as template – meaning that any property not present in either body or header will be taken from the Endpoint configuration. Or you can set the approval template on the Endpoint by assigning **approval** property to a reference onto a bean in the Registry.

You can also provide header values using the same **approval.PropertyName** in the incoming message headers.

And finally body can contain one **ApprovalRequest** or an **Iterable** of **ApprovalRequest** objects to process as a batch.

The important thing to remember is the priority of the values specified in these three mechanisms:

1. value in body takes precedence before any other

2. value in message header takes precedence before template value
3. value in template is set if no other value in header or body was given

For example to send one record for approval using values in headers use:

Given a route:

```
from("direct:example1")//
  .setHeader("approval.ContextId", simple("${body['contextId']}"))
  .setHeader("approval.NextApproverIds", simple("${body['nextApproverIds']}"))
  .to("salesforce:approval?"//
    + "approval.actionType=Submit"//
    + "&approval.comments=this is a test"//
    + "&approval.processDefinitionNameOrId=Test_Account_Process"//
    + "&approval.skipEntryCriteria=true");
```

You could send a record for approval using:

```
final Map<String, String> body = new HashMap<>();
body.put("contextId", accountIds.iterator().next());
body.put("nextApproverIds", userId);

final ApprovalResult result = template.requestBody("direct:example1", body, ApprovalResult.class);
```

288.8. USING SALESFORCE RECENT ITEMS API

To fetch the recent items use **salesforce:recent** operation. This operation returns an **java.util.List** of **org.apache.camel.component.salesforce.api.dto.RecentItem** objects (**List<RecentItem>**) that in turn contain the **Id**, **Name** and **Attributes** (with **type** and **url** properties). You can limit the number of returned items by specifying **limit** parameter set to maximum number of records to return. For example:

```
from("direct:fetchRecentItems")
  to("salesforce:recent")
  .split().body()
  .log("${body.name} at ${body.attributes.url}");
```

288.9. WORKING WITH APPROVALS

All the properties are named exactly the same as in the Salesforce REST API prefixed with **approval.** You can set approval properties by setting **approval.PropertyName** of the Endpoint these will be used as template – meaning that any property not present in either body or header will be taken from the Endpoint configuration. Or you can set the approval template on the Endpoint by assigning **approval** property to a reference onto a bean in the Registry.

You can also provide header values using the same **approval.PropertyName** in the incoming message headers.

And finally body can contain one **ApprovalRequest** or an **Iterable** of **ApprovalRequest** objects to process as a batch.

The important thing to remember is the priority of the values specified in these three mechanisms:

1. value in body takes precedence before any other

2. value in message header takes precedence before template value
3. value in template is set if no other value in header or body was given

For example to send one record for approval using values in headers use:

Given a route:

```
from("direct:example1")//
  .setHeader("approval.ContextId", simple("${body['contextId']}"))
  .setHeader("approval.NextApproverIds", simple("${body['nextApproverIds']}"))
  .to("salesforce:approval?"//
    + "approvalActionType=Submit"//
    + "&approvalComments=this is a test"//
    + "&approvalProcessDefinitionNameOrId=Test_Account_Process"//
    + "&approvalSkipEntryCriteria=true");
```

You could send a record for approval using:

```
final Map<String, String> body = new HashMap<>();
body.put("contextId", accountIds.iterator().next());
body.put("nextApproverIds", userId);

final ApprovalResult result = template.requestBody("direct:example1", body, ApprovalResult.class);
```

288.10. USING SALESFORCE COMPOSITE API TO SUBMIT SUBJECT TREE

To create up to 200 records including parent-child relationships use **salesforce:composite-tree** operation. This requires an instance of **org.apache.camel.component.salesforce.api.dto.composite.SObjectTree** in the input message and returns the same tree of objects in the output message. The **org.apache.camel.component.salesforce.api.dto.AbstractSObjectBase** instances within the tree get updated with the identifier values (**Id** property) or their corresponding **org.apache.camel.component.salesforce.api.dto.composite.SObjectNode** is populated with **errors** on failure.

Note that for some records operation can succeed and for some it can fail – so you need to manually check for errors.

Easiest way to use this functionality is to use the DTOs generated by the **camel-salesforce-maven-plugin**, but you also have the option of customizing the references that identify the each object in the tree, for instance primary keys from your database.

Lets look at an example:

```
Account account = ...
Contact president = ...
Contact marketing = ...

Account anotherAccount = ...
Contact sales = ...
Asset someAsset = ...
```

```
// build the tree
SObjectTree request = new SObjectTree();
request.addObject(account).addChildren(president, marketing);
request.addObject(anotherAccount).addChild(sales).addChild(someAsset);

final SObjectTree response = template.requestBody("salesforce:composite-tree", tree,
SObjectTree.class);
final Map<Boolean, List<SObjectNode>> result = response.allNodes()
.collect(Collectors.groupingBy(SObjectNode::hasErrors));

final List<SObjectNode> withErrors = result.get(true);
final List<SObjectNode> succeeded = result.get(false);

final String firstId = succeeded.get(0).getId();
```

288.11. USING SALESFORCE COMPOSITE API TO SUBMIT MULTIPLE REQUESTS IN A BATCH

The Composite API batch operation (**composite-batch**) allows you to accumulate multiple requests in a batch and then submit them in one go, saving the round trip cost of multiple individual requests. Each response is then received in a list of responses with the order preserved, so that the n-th requests response is in the n-th place of the response.

NOTE

The results can vary from API to API so the result of the request is given as a **java.lang.Object**. In most cases the result will be a **java.util.Map** with string keys and values or other **java.util.Map** as value. Requests made in JSON format hold some type information (i.e. it is known what values are strings and what values are numbers), so in general those will be more type friendly. Note that the responses will vary between XML and JSON, this is due to the responses from Salesforce API being different. So be careful if you switch between formats without changing the response handling code.

Lets look at an example:

```
final String accountId = ...
final SObjectBatch batch = new SObjectBatch("38.0");

final Account updates = new Account();
updates.setName("NewName");
batch.addUpdate("Account", accountId, updates);

final Account newAccount = new Account();
newAccount.setName("Account created from Composite batch API");
batch.addCreate(newAccount);

batch.addGet("Account", accountId, "Name", "BillingPostalCode");

batch.addDelete("Account", accountId);

final SObjectBatchResponse response = template.requestBody("salesforce:composite-batch?
format=JSON", batch, SObjectBatchResponse.class);

boolean hasErrors = response.hasErrors(); // if any of the requests has resulted in either 4xx or 5xx
```

HTTP status

```
final List<SObjectBatchResult> results = response.getResults(); // results of three operations sent in
batch

final SObjectBatchResult updateResult = results.get(0); // update result
final int updateStatus = updateResult.getStatusCode(); // probably 204
final Object updateResultData = updateResult.getResult(); // probably null

final SObjectBatchResult createResult = results.get(1); // create result
@SuppressWarnings("unchecked")
final Map<String, Object> createData = (Map<String, Object>) createResult.getResult();
final String newAccountId = createData.get("id"); // id of the new account, this is for JSON, for XML it
would be createData.get("Result").get("id")

final SObjectBatchResult retrieveResult = results.get(2); // retrieve result
@SuppressWarnings("unchecked")
final Map<String, Object> retrieveData = (Map<String, Object>) retrieveResult.getResult();
final String accountName = retrieveData.get("Name"); // Name of the retrieved account, this is for
JSON, for XML it would be createData.get("Account").get("Name")
final String accountBillingPostalCode = retrieveData.get("BillingPostalCode"); // Name of the retrieved
account, this is for JSON, for XML it would be createData.get("Account").get("BillingPostalCode")

final SObjectBatchResult deleteResult = results.get(3); // delete result
final int updateStatus = deleteResult.getStatusCode(); // probably 204
final Object updateResultData = deleteResult.getResult(); // probably null
```

288.12. USING SALESFORCE COMPOSITE API TO SUBMIT MULTIPLE CHAINED REQUESTS

The **composite** operation allows submitting up to 25 requests that can be chained together, for instance identifier generated in previous request can be used in subsequent request. Individual requests and responses are linked with the provided *reference*.

NOTE

Composite API supports only JSON payloads.

NOTE

As with the batch API the results can vary from API to API so the result of the request is given as a **java.lang.Object**. In most cases the result will be a **java.util.Map** with string keys and values or other **java.util.Map** as value. Requests made in JSON format hold some type information (i.e. it is known what values are strings and what values are numbers), so in general those will be more type friendly.

Lets look at an example:

```
SObjectComposite composite = new SObjectComposite("38.0", true);

// first insert operation via an external id
final Account updateAccount = new TestAccount();
updateAccount.setName("Salesforce");
updateAccount.setBillingStreet("Landmark @ 1 Market Street");
```

```

updateAccount.setBillingCity("San Francisco");
updateAccount.setBillingState("California");
updateAccount.setIndustry(Account_IndustryEnum.TECHNOLOGY);
composite.addUpdate("Account", "001xx000003DlpcAAG", updateAccount, "UpdatedAccount");

final Contact newContact = new TestContact();
newContact.setLastName("John Doe");
newContact.setPhone("1234567890");
composite.addCreate(newContact, "NewContact");

final AccountContactJunction__c junction = new AccountContactJunction__c();
junction.setAccount__c("001xx000003DlpcAAG");
junction.setContactId__c("@{NewContact.id}");
composite.addCreate(junction, "JunctionRecord");

final SObjectCompositeResponse response = template.requestBody("salesforce:composite?
format=JSON", composite, SObjectCompositeResponse.class);
final List<SObjectCompositeResult> results = response.getCompositeResponse();

final SObjectCompositeResult accountUpdateResult = results.stream().filter(r ->
"UpdatedAccount".equals(r.getReferenceId())).findFirst().get()
final int statusCode = accountUpdateResult.getHttpStatusCode(); // should be 200
final Map<String, ?> accountUpdateBody = accountUpdateResult.getBody();

final SObjectCompositeResult contactCreationResult = results.stream().filter(r ->
"JunctionRecord".equals(r.getReferenceId())).findFirst().get()

```

288.13. GENERATING SOQL QUERY STRINGS

org.apache.camel.component.salesforce.api.utils.QueryHelper contains helper methods to generate SOQL queries. For instance to fetch all custom fields from *Account* SObject you can simply generate the SOQL SELECT by invoking:

```
String allCustomFieldsQuery = QueryHelper.queryToFetchFilteredFieldsOf(new Account(),
SObjectField::isCustom);
```

288.14. CAMEL SALESFORCE MAVEN PLUGIN

This Maven plugin generates DTOs for the Camel [Salesforce](#).

For obvious security reasons it is recommended that the `clientId`, `clientSecret`, `userName` and `password` fields be not set in the `pom.xml`. The plugin should be configured for the rest of the properties, and can be executed using the following command:

```

mvn camel-salesforce:generate -DcamelSalesforce.clientId=<clientid> -
DcamelSalesforce.clientSecret=<clientsecret> \
-DcamelSalesforce.userName=<username> -DcamelSalesforce.password=<password>

```

The generated DTOs use Jackson and XStream annotations. All Salesforce field types are supported. Date and time fields are mapped to **java.time.ZonedDateTime** by default, and picklist fields are mapped to generated Java Enumerations.

288.15. OPTIONS

The Salesforce component supports 29 options, which are listed below.

Name	Description	Default	Type
authenticationType (security)	Explicit authentication method to be used, one of USERNAME_PASSWORD, REFRESH_TOKEN or JWT. Salesforce component can auto-determine the authentication method to use from the properties set, set this property to eliminate any ambiguity.		AuthenticationType
loginConfig (security)	All authentication configuration in one nested bean, all properties set there can be set directly on the component as well		SalesforceLoginConfig
instanceUrl (security)	URL of the Salesforce instance used after authentication, by default received from Salesforce on successful authentication		String
loginUrl (security)	Required URL of the Salesforce instance used for authentication, by default set to https://login.salesforce.com	https://login.salesforce.com	String
clientId (security)	Required OAuth Consumer Key of the connected app configured in the Salesforce instance setup. Typically a connected app needs to be configured but one can be provided by installing a package.		String
clientSecret (security)	OAuth Consumer Secret of the connected app configured in the Salesforce instance setup.		String
keystore (security)	KeyStore parameters to use in OAuth JWT flow. The KeyStore should contain only one entry with private key and certificate. Salesforce does not verify the certificate chain, so this can easily be a selfsigned certificate. Make sure that you upload the certificate to the corresponding connected app.		KeyStoreParameters
refreshToken (security)	Refresh token already obtained in the refresh token OAuth flow. One needs to setup a web application and configure a callback URL to receive the refresh token, or configure using the builtin callback at https://login.salesforce.com/services/oauth2/success or https://test.salesforce.com/services/oauth2/success and then retrieve the refresh_token from the URL at the end of the flow. Note that in development organizations Salesforce allows hosting the callback web application at localhost.		String

Name	Description	Default	Type
userName (security)	Username used in OAuth flow to gain access to access token. It's easy to get started with password OAuth flow, but in general one should avoid it as it is deemed less secure than other flows.		String
password (security)	Password used in OAuth flow to gain access to access token. It's easy to get started with password OAuth flow, but in general one should avoid it as it is deemed less secure than other flows. Make sure that you append security token to the end of the password if using one.		String
lazyLogin (security)	If set to true prevents the component from authenticating to Salesforce with the start of the component. You would generally set this to the (default) false and authenticate early and be immediately aware of any authentication issues.	false	boolean
config (common)	Global endpoint configuration - use to set values that are common to all endpoints		SalesforceEndpoint Config
httpClientProperties (common)	Used to set any properties that can be configured on the underlying HTTP client. Have a look at properties of SalesforceHttpClient and the Jetty HttpClient for all available options.		Map
longPollingTransport Properties (common)	Used to set any properties that can be configured on the LongPollingTransport used by the BayeuxClient (CometD) used by the streaming api		Map
sslContextParameters (security)	SSL parameters to use, see SSLContextParameters class for all available options.		SSLContextParameters
useGlobalSslContext Parameters (security)	Enable usage of global SSL context parameters	false	boolean
httpProxyHost (proxy)	Hostname of the HTTP proxy server to use.		String
httpProxyPort (proxy)	Port number of the HTTP proxy server to use.		Integer
httpProxyUsername (security)	Username to use to authenticate against the HTTP proxy server.		String

Name	Description	Default	Type
httpProxyPassword (security)	Password to use to authenticate against the HTTP proxy server.		String
isHttpProxySocks4 (proxy)	If set to true the configures the HTTP proxy to use as a SOCKS4 proxy.	false	boolean
isHttpProxySecure (security)	If set to false disables the use of TLS when accessing the HTTP proxy.	true	boolean
httpProxyIncluded Addresses (proxy)	A list of addresses for which HTTP proxy server should be used.		Set
httpProxyExcluded Addresses (proxy)	A list of addresses for which HTTP proxy server should not be used.		Set
httpProxyAuthUri (security)	Used in authentication against the HTTP proxy server, needs to match the URI of the proxy server in order for the httpProxyUsername and httpProxyPassword to be used for authentication.		String
httpProxyRealm (security)	Realm of the proxy server, used in preemptive Basic/Digest authentication methods against the HTTP proxy server.		String
httpProxyUseDigest Auth (security)	If set to true Digest authentication will be used when authenticating to the HTTP proxy, otherwise Basic authorization method will be used	false	boolean
packages (common)	In what packages are the generated DTO classes. Typically the classes would be generated using camel-salesforce-maven-plugin. Set it if using the generated DTOs to gain the benefit of using short SObject names in parameters/header values.		String[]
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Salesforce endpoint is configured using URI syntax:

```
salesforce:operationName:topicName
```

with the following path and query parameters:

288.15.1. Path Parameters (2 parameters):

Name	Description	Default	Type
operationName	The operation to use		OperationName
topicName	The name of the topic to use		String

288.15.2. Query Parameters (44 parameters):

Name	Description	Default	Type
apexMethod (common)	APEX method name		String
apexQueryParams (common)	Query params for APEX method		Map
apexUrl (common)	APEX method URL		String
apiVersion (common)	Salesforce API version, defaults to SalesforceEndpointConfig.DEFAULT_VERSION		String
backoffIncrement (common)	Backoff interval increment for Streaming connection restart attempts for failures beyond CometD auto-reconnect.		long
batchId (common)	Bulk API Batch ID		String
contentType (common)	Bulk API content type, one of XML, CSV, ZIP_XML, ZIP_CSV		ContentType
defaultReplayId (common)	Default replayId setting if no value is found in initialReplayIdMap		Long
format (common)	Payload format to use for Salesforce API calls, either JSON or XML, defaults to JSON		PayloadFormat
httpClient (common)	Custom Jetty Http Client to use to connect to Salesforce.		SalesforceHttpClient
includeDetails (common)	Include details in Salesforce Analytics report, defaults to false.		Boolean
initialReplayIdMap (common)	Replay IDs to start from per channel name.		Map

Name	Description	Default	Type
instanceId (common)	Salesforce1 Analytics report execution instance ID		String
jobId (common)	Bulk API Job ID		String
limit (common)	Limit on number of returned records. Applicable to some of the API, check the Salesforce documentation.		Integer
maxBackoff (common)	Maximum backoff interval for Streaming connection restart attempts for failures beyond CometD auto-reconnect.		long
notFoundBehaviour (common)	Sets the behaviour of 404 not found status received from Salesforce API. Should the body be set to NULL NotFoundBehaviour#NULL or should a exception be signaled on the exchange NotFoundBehaviour#EXCEPTION - the default.		NotFoundBehaviour
notifyForFields (common)	Notify for fields, options are ALL, REFERENCED, SELECT, WHERE		NotifyForFieldsEnum
notifyForOperationCreate (common)	Notify for create operation, defaults to false (API version = 29.0)		Boolean
notifyForOperationDelete (common)	Notify for delete operation, defaults to false (API version = 29.0)		Boolean
notifyForOperations (common)	Notify for operations, options are ALL, CREATE, EXTENDED, UPDATE (API version 29.0)		NotifyForOperationsEnum
notifyForOperationUndelete (common)	Notify for un-delete operation, defaults to false (API version = 29.0)		Boolean
notifyForOperationUpdate (common)	Notify for update operation, defaults to false (API version = 29.0)		Boolean
objectMapper (common)	Custom Jackson ObjectMapper to use when serializing/deserializing Salesforce objects.		ObjectMapper
rawPayload (common)	Use raw payload String for request and response (either JSON or XML depending on format), instead of DTOs, false by default	false	boolean

Name	Description	Default	Type
reportId (common)	Salesforce1 Analytics report Id		String
reportMetadata (common)	Salesforce1 Analytics report metadata for filtering		ReportMetadata
resultId (common)	Bulk API Result ID		String
serializeNulls (common)	Should the NULL values of given DTO be serialized with empty (NULL) values. This affects only JSON data format.	false	boolean
sObjectBlobFieldName (common)	SObject blob field name		String
sObjectClass (common)	Fully qualified SObject class name, usually generated using camel-salesforce-maven-plugin		String
sObjectFields (common)	SObject fields to retrieve		String
sObjectId (common)	SObject ID if required by API		String
sObjectIdName (common)	SObject external ID field name		String
sObjectIdValue (common)	SObject external ID field value		String
sObjectName (common)	SObject name if required or supported by API		String
sObjectQuery (common)	Salesforce SOQL query string		String
sObjectSearch (common)	Salesforce SOSL search string		String
updateTopic (common)	Whether to update an existing Push Topic when using the Streaming API, defaults to false	false	boolean

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
replayId (consumer)	The replayId value to use when subscribing		Long
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

288.16. SPRING BOOT AUTO-CONFIGURATION

The component supports 85 options, which are listed below.

Name	Description	Default	Type
camel.component.salesforce.authentication-type	Explicit authentication method to be used, one of USERNAME_PASSWORD, REFRESH_TOKEN or JWT. Salesforce component can auto-determine the authentication method to use from the properties set, set this property to eliminate any ambiguity.		AuthenticationType
camel.component.salesforce.client-id	OAuth Consumer Key of the connected app configured in the Salesforce instance setup. Typically a connected app needs to be configured but one can be provided by installing a package.		String
camel.component.salesforce.client-secret	OAuth Consumer Secret of the connected app configured in the Salesforce instance setup.		String

Name	Description	Default	Type
<code>camel.component.salesforce.config.apex-method</code>	APEX method name		String
<code>camel.component.salesforce.config.apex-query-params</code>	Query params for APEX method		Map
<code>camel.component.salesforce.config.apex-url</code>	APEX method URL		String
<code>camel.component.salesforce.config.api-version</code>	Salesforce API version, defaults to <code>SalesforceEndpointConfig.DEFAULT_VERSION</code>		String
<code>camel.component.salesforce.config.approval</code>	The approval request for Approval API. @param approval		ApprovalRequest
<code>camel.component.salesforce.config.approval-action-type</code>	Represents the kind of action to take: Submit, Approve, or Reject. @param actionType		ApprovalRequest\$Action
<code>camel.component.salesforce.config.approval-comments</code>	The comment to add to the history step associated with this request. @param comments		String
<code>camel.component.salesforce.config.approval-context-actor-id</code>	The ID of the submitter who's requesting the approval record. @param contextActorId		String
<code>camel.component.salesforce.config.approval-context-id</code>	The ID of the item that is being acted upon. @param contextId		String
<code>camel.component.salesforce.config.approval-next-approver-ids</code>	If the process requires specification of the next approval, the ID of the user to be assigned the next request. @param nextApproverIds		List

Name	Description	Default	Type
<code>camel.component.salesforce.config.approval-process-definition-name-or-id</code>	The developer name or ID of the process definition. @param processDefinitionNameOrId		String
<code>camel.component.salesforce.config.approval-skip-entry-criteria</code>	Determines whether to evaluate the entry criteria for the process (true) or not (false) if the process definition name or ID isn't null. If the process definition name or ID isn't specified, this argument is ignored, and standard evaluation is followed based on process order. By default, the entry criteria isn't skipped if it's not set by this request. @param skipEntryCriteria		Boolean
<code>camel.component.salesforce.config.backoff-increment</code>	Backoff interval increment for Streaming connection restart attempts for failures beyond CometD auto-reconnect.		Long
<code>camel.component.salesforce.config.batch-id</code>	Bulk API Batch ID		String
<code>camel.component.salesforce.config.content-type</code>	Bulk API content type, one of XML, CSV, ZIP_XML, ZIP_CSV		ContentType
<code>camel.component.salesforce.config.default-replay-id</code>	Default replayId setting if no value is found in initialReplayIdMap		Long
<code>camel.component.salesforce.config.format</code>	Payload format to use for Salesforce API calls, either JSON or XML, defaults to JSON		PayloadFormat
<code>camel.component.salesforce.config.http-client</code>	Custom Jetty Http Client to use to connect to Salesforce.		SalesforceHttpClient
<code>camel.component.salesforce.config.include-details</code>	Include details in Salesforce Analytics report, defaults to false.		Boolean

Name	Description	Default	Type
<code>camel.component.salesforce.config.initial-replay-id-map</code>	Replay IDs to start from per channel name.		Map
<code>camel.component.salesforce.config.instance-id</code>	Salesforce1 Analytics report execution instance ID		String
<code>camel.component.salesforce.config.job-id</code>	Bulk API Job ID		String
<code>camel.component.salesforce.config.limit</code>	Limit on number of returned records. Applicable to some of the API, check the Salesforce documentation.		Integer
<code>camel.component.salesforce.config.max-backoff</code>	Maximum backoff interval for Streaming connection restart attempts for failures beyond CometD auto-reconnect.		Long
<code>camel.component.salesforce.config.not-found-behaviour</code>	Sets the behaviour of 404 not found status received from Salesforce API. Should the body be set to NULL NotFoundBehaviour#NULL or should a exception be signaled on the exchange NotFoundBehaviour#EXCEPTION - the default.		NotFoundBehaviour
<code>camel.component.salesforce.config.notify-for-fields</code>	Notify for fields, options are ALL, REFERENCED, SELECT, WHERE		NotifyForFieldsEnum
<code>camel.component.salesforce.config.notify-for-operation-create</code>	Notify for create operation, defaults to false (API version = 29.0)		Boolean
<code>camel.component.salesforce.config.notify-for-operation-delete</code>	Notify for delete operation, defaults to false (API version = 29.0)		Boolean
<code>camel.component.salesforce.config.notify-for-operation-undelete</code>	Notify for un-delete operation, defaults to false (API version = 29.0)		Boolean

Name	Description	Default	Type
<code>camel.component.salesforce.config.notify-for-operation-update</code>	Notify for update operation, defaults to false (API version = 29.0)		Boolean
<code>camel.component.salesforce.config.notify-for-operations</code>	Notify for operations, options are ALL, CREATE, EXTENDED, UPDATE (API version 29.0)		NotifyForOperations Enum
<code>camel.component.salesforce.config.object-mapper</code>	Custom Jackson ObjectMapper to use when serializing/deserializing Salesforce objects.		ObjectMapper
<code>camel.component.salesforce.config.raw-payload</code>	Use raw payload String for request and response (either JSON or XML depending on format), instead of DTOs, false by default	false	Boolean
<code>camel.component.salesforce.config.report-id</code>	Salesforce1 Analytics report Id		String
<code>camel.component.salesforce.config.report-metadata</code>	Salesforce1 Analytics report metadata for filtering		ReportMetadata
<code>camel.component.salesforce.config.result-id</code>	Bulk API Result ID		String
<code>camel.component.salesforce.config.s-object-blob-field-name</code>	SObject blob field name		String
<code>camel.component.salesforce.config.s-object-class</code>	Fully qualified SObject class name, usually generated using camel-salesforce-maven-plugin		String
<code>camel.component.salesforce.config.s-object-fields</code>	SObject fields to retrieve		String
<code>camel.component.salesforce.config.s-object-id</code>	SObject ID if required by API		String

Name	Description	Default	Type
<code>camel.component.salesforce.config.s-object-id-name</code>	SObject external ID field name		String
<code>camel.component.salesforce.config.s-object-id-value</code>	SObject external ID field value		String
<code>camel.component.salesforce.config.s-object-name</code>	SObject name if required or supported by API		String
<code>camel.component.salesforce.config.s-object-query</code>	Salesforce SOQL query string		String
<code>camel.component.salesforce.config.s-object-search</code>	Salesforce SOSL search string		String
<code>camel.component.salesforce.config.serialize-nulls</code>	Should the NULL values of given DTO be serialized with empty (NULL) values. This affects only JSON data format.	false	Boolean
<code>camel.component.salesforce.config.update-topic</code>	Whether to update an existing Push Topic when using the Streaming API, defaults to false	false	Boolean
<code>camel.component.salesforce.enabled</code>	Enable salesforce component	true	Boolean
<code>camel.component.salesforce.http-client-properties</code>	Used to set any properties that can be configured on the underlying HTTP client. Have a look at properties of SalesforceHttpClient and the Jetty HttpClient for all available options.		Map
<code>camel.component.salesforce.http-proxy-auth-uri</code>	Used in authentication against the HTTP proxy server, needs to match the URI of the proxy server in order for the httpProxyUsername and httpProxyPassword to be used for authentication.		String
<code>camel.component.salesforce.http-proxy-excluded-addresses</code>	A list of addresses for which HTTP proxy server should not be used.		Set

Name	Description	Default	Type
<code>camel.component.salesforce.http-proxy-host</code>	Hostname of the HTTP proxy server to use.		String
<code>camel.component.salesforce.http-proxy-included-addresses</code>	A list of addresses for which HTTP proxy server should be used.		Set
<code>camel.component.salesforce.http-proxy-password</code>	Password to use to authenticate against the HTTP proxy server.		String
<code>camel.component.salesforce.http-proxy-port</code>	Port number of the HTTP proxy server to use.		Integer
<code>camel.component.salesforce.http-proxy-realm</code>	Realm of the proxy server, used in preemptive Basic/Digest authentication methods against the HTTP proxy server.		String
<code>camel.component.salesforce.http-proxy-use-digest-auth</code>	If set to true Digest authentication will be used when authenticating to the HTTP proxy, otherwise Basic authorization method will be used	false	Boolean
<code>camel.component.salesforce.http-proxy-username</code>	Username to use to authenticate against the HTTP proxy server.		String
<code>camel.component.salesforce.instance-url</code>	URL of the Salesforce instance used after authentication, by default received from Salesforce on successful authentication		String
<code>camel.component.salesforce.is-http-proxy-secure</code>	If set to false disables the use of TLS when accessing the HTTP proxy.	true	Boolean
<code>camel.component.salesforce.is-http-proxy-socks4</code>	If set to true the configures the HTTP proxy to use as a SOCKS4 proxy.	false	Boolean

Name	Description	Default	Type
<code>camel.component.salesforce.keystore</code>	KeyStore parameters to use in OAuth JWT flow. The KeyStore should contain only one entry with private key and certificate. Salesforce does not verify the certificate chain, so this can easily be a selfsigned certificate. Make sure that you upload the certificate to the corresponding connected app. The option is a <code>org.apache.camel.util.jsse.KeyStoreParameters</code> type.		String
<code>camel.component.salesforce.lazy-login</code>	If set to true prevents the component from authenticating to Salesforce with the start of the component. You would generally set this to the (default) false and authenticate early and be immediately aware of any authentication issues.	false	Boolean
<code>camel.component.salesforce.login-config.client-id</code>	Salesforce connected application Consumer Key		String
<code>camel.component.salesforce.login-config.client-secret</code>	Salesforce connected application Consumer Secret		String
<code>camel.component.salesforce.login-config.instance-url</code>			String
<code>camel.component.salesforce.login-config.keystore</code>	Keystore parameters for keystore containing certificate and private key needed for OAuth 2.0 JWT Bearer Token Flow.		KeyStoreParameters
<code>camel.component.salesforce.login-config.lazy-login</code>	Flag to enable/disable lazy OAuth, default is false. When enabled, OAuth token retrieval or generation is not done until the first API call		Boolean
<code>camel.component.salesforce.login-config.login-url</code>	Salesforce login URL, defaults to https://login.salesforce.com		String
<code>camel.component.salesforce.login-config.password</code>	Salesforce account password		String
<code>camel.component.salesforce.login-config.refresh-token</code>	Salesforce connected application Consumer token		String

Name	Description	Default	Type
<code>camel.component.salesforce.login-config.type</code>			AuthenticationType
<code>camel.component.salesforce.login-config.user-name</code>	Salesforce account user name		String
<code>camel.component.salesforce.login-url</code>	URL of the Salesforce instance used for authentication, by default set to https://login.salesforce.com	https://login.salesforce.com	String
<code>camel.component.salesforce.long-polling-transport-properties</code>	Used to set any properties that can be configured on the LongPollingTransport used by the BayeuxClient (CometD) used by the streaming api		Map
<code>camel.component.salesforce.packages</code>	In what packages are the generated DTO classes. Typically the classes would be generated using camel-salesforce-maven-plugin. Set it if using the generated DTOs to gain the benefit of using short SObject names in parameters/header values.		String[]
<code>camel.component.salesforce.password</code>	Password used in OAuth flow to gain access to access token. It's easy to get started with password OAuth flow, but in general one should avoid it as it is deemed less secure than other flows. Make sure that you append security token to the end of the password if using one.		String
<code>camel.component.salesforce.refresh-token</code>	Refresh token already obtained in the refresh token OAuth flow. One needs to setup a web application and configure a callback URL to receive the refresh token, or configure using the builtin callback at https://login.salesforce.com/services/oauth2/success or https://test.salesforce.com/services/oauth2/success and then retrieve the refresh_token from the URL at the end of the flow. Note that in development organizations Salesforce allows hosting the callback web application at localhost.		String
<code>camel.component.salesforce.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

Name	Description	Default	Type
<code>camel.component.salesforce.ssl-context-parameters</code>	SSL parameters to use, see <code>SSLContextParameters</code> class for all available options. The option is a <code>org.apache.camel.util.jsse.SSLContextParameters</code> type.		String
<code>camel.component.salesforce.use-global-ssl-context-parameters</code>	Enable usage of global SSL context parameters	false	Boolean
<code>camel.component.salesforce.username</code>	Username used in OAuth flow to gain access to access token. It's easy to get started with password OAuth flow, but in general one should avoid it as it is deemed less secure than other flows.		String

CHAPTER 289. SAP COMPONENT

The SAP component is a package consisting of a suite of ten different SAP components. There are remote function call (RFC) components that support the sRFC, tRFC, and qRFC protocols; and there are IDoc components that facilitate communication using messages in IDoc format. The component uses the SAP Java Connector (SAP JCo) library to facilitate bidirectional communication with SAP and the SAP IDoc library to facilitate the transmission of documents in the Intermediate Document (IDoc) format.

289.1. OVERVIEW

Dependencies

Maven users need to add the following dependency to their **pom.xml** file to use this component:

```
<dependency>
  <groupId>org.fusesource</groupId>
  <artifactId>camel-sap</artifactId>
  <version>x.x.x</version>
</dependency>
```

Additional platform restrictions for the SAP component

Because the SAP component depends on the third-party JCo 3 and IDoc 3 libraries, it can only be installed on the platforms that these libraries support. For more details about the supported library versions and platform restrictions, see [Red Hat JBoss Fuse Supported Configurations](#).

SAP JCo and SAP IDoc libraries

A prerequisite for using the SAP component is that the SAP Java Connector (SAP JCo) libraries and the SAP IDoc library are installed into the **lib/** directory of the Java runtime. You must make sure that you download the appropriate set of SAP libraries for your target operating system from the SAP Service Marketplace.

The names of the library files vary depending on the target operating system, as shown in [Table 289.1, "Required SAP Libraries"](#).

Table 289.1. Required SAP Libraries

SAP Component	Linux and UNIX	Windows
SAP JCo 3	sapjco3.jar	sapjco3.jar
	libsapjco3.so	sapjco3.dll
SAP IDoc	sapidoc3.jar	sapidoc3.jar

Deploying in a Fuse OSGi Container

You can install the SAP JCo libraries and the SAP IDoc library into the JBoss Fuse OSGi container as follows:

1. Download the SAP JCo libraries and the SAP IDoc library from the SAP Service Marketplace (<http://service.sap.com/public/connectors>), making sure to choose the appropriate version of the libraries for your operating system.

**NOTE**

You must have an **SAP Service Marketplace Account** in order to download and use these libraries.

2. Copy the **sapjco3.jar**, **libsapjco3.so** (or **sapjco3.dll** on Windows), and **sapidoc3.jar** library files into the **lib/** directory of your Fuse installation.
3. Open both the configuration properties file, **etc/config.properties**, and the custom properties file, **etc/custom.properties**, in a text editor. In the **etc/config.properties** file, look for the **org.osgi.framework.system.packages.extra** property and copy the complete property setting (this setting extends over multiple lines, with a backslash character, \, used to indicate line continuation). Now paste this setting into the **etc/custom.properties** file. You can now add the extra packages required to support the SAP libraries. In the **etc/custom.properties** file, add the required packages to the **org.osgi.framework.system.packages.extra** setting as shown:

```
org.osgi.framework.system.packages.extra = \
... , \
com.sap.conn.idoc, \
com.sap.conn.idoc.jco, \
com.sap.conn.jco, \
com.sap.conn.jco.ext, \
com.sap.conn.jco.monitor, \
com.sap.conn.jco.rt, \
com.sap.conn.jco.server
```

Don't forget to include a comma and a backslash, , \, at the end of each line preceding the new entries, so that the list is properly continued.

4. You need to restart the container for these changes to take effect.
5. You need to install the **camel-sap** feature in the container. In the Karaf console, enter the following command:

```
JBossFuse:karaf@root> features:install camel-sap
```

Deploying in a JBoss EAP container

To deploy the SAP component in a JBoss EAP container, perform the following steps:

1. Download the SAP JCo libraries and the SAP IDoc library from the SAP Service Marketplace (<http://service.sap.com/public/connectors>), making sure to choose the appropriate version of the libraries for your operating system.

**NOTE**

You must have an **SAP Service Marketplace Account** in order to download and use these libraries.

- Copy the JCo library files and the IDoc library file into the appropriate subdirectory of your JBoss EAP installation. For example, if your host platform is 64-bit Linux (**linux-x86_64**), install the library files as follows:

```
cp sapjco3.jar sapidoc3.jar
$JBOSS_HOME/modules/system/layers/fuse/com/sap/conn/jco/main/
mkdir -p $JBOSS_HOME/modules/system/layers/fuse/com/sap/conn/jco/main/lib/linux-
x86_64
cp libsapjco3.so
$JBOSS_HOME/modules/system/layers/fuse/com/sap/conn/jco/main/lib/linux-x86_64/
```

IMPORTANT

For installing native libraries (such as **libsapjco3.so**) into the JBoss EAP installation, there is a standardized convention for naming the library subdirectory, which must be followed. In the case of 64-bit Linux, the subdirectory is **linux-x86_64**. For other platforms, see <https://docs.jboss.org/author/display/MODULES/Native+Libraries>.

- Create a new file called **\$JBOSS_HOME/modules/system/layers/fuse/org/wildfly/camel/extras/main/module.xml** and **add** the following content:

```
<?xml version="1.0" encoding="UTF-8"?>
<module xmlns="urn:jboss:module:1.1" name="org.wildfly.camel.extras">

  <dependencies>
    <module name="org.fusesource.camel.component.sap" export="true" services="export" />
  </dependencies>

</module>
```

URI format

There are two different kinds of endpoint provided by the SAP component: the Remote Function Call (RFC) endpoints, and the Intermediate Document (IDoc) endpoints.

The URI formats for the RFC endpoints are as follows:

```
sap-srfc-destination:destinationName:rfcName
sap-trfc-destination:destinationName:rfcName
sap-qrfc-destination:destinationName:queueName:rfcName
sap-srfc-server:serverName:rfcName[?options]
sap-trfc-server:serverName:rfcName[?options]
```

The URI formats for the IDoc endpoints are as follows:

```
sap-idoc-
destination:destinationName:idocType[:idocTypeExtension[:systemRelease[:applicationRelease]]]
sap-idoclist-
destination:destinationName:idocType[:idocTypeExtension[:systemRelease[:applicationRelease]]]
sap-qidoc-
destination:destinationName:queueName:idocType[:idocTypeExtension[:systemRelease[:applicationR
```

```

elease]]]
sap-queueName-
destination:destinationName:queueName:idocType[:idocTypeExtension[:systemRelease[:applicationR
elease]]]
sap-idoclist-server:serverName:idocType[:idocTypeExtension[:systemRelease[:applicationRelease]]]
[?options]

```

The URI formats prefixed by `sap-endpointKind-destination` are used to define destination endpoints (in other words, Camel producer endpoints) and `destinationName` is the name of a specific outbound connection to an SAP instance. Outbound connections are named and configured at the component level, as described in [Section 289.2.2, "Destination Configuration"](#).

The URI formats prefixed by `sap-endpointKind-server` are used to define server endpoints (in other words, Camel consumer endpoints) and `serverName` is the name of a specific inbound connection from an SAP instance. Inbound connections are named and configured at the component level, as described in the [Section 289.2.3, "Server Configuration"](#).

The other components of an RFC endpoint URI are as follows:

rfcName

(Required) In a destination endpoint URI, is the name of the RFC invoked by the endpoint in the connected SAP instance. In a server endpoint URI, is the name of the RFC handled by the endpoint when invoked from the connected SAP instance.

queueName

Specifies the queue this endpoint sends an SAP request to.

The other components of an IDoc endpoint URI are as follows:

idocType

(Required) Specifies the Basic IDoc Type of an IDoc produced by this endpoint.

idocTypeExtension

Specifies the IDoc Type Extension, if any, of an IDoc produced by this endpoint.

systemRelease

Specifies the associated SAP Basis Release, if any, of an IDoc produced by this endpoint.

applicationRelease

Specifies the associated Application Release, if any, of an IDoc produced by this endpoint.

queueName

Specifies the queue this endpoint sends an SAP request to.

Options for RFC destination endpoints

The RFC destination endpoints (**sap-srfc-destination**, **sap-trfc-destination**, and **sap-qrfc-destination**) support the following URI options:

Name	Default	Description
stateful	false	If true , specifies that this endpoint initiates an SAP stateful session

Name	Default	Description
transacted	false	If true , specifies that this endpoint initiates an SAP transaction

Options for RFC server endpoints

The SAP RFC server endpoints (**sap-srfc-server** and **sap-trfc-server**) support the following URI options:

Name	Default	Description
stateful	false	If true , specifies that this endpoint initiates an SAP stateful session.
propagateExceptions	false	(sap-trfc-server endpoint only) If true , specifies that this endpoint propagates exceptions back to the caller in SAP, instead of the exchange's exception handler

Options for the IDoc List Server endpoint

The SAP IDoc List Server endpoint (**sap-idoclist-server**) supports the following URI options:

Name	Default	Description
stateful	false	If true , specifies that this endpoint initiates an SAP stateful session.
propagateExceptions	false	If true , specifies that this endpoint propagates exceptions back to the caller in SAP, instead of the exchange's exception handler

Summary of the RFC and IDoc endpoints

The SAP component package provides the following RFC and IDoc endpoints:

sap-srfc-destination

JBoss Fuse SAP Synchronous Remote Function Call Destination Camel component. This endpoint should be used in cases where Camel routes require synchronous delivery of requests to and responses from an SAP system.

NOTE

The sRFC protocol used by this component delivers requests and responses to and from an SAP system with **best effort**. In case of a communication error while sending a request, the completion status of a remote function call in the receiving SAP system remains **in doubt**.

sap-trfc-destination

JBoss Fuse SAP Transactional Remote Function Call Destination Camel component. This endpoint should be used in cases where requests must be delivered to the receiving SAP system **at most once**. To accomplish this, the component generates a transaction ID, **tid**, which accompanies every request sent through the component in a route's exchange. The receiving SAP system records the **tid** accompanying a request before delivering the request; if the SAP system receives the request again with the same **tid** it will not deliver the request. Thus if a route encounters a communication error when sending a request through an endpoint of this component, it can retry sending the request within the same exchange knowing it will be delivered and executed only once.

NOTE

The tRFC protocol used by this component is asynchronous and does not return a response. Thus the endpoints of this component do not return a response message.

NOTE

This component does not guarantee the order of a series of requests through its endpoints, and the delivery and execution order of these requests may differ on the receiving SAP system due to communication errors and resends of a request. For guaranteed delivery order, please see the JBoss Fuse SAP Queued Remote Function Call Destination Camel component.

sap-qrfc-destination

JBoss Fuse SAP Queued Remote Function Call Destination Camel component. This component extends the capabilities of the JBoss Fuse Transactional Remote Function Call Destination camel component by adding **in order** delivery guarantees to the delivery of requests through its endpoints. This endpoint should be used in cases where a series of requests depend on each other and must be delivered to the receiving SAP system **at most once** and **in order**. The component accomplishes the **at most once** delivery guarantees using the same mechanisms as the JBoss Fuse SAP Transactional Remote Function Call Destination Camel component. The ordering guarantee is accomplished by serializing the requests in the order they are received by the SAP system to an *inbound queue*. Inbound queues are processed by the *QIN scheduler* within SAP. When the inbound queue is **activated**, the QIN Scheduler will execute the queue requests in order.

NOTE

The qRFC protocol used by this component is asynchronous and does not return a response. Thus the endpoints of this component do not return a response message.

sap-srfc-server

JBoss Fuse SAP Synchronous Remote Function Call Server Camel component. This component and its endpoints should be used in cases where a Camel route is required to synchronously handle requests from and responses to an SAP system.

sap-trfc-server

JBoss Fuse SAP Transactional Remote Function Call Server Camel component. This endpoint should be used in cases where the sending SAP system requires **at most once** delivery of its requests to a Camel route. To accomplish this, the sending SAP system generates a transaction ID, **tid**, which accompanies every request it sends to the component's endpoints. The sending SAP system will first check with the component whether a given **tid** has been received by it before sending a series of requests associated with the **tid**. The component will check the list of received **tids** it maintains, record the sent **tid** if it is not in that list, and then respond to the sending SAP system, indicating whether or not the **tid** had already been recorded. The sending SAP system will only then send the series of requests, if the **tid** has not been previously recorded. This enables a sending SAP system to reliably send a series of requests once to a camel route.

sap-idoc-destination

JBoss Fuse SAP IDoc Destination Camel component. This endpoint should be used in cases where a Camel route is required to send a list of Intermediate Documents (IDocs) to an SAP system.

sap-idoclist-destination

JBoss Fuse SAP IDoc List Destination Camel component. This endpoint should be used in cases where a Camel route is required to send a list of Intermediate documents (IDocs) list to an SAP system.

sap-qidoc-destination

JBoss Fuse SAP Queued IDoc Destination Camel component. This component and its endpoints should be used in cases where a Camel route is required to send a list of Intermediate documents (IDocs) to an SAP system in order.

sap-qidoclist-destination

JBoss Fuse SAP Queued IDoc List Destination Camel component. This component and its endpoints should be used in cases where a camel route is required to send a list of Intermediate documents (IDocs) list to an SAP system in order.

sap-idoclist-server

JBoss Fuse SAP IDoc List Server Camel component. This endpoint should be used in cases where a sending SAP system requires delivery of Intermediate Document lists to a Camel route. This component uses the tRFC protocol to communicate with SAP as described in the **sap-trfc-server-standalone** quick start.

SAP RFC destination endpoint

An RFC destination endpoint supports outbound communication to SAP, which enable these endpoints to make RFC calls out to ABAP function modules in SAP. An RFC destination endpoint is configured to make an RFC call to a specific ABAP function over a specific connection to an SAP instance. An RFC destination is a logical designation for an outbound connection and has a unique name. An RFC destination is specified by a set of connection parameters called *destination data*.

An RFC destination endpoint will extract an RFC request from the input message of the IN-OUT exchanges it receives and dispatch that request in a function call to SAP. The response from the function call will be returned in the output message of the exchange. Since SAP RFC destination endpoints only support outbound communication, an RFC destination endpoint only supports the creation of producers.

SAP RFC server endpoint

An RFC server endpoint supports inbound communication from SAP, which enables ABAP applications in SAP to make RFC calls into server endpoints. An ABAP application interacts with an RFC server endpoint as if it were a remote function module. An RFC server endpoint is configured to receive an RFC call to a specific RFC function over a specific connection from an SAP instance. An RFC server is a logical designation for an inbound connection and has a unique name. An RFC server is specified by a set of connection parameters called *server data*.

An RFC server endpoint will handle an incoming RFC request and dispatch it as the input message of an IN-OUT exchange. The output message of the exchange will be returned as the response of the RFC call. Since SAP RFC server endpoints only support inbound communication, an RFC server endpoint only supports the creation of consumers.

SAP IDoc and IDoc list destination endpoints

An IDoc destination endpoint supports outbound communication to SAP, which can then perform further processing on the IDoc message. An IDoc document represents a business transaction, which can easily be exchanged with non-SAP systems. An IDoc destination is specified by a set of connection parameters called *destination data*.

An IDoc list destination endpoint is similar to an IDoc destination endpoint, except that the messages it handles consist of a **list** of IDoc documents.

SAP IDoc list server endpoint

An IDoc list server endpoint supports inbound communication from SAP, enabling a Camel route to receive a list of IDoc documents from an SAP system. An IDoc list server is specified by a set of connection parameters called *server data*.

Meta-data repositories

A meta-data repository is used to store the following kinds of meta-data:

Interface descriptions of function modules

This meta-data is used by the JCo and ABAP runtimes to check RFC calls to ensure the type-safe transfer of data between communication partners before dispatching those calls. A repository is populated with repository data. Repository data is a map of named function templates. A function template contains the meta-data describing all the parameters and their typing information passed to and from a function module and has the unique name of the function module it describes.

IDoc type descriptions

This meta-data is used by the IDoc runtime to ensure that the IDoc documents are correctly formatted before being sent to a communication partner. A basic IDoc type consists of a name, a list of permitted segments, and a description of the hierarchical relationship between the segments. Some additional constraints can be imposed on the segments: a segment can be mandatory or optional; and it is possible to specify a minimum/maximum range for each segment (defining the number of allowed repetitions of that segment).

SAP destination and server endpoints thus require access to a repository, in order to send and receive RFC calls and in order to send and receive IDoc documents. For RFC calls, the meta-data for all function modules invoked and handled by the endpoints must reside within the repository; and for IDoc endpoints, the meta-data for all IDoc types and IDoc type extensions handled by the endpoints must reside within the repository. The location of the repository used by a destination and server endpoint is specified in the destination data and the server data of their respective connections.

In the case of an SAP destination endpoint, the repository it uses typically resides in an SAP system and

it defaults to the SAP system it is connected to. This default requires no explicit configuration in the destination data. Furthermore, the meta-data for the remote function call that a destination endpoint makes will already exist in a repository for any existing function module that it calls. The meta-data for calls made by destination endpoints thus require no configuration in the SAP component.

On the other hand, the meta-data for function calls handled by server endpoints do not typically reside in the repository of an SAP system and must instead be provided by a repository residing in the SAP component. The SAP component maintains a map of named meta-data repositories. The name of a repository corresponds to the name of the server to which it provides meta-data.

289.2. CONFIGURATION

The SAP component maintains three maps to store destination data, server data and repository data. The *destination data store* and the *server data store* are configured on a special configuration object, **SapConnectionConfiguration**, which automatically gets injected into the SAP component (in the context of Blueprint XML configuration or Spring XML configuration files). The *repository data store* must be configured directly on the relevant SAP component.

289.2.1. Configuration Overview

Overview

The SAP component maintains three maps to store destination data, server data and repository data. The component's property, **destinationDataStore**, stores destination data keyed by destination name, the property, **serverDataStore**, stores server data keyed by server name and the property, **repositoryDataStore**, stores repository data keyed by repository name. These configurations must be passed to the component during its initialization.

Example

The following example shows how to configure a sample destination data store and a sample server data store in a Blueprint XML file. The **sap-configuration** bean (of type **SapConnectionConfiguration**) will automatically be injected into any SAP component that is used in this XML file.

```
<?xml version="1.0" encoding="UTF-8"?>
<blueprint ... >
  ...
  <!-- Configures the Inbound and Outbound SAP Connections -->
  <bean id="sap-configuration"
    class="org.fusesource.camel.component.sap.SapConnectionConfiguration">
    <property name="destinationDataStore">
      <map>
        <entry key="quickstartDest" value-ref="quickstartDestinationData" />
      </map>
    </property>
    <property name="serverDataStore">
      <map>
        <entry key="quickstartServer" value-ref="quickstartServerData" />
      </map>
    </property>
  </bean>

  <!-- Configures an Outbound SAP Connection -->
  <!-- *** Please enter the connection property values for your environment *** -->
```

```

<bean id="quickstartDestinationData"
  class="org.fusesource.camel.component.sap.model.rfc.impl.DestinationDataImpl">
  <property name="ashost" value="example.com" />
  <property name="sysnr" value="00" />
  <property name="client" value="000" />
  <property name="user" value="username" />
  <property name="passwd" value="password" />
  <property name="lang" value="en" />
</bean>

<!-- Configures an Inbound SAP Connection -->
<!-- *** Please enter the connection property values for your environment ** -->
<bean id="quickstartServerData"
  class="org.fusesource.camel.component.sap.model.rfc.impl.ServerDataImpl">
  <property name="gwhost" value="example.com" />
  <property name="gwserv" value="3300" />
  <!-- The following property values should not be changed -->
  <property name="progid" value="QUICKSTART" />
  <property name="repositoryDestination" value="quickstartDest" />
  <property name="connectionCount" value="2" />
</bean>
</blueprint>

```

289.2.2. Destination Configuration

Overview

The configurations for destinations are maintained in the **destinationDataStore** property of the SAP component. Each entry in this map configures a distinct outbound connection to an SAP instance. The key for each entry is the name of the outbound connection and is used in the *destinationName* component of a destination endpoint URI as described in the URI format section.

The value for each entry is a destination data configuration object -

org.fusesource.camel.component.sap.model.rfc.impl.DestinationDataImpl - that specifies the configuration of an outbound SAP connection.

Sample destination configuration

The following Blueprint XML code shows how to configure a sample destination with the name, **quickstartDest**.

```

<?xml version="1.0" encoding="UTF-8"?>
<blueprint ... >
  ...
  <!-- Create interceptor to support tRFC processing -->
  <bean id="currentProcessorDefinitionInterceptor"
    class="org.fusesource.camel.component.sap.CurrentProcessorDefinitionInterceptStrategy" />

  <!-- Configures the Inbound and Outbound SAP Connections -->
  <bean id="sap-configuration"
    class="org.fusesource.camel.component.sap.SapConnectionConfiguration">
    <property name="destinationDataStore">
      <map>
        <entry key="quickstartDest" value-ref="quickstartDestinationData" />

```

```

    </map>
  </property>
</bean>

<!-- Configures an Outbound SAP Connection -->
<!-- *** Please enter the connection property values for your environment *** -->
<bean id="quickstartDestinationData"
  class="org.fusesource.camel.component.sap.model.rfc.impl.DestinationDataImpl">
  <property name="ashost" value="example.com" />
  <property name="sysnr" value="00" />
  <property name="client" value="000" />
  <property name="user" value="username" />
  <property name="passwd" value="password" />
  <property name="lang" value="en" />
</bean>

</blueprint>

```

For example, after configuring the destination as shown in the preceding Blueprint XML file, you could invoke the **BAPI_FLCUST_GETLIST** remote function call on the **quickstartDest** destination using the following URI:

```
sap-srfc-destination:quickstartDest:BAPI_FLCUST_GETLIST
```

Interceptor for tRFC and qRFC destinations

The preceding sample destination configuration shows the instantiation of a **CurrentProcessorDefinitionInterceptStrategy** object. This object installs an interceptor in the Camel runtime, which enables the Camel SAP component to keep track of its position within a Camel route while it is handling RFC transactions. For more details, see [the section called "Transactional RFC destination endpoints"](#).

IMPORTANT

This interceptor is critically important for transactional RFC destination endpoints (such as **sap-trfc-destination** and **sap-qrfc-destination**) and must be installed in the Camel runtime in order for outbound transactional RFC communication to be properly managed. The Destination RFC Transaction Handlers will issue warnings into the Camel log if the strategy is not found at runtime and in this situation the Camel runtime will need to be re-provisioned and restarted to properly manage outbound transactional RFC communication.

Logon and authentication options

The following table lists the **logon and authentication** options for configuring a destination in the SAP destination data store:

Name	Default Value	Description
client		SAP client, mandatory logon parameter

user		Logon user, logon parameter for password based authentication
aliasUser		Logon user alias, can be used instead of logon user
userId		User identity which is used for logon to the ABAP AS. Used by the JCo runtime, if the destination configuration uses SSO/assertion ticket, certificate, current user ,or SNC environment for authentication. The user ID is mandatory, if neither user nor user alias is set. This ID will never be sent to the SAP backend, it will be used by the JCo runtime locally.
passwd		Logon password, logon parameter for password-based authentication
lang		Logon language, if not defined, the default user language is used
mysapssso2		Use the specified SAP Cookie Version 2 as logon ticket for SSO based authentication
x509cert		Use the specified X509 certificate for certificate based authentication
lcheck		Postpone the authentication until the first call - 1 (enable). Used in special cases only .
useSapGui		Use a visible, hidden, or do not use SAP GUI
codePage		Additional logon parameter to define the codepage that will be used to convert the logon parameters. Used in special cases only
getssso2		Order a SSO ticket after logon, the obtained ticket is available in the destination attributes

denyInitialPassword		If set to 1 , using initial passwords will lead to an exception (default is 0).
----------------------------	--	--

Connection options

The following table lists the **connection** options for configuring a destination in the SAP destination data store:

Name	Default Value	Description
saprouter		SAP Router string for connection to systems behind a SAP Router. SAP Router string contains the chain of SAP Routers and its port numbers and has the form: (/H/<host>[/S/<port>])+
sysnr		System number of the SAP ABAP application server, mandatory for a direct connection
ashost		SAP ABAP application server, mandatory for a direct connection
mshost		SAP message server, mandatory property for a load balancing connection
msserv		SAP message server port, optional property for a load balancing connection. In order to resolve the service names sapmsXXX a lookup in etc/services is performed by the network layer of the operating system. If using port numbers instead of symbolic service names, no look-ups are performed and no additional entries are needed.
gwhost		Allows specifying a concrete gateway, which should be used for establishing the connection to an application server. If not specified the gateway on the application server is used

gwserv		Should be set, when using gwshost. Allows specifying the port used on that gateway. If not specified the port of the gateway on the application server is used. In order to resolve the service names sapgwXXX a lookup in etc/services is performed by the network layer of the operating system. If using port numbers instead of symbolic service names, no lookups are performed and no additional entries are needed.
r3name		System ID of the SAP system, mandatory property for a load balancing connection.
group		Group of SAP application servers, mandatory property for a load balancing connection

Connection pool options

The following table lists the **connection pool** options for configuring a destination in the SAP destination data store:

Name	Default Value	Description
peakLimit	0	Maximum number of active outbound connections that can be created for a destination simultaneously. A value of 0 allows an unlimited number of active connections, otherwise if the value is less than the value of jpoolCapacity , it will be automatically increased to this value. Default setting is the value of poolCapacity , or in case of poolCapacity not being specified as well, the default is 0 (unlimited).
poolCapacity	1	Maximum number of idle outbound connections kept open by the destination. A value of 0 has the effect that there is no connection pooling (default is 1).

expirationTime		Time in milliseconds after which a free connection held internally by the destination can be closed
expirationPeriod		Period in milliseconds after which the destination checks the released connections for expiration.
maxGetTime		Maximum time in milliseconds to wait for a connection, if the maximum allowed number of connections has already been allocated by the application.

Secure network connection options

The following table lists the **secure network** options for configuring a destination in the SAP destination data store:

Name	Default Value	Description
sncMode		Secure network connection (SNC) mode, 0 (off) or 1 (on)
sncPartnername		SNC partner, for example: p:CN=R3, O=XYZ-INC, C=EN
sncQop		SNC level of security: 1 to 9
sncMyname		Own SNC name. Overrides environment settings
sncLibrary		Path to library that provides SNC service

Repository options

The following table lists the **repository** options for configuring a destination in the SAP destination data store:

Name	Default Value	Description
repositoryDest		Specifies which destination should be used as repository.

repositoryUser		If a repository destination is not set, and this property is set, it will be used as user for repository calls. This enables you to use a different user for repository look-ups.
repositoryPasswd		The password for a repository user. Mandatory, if a repository user should be used.
repositorySnc		(Optional) If SNC is used for this destination, it is possible to turn it off for repository connections, if this property is set to 0 . Default setting is the value of jco.client.snc_mode . For special cases only.
repositoryRoundtripOptimization		<p>Enable the RFC_METADATA_GET API, which provides repository data in one single round trip.</p> <p>1 Activates use of RFC_METADATA_GET in ABAP System,</p> <p>0 Deactivates RFC_METADATA_GET in ABAP System.</p> <p>If the property is not set, the destination initially does a remote call to check whether RFC_METADATA_GET is available. If it is available, the destination will use it.</p> <p>Note: If the repository is already initialized (for example because it is used by some other destination) this property does not have any effect. Generally, this property is related to the ABAP System, and should have the same value on all destinations pointing to the same ABAP System. See note 1456826 for backend prerequisites.</p>

Trace configuration options

The following table lists the **trace configuration** options for configuring a destination in the SAP destination data store:

Name	Default Value	Description
trace		Enable/disable RFC trace (0 or 1)
cpicTrace		Enable/disable CPIC trace [0..3]

289.2.3. Server Configuration

Overview

The configurations for servers are maintained in the **serverDataStore** property of the SAP component. Each entry in this map configures a distinct inbound connection from an SAP instance. The key for each entry is the name of the outbound connection and is used in the **serverName** component of a server endpoint URI as described in the URI format section.

The value for each entry is a *server data configuration object*, **org.fusesource.camel.component.sap.model.rfc.impl.ServerDataImpl**, that defines the configuration of an inbound SAP connection.

Sample server configuration

The following Blueprint XML code shows how to create a sample server configuration with the name, **quickstartServer**.

```
<?xml version="1.0" encoding="UTF-8"?>
<blueprint ... >
  ...
  <!-- Configures the Inbound and Outbound SAP Connections -->
  <bean id="sap-configuration"
    class="org.fusesource.camel.component.sap.SapConnectionConfiguration">
    <property name="destinationDataStore">
      <map>
        <entry key="quickstartDest" value-ref="quickstartDestinationData" />
      </map>
    </property>
    <property name="serverDataStore">
      <map>
        <entry key="quickstartServer" value-ref="quickstartServerData" />
      </map>
    </property>
  </bean>

  <!-- Configures an Outbound SAP Connection -->
  <!-- *** Please enter the connection property values for your environment *** -->
  <bean id="quickstartDestinationData"
    class="org.fusesource.camel.component.sap.model.rfc.impl.DestinationDataImpl">
    <property name="ashost" value="example.com" />
    <property name="sysnr" value="00" />
  </bean>
```

```

    <property name="client" value="000" />
    <property name="user" value="username" />
    <property name="passwd" value="password" />
    <property name="lang" value="en" />
  </bean>

  <!-- Configures an Inbound SAP Connection -->
  <!-- *** Please enter the connection property values for your environment ** -->
  <bean id="quickstartServerData"
    class="org.fusesource.camel.component.sap.model.rfc.impl.ServerDataImpl">
    <property name="gwhost" value="example.com" />
    <property name="gwserv" value="3300" />
    <!-- The following property values should not be changed -->
    <property name="progid" value="QUICKSTART" />
    <property name="repositoryDestination" value="quickstartDest" />
    <property name="connectionCount" value="2" />
  </bean>
</blueprint>

```

Notice how this example also configures a destination connection, **quickstartDest**, which the server uses to retrieve meta-data from a remote SAP instance. This destination is configured in the server data through the **repositoryDestination** option. If you do not configure this option, you would need to create a local meta-data repository instead (see [Section 289.2.4, "Repository Configuration"](#)).

For example, after configuring the destination as shown in the preceding Blueprint XML file, you could handle the **BAPI_FLCUST_GETLIST** remote function call from an invoking client, using the following URI:

```
sap-srfc-server:quickstartServer:BAPI_FLCUST_GETLIST
```

Required options

The required options for the server data configuration object are, as follows:

Name	Default Value	Description
gwhost		Gateway host on which the server connection should be registered.
gwserv		Gateway service, which is the port on which a registration can be done. In order to resolve the service names sapgwXXX , a look-up in etc/services is performed by the network layer of the operating system. If using port numbers instead of symbolic service names, no look-ups are performed and no additional entries are needed.

progid		The program ID with which the registration is done. Serves as identifier on the gateway and in the destination in the ABAP system.
repositoryDestination		Specifies a destination name that the server can use in order to retrieve meta-data from a meta-data repository hosted in a remote SAP server.
connectionCount		The number of connections that should be registered at the gateway.

Secure network connection options

The secure network connection options for the server data configuration object are, as follows:

Name	Default Value	Description
sncMode		Secure network connection (SNC) mode, 0 (off) or 1 (on)
sncQop		SNC level of security, 1 to 9
sncMyname		SNC name of your server. Overrides the default SNC name. Typically something like p:CN=JCoServer, O=ACompany, C=EN .
sncLib		Path to library which provides SNC service. If this property is not provided, the value of the jco.middleware.snc_lib property is used instead

Other options

The other options for the server data configuration object are, as follows:

Name	Default Value	Description
------	---------------	-------------

saprouter		SAP router string to use for a system protected by a firewall, which can therefore only be reached through a SAProuter, when registering the server at the gateway of that ABAP System. A typical router string is /H/firewall.hostname/H/
maxStartupDelay		The maximum time (in seconds) between two start-up attempts in case of failures. The waiting time is doubled from initially 1 second after each start-up failure until either the maximum value is reached or the server could be started successfully.
trace		Enable/disable RFC trace (0 or 1)
workerThreadCount		The maximum number of threads used by the server connection. If not set, the value for the connectionCount is used as the workerThreadCount . The maximum number of threads can not exceed 99.
workerThreadMinCount		The minimum number of threads used by server connection. If not set, the value for connectionCount is used as the workerThreadMinCount .

289.2.4. Repository Configuration

Overview

The configurations for repositories are maintained in the **repositoryDataStore** property of the SAP Component. Each entry in this map configures a distinct repository. The key for each entry is the name of the repository and this key also corresponds to the name of server to which this repository is attached.

The value of each entry is a repository data configuration object, **org.fusesource.camel.component.sap.model.rfc.impl.RepositoryDataImpl**, that defines the contents of a meta-data repository. A repository data object is a map of function template configuration objects, **org.fusesource.camel.component.sap.model.rfc.impl.FunctionTemplateImpl**. Each entry in this map specifies the interface of a function module and the key for each entry is the name of the function module specified.

Repository data example

The following code shows a simple example of configuring a meta-data repository:

```
<?xml version="1.0" encoding="UTF-8"?>
<blueprint ... >
  ...
  <!-- Configures the sap-srfc-server component -->
  <bean id="sap-configuration"
    class="org.fusesource.camel.component.sap.SapConnectionConfiguration">
    <property name="repositoryDataStore">
      <map>
        <entry key="nplServer" value-ref="nplRepositoryData" />
      </map>
    </property>
  </bean>

  <!-- Configures a Meta-Data Repository -->
  <bean id="nplRepositoryData"
    class="org.fusesource.camel.component.sap.model.rfc.impl.RepositoryDataImpl">
    <property name="functionTemplates">
      <map>
        <entry key="BOOK_FLIGHT" value-ref="bookFlightFunctionTemplate" />
      </map>
    </property>
  </bean>
  ...
</blueprint>
```

Function template properties

The interface of a function module consists of four parameter lists by which data is transferred back and forth to the function module in an RFC call. Each parameter list consists of one or more fields, each of which is a named parameter transferred in an RFC call. The following parameter lists and exception list are supported:

- The *import parameter list* contains parameter values that are sent to a function module in an RFC call;
- The *export parameter list* contains parameter values that are returned by a function module in an RFC call;
- The *changing parameter list* contains parameter values that are sent to and returned by a function module in an RFC call;
- The *table parameter list* contains internal table values that are sent to and returned by a function module in an RFC call.
- The interface of a function module also consists of an *exception list* of ABAP exceptions that may be raised when the module is invoked in an RFC call.

A function template describes the name and type of parameters in each parameter list of a function interface and the ABAP exceptions thrown by the function. A function template object maintains five property lists of meta-data objects, as described in the following table.

Property	Description
----------	-------------

importParameterList	A list of list field meta-data objects, org.fusesource.camel.component.sap.model.rfc.impl.ListFieldMeataDataImpl . Specifies the parameters that are sent in an RFC call to a function module.
changingParameterList	A list of list field meta-data objects, org.fusesource.camel.component.sap.model.rfc.impl.ListFieldMeataDataImpl . Specifies the parameters that sent and returned in an RFC call to and from a function module.
exportParameterList	A list of list field meta-data objects, org.fusesource.camel.component.sap.model.rfc.impl.ListFieldMeataDataImpl . Specifies the parameters that are returned in an RFC call from a function module.
tableParameterList	A list of list field meta-data objects, org.fusesource.camel.component.sap.model.rfc.impl.ListFieldMeataDataImpl . Specifies the table parameters that are sent and returned in an RFC call to and from a function module.
exceptionList	A list of ABAP exception meta-data objects, org.fusesource.camel.component.sap.model.rfc.impl.AbapExceptionImpl . Specifies the ABAP exceptions potentially raised in an RFC call of function module.

Function template example

The following example shows an outline of how to configure a function template:

```
<bean id="bookFlightFunctionTemplate"
  class="org.fusesource.camel.component.sap.model.rfc.impl.FunctionTemplateImpl">
  <property name="importParameterList">
    <list>
      ...
    </list>
  </property>
  <property name="changingParameterList">
    <list>
      ...
    </list>
  </property>
  <property name="exportParameterList">
    <list>
      ...
    </list>
  </property>
  <property name="tableParameterList">
```

```

    <list>
      ...
    </list>
  </property>
  <property name="exceptionList">
    <list>
      ...
    </list>
  </property>
</bean>

```

List field meta-data properties

A list field meta-data object,

org.fusesource.camel.component.sap.model.rfc.impl.ListFieldMeataDataImpl, specifies the name and type of a field in a parameter list. For an elementary parameter field (**CHAR**, **DATE**, **BCD**, **TIME**, **BYTE**, **NUM**, **FLOAT**, **INT**, **INT1**, **INT2**, **DECF16**, **DECF34**, **STRING**, **XSTRING**), the following table lists the configuration properties that may be set on a list field meta-data object:

Name	Default Value	Description
name	-	The name of the parameter field.
type	-	The parameter type of the field.
byteLength	-	The field length in bytes for a non-Unicode layout. This value depends on the parameter type. See Section 289.5, "Message Body for RFC" .
unicodeByteLength	-	The field length in bytes for a Unicode layout. This value depends on the parameter type. See Section 289.5, "Message Body for RFC" .
decimals	0	The number of decimals in field value; only required for parameter types BCD and FLOAT. See Section 289.5, "Message Body for RFC" .
optional	false	If true , the field is optional and need not be set in a RFC call

Note that all elementary parameter fields require that the **name**, **type**, **byteLength** and **unicodeByteLength** properties be specified in the field meta-data object. In addition, the **BCD**, **FLOAT**, **DECF16** and **DECF34** fields require the decimal property to be specified in the field meta-data object.

For a complex parameter field of type **TABLE** or **STRUCTURE**, the following table lists the configuration properties that may be set on a list field meta-data object:

Name	Default Value	Description
name	-	The name of the parameter field
type	-	The parameter type of the field
recordMetaData	-	The meta-data for the structure or table. A record meta-data object, org.fusesource.camel.component.sap.model.rfc.impl.RecordMetaDataImpl , is passed to specify the fields in the structure or table rows.
optional	false	If true , the field is optional and need not be set in a RFC call

Note that all complex parameter fields require that the **name**, **type** and **recordMetaData** properties be specified in the field meta-data object. The value of the **recordMetaData** property is a record field meta-data object, **org.fusesource.camel.component.sap.model.rfc.impl.RecordMetaDataImpl**, which specifies the structure of a nested structure or the structure of a table row.

Elementary list field meta-data example

The following meta-data configuration specifies an optional, 24-digit packed BCD number parameter with two decimal places named **TICKET_PRICE**:

```
<bean class="org.fusesource.camel.component.sap.model.rfc.impl.ListFieldMetaDataImpl">
  <property name="name" value="TICKET_PRICE" />
  <property name="type" value="BCD" />
  <property name="byteLength" value="12" />
  <property name="unicodeByteLength" value="24" />
  <property name="decimals" value="2" />
  <property name="optional" value="true" />
</bean>
```

Complex list field meta-data example

The following meta-data configuration specifies a required **TABLE** parameter named **CONNINFO** with a row structure specified by the **connectionInfo** record meta-data object:

```
<bean class="org.fusesource.camel.component.sap.model.rfc.impl.ListFieldMetaDataImpl">
  <property name="name" value="CONNINFO" />
  <property name="type" value="TABLE" />
  <property name="recordMetaData" ref="connectionInfo" />
</bean>
```

Record meta-data properties

A record meta-data object,

org.fusesource.camel.component.sap.model.rfc.impl.RecordMetaDataImpl, specifies the name and contents of a nested **STRUCTURE** or the row of a **TABLE** parameter. A record meta-data object maintains a list of record field meta data objects, **org.fusesource.camel.component.sap.model.rfc.impl.FieldMetaDataImpl**, which specify the parameters that reside in the nested structure or table row.

The following table lists configuration properties that may be set on a record meta-data object:

Name	Default Value	Description
name	-	The name of the record.
recordFieldMetaData	-	The list of record field meta-data objects, org.fusesource.camel.component.sap.model.rfc.impl.FieldMetaDataImpl . Specifies the fields contained within the structure.

NOTE

All properties of the record meta-data object are required.

Record meta-data example

The following example shows how to configure a record meta-data object:

```
<bean id="connectionInfo"
  class="org.fusesource.camel.component.sap.model.rfc.impl.RecordMetaDataImpl">
  <property name="name" value="CONNECTION_INFO" />
  <property name="recordFieldMetaData">
    <list>
      ...
    </list>
  </property>
</bean>
```

Record field meta-data properties

A record field meta-data object, **org.fusesource.camel.component.sap.model.rfc.impl.FieldMetaDataImpl**, specifies the name and type of a parameter field within a structure.

A record field meta-data object is similar to a parameter field meta-data object, except that the offsets of the individual field locations within the nested structure or table row must be additionally specified. The non-Unicode and Unicode offsets of an individual field must be calculated and specified from the sum of non-Unicode and Unicode byte lengths of the preceding fields in the structure or row. Note that failure to properly specify the offsets of fields in nested structures and table rows will cause the field storage of parameters in the underlying JCo and ABAP runtimes to overlap and prevent the proper transfer of values in RFC calls.

For an elementary parameter field (**CHAR**, **DATE**, **BCD**, **TIME**, **BYTE**, **NUM**, **FLOAT**, **INT**, **INT1**, **INT2**, **DECF16**, **DECF34**, **STRING**, **XSTRING**), the following table lists the configuration properties that may be set on a record field meta-data object:

Name	Default Value	Description
name	-	The name of the parameter field
type	-	The parameter type of the field
byteLength	-	The field length in bytes for a non-Unicode layout. This value depends on the parameter type. See Section 289.5, "Message Body for RFC" .
unicodeByteLength	-	The field length in bytes for a Unicode layout. This value depends on the parameter type. See Section 289.5, "Message Body for RFC" .
byteOffset	-	The field offset in bytes for non-Unicode layout. This offset is the byte location of the field within the enclosing structure.
unicodeByteOffset	-	The field offset in bytes for Unicode layout. This offset is the byte location of the field within the enclosing structure.
decimals	0	The number of decimals in field value; only required for parameter types BCD and FLOAT . See Section 289.5, "Message Body for RFC" .

For a complex parameter field of type **TABLE** or **STRUCTURE**, the following table lists the configuration properties that may be set on a record field meta-data object:

Name	Default Value	Description
name	-	The name of the parameter field
type	-	The parameter type of the field

byteOffset	-	The field offset in bytes for non-Unicode layout. This offset is the byte location of the field within the enclosing structure.
unicodeByteOffset	-	The field offset in bytes for Unicode layout. This offset is the byte location of the field within the enclosing structure.
recordMetaData	-	The meta-data for the structure or table. A record meta-data object, org.fusesource.camel.component.sap.model.rfc.impl.RecordMetaDataImpl , is passed to specify the fields in the structure or table rows.

Elementary record field meta-data example

The following meta-data configuration specifies a **DATE** field parameter named **ARRDATE** located 85 bytes into the enclosing structure in the case of a non-Unicode layout and located 170 bytes into the enclosing structure in the case of a Unicode layout:

```
<bean class="org.fusesource.camel.component.sap.model.rfc.impl.FieldMetaDataImpl">
  <property name="name" value="ARRDATE" />
  <property name="type" value="DATE" />
  <property name="byteLength" value="8" />
  <property name="unicodeByteLength" value="16" />
  <property name="byteOffset" value="85" />
  <property name="unicodeByteOffset" value="170" />
</bean>
```

Complex record field meta-data example

The following meta-data configuration specifies a **STRUCTURE** field parameter named **FLTINFO** with a structure specified by the **flightInfo** record meta-data object. The parameter is located at the beginning of the enclosing structure in both the case of a non-Unicode and Unicode layout.

```
<bean class="org.fusesource.camel.component.sap.model.rfc.impl.FieldMetaDataImpl">
  <property name="name" value="FLTINFO" />
  <property name="type" value="STRUCTURE" />
  <property name="byteOffset" value="0" />
  <property name="unicodeByteOffset" value="0" />
  <property name="recordMetaData" ref="flightInfo" />
</bean>
```

289.3. MESSAGE HEADERS

The SAP component supports the following message headers:

Header	Description
CamelSap.scheme	<p>The URI scheme of the last endpoint to process the message. Use one of the following values:</p> <p>sap-srfc-destination</p> <p>sap-trfc-destination</p> <p>sap-qrfc-destination</p> <p>sap-srfc-server</p> <p>sap-trfc-server</p> <p>sap-idoc-destination</p> <p>sap-idoclist-destination</p> <p>sap-qidoc-destination</p> <p>sap-qidoclist-destination</p> <p>sap-idoclist-server</p>
CamelSap.destinationName	The destination name of the last destination endpoint to process the message.
CamelSap.serverName	The server name of the last server endpoint to process the message.
CamelSap.queueName	The queue name of the last queuing endpoint to process the message.
CamelSap.rfcName	The RFC name of the last RFC endpoint to process the message.
CamelSap.idocType	The IDoc type of the last IDoc endpoint to process the message.
CamelSap.idocTypeExtension	The IDoc type extension, if any, of the last IDoc endpoint to process the message.
CamelSap.systemRelease	The system release, if any, of the last IDoc endpoint to process the message.
CamelSap.applicationRelease	The application release, if any, of the last IDoc endpoint to process the message.

289.4. EXCHANGE PROPERTIES

The SAP component adds the following exchange properties:

Property	Description
CamelSap.destinationPropertiesMap	A map containing the properties of each SAP destination encountered by the exchange. The map is keyed by destination name and each entry is a java.util.Properties object containing the configuration properties of that destination.
CamelSap.serverPropertiesMap	A map containing the properties of each SAP server encountered by the exchange. The map is keyed by server name and each entry is a java.util.Properties object containing the configuration properties of that server.

289.5. MESSAGE BODY FOR RFC

Request and response objects

An SAP endpoint expects to receive a message with a message body containing an SAP request object and will return a message with a message body containing an SAP response object. SAP requests and responses are fixed map data structures containing named fields with each field having a predefined data type.

Note that the named fields in an SAP request and response are specific to an SAP endpoint, with each endpoint defining the parameters in the SAP request and response it will accept. An SAP endpoint provides factory methods to create the request and response objects that are specific to it.

```
public class SAPEndpoint ... {
    ...
    public Structure getRequest() throws Exception;

    public Structure getResponse() throws Exception;
    ...
}
```

Structure objects

Both SAP request and response objects are represented in Java as a structure object which supports the **org.fusesource.camel.component.sap.model.rfc.Structure** interface. This interface extends both the **java.util.Map** and **org.eclipse.emf.ecore.EObject** interfaces.

```
public interface Structure extends org.eclipse.emf.ecore.EObject,
    java.util.Map<String, Object> {

    <T> T get(Object key, Class<T> type);

}
```

The field values in a structure object are accessed through the field's getter methods in the map interface. In addition, the structure interface provides a type-restricted method to retrieve field values.

Structure objects are implemented in the component runtime using the Eclipse Modeling Framework

(EMF) and support that framework's **EObject** interface. Instances of a structure object have attached meta-data which define and restrict the structure and contents of the map of fields it provides. This meta-data can be accessed and introspected using the standard methods provided by EMF. Please refer to the EMF documentation for further details.

NOTE

Attempts to get a parameter not defined on a structure object will return null. Attempts to set a parameter not defined on a structure will throw an exception as well as attempts to set the value of a parameter with an incorrect type.

As discussed in the following sections, structure objects can contain fields that contain values of the complex field types, **STRUCTURE** and **TABLE**. Note that it is unnecessary to create instances of these types and add them to the structure. Instances of these field values are created on demand if necessary when accessed in the enclosing structure.

Field types

The fields that reside within the structure object of an SAP request or response may be either *elementary* or *complex*. An elementary field contains a single scalar value, whereas a complex field will contain one or more fields of either a elementary or complex type.

Elementary field types

An elementary field may be either a character, numeric, hexadecimal or string field type. The following table summarizes the types of elementary fields that may reside in a structure object:

Field Type	Corresponding Java Type	Byte Length	Unicode Byte Length	Number Decimals Digits	Description
CHAR	java.lang.String	1 to 65535	1 to 65535	-	ABAP Type 'C': Fixed sized character string
DATE	java.util.Date	8	16	-	ABAP Type 'D': Date (format: YYYYMMDD)
BCD	java.math.BigDecimal	1 to 16	1 to 16	0 to 14	ABAP Type 'P': Packed BCD number. A BCD number contains two digits per byte.
TIME	java.util.Date	6	12	-	ABAP Type 'T': Time (format: HHMMSS)

BYTE	byte[]	1 to 65535	1 to 65535	-	ABAP Type 'X': Fixed sized byte array
NUM	java.lang.String	1 to 65535	1 to 65535	-	ABAP Type 'N': Fixed sized numeric character string
FLOAT	java.lang.Double	8	8	0 to 15	ABAP Type 'F': Floating point number
INT	java.lang.Integer	4	4	-	ABAP Type 'I': 4-byte Integer
INT2	java.lang.Integer	2	2	-	ABAP Type 'S': 2-byte Integer
INT1	java.lang.Integer	1	1	-	ABAP Type 'B': 1-byte Integer
DECF16	java.math.BigDecimal	8	8	16	ABAP Type 'decfloat16': 8-byte Decimal Floating Point Number
DECF34	java.math.BigDecimal	16	16	34	ABAP Type 'decfloat34': 16-byte Decimal Floating Point Number
STRING	java.lang.String	8	8	-	ABAP Type 'G': Variable length character string
XSTRING	byte[]	8	8	-	ABAP Type 'Y': Variable length byte array

Character field types

A character field contains a fixed sized character string that may use either a non-Unicode or Unicode

character encoding in the underlying JCo and ABAP runtimes. Non-Unicode character strings encode one character per byte. Unicode character strings are encoded in two bytes using UTF-16 encoding. Character field values are represented in Java as **java.lang.String** objects and the underlying JCo runtime is responsible for the conversion to their ABAP representation.

A character field declares its field length in its associated **byteLength** and **unicodeByteLength** properties, which determine the length of the field's character string in each encoding system.

CHAR

A **CHAR** character field is a text field containing alphanumeric characters and corresponds to the ABAP type C.

NUM

A **NUM** character field is a numeric text field containing numeric characters only and corresponds to the ABAP type N.

DATE

A **DATE** character field is an 8 character date field with the year, month and day formatted as **YYYYMMDD** and corresponds to the ABAP type D.

TIME

A **TIME** character field is a 6 character time field with the hours, minutes and seconds formatted as **HHMMSS** and corresponds to the ABAP type T.

Numeric field types

A numeric field contains a number. The following numeric field types are supported:

INT

An **INT** numeric field is an integer field stored as a 4-byte integer value in the underlying JCo and ABAP runtimes and corresponds to the ABAP type I. An **INT** field value is represented in Java as a **java.lang.Integer** object.

INT2

An **INT2** numeric field is an integer field stored as a 2-byte integer value in the underlying JCo and ABAP runtimes and corresponds to the ABAP type S. An **INT2** field value is represented in Java as a **java.lang.Integer** object.

INT1

An **INT1** field is an integer field stored as a 1-byte integer value in the underlying JCo and ABAP runtimes value and corresponds to the ABAP type B. An **INT1** field value is represented in Java as a **java.lang.Integer** object.

FLOAT

A **FLOAT** field is a binary floating point number field stored as an 8-byte double value in the underlying JCo and ABAP runtimes and corresponds to the ABAP type F. A **FLOAT** field declares the number of decimal digits that the field's value contains in its associated decimal property. In the case of a **FLOAT** field, this decimal property can have a value between 1 and 15 digits. A **FLOAT** field value is represented in Java as a **java.lang.Double** object.

BCD

A **BCD** field is a binary coded decimal field stored as a 1 to 16 byte packed number in the underlying JCo and ABAP runtimes and corresponds to the ABAP type P. A packed number stores two decimal digits per byte. A **BCD** field declares its field length in its associated **byteLength** and **unicodeByteLength** properties. In the case of a **BCD** field, these properties can have a value between 1 and 16 bytes and both properties will have the same value. A **BCD** field declares the

number of decimal digits that the field's value contains in its associated decimal property. In the case of a **BCD** field, this decimal property can have a value between 1 and 14 digits. A **BCD** field value is represented in Java as a **java.math.BigDecimal**.

DECF16

A **DECF16** field is a decimal floating point stored as an 8-byte IEEE 754 decimal64 floating point value in the underlying JCo and ABAP runtimes and corresponds to the ABAP type **decfloat16**. The value of a **DECF16** field has 16 decimal digits. The value of a **DECF16** field is represented in Java as **java.math.BigDecimal**.

DECF34

A **DECF34** field is a decimal floating point stored as a 16-byte IEEE 754 decimal128 floating point value in the underlying JCo and ABAP runtimes and corresponds to the ABAP type **decfloat34**. The value of a **DECF34** field has 34 decimal digits. The value of a **DECF34** field is represented in Java as **java.math.BigDecimal**.

Hexadecimal field types

A hexadecimal field contains raw binary data. The following hexadecimal field types are supported:

BYTE

A **BYTE** field is a fixed sized byte string stored as a byte array in the underlying JCo and ABAP runtimes and corresponds to the ABAP type X. A **BYTE** field declares its field length in its associated **byteLength** and **unicodeByteLength** properties. In the case of a **BYTE** field, these properties can have a value between 1 and 65535 bytes and both properties will have the same value. The value of a **BYTE** field is represented in Java as a **byte[]** object.

String field types

A string field references a variable length string value. The length of that string value is not fixed until runtime. The storage for the string value is dynamically created in the underlying JCo and ABAP runtimes. The storage for the string field itself is fixed and contains only a string header.

STRING

A **STRING** field refers to a character string and is stored in the underlying JCo and ABAP runtimes as an 8-byte value. It corresponds to the ABAP type G. The value of the **STRING** field is represented in Java as a **java.lang.String** object.

XSTRING

An **XSTRING** field refers to a byte string and is stored in the underlying JCo and ABAP runtimes as an 8-byte value. It corresponds to the ABAP type Y. The value of the **STRING** field is represented in Java as a **byte[]** object.

Complex field types

A complex field may be either a structure or table field type. The following table summarizes these complex field types.

Field Type	Corresponding Java Type	Byte Length	Unicode Byte Length	Number Decimals Digits	Description

STRUCTURE	org.fusesource.camel.component.sap.model.rfc.Structure	Total of individual field byte lengths	Total of individual field Unicode byte lengths	-	ABAP Type 'u' & 'v': Heterogeneous Structure
TABLE	org.fusesource.camel.component.sap.model.rfc.Table	Byte length of row structure	Unicode byte length of row structure	-	ABAP Type 'h': Table

Structure field types

A **STRUCTURE** field contains a structure object and is stored in the underlying JCo and ABAP runtimes as an ABAP structure record. It corresponds to either an ABAP type **u** or **v**. The value of a **STRUCTURE** field is represented in Java as a structure object with the interface **org.fusesource.camel.component.sap.model.rfc.Structure**.

Table field types

A **TABLE** field contains a table object and is stored in the underlying JCo and ABAP runtimes as an ABAP internal table. It corresponds to the ABAP type **h**. The value of the field is represented in Java by a table object with the interface **org.fusesource.camel.component.sap.model.rfc.Table**.

Table objects

A table object is a homogeneous list data structure containing rows of structure objects with the same structure. This interface extends both the **java.util.List** and **org.eclipse.emf.ecore.EObject** interfaces.

```
public interface Table<S extends Structure>
    extends org.eclipse.emf.ecore.EObject,
        java.util.List<S> {

    /**
     * Creates and adds table row at end of row list
     */
    S add();

    /**
     * Creates and adds table row at index in row list
     */
    S add(int index);

}
```

The list of rows in a table object are accessed and managed using the standard methods defined in the list interface. In addition the table interface provides two factory methods for creating and adding structure objects to the row list.

Table objects are implemented in the component runtime using the Eclipse Modeling Framework (EMF) and support that framework's EObject interface. Instances of a table object have attached meta-data which define and restrict the structure and contents of the rows it provides. This meta-data can be

accessed and introspected using the standard methods provided by EMF. Please refer to the EMF documentation for further details.

NOTE

Attempts to add or set a row structure value of the wrong type will throw an exception.

289.6. MESSAGE BODY FOR IDOC

IDoc message type

When using one of the IDoc Camel SAP endpoints, the type of the message body depends on which particular endpoint you are using.

For a **sap-idoc-destination** endpoint or a **sap-qidoc-destination** endpoint, the message body is of **Document** type:

```
org.fusesource.camel.component.sap.model.idoc.Document
```

For a **sap-idoclist-destination** endpoint, a **sap-qidoclist-destination** endpoint, or a **sap-idoclist-server** endpoint, the message body is of **DocumentList** type:

```
org.fusesource.camel.component.sap.model.idoc.DocumentList
```

The IDoc document model

For the Camel SAP component, an IDoc document is modelled using the Eclipse Modelling Framework (EMF), which provides a wrapper API around the underlying SAP IDoc API. The most important types in this model are:

```
org.fusesource.camel.component.sap.model.idoc.Document
org.fusesource.camel.component.sap.model.idoc.Segment
```

The **Document** type represents an IDoc document instance. In outline, the **Document** interface exposes the following methods:

```
// Java
package org.fusesource.camel.component.sap.model.idoc;
...
public interface Document extends EObject {
    // Access the field values from the IDoc control record
    String getArchiveKey();
    void setArchiveKey(String value);
    String getClient();
    void setClient(String value);
    ...

    // Access the IDoc document contents
    Segment getRootSegment();
}
```

The following kinds of method are exposed by the **Document** interface:

Methods for accessing the control record

Most of the methods are for accessing or modifying field values of the IDoc control record. These methods are of the form *AttributeName*, *AttributeName*, where *AttributeName* is the name of a field value (see [Table 289.2, "IDoc Document Attributes"](#)).

Method for accessing the document contents

The **getRootSegment** method provides access to the document contents (IDoc data records), returning the contents as a **Segment** object. Each **Segment** object can contain an arbitrary number of child segments, and the segments can be nested to an arbitrary degree.

Note, however, that the precise layout of the segment hierarchy is defined by the particular *IDoc* type of the document. When creating (or reading) a segment hierarchy, therefore, you must be sure to follow the exact structure as defined by the IDoc type.

The **Segment** type is used to access the data records of the IDoc document, where the segments are laid out in accordance with the structure defined by the document's IDoc type. In outline, the **Segment** interface exposes the following methods:

```
// Java
package org.fusesource.camel.component.sap.model.idoc;
...
public interface Segment extends EObject, java.util.Map<String, Object> {
    // Returns the value of the '<em><b>Parent</b></em>' reference.
    Segment getParent();

    // Return a immutable list of all child segments
    <S extends Segment> EList<S> getChildren();

    // Returns a list of child segments of the specified segment type.
    <S extends Segment> SegmentList<S> getChildren(String segmentType);

    EList<String> getTypes();

    Document getDocument();

    String getDescription();

    String getType();

    String getDefinition();

    int getHierarchyLevel();

    String getIdocType();

    String getIdocTypeExtension();

    String getSystemRelease();

    String getApplicationRelease();

    int getNumFields();

    long getMaxOccurrence();

    long getMinOccurrence();
}
```

```

boolean isMandatory();

boolean isQualified();

int getRecordLength();

<T> T get(Object key, Class<T> type);
}

```

The **getChildren(String segmentType)** method is particularly useful for adding new (nested) children to a segment. It returns an object of type, **SegmentList**, which is defined as follows:

```

// Java
package org.fusesource.camel.component.sap.model.idoc;
...
public interface SegmentList<S extends Segment> extends EObject, EList<S> {
    S add();

    S add(int index);
}

```

Hence, to create a data record of **E1SCU_CRE** type, you could use Java code like the following:

```

Segment rootSegment = document.getRootSegment();

Segment E1SCU_CRE_Segment = rootSegment.getChildren("E1SCU_CRE").add();

```

How an IDoc is related to a Document object

According to the SAP documentation, an IDoc document consists of the following main parts:

Control record

The control record (which contains the meta-data for the IDoc document) is represented by the attributes on the **Document** object – see [Table 289.2, “IDoc Document Attributes”](#) for details.

Data records

The data records are represented by the **Segment** objects, which are constructed as a nested hierarchy of segments. You can access the root segment through the **Document.getRootSegment** method.

Status records

In the Camel SAP component, the status records are **not** represented by the document model. But you do have access to the latest status value through the **status** attribute on the control record.

Example of creating a Document instance

For example, [Example 289.1, “Creating an IDoc Document in Java”](#) shows how to create an IDoc document with the IDoc type, **FLCUSTOMER_CREATEFROMDATA01**, using the IDoc model API in Java.

Example 289.1. Creating an IDoc Document in Java

```

// Java

```

```

import org.fusesource.camel.component.sap.model.idoc.Document;
import org.fusesource.camel.component.sap.model.idoc.Segment;
import org.fusesource.camel.component.sap.util.IDocUtil;

import org.fusesource.camel.component.sap.model.idoc.Document;
import org.fusesource.camel.component.sap.model.idoc.DocumentList;
import org.fusesource.camel.component.sap.model.idoc.IdocFactory;
import org.fusesource.camel.component.sap.model.idoc.IdocPackage;
import org.fusesource.camel.component.sap.model.idoc.Segment;
import org.fusesource.camel.component.sap.model.idoc.SegmentChildren;
...
//
// Create a new IDoc instance using the modelling classes
//

// Get the SAP Endpoint bean from the Camel context.
// In this example, it's a 'sap-idoc-destination' endpoint.
SapTransactionalIdocDestinationEndpoint endpoint =
    exchange.getContext().getEndpoint(
        "bean:SapEndpointBeanID",
        SapTransactionalIdocDestinationEndpoint.class
    );

// The endpoint automatically populates some required control record attributes
Document document = endpoint.createDocument()

// Initialize additional control record attributes
document.setMessageType("FLCUSTOMER_CREATEFROMDATA");
document.setRecipientPartnerNumber("QUICKCLNT");
document.setRecipientPartnerType("LS");
document.setSenderPartnerNumber("QUICKSTART");
document.setSenderPartnerType("LS");

Segment rootSegment = document.getRootSegment();

Segment E1SCU_CRE_Segment = rootSegment.getChildren("E1SCU_CRE").add();

Segment E1BPSCUNEW_Segment =
    E1SCU_CRE_Segment.getChildren("E1BPSCUNEW").add();
E1BPSCUNEW_Segment.put("CUSTNAME", "Fred Flintstone");
E1BPSCUNEW_Segment.put("FORM", "Mr.");
E1BPSCUNEW_Segment.put("STREET", "123 Rubble Lane");
E1BPSCUNEW_Segment.put("POSTCODE", "01234");
E1BPSCUNEW_Segment.put("CITY", "Bedrock");
E1BPSCUNEW_Segment.put("COUNTR", "US");
E1BPSCUNEW_Segment.put("PHONE", "800-555-1212");
E1BPSCUNEW_Segment.put("EMAIL", "fred@bedrock.com");
E1BPSCUNEW_Segment.put("CUSTTYPE", "P");
E1BPSCUNEW_Segment.put("DISCOUNT", "005");
E1BPSCUNEW_Segment.put("LANGU", "E");

```

Document attributes

Table 289.2, “IDoc Document Attributes” shows the control record attributes that you can set on the **Document** object.

Table 289.2. IDoc Document Attributes

Attribute	Length	SAP Field	Description
archiveKey	70	ARCKEY	EDI archive key
client	3	MANDT	Client
creationDate	8	CREDAT	Date IDoc was created
creationTime	6	CRETIM	Time IDoc was created
direction	1	DIRECT	Direction
eDIMessage	14	REFMES	Reference to message
eDIMessageGroup	14	REFGRP	Reference to message group
eDIMessageType	6	STDMES	EDI message type
eDIStandardFlag	1	STD	EDI standard
eDIStandardVersion	6	STDVRS	Version of EDI standard
eDITransmissionFile	14	REFINT	Reference to interchange file
iDocCompoundType	8	DOCTYP	IDoc type
iDocNumber	16	DOCNUM	IDoc number
iDocSAPRelease	4	DOCREL	SAP Release of IDoc
iDocType	30	IDOCTP	Name of basic IDoc type
iDocTypeExtension	30	CIMTYP	Name of extension type
messageCode	3	MESCOD	Logical message code
messageFunction	3	MESFCT	Logical message function
messageType	30	MESTYP	Logical message type

Attribute	Length	SAP Field	Description
outputMode	1	OUTMOD	Output mode
recipientAddress	10	RCVSAD	Receiver address (SADR)
recipientLogicalAddress	70	RCVLAD	Logical address of receiver
recipientPartnerFunction	2	RCVPFC	Partner function of receiver
recipientPartnerNumber	10	RCVPRN	Partner number of receiver
recipientPartnerType	2	RCVPRT	Partner type of receiver
recipientPort	10	RCVPOR	Receiver port (SAP System, EDI subsystem)
senderAddress		SNDSAD	Sender address (SADR)
senderLogicalAddress	70	SNDLAD	Logical address of sender
senderPartnerFunction	2	SNDPFC	Partner function of sender
senderPartnerNumber	10	SNDPRN	Partner number of sender
senderPartnerType	2	SNDPRT	Partner type of sender
senderPort	10	SNDPOR	Sender port (SAP System, EDI subsystem)
serialization	20	SERIAL	EDI/ALE: Serialization field
status	2	STATUS	Status of IDoc
testFlag	1	TEST	Test flag

Setting document attributes in Java

When setting the control record attributes in Java (from [Table 289.2, "IDoc Document Attributes"](#)), the usual convention for Java bean properties is followed. That is, a **name** attribute can be accessed through the **getName** and **setName** methods, for getting and setting the attribute value. For example,

the **iDocType**, **iDocTypeExtension**, and **messageType** attributes can be set as follows on a **Document** object:

```
// Java
document.setIDocType("FLCUSTOMER_CREATEFROMDATA01");
document.setIDocTypeExtension("");
document.setMessageType("FLCUSTOMER_CREATEFROMDATA");
```

Setting document attributes in XML

When setting the control record attributes in XML, the attributes must be set on the **idoc:Document** element. For example, the **iDocType**, **iDocTypeExtension**, and **messageType** attributes can be set as follows:

```
<?xml version="1.0" encoding="ASCII"?>
<idoc:Document ...
    iDocType="FLCUSTOMER_CREATEFROMDATA01"
    iDocTypeExtension=""
    messageType="FLCUSTOMER_CREATEFROMDATA" ... >
...
</idoc:Document>
```

289.7. TRANSACTION SUPPORT

BAPI transaction model

The SAP Component supports the BAPI transaction model for outbound communication with SAP. A destination endpoint with a URL containing the transacted option set to **true** will, if necessary, initiate a stateful session on the outbound connection of the endpoint and register a Camel Synchronization object with the exchange. This synchronization object will call the BAPI service method **BAPI_TRANSACTION_COMMIT** and end the stateful session when the processing of the message exchange is complete. If the processing of the message exchange fails, the synchronization object will call the BAPI server method **BAPI_TRANSACTION_ROLLBACK** and end the stateful session.

RFC transaction model

The tRFC protocol accomplishes an AT-MOST-ONCE delivery and processing guarantee by identifying each transactional request with a unique transaction identifier (TID). A TID accompanies each request sent in the protocol. A sending application using the tRFC protocol must identify each instance of a request with a unique TID when sending the request. An application may send a request with a given TID multiple times, but the protocol ensures that the request is delivered and processed in the receiving system at most once. An application may choose to resend a request with a given TID when encountering a communication or system error when sending the request, and is thus in doubt as to whether that request was delivered and processed in the receiving system. By resending a request when encountering an communication error, a client application using the tRFC protocol can thus ensure EXACTLY-ONCE delivery and processing guarantees for its request.

Which transaction model to use?

A BAPI transaction is an application level transaction, in the sense that it imposes ACID guarantees on the persistent data changes performed by a BAPI method or RFC function in the SAP database. An RFC transaction is a communication transaction, in the sense that it imposes delivery guarantees (AT-MOST-

ONCE, EXACTLY-ONCE, EXACTLY-ONCE-IN-ORDER) on requests to a BAPI method and/or RFC function.

Transactional RFC destination endpoints

The following destination endpoints support RFC transactions:

- **sap-trfc-destination**
- **sap-qrfc-destination**

A single Camel route can include multiple transactional RFC destination endpoints, sending messages to multiple RFC destinations and even sending messages to the same RFC destination multiple times. This implies that the Camel SAP component potentially needs to keep track of **many** transaction IDs (TIDs) for each **Exchange** object passing along a route. Now if the route processing fails and must be retried, the situation gets quite complicated. The RFC transaction semantics demand that each RFC destination along the route must be invoked using the **same** TID that was used the first time around (and where the TIDs for each of the destinations are distinct from each other). In other words, the Camel SAP component must keep track of which TID was used at which point along the route, and remember this information, so that the TIDs can be replayed in the correct order.

By default, Camel does not provide a mechanism that enables an **Exchange** to know where it is in a route. To provide such a mechanism, it is necessary to install the **CurrentProcessorDefinitionInterceptStrategy** interceptor into the Camel runtime. This interceptor must be installed into the Camel runtime, in order for the Camel SAP component to keep track of the TIDs in a route. For details of how to configure the interceptor, see [the section called "Interceptor for tRFC and qRFC destinations"](#).

Transactional RFC server endpoints

The following server endpoints support RFC transactions:

- **sap-trfc-server**

When a Camel exchange processing a transactional request encounters a processing error, Camel handles the processing error through its standard error handling mechanisms. If the Camel route processing the exchange is configured to propagate the error back to the caller, the SAP server endpoint that initiated the exchange takes note of the failure and the sending SAP system is notified of the error. The sending SAP system can then respond by sending another transaction request with the same TID to process the request again.

289.8. XML SERIALIZATION FOR RFC

Overview

SAP request and response objects support an XML serialization format which enable these objects to be serialized to and from an XML document.

XML namespace

Each RFC in a repository defines a specific XML name space for the elements which compose the serialized forms of its Request and Response objects. The form of this namespace URL is as follows:

```
http://sap.fusesource.org/rfc/<Repository Name>/<RFC Name>
```

RFC namespace URLs have a common <http://sap.fusesource.org/rfc> prefix followed by the name of the repository in which the RFC's metadata is defined. The final component in the URL is the name of the RFC itself.

Request and response XML documents

An SAP request object will be serialized into an XML document with the root element of that document named Request and scoped by the namespace of the request's RFC.

```
<?xml version="1.0" encoding="ASCII"?>
<BOOK_FLIGHT:Request
  xmlns:BOOK_FLIGHT="http://sap.fusesource.org/rfc/nplServer/BOOK_FLIGHT">
  ...
</BOOK_FLIGHT:Request>
```

An SAP response object will be serialized into an XML document with the root element of that document named Response and scoped by the namespace of the response's RFC.

```
<?xml version="1.0" encoding="ASCII"?>
<BOOK_FLIGHT:Response
  xmlns:BOOK_FLIGHT="http://sap.fusesource.org/rfc/nplServer/BOOK_FLIGHT">
  ...
</BOOK_FLIGHT:Response>
```

Structure fields

Structure fields in parameter lists or nested structures are serialized as elements. The element name of the serialized structure corresponds to the field name of the structure within the enclosing parameter list, structure or table row entry it resides.

```
<BOOK_FLIGHT:FLTINFO
  xmlns:BOOK_FLIGHT="http://sap.fusesource.org/rfc/nplServer/BOOK_FLIGHT">
  ...
</BOOK_FLIGHT:FLTINFO>
```

Note that the type name of the structure element in the RFC namespace will correspond to the name of the record meta data object which defines the structure, as in the following example:

```
<xs:schema
  targetNamespace="http://sap.fusesource.org/rfc/nplServer/BOOK_FLIGHT">
  xmlns:xs="http://www.w3.org/2001/XMLSchema">
  ...
  <xs:complexType name="FLTINFO_STRUCTURE">
  ...
  </xs:complexType>
  ...
</xs:schema>
```

This distinction will be important when specifying a JAXB bean to marshal and unmarshal the structure as will be seen in [Section 289.12, "Example 3: Handling Requests from SAP"](#).

Table fields

Table fields in parameter lists or nested structures are serialized as elements. The element name of the serialized structure will correspond to the field name of the table within the enclosing parameter list, structure, or table row entry it resides. The table element will contain a series of row elements to hold the serialized values of the table's row entries.

```
<BOOK_FLIGHT:CONNINFO
  xmlns:BOOK_FLIGHT="http://sap.fusesource.org/rfc/nplServer/BOOK_FLIGHT">
  <row ... > ... </row>
  ...
  <row ... > ... </row>
</BOOK_FLIGHT:CONNINFO>
```

Note that the type name of the table element in the RFC namespace will correspond to the name of the record meta data object which defines the row structure of the table suffixed by **_TABLE**. The type name of the table row element in the RFC name corresponds to the name of the record meta data object which defines the row structure of the table, as in the following example:

```
<xs:schema
  targetNamespace="http://sap.fusesource.org/rfc/nplServer/BOOK_FLIGHT"
  xmlns:xs="http://www.w3.org/2001/XMLSchema">
  ...
  <xs:complexType name="CONNECTION_INFO_STRUCTURE_TABLE">
    <xs:sequence>
      <xs:element
        name="row"
        minOccurs="0"
        maxOccurs="unbounded"
        type="CONNECTION_INFO_STRUCTURE"/>
      ...
    </xs:sequence>
  </xs:complexType>

  <xs:complexType name="CONNECTION_INFO_STRUCTURE">
    ...
  </xs:complexType>
  ...
</xs:schema>
```

This distinction will be important when specifying a JAXB bean to marshal and unmarshal the structure as will be seen in [Section 289.12, "Example 3: Handling Requests from SAP"](#).

Elementary fields

Elementary fields in parameter lists or nested structures are serialized as attributes on the element of the enclosing parameter list or structure. The attribute name of the serialized field corresponds to the field name of the field within the enclosing parameter list, structure, or table row entry it resides, as in the following example:

```
<?xml version="1.0" encoding="ASCII"?>
<BOOK_FLIGHT:Request
  xmlns:BOOK_FLIGHT="http://sap.fusesource.org/rfc/nplServer/BOOK_FLIGHT"
  CUSTNAME="James Legrand"
  PASSFORM="Mr"
  PASSNAME="Travelin Joe"
```

```
PASSBIRTH="1990-03-17T00:00:00.000-0500"
FLIGHTDATE="2014-03-19T00:00:00.000-0400"
TRAVELAGENCYNUMBER="00000110"
DESTINATION_FROM="SFO"
DESTINATION_TO="FRA"/>
```

Date and time formats

Date and Time fields are serialized into attribute values using the following format:

```
yyyy-MM-dd'T'HH:mm:ss.SSSZ
```

Date fields will be serialized with only the year, month, day and timezone components set:

```
DEPDATE="2014-03-19T00:00:00.000-0400"
```

Time fields will be serialized with only the hour, minute, second, millisecond and timezone components set:

```
DEPTIME="1970-01-01T16:00:00.000-0500"
```

289.9. XML SERIALIZATION FOR IDOC

Overview

An IDoc message body can be serialized into an XML string format, with the help of a built-in type converter.

XML namespace

Each serialized IDoc is associated with an XML namespace, which has the following general format:

```
http://sap.fusesource.org/idoc/repositoryName/idocType/idocTypeExtension/systemRelease/applicationRelease
```

Both the *repositoryName* (name of the remote SAP meta-data repository) and the *idocType* (IDoc document type) are mandatory, but the other components of the namespace can be left blank. For example, you could have an XML namespace like the following:

```
http://sap.fusesource.org/idoc/MY_REPO/FLCUSTOMER_CREATEFROMDATA01///
```

Built-in type converter

The Camel SAP component has a built-in type converter, which is capable of converting a **Document** object or a **DocumentList** object to and from a **String** type.

For example, to serialize a **Document** object to an XML string, you can simply add the following line to a route in XML DSL:

```
<convertBodyTo type="java.lang.String"/>
```

You can also use this approach to a serialized XML message into a **Document** object. For example, given that the current message body is a serialized XML string, you can convert it back into a **Document** object by adding the following line to a route in XML DSL:

```
<convertBodyTo type="org.fusesource.camel.component.sap.model.idoc.Document"/>
```

Sample IDoc message body in XML format

When you convert an IDoc message to a **String**, it is serialized into an XML document, where the root element is either **idoc:Document** (for a single document) or **idoc:DocumentList** (for a list of documents). [Example 289.2, "IDoc Message Body in XML"](#) shows a single IDoc document that has been serialized to an **idoc:Document** element.

Example 289.2. IDoc Message Body in XML

```
<?xml version="1.0" encoding="ASCII"?>
<idoc:Document
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xmlns:FLCUSTOMER_CREATEFROMDATA01---
="http://sap.fusesource.org/idoc/XXX/FLCUSTOMER_CREATEFROMDATA01///"
  xmlns:idoc="http://sap.fusesource.org/idoc"
  creationDate="2015-01-28T12:39:13.980-0500"
  creationTime="2015-01-28T12:39:13.980-0500"
  iDocType="FLCUSTOMER_CREATEFROMDATA01"
  iDocTypeExtension=""
  messageType="FLCUSTOMER_CREATEFROMDATA"
  recipientPartnerNumber="QUICKCLNT"
  recipientPartnerType="LS"
  senderPartnerNumber="QUICKSTART"
  senderPartnerType="LS">
<rootSegment xsi:type="FLCUSTOMER_CREATEFROMDATA01---:ROOT" document="/">
  <segmentChildren parent="//@rootSegment">
    <E1SCU_CRE parent="//@rootSegment" document="/">
      <segmentChildren parent="//@rootSegment/@segmentChildren/@E1SCU_CRE.0">
        <E1BPSCUNEW parent="//@rootSegment/@segmentChildren/@E1SCU_CRE.0"
          document="/"
          CUSTNAME="Fred Flintstone" FORM="Mr."
          STREET="123 Rubble Lane"
          POSTCODE="01234"
          CITY="Bedrock"
          COUNTR="US"
          PHONE="800-555-1212"
          EMAIL="fred@bedrock.com"
          CUSTTYPE="P"
          DISCOUNT="005"
          LANGU="E"/>
      </segmentChildren>
    </E1SCU_CRE>
  </segmentChildren>
</rootSegment>
</idoc:Document>
```

289.10. EXAMPLE 1: READING DATA FROM SAP

Overview

This example demonstrates a route which reads **FlightCustomer** business object data from SAP. The route invokes the **FlightCustomer** BAPI method, **BAPI_FLCUST_GETLIST**, using an SAP synchronous RFC destination endpoint to retrieve the data.

Java DSL for route

The Java DSL for the example route is as follows:

```
from("direct:getFlightCustomerInfo")
  .to("bean:createFlightCustomerGetListRequest")
  .to("sap-srfc-destination:nplDest:BAPI_FLCUST_GETLIST")
  .to("bean:returnFlightCustomerInfo");
```

XML DSL for route

And the Spring DSL for the same route is as follows:

```
<route>
  <from uri="direct:getFlightCustomerInfo"/>
  <to uri="bean:createFlightCustomerGetListRequest"/>
  <to uri="sap-srfc-destination:nplDest:BAPI_FLCUST_GETLIST"/>
  <to uri="bean:returnFlightCustomerInfo"/>
</route>
```

createFlightCustomerGetListRequest bean

The **createFlightCustomerGetListRequest** bean is responsible for building an SAP request object in its exchange method that is used in the RFC call of the subsequent SAP endpoint. The following code snippet demonstrates the sequence of operations to build the request object:

```
public void create(Exchange exchange) throws Exception {

    // Get SAP Endpoint to be called from context.
    SapSynchronousRfcDestinationEndpoint endpoint =
        exchange.getContext().getEndpoint("sap-srfc-destination:nplDest:BAPI_FLCUST_GETLIST",
            SapSynchronousRfcDestinationEndpoint.class);

    // Retrieve bean from message containing Flight Customer name to
    // look up.
    BookFlightRequest bookFlightRequest =
        exchange.getIn().getBody(BookFlightRequest.class);

    // Create SAP Request object from target endpoint.
    Structure request = endpoint.getRequest();

    // Add Customer Name to request if set
    if (bookFlightRequest.getCustomerName() != null &&
        bookFlightRequest.getCustomerName().length() > 0) {
        request.put("CUSTOMER_NAME",
```

```

        bookFlightRequest.getCustomerName());
    }
} else {
    throw new Exception("No Customer Name");
}

// Put request object into body of exchange message.
exchange.getIn().setBody(request);
}

```

returnFlightCustomerInfo bean

The **returnFlightCustomerInfo** bean is responsible for extracting data from the SAP response object in its exchange method that it receives from the previous SAP endpoint . The following code snippet demonstrates the sequence of operations to extract the data from the response object:

```

public void createFlightCustomerInfo(Exchange exchange) throws Exception {

    // Retrieve SAP response object from body of exchange message.
    Structure flightCustomerGetListResponse =
        exchange.getIn().getBody(Structure.class);

    if (flightCustomerGetListResponse == null) {
        throw new Exception("No Flight Customer Get List Response");
    }

    // Check BAPI return parameter for errors
    @SuppressWarnings("unchecked")
    Table<Structure> bapiReturn =
        flightCustomerGetListResponse.get("RETURN", Table.class);
    Structure bapiReturnEntry = bapiReturn.get(0);
    if (bapiReturnEntry.get("TYPE", String.class) != "S") {
        String message = bapiReturnEntry.get("MESSAGE", String.class);
        throw new Exception("BAPI call failed: " + message);
    }

    // Get customer list table from response object.
    @SuppressWarnings("unchecked")
    Table<? extends Structure> customerList =
        flightCustomerGetListResponse.get("CUSTOMER_LIST", Table.class);

    if (customerList == null || customerList.size() == 0) {
        throw new Exception("No Customer Info.");
    }

    // Get Flight Customer data from first row of table.
    Structure customer = customerList.get(0);

    // Create bean to hold Flight Customer data.
    FlightCustomerInfo flightCustomerInfo = new FlightCustomerInfo();

    // Get customer id from Flight Customer data and add to bean.
    String customerId = customer.get("CUSTOMERID", String.class);
    if (customerId != null) {
        flightCustomerInfo.setCustomerNumber(customerId);
    }
}

```

```

    }

    ...

    // Put bean into body of exchange message.
    exchange.getIn().setHeader("flightCustomerInfo", flightCustomerInfo);

}

```

289.11. EXAMPLE 2: WRITING DATA TO SAP

Overview

This example demonstrates a route which creates a **FlightTrip** business object instance in SAP. The route invokes the **FlightTrip** BAPI method, **BAPI_FLTRIP_CREATE**, using a destination endpoint to create the object.

Java DSL for route

The Java DSL for the example route is as follows:

```

from("direct:createFlightTrip")
  .to("bean:createFlightTripRequest")
  .to("sap-srfc-destination:nplDest:BAPI_FLTRIP_CREATE?transacted=true")
  .to("bean:returnFlightTripResponse");

```

XML DSL for route

And the Spring DSL for the same route is as follows:

```

<route>
  <from uri="direct:createFlightTrip"/>
  <to uri="bean:createFlightTripRequest"/>
  <to uri="sap-srfc-destination:nplDest:BAPI_FLTRIP_CREATE?transacted=true"/>
  <to uri="bean:returnFlightTripResponse"/>
</route>

```

Transaction support

Note that the URL for the SAP endpoint has the **transacted** option set to **true**. As discussed in [Section 289.7, "Transaction Support"](#), when this option is enabled the endpoint ensures that an SAP transaction session has been initiated before invoking the RFC call. Because this endpoint's RFC creates new data in SAP, this options is necessary to make the route's changes permanent in SAP.

Populating request parameters

The **createFlightTripRequest** and **returnFlightTripResponse** beans are responsible for populating request parameters into the SAP request and extracting response parameters from the SAP response respectively following the same sequence of operations as demonstrated in the previous example.

289.12. EXAMPLE 3: HANDLING REQUESTS FROM SAP

Overview

This example demonstrates a route which handles a request from SAP to the **BOOK_FLIGHT** RFC, which is implemented by the route. In addition, it demonstrates the component's XML serialization support, using JAXB to unmarshal and marshal SAP request objects and response objects to custom beans.

This route creates a **FlightTrip** business object on behalf of a travel agent, **FlightCustomer**. The route first unmarshals the SAP request object received by the SAP server endpoint into a custom JAXB bean. This custom bean is then multicasted in the exchange to three sub-routes, which gather the travel agent, flight connection and passenger information required to create the flight trip. The final sub-route creates the flight trip object in SAP as demonstrated in the previous example. The final sub-route also creates and returns a custom JAXB bean which is marshaled into an SAP response object and returned by the server endpoint.

Java DSL for route

The Java DSL for the example route is as follows:

```
DataFormat jaxb = new JaxbDataFormat("org.fusesource.sap.example.jaxb");

from("sap-srfc-server:nplserver:BOOK_FLIGHT")
    .unmarshal(jaxb)
    .multicast()
    .to("direct:getFlightConnectionInfo",
        "direct:getFlightCustomerInfo",
        "direct:getPassengerInfo")
    .end()
    .to("direct:createFlightTrip")
    .marshal(jaxb);
```

XML DSL for route

And the XML DSL for the same route is as follows:

```
<route>
  <from uri="sap-srfc-server:nplserver:BOOK_FLIGHT"/>
  <unmarshal>
    <jaxb contextPath="org.fusesource.sap.example.jaxb"/>
  </unmarshal>
  <multicast>
    <to uri="direct:getFlightConnectionInfo"/>
    <to uri="direct:getFlightCustomerInfo"/>
    <to uri="direct:getPassengerInfo"/>
  </multicast>
  <to uri="direct:createFlightTrip"/>
  <marshal>
    <jaxb contextPath="org.fusesource.sap.example.jaxb"/>
  </marshal>
</route>
```

BookFlightRequest bean

The following listing illustrates a JAXB bean which unmarshals from the serialized form of an SAP **BOOK_FLIGHT** request object:

```

@XmlRootElement(name="Request",
namespace="http://sap.fusesource.org/rfc/nplServer/BOOK_FLIGHT")
@XmlAccessorType(XmlAccessType.FIELD)
public class BookFlightRequest {

    @XmlAttribute(name="CUSTNAME")
    private String customerName;

    @XmlAttribute(name="FLIGHTDATE")
    @XmlJavaTypeAdapter(DateAdapter.class)
    private Date flightDate;

    @XmlAttribute(name="TRAVELAGENCYNUMBER")
    private String travelAgencyNumber;

    @XmlAttribute(name="DESTINATION_FROM")
    private String startAirportCode;

    @XmlAttribute(name="DESTINATION_TO")
    private String endAirportCode;

    @XmlAttribute(name="PASSFORM")
    private String passengerFormOfAddress;

    @XmlAttribute(name="PASSNAME")
    private String passengerName;

    @XmlAttribute(name="PASSBIRTH")
    @XmlJavaTypeAdapter(DateAdapter.class)
    private Date passengerDateOfBirth;

    @XmlAttribute(name="CLASS")
    private String flightClass;

    ...
}

```

BookFlightResponse bean

The following listing illustrates a JAXB bean which marshals to the serialized form of an SAP **BOOK_FLIGHT** response object:

```

@XmlRootElement(name="Response",
namespace="http://sap.fusesource.org/rfc/nplServer/BOOK_FLIGHT")
@XmlAccessorType(XmlAccessType.FIELD)
public class BookFlightResponse {

    @XmlAttribute(name="TRIPNUMBER")
    private String tripNumber;

    @XmlAttribute(name="TICKET_PRICE")
    private BigDecimal ticketPrice;
}

```

```

@XmlAttribute(name="TICKET_TAX")
private BigDecimal ticketTax;

@XmlAttribute(name="CURRENCY")
private String currency;

@XmlAttribute(name="PASSFORM")
private String passengerFormOfAddress;

@XmlAttribute(name="PASSNAME")
private String passengerName;

@XmlAttribute(name="PASSBIRTH")
@XmlJavaTypeAdapter(DateAdapter.class)
private Date passengerDateOfBirth;

@XmlElement(name="FLTINFO")
private FlightInfo flightInfo;

@XmlElement(name="CONNINFO")
private ConnectionInfoTable connectionInfo;

...
}

```

**NOTE**

The complex parameter fields of the response object are serialized as child elements of the response.

FlightInfo bean

The following listing illustrates a JAXB bean which marshals to the serialized form of the complex structure parameter **FLTINFO**:

```

@XmlRootElement(name="FLTINFO",
namespace="http://sap.fusesource.org/rfc/nplServer/BOOK_FLIGHT")
@XmlAccessorType(XmlAccessType.FIELD)
public class FlightInfo {

    @XmlAttribute(name="FLIGHTTIME")
    private String flightTime;

    @XmlAttribute(name="CITYFROM")
    private String cityFrom;

    @XmlAttribute(name="DEPDATE")
    @XmlJavaTypeAdapter(DateAdapter.class)
    private Date departureDate;

    @XmlAttribute(name="DEPTIME")
    @XmlJavaTypeAdapter(DateAdapter.class)
    private Date departureTime;
}

```

```

@XmlAttribute(name="CITYTO")
private String cityTo;

@XmlAttribute(name="ARRDATE")
@XmlJavaTypeAdapter(DateAdapter.class)
private Date arrivalDate;

@XmlAttribute(name="ARRTIME")
@XmlJavaTypeAdapter(DateAdapter.class)
private Date arrivalTime;

...
}

```

ConnectionInfoTable bean

The following listing illustrates a JAXB bean which marshals to the serialized form of the complex table parameter, **CONNINFO**. Note that the name of the root element type of the JAXB bean corresponds to the name of the row structure type suffixed with **_TABLE** and the bean contains a list of row elements.

```

@XmlRootElement(name="CONNINFO_TABLE",
namespace="http://sap.fusesource.org/rfc/nplServer/BOOK_FLIGHT")
@XmlAccessorType(XmlAccessType.FIELD)
public class ConnectionInfoTable {

    @XmlElement(name="row")
    List<ConnectionInfo> rows;

    ...
}

```

ConnectionInfo bean

The following listing illustrates a JAXB bean, which marshals to the serialized form of the above tables row elements:

```

@XmlRootElement(name="CONNINFO",
namespace="http://sap.fusesource.org/rfc/nplServer/BOOK_FLIGHT")
@XmlAccessorType(XmlAccessType.FIELD)
public class ConnectionInfo {

    @XmlAttribute(name="CONNID")
    String connectionId;

    @XmlAttribute(name="AIRLINE")
    String airline;

    @XmlAttribute(name="PLANETYPE")
    String planeType;

    @XmlAttribute(name="CITYFROM")
    String cityFrom;

    @XmlAttribute(name="DEPDATE")

```

```
@XmlJavaTypeAdapter(DateAdapter.class)
Date departureDate;
```

```
@XmlAttribute(name="DEPTIME")
@XmlJavaTypeAdapter(DateAdapter.class)
Date departureTime;
```

```
@XmlAttribute(name="CITYTO")
String cityTo;
```

```
@XmlAttribute(name="ARRDATE")
@XmlJavaTypeAdapter(DateAdapter.class)
Date arrivalDate;
```

```
@XmlAttribute(name="ARRTIME")
@XmlJavaTypeAdapter(DateAdapter.class)
Date arrivalTime;
```

```
...
```

```
}
```

CHAPTER 290. SAP NETWEAVER COMPONENT

Available as of Camel version 2.12

The `sap-netweaver` integrates with the [SAP NetWeaver Gateway](#) using HTTP transports.

This camel component supports only producer endpoints.

Maven users will need to add the following dependency to their `pom.xml` for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-sap-netweaver</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

290.1. URI FORMAT

The URI scheme for a sap netweaver gateway component is as follows

```
sap-netweaver:https://host:8080/path?username=foo&password=secret
```

You can append query options to the URI in the following format, **?option=value&option=value&...**

290.2. PREREQUISITES

You would need to have an account to the SAP NetWeaver system to be able to leverage this component. SAP provides a [demo setup](#) where you can requires for an account.

This component uses the basic authentication scheme for logging into SAP NetWeaver.

290.3. SAPNETWEAVER OPTIONS

The SAP NetWeaver component has no options.

The SAP NetWeaver endpoint is configured using URI syntax:

```
sap-netweaver:url
```

with the following path and query parameters:

290.3.1. Path Parameters (1 parameters):

Name	Description	Default	Type
url	Required Url to the SAP net-weaver gateway server.		String

290.3.2. Query Parameters (6 parameters):

Name	Description	Default	Type
flattenMap (producer)	If the JSON Map contains only a single entry, then flatten by storing that single entry value as the message body.	true	boolean
json (producer)	Whether to return data in JSON format. If this option is false, then XML is returned in Atom format.	true	boolean
jsonAsMap (producer)	To transform the JSON from a String to a Map in the message body.	true	boolean
password (producer)	Required Password for account.		String
username (producer)	Required Username for account.		String
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

290.4. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.component.sap-netweaver.enabled	Enable sap-netweaver component	true	Boolean
camel.component.sap-netweaver.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

290.5. MESSAGE HEADERS

The following headers can be used by the producer.

Name	Type	Description
Camel NetWeaverCommand	String	Mandatory: The command to execute in MS ADO.Net Data Service format.

290.6. EXAMPLES

This example is using the flight demo example from SAP, which is available online over the internet [here](#).

In the route below we request the SAP NetWeaver demo server using the following url

```
https://sapes1.sapdevcenter.com/sap/opu/odata/IWBEP/RMTSAMPLEFLIGHT_2/
```

And we want to execute the following command

```
FlightCollection(AirLineID='AA',FlightConnectionID='0017',FlightDate=datetime'2012-08-29T00%3A00%3A00')
```

To get flight details for the given flight. The command syntax is in [MS ADO.Net Data Service](#) format.

We have the following Camel route

```
from("direct:start")
  .setHeader(NetWeaverConstants.COMMAND, constant(command))
  .toF("sap-netweaver:%s?username=%s&password=%s", url, username, password)
  .to("log:response")
  .to("velocity:flight-info.vm")
```

Where url, username, password and command is defined as:

```
private String username = "P1909969254";
private String password = "TODO";
private String url =
  "https://sapes1.sapdevcenter.com/sap/opu/odata/IWBEP/RMTSAMPLEFLIGHT_2/";
private String command =
  "FlightCollection(AirLineID='AA',FlightConnectionID='0017',FlightDate=datetime'2012-08-29T00%3A00%3A00')";
```

The password is invalid. You would need to create an account at SAP first to run the demo.

The velocity template is used for formatting the response to a basic HTML page

```
<html>
<body>
  Flight information:
<p/>
```

```
<br/>Airline ID: $body["AirLineID"]  
<br/>Aircraft Type: $body["AirCraftType"]  
<br/>Departure city: $body["FlightDetails"]["DepartureCity"]  
<br/>Departure airport: $body["FlightDetails"]["DepartureAirPort"]  
<br/>Destination city: $body["FlightDetails"]["DestinationCity"]  
<br/>Destination airport: $body["FlightDetails"]["DestinationAirPort"]  
  
</body>  
</html>
```

When running the application you get sampel output:

```
Flight information:  
Airline ID: AA  
Aircraft Type: 747-400  
Departure city: new york  
Departure airport: JFK  
Destination city: SAN FRANCISCO  
Destination airport: SFO
```

290.7. SEE ALSO

- [Configuring Camel](#)
- [Component](#)
- [Endpoint](#)
- [Getting Started](#)
- [HTTP](#)

CHAPTER 291. SCHEDULER COMPONENT

Available as of Camel version 2.15

The **scheduler**: component is used to generate message exchanges when a scheduler fires. This component is similar to the [Timer](#) component, but it offers more functionality in terms of scheduling. Also this component uses JDK **ScheduledExecutorService**. Where as the timer uses a JDK **Timer**.

You can only consume events from this endpoint.

291.1. URI FORMAT

```
scheduler:name[?options]
```

Where **name** is the name of the scheduler, which is created and shared across endpoints. So if you use the same name for all your scheduler endpoints, only one scheduler thread pool and thread will be used - but you can configure the thread pool to allow more concurrent threads.

You can append query options to the URI in the following format, **?option=value&option=value&...**

Note: The IN body of the generated exchange is **null**. So **exchange.getIn().getBody()** returns **null**.

291.2. OPTIONS

The Scheduler component supports 2 options, which are listed below.

Name	Description	Default	Type
concurrentTasks (scheduler)	Number of threads used by the scheduling thread pool. Is by default using a single thread	1	int
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Scheduler endpoint is configured using URI syntax:

```
scheduler:name
```

with the following path and query parameters:

291.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
name	Required The name of the scheduler		String

291.2.2. Query Parameters (20 parameters):

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN/ERROR level and ignored.	false	boolean
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean
exceptionHandler (consumer)	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN/ERROR level and ignored.		<code>ExceptionHandler</code>
exchangePattern (consumer)	Sets the default exchange pattern when creating an exchange.		<code>ExchangePattern</code>
pollStrategy (consumer)	A pluggable <code>org.apache.camel.PollingConsumerPollingStrategy</code> allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel. In other words the error occurred while the polling was gathering information, for instance access to a file network failed so Camel cannot access it to scan for files. The default implementation will log the caused exception at WARN level and ignore it.		<code>PollingConsumerPollStrategy</code>
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the <code>backoffMultiplier</code> should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the <code>backoffMultiplier</code> should kick-in.		int

Name	Description	Default	Type
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then <code>backoffIdleThreshold</code> and/or <code>backoffErrorThreshold</code> must also be configured.		int
concurrentTasks (scheduler)	Number of threads used by the scheduling thread pool. Is by default using a single thread	1	int
delay (scheduler)	Milliseconds before the next poll. The default value is 500. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	500	long
greedy (scheduler)	If greedy is enabled, then the <code>ScheduledPollConsumer</code> will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts. The default value is 1000. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	1000	long
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that.	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool. This option allows you to share a thread pool among multiple consumers.		ScheduledExecutorService

Name	Description	Default	Type
scheduler (scheduler)	Allow to plugin a custom <code>org.apache.camel.spi.ScheduledPollConsumerScheduler</code> to use as the scheduler for firing when the polling consumer runs. The default implementation uses the <code>ScheduledExecutorService</code> and there is a Quartz2, and Spring based which supports CRON expressions. Notice: If using a custom scheduler then the options for <code>initialDelay</code> , <code>useFixedDelay</code> , <code>timeUnit</code> , and <code>scheduledExecutorService</code> may not be in use. Use the text <code>quartz2</code> to refer to use the Quartz2 scheduler; and use the text <code>spring</code> to use the Spring based; and use the text <code>#myScheduler</code> to refer to a custom scheduler by its id in the Registry. See Quartz2 page for an example.	none	ScheduledPollConsumer Scheduler
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz2, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for <code>initialDelay</code> and delay options.	MILLIS ECON DS	TimeUnit
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See <code>ScheduledExecutorService</code> in JDK for details.	true	boolean

291.3. MORE INFORMATION

This component is a scheduler [Polling Consumer](#) where you can find more information about the options above, and examples at the [Polling Consumer](#) page.

291.4. EXCHANGE PROPERTIES

When the timer is fired, it adds the following information as properties to the **Exchange**:

Name	Type	Description
Exchange.TIMER_NAME	String	The value of the name option.

Name	Type	Description
Exchange.TIMER_FIRED_TIME	Date	The time when the consumer fired.

291.5. SAMPLE

To set up a route that generates an event every 60 seconds:

```
from("scheduler://foo?delay=60s").to("bean:myBean?method=someMethodName");
```

The above route will generate an event and then invoke the **someMethodName** method on the bean called **myBean** in the Registry such as JNDI or Spring.

And the route in Spring DSL:

```
<route>
  <from uri="scheduler://foo?delay=60s"/>
  <to uri="bean:myBean?method=someMethodName"/>
</route>
```

291.6. FORCING THE SCHEDULER TO TRIGGER IMMEDIATELY WHEN COMPLETED

To let the scheduler trigger as soon as the previous task is complete, you can set the option **greedy=true**. But beware then the scheduler will keep firing all the time. So use this with caution.

291.7. FORCING THE SCHEDULER TO BE IDLE

There can be use cases where you want the scheduler to trigger and be greedy. But sometimes you want "tell the scheduler" that there was no task to poll, so the scheduler can change into idle mode using the backoff options. To do this you would need to set a property on the exchange with the key **Exchange.SCHEDULER_POLLED_MESSAGES** to a boolean value of false. This will cause the consumer to indicate that there was no messages polled.

The consumer will otherwise as by default return 1 message polled to the scheduler, every time the consumer has completed processing the exchange.

291.8. SEE ALSO

- [Timer](#)
- [Quartz](#)

CHAPTER 292. SCHEMATRON COMPONENT

Available as of Camel version 2.15

Schematron is an XML-based language for validating XML instance documents. It is used to make assertions about data in an XML document and it is also used to express operational and business rules. Schematron is an [ISO Standard](#). The schematron component uses the leading [implementation](#) of ISO schematron. It is an XSLT based implementation. The schematron rules is run through [four XSLT pipelines](#), which generates a final XSLT which will be used as the basis for running the assertion against the XML document. The component is written in a way that Schematron rules are loaded at the start of the endpoint (only once) this is to minimise the overhead of instantiating a Java Templates object representing the rules.

292.1. URI FORMAT

```
schematron://path?[options]
```

292.2. URI OPTIONS

The Schematron component has no options.

The Schematron endpoint is configured using URI syntax:

```
schematron:path
```

with the following path and query parameters:

292.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
path	Required The path to the schematron rules file. Can either be in class path or location in the file system.		String

292.2.2. Query Parameters (4 parameters):

Name	Description	Default	Type
abort (producer)	Flag to abort the route and throw a schematron validation exception.	false	boolean
rules (producer)	To use the given schematron rules instead of loading from the path		Templates
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

Name	Description	Default	Type
uriResolver (advanced)	Set the URIResolver to be used for resolving schematron includes in the rules file.		URIResolver

292.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.component.schematron.enabled	Enable schematron component	true	Boolean
camel.component.schematron.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

292.4. HEADERS

Name	Description	Type	In/Out
CamelSchematronValidationStatus	The schematron validation status: SUCCESS / FAILED	String	IN
CamelSchematronValidationReport	The schematron report body in XML format. See an example below	String	IN

292.5. URI AND PATH SYNTAX

The following example shows how to invoke the schematron processor in Java DSL. The schematron rules file is sourced from the class path:

```
from("direct:start").to("schematron://sch/schematron.sch").to("mock:result")
```

The following example shows how to invoke the schematron processor in XML DSL. The schematron rules file is sourced from the file system:

```
<route>
  <from uri="direct:start" />
  <to uri="schematron:///usr/local/sch/schematron.sch" />
  <log message="Schematron validation status: ${in.header.CamelSchematronValidationStatus}" />
  <choice>
    <when>
      <simple>${in.header.CamelSchematronValidationStatus} == 'SUCCESS'</simple>
      <to uri="mock:success" />
    </when>
    <otherwise>
      <log message="Failed schematron validation" />
      <setBody>
        <header>CamelSchematronValidationReport</header>
      </setBody>
      <to uri="mock:failure" />
    </otherwise>
  </choice>
</route>
```

TIP

Where to store schematron rules? Schematron rules can change with business requirement, as such it is recommended to store these rules somewhere in file system. When the schematron component endpoint is started, the rules are compiled into XSLT as a Java Templates Object. This is done only once to minimise the overhead of instantiating Java Templates object, which can be an expensive operation for large set of rules and given that the process goes through four pipelines of [XSLT transformations](#). So if you happen to store the rules in the file system, in the event of an update, all you need is to restart the route or the component. No harm in storing these rules in the class path though, but you will have to build and deploy the component to pick up the changes.

292.6. SCHEMATRON RULES AND REPORT SAMPLES

Here is an example of schematron rules

```
<?xml version="1.0" encoding="UTF-8"?>
<schema xmlns="http://purl.oclc.org/dsdl/schematron">
  <title>Check Sections 12/07</title>
  <pattern id="section-check">
    <rule context="section">
      <assert test="title">This section has no title</assert>
      <assert test="para">This section has no paragraphs</assert>
```

```

    </rule>
  </pattern>
</schema>

```

Here is an example of schematron report:

```

<?xml version="1.0" encoding="UTF-8"?>
<svrl:schematron-output xmlns:svrl="http://purl.oclc.org/dsdl/svrl"
  xmlns:iso="http://purl.oclc.org/dsdl/schematron"
  xmlns:saxon="http://saxon.sf.net/"
  xmlns:schold="http://www.ascc.net/xml/schematron"
  xmlns:xhtml="http://www.w3.org/1999/xhtml"
  xmlns:xs="http://www.w3.org/2001/XMLSchema"
  xmlns:xsd="http://www.w3.org/2001/XMLSchema" schemaVersion="" title="">

  <svrl:active-pattern document="" />
  <svrl:fired-rule context="chapter" />
  <svrl:failed-assert test="title" location="/doc[1]/chapter[1]">
    <svrl:text>A chapter should have a title</svrl:text>
  </svrl:failed-assert>
  <svrl:fired-rule context="chapter" />
  <svrl:failed-assert test="title" location="/doc[1]/chapter[2]">
    <svrl:text>A chapter should have a title</svrl:text>
  </svrl:failed-assert>
  <svrl:fired-rule context="chapter" />
</svrl:schematron-output>

```

TIP

Useful Links and resources* [Introduction to Schematron](#) by Mulleberry technologies. An excellent document in PDF to get you started on Schematron. * [Schematron official site](#). This contains links to other resources

CHAPTER 293. SCP COMPONENT

Available as of Camel version 2.10

The `camel-jsch` component supports the [SCP protocol](#) using the Client API of the [Jsch](#) project. Jsch is already used in camel by the [FTP](#) component for the `sftp:` protocol.

Maven users will need to add the following dependency to their `pom.xml` for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-jsch</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

293.1. URI FORMAT

```
scp://host[:port]/destination[?options]
```

You can append query options to the URI in the following format, `?option=value&option=value&...`

The file name can be specified either in the `<path>` part of the URI or as a "CamelFileName" header on the message (**Exchange.FILE_NAME** if used in code).

293.2. OPTIONS

The SCP component supports 2 options, which are listed below.

Name	Description	Default	Type
verboseLogging (producer)	JSCH is verbose logging out of the box. Therefore we turn the logging down to DEBUG logging by default. But setting this option to true turns on the verbose logging again.	false	boolean
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The SCP endpoint is configured using URI syntax:

```
scp:host:port/directoryName
```

with the following path and query parameters:

293.2.1. Path Parameters (3 parameters):

Name	Description	Default	Type
host	Required Hostname of the FTP server		String
port	Port of the FTP server		int
directoryName	The starting directory		String

293.2.2. Query Parameters (22 parameters):

Name	Description	Default	Type
disconnect (common)	Whether or not to disconnect from remote FTP server right after use. Disconnect will only disconnect the current connection to the FTP server. If you have a consumer which you want to stop, then you need to stop the consumer/route instead.	false	boolean
chmod (producer)	Allows you to set chmod on the stored file. For example chmod=664.	664	String
fileName (producer)	Use Expression such as File Language to dynamically set the filename. For consumers, it's used as a filename filter. For producers, it's used to evaluate the filename to write. If an expression is set, it take precedence over the CamelFileName header. (Note: The header itself can also be an Expression). The expression options support both String and Expression types. If the expression is a String type, it is always evaluated using the File Language. If the expression is an Expression type, the specified Expression type is used - this allows you, for instance, to use OGNL expressions. For the consumer, you can use it to filter filenames, so you can for instance consume today's file using the File Language syntax: mydata-\$date:now:yyyyMMdd.txt. The producers support the CamelOverrideFileName header which takes precedence over any existing CamelFileName header; the CamelOverrideFileName is a header that is used only once, and makes it easier as this avoids to temporary store CamelFileName and have to restore it afterwards.		String

Name	Description	Default	Type
flatten (producer)	Flatten is used to flatten the file name path to strip any leading paths, so it's just the file name. This allows you to consume recursively into sub-directories, but when you eg write the files to another directory they will be written in a single directory. Setting this to true on the producer enforces that any file name in CamelFileName header will be stripped for any leading paths.	false	boolean
jailStartingDirectory (producer)	Used for jailing (restricting) writing files to the starting directory (and sub) only. This is enabled by default to not allow Camel to write files to outside directories (to be more secured out of the box). You can turn this off to allow writing files to directories outside the starting directory, such as parent or root folders.	true	boolean
strictHostKeyChecking (producer)	Sets whether to use strict host key checking. Possible values are: no, yes	no	String
allowNullBody (producer)	Used to specify if a null body is allowed during file writing. If set to true then an empty file will be created, when set to false, and attempting to send a null body to the file component, a GenericFileWriteException of 'Cannot write null body to file.' will be thrown. If the fileExist option is set to 'Override', then the file will be truncated, and if set to append the file will remain unchanged.	false	boolean
disconnectOnBatchComplete (producer)	Whether or not to disconnect from remote FTP server right after a Batch upload is complete. disconnectOnBatchComplete will only disconnect the current connection to the FTP server.	false	boolean
moveExistingFileStrategy (producer)	Strategy (Custom Strategy) used to move file with special naming token to use when fileExist=Move is configured. By default, there is an implementation used if no custom strategy is provided		FileMoveExistingStrategy
connectTimeout (advanced)	Sets the connect timeout for waiting for a connection to be established Used by both FTPClient and JSCH	10000	int
soTimeout (advanced)	Sets the so timeout Used only by FTPClient	30000 0	int

Name	Description	Default	Type
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
timeout (advanced)	Sets the data timeout for waiting for reply Used only by FTPClient	30000	int
knownHostsFile (security)	Sets the known_hosts file, so that the jsch endpoint can do host key verification. You can prefix with classpath: to load the file from classpath instead of file system.		String
password (security)	Password to use for login		String
preferredAuthentications (security)	Set a comma separated list of authentications that will be used in order of preference. Possible authentication methods are defined by JCraft JSCH. Some examples include: gssapi-with-mic,publickey,keyboard-interactive,password If not specified the JSCH and/or system defaults will be used.		String
privateKeyBytes (security)	Set the private key bytes to that the endpoint can do private key verification. This must be used only if privateKeyFile wasn't set. Otherwise the file will have the priority.		byte[]
privateKeyFile (security)	Set the private key file to that the endpoint can do private key verification. You can prefix with classpath: to load the file from classpath instead of file system.		String
privateKeyFilePassphrase (security)	Set the private key file passphrase to that the endpoint can do private key verification.		String
username (security)	Username to use for login		String
useUserKnownHostsFile (security)	If knownHostFile has not been explicit configured, then use the host file from System.getProperty(user.home) /.ssh/known_hosts	true	boolean
ciphers (security)	Set a comma separated list of ciphers that will be used in order of preference. Possible cipher names are defined by JCraft JSCH. Some examples include: aes128-ctr,aes128-cbc,3des-ctr,3des-cbc,blowfish-cbc,aes192-cbc,aes256-cbc. If not specified the default list from JSCH will be used.		String

293.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 3 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.scp.enabled</code>	Enable scp component	true	Boolean
<code>camel.component.scp.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.component.scp.verbose-logging</code>	JSCH is verbose logging out of the box. Therefore we turn the logging down to DEBUG logging by default. But setting this option to true turns on the verbose logging again.	false	Boolean

293.4. LIMITATIONS

Currently camel-jsch only supports a [Producer](#) (i.e. copy files to another host).

CHAPTER 294. CAMEL SCR (DEPRECATED)

Available as of Camel 2.15

SCR stands for Service Component Runtime and is an implementation of OSGi Declarative Services specification. SCR enables any plain old Java object to expose and use OSGi services with no boilerplate code.

OSGi framework knows your object by looking at SCR descriptor files in its bundle which are typically generated from Java annotations by a plugin such as **org.apache.felix:maven-scr-plugin**.

Running Camel in an SCR bundle is a great alternative for Spring DM and Blueprint based solutions having significantly fewer lines of code between you and the OSGi framework. Using SCR your bundle can remain completely in Java world; there is no need to edit XML or properties files. This offers you full control over everything and means your IDE of choice knows exactly what is going on in your project.

294.1. CAMEL SCR SUPPORT

Camel-scr bundle is not included in Apache Camel versions prior 2.15.0, but the artifact itself can be used with any Camel version since 2.12.0.

org.apache.camel/camel-scr bundle provides a base class, **AbstractCamelRunner**, which manages a Camel context for you and a helper class, **ScrHelper**, for using your SCR properties in unit tests. Camel-scr feature for Apache Karaf defines all features and bundles required for running Camel in SCR bundles.

AbstractCamelRunner class ties CamelContext's lifecycle to Service Component's lifecycle and handles configuration with help of Camel's PropertiesComponent. All you have to do to make a Service Component out of your java class is to extend it from **AbstractCamelRunner** and add the following **org.apache.felix.scr.annotations** on class level:

Add required annotations

```
@Component
@References({
    @Reference(name = "camelComponent",referenceInterface = ComponentResolver.class,
        cardinality = ReferenceCardinality.MANDATORY_MULTIPLE, policy =
        ReferencePolicy.DYNAMIC,
        policyOption = ReferencePolicyOption.GREEDY, bind = "gotCamelComponent", unbind =
        "lostCamelComponent")
})
```

Then implement **getRouteBuilders()** method which returns the Camel routes you want to run:

Implement **getRouteBuilders()**

```
@Override
protected List<RoutesBuilder> getRouteBuilders() {
    List<RoutesBuilder> routesBuilders = new ArrayList<>();
    routesBuilders.add(new YourRouteBuilderHere(registry));
    routesBuilders.add(new AnotherRouteBuilderHere(registry));
    return routesBuilders;
}
```

And finally provide the default configuration with:

Default configuration in annotations

```
@Properties({
    @Property(name = "camelContextId", value = "my-test"),
    @Property(name = "active", value = "true"),
    @Property(name = "...", value = "..."),
    ...
})
```

That's all. And if you used **camel-archetype-scr** to generate a project all this is already taken care of.

Below is an example of a complete Service Component class, generated by **camel-archetype-scr**:

CamelScrExample.java

```
// This file was generated from org.apache.camel.archetypes/camel-archetype-scr/2.15-SNAPSHOT
package example;

import java.util.ArrayList;
import java.util.List;

import org.apache.camel.scr.AbstractCamelRunner;
import example.internal.CamelScrExampleRoute;
import org.apache.camel.RoutesBuilder;
import org.apache.camel.spi.ComponentResolver;
import org.apache.felix.scr.annotations.*;

@Component(label = CamelScrExample.COMPONENT_LABEL, description =
CamelScrExample.COMPONENT_DESCRIPTION, immediate = true, metatype = true)
@Properties({
    @Property(name = "camelContextId", value = "camel-scr-example"),
    @Property(name = "camelRouteId", value = "foo/timer-log"),
    @Property(name = "active", value = "true"),
    @Property(name = "from", value = "timer:foo?period=5000"),
    @Property(name = "to", value = "log:foo?showHeaders=true"),
    @Property(name = "messageOk", value = "Success: {{from}} -> {{to}}"),
    @Property(name = "messageError", value = "Failure: {{from}} -> {{to}}"),
    @Property(name = "maximumRedeliveries", value = "0"),
    @Property(name = "redeliveryDelay", value = "5000"),
    @Property(name = "backOffMultiplier", value = "2"),
    @Property(name = "maximumRedeliveryDelay", value = "60000")
})
@References({
    @Reference(name = "camelComponent", referenceInterface = ComponentResolver.class,
        cardinality = ReferenceCardinality.MANDATORY_MULTIPLE, policy =
ReferencePolicy.DYNAMIC,
        policyOption = ReferencePolicyOption.GREEDY, bind = "gotCamelComponent", unbind =
"lostCamelComponent")
})
public class CamelScrExample extends AbstractCamelRunner {

    public static final String COMPONENT_LABEL = "example.CamelScrExample";
    public static final String COMPONENT_DESCRIPTION = "This is the description for camel-scr-
example.";
}
```

```

@Override
protected List<RoutesBuilder> getRouteBuilders() {
    List<RoutesBuilder> routesBuilders = new ArrayList<>();
    routesBuilders.add(new CamelScrExampleRoute(registry));
    return routesBuilders;
}
}

```

CamelContextId and **active** properties control the CamelContext's name (defaults to "camel-runner-default") and whether it will be started or not (defaults to "false"), respectively. In addition to these you can add and use as many properties as you like. Camel's PropertiesComponent handles recursive properties and prefixing with fallback without problem.

AbstractCamelRunner will make these properties available to your RouteBuilders with help of Camel's PropertiesComponent and it will also inject these values into your Service Component's and RouteBuilder's fields when their names match. The fields can be declared with any visibility level, and many types are supported (String, int, boolean, URL, ...).

Below is an example of a RouteBuilder class generated by **camel-archetype-scr**:

CamelScrExampleRoute.java

```

// This file was generated from org.apache.camel.archetypes/camel-archetype-scr/2.15-SNAPSHOT
package example.internal;

import org.apache.camel.LoggingLevel;
import org.apache.camel.builder.RouteBuilder;
import org.apache.camel.impl.SimpleRegistry;
import org.apache.commons.lang.Validate;

public class CamelScrExampleRoute extends RouteBuilder {

    SimpleRegistry registry;

    // Configured fields
    private String camelRouteId;
    private Integer maximumRedeliveries;
    private Long redeliveryDelay;
    private Double backOffMultiplier;
    private Long maximumRedeliveryDelay;

    public CamelScrExampleRoute(final SimpleRegistry registry) {
        this.registry = registry;
    }

    @Override
    public void configure() throws Exception {
        checkProperties();

        // Add a bean to Camel context registry
        registry.put("test", "bean");
    }
}

```

```

    errorHandler(defaultErrorHandler()
        .retryAttemptedLogLevel(LoggingLevel.WARN)
        .maximumRedeliveries(maximumRedeliveries)
        .redeliveryDelay(redeliveryDelay)
        .backOffMultiplier(backOffMultiplier)
        .maximumRedeliveryDelay(maximumRedeliveryDelay));

    from("${from}")
        .startupOrder(2)
        .routeId(camelRouteId)
        .onCompletion()
            .to("direct:processCompletion")
        .end()
        .removeHeaders("CamelHttp*")
        .to("${to}");

    from("direct:processCompletion")
        .startupOrder(1)
        .routeId(camelRouteId + ".completion")
        .choice()
            .when(simple("${exception} == null"))
                .log("${messageOk}")
            .otherwise()
                .log(LoggingLevel.ERROR, "${messageError}")
        .end();
    }
}

public void checkProperties() {
    Validate.notNull(camelRouteId, "camelRouteId property is not set");
    Validate.notNull(maximumRedeliveries, "maximumRedeliveries property is not set");
    Validate.notNull(redeliveryDelay, "redeliveryDelay property is not set");
    Validate.notNull(backOffMultiplier, "backOffMultiplier property is not set");
    Validate.notNull(maximumRedeliveryDelay, "maximumRedeliveryDelay property is not set");
}
}

```

Let's take a look at **CamelScrExampleRoute** in more detail.

```

// Configured fields
private String camelRouteId;
private Integer maximumRedeliveries;
private Long redeliveryDelay;
private Double backOffMultiplier;
private Long maximumRedeliveryDelay;

```

The values of these fields are set with values from properties by matching their names.

```
// Add a bean to Camel context registry
registry.put("test", "bean");
```

If you need to add some beans to CamelContext's registry for your routes, you can do it like this.

```
public void checkProperties() {
    Validate.notNull(camelRouteId, "camelRouteId property is not set");
    Validate.notNull(maximumRedeliveries, "maximumRedeliveries property is not set");
    Validate.notNull(redeliveryDelay, "redeliveryDelay property is not set");
    Validate.notNull(backOffMultiplier, "backOffMultiplier property is not set");
    Validate.notNull(maximumRedeliveryDelay, "maximumRedeliveryDelay property is not set");
}
```

It is a good idea to check that required parameters are set and they have meaningful values before allowing the routes to start.

```
from("${from}")
    .startupOrder(2)
    .routeId(camelRouteId)
    .onCompletion()
        .to("direct:processCompletion")
    .end()
    .removeHeaders("CamelHttp*")
    .to("${to}");

from("direct:processCompletion")
    .startupOrder(1)
    .routeId(camelRouteId + ".completion")
    .choice()
        .when(simple("${exception} == null"))
            .log("${messageOk}")
        .otherwise()
            .log(LoggingLevel.ERROR, "${messageError}")
    .end();
```

Note that pretty much everything in the route is configured with properties. This essentially makes your RouteBuilder a template. SCR allows you to create more instances of your routes just by providing alternative configurations. More on this in section *Using Camel SCR bundle as a template*.

294.2. ABSTRACTCAMELRUNNER'S LIFECYCLE IN SCR

1. When component's configuration policy and mandatory references are satisfied SCR calls **activate()**. This creates and sets up a CamelContext through the following call chain: **activate()** → **prepare()** → **createCamelContext()** → **setupPropertiesComponent()** → **configure()** → **setupCamelContext()**. Finally, the context is scheduled to start after a delay defined in **AbstractCamelRunner.START_DELAY** with **runWithDelay()**.
2. When Camel components (**ComponentResolver** services, to be exact) are registered in OSGi, SCR calls **gotCamelComponent`()** which reschedules/delays the CamelContext start further

by the same **AbstractCamelRunner.START_DELAY**. This in effect makes CamelContext wait until all Camel components are loaded or there is a sufficient gap between them. The same logic will tell a failed-to-start CamelContext to try again whenever we add more Camel components.

3. When Camel components are unregistered SCR calls **lostCamelComponent`()**. This call does nothing.
4. When one of the requirements that caused the call to **activate() is lost SCR will call deactivate()**. This will shutdown the CamelContext.

In (non-OSGi) unit tests you should use **prepare() → run() → stop()** instead of **activate() → deactivate()** for more fine-grained control. Also, this allows us to avoid possible SCR specific operations in tests.

294.3. USING CAMEL-ARCHETYPE-SCR

The easiest way to create an Camel SCR bundle project is to use **camel-archetype-scr** and Maven.

You can generate a project with the following steps:

Generating a project

```
$ mvn archetype:generate -Dfilter=org.apache.camel.archetypes:camel-archetype-scr
```

Choose archetype:

1: local -> org.apache.camel.archetypes:camel-archetype-scr (Creates a new Camel SCR bundle project for Karaf)

Choose a number or apply filter (format: [groupId:]artifactId, case sensitive contains): : 1

Define value for property 'groupId': : example

[INFO] Using property: groupId = example

Define value for property 'artifactId': : camel-scr-example

Define value for property 'version': 1.0-SNAPSHOT: :

Define value for property 'package': example: :

[INFO] Using property: archetypeArtifactId = camel-archetype-scr

[INFO] Using property: archetypeGroupId = org.apache.camel.archetypes

[INFO] Using property: archetypeVersion = 2.15-SNAPSHOT

Define value for property 'className': : CamelScrExample

Confirm properties configuration:

groupId: example

artifactId: camel-scr-example

version: 1.0-SNAPSHOT

package: example

archetypeArtifactId: camel-archetype-scr

archetypeGroupId: org.apache.camel.archetypes

archetypeVersion: 2.15-SNAPSHOT

className: CamelScrExample

Y: :

Done!

Now run:

```
mvn install
```

and the bundle is ready to be deployed.

294.4. UNIT TESTING CAMEL ROUTES

Service Component is a POJO and has no special requirements for (non-OSGi) unit testing. There are however some techniques that are specific to Camel SCR or just make testing easier.

Below is an example unit test, generated by **camel-archetype-scr**:

```
// This file was generated from org.apache.camel.archetypes/camel-archetype-scr/2.15-SNAPSHOT
package example;

import java.util.List;

import org.apache.camel.scr.internal.ScrHelper;
import org.apache.camel.builder.AdviceWithRouteBuilder;
import org.apache.camel.component.mock.MockComponent;
import org.apache.camel.component.mock.MockEndpoint;
import org.apache.camel.model.ModelCamelContext;
import org.apache.camel.model.RouteDefinition;
import org.junit.After;
import org.junit.Before;
import org.junit.Rule;
import org.junit.Test;
import org.junit.rules.TestName;
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import org.junit.runner.RunWith;
import org.junit.runners.JUnit4;

@RunWith(JUnit4.class)
public class CamelScrExampleTest {

    Logger log = LoggerFactory.getLogger(getClass());

    @Rule
    public TestName testName = new TestName();

    CamelScrExample integration;
    ModelCamelContext context;

    @Before
    public void setUp() throws Exception {
        log.info("*****");
        log.info("Test: " + testName.getMethodName());
        log.info("*****");

        // Set property prefix for unit testing
        System.setProperty(CamelScrExample.PROPERTY_PREFIX, "unit");

        // Prepare the integration
        integration = new CamelScrExample();
        integration.prepare(null, ScrHelper.getScrProperties(integration.getClass().getName()));
        context = integration.getContext();

        // Disable JMX for test
        context.disableJMX();
    }
}
```

```

    // Fake a component for test
    context.addComponent("amq", new MockComponent());
}

@After
public void tearDown() throws Exception {
    integration.stop();
}

@Test
public void testRoutes() throws Exception {
    // Adjust routes
    List<RouteDefinition> routes = context.getRouteDefinitions();

    routes.get(0).adviceWith(context, new AdviceWithRouteBuilder() {
        @Override
        public void configure() throws Exception {
            // Replace "from" endpoint with direct:start
            replaceFromWith("direct:start");
            // Mock and skip result endpoint
            mockEndpoints("log:*");
        }
    });

    MockEndpoint resultEndpoint = context.getEndpoint("mock:log:foo", MockEndpoint.class);
    // resultEndpoint.expectedMessageCount(1); // If you want to just check the number of messages
    resultEndpoint.expectedBodiesReceived("hello"); // If you want to check the contents

    // Start the integration
    integration.run();

    // Send the test message
    context.createProducerTemplate().sendBody("direct:start", "hello");

    resultEndpoint.assertIsSatisfied();
}
}

```

Now, let's take a look at the interesting bits one by one.

Using property prefixing

```

// Set property prefix for unit testing
System.setProperty(CamelScrExample.PROPERTY_PREFIX, "unit");

```

This allows you to override parts of the configuration by prefixing properties with "unit.". For example, **unit.from** overrides **from** for the unit test.

Prefixes can be used to handle the differences between the runtime environments where your routes might run. Moving the unchanged bundle through development, testing and production environments is a typical use case.

Getting test configuration from annotations

```
integration.prepare(null, ScrHelper.getScrProperties(integration.getClass().getName()));
```

Here we configure the Service Component in test with the same properties that would be used in OSGi environment.

Mocking components for test

```
// Fake a component for test
context.addComponent("amq", new MockComponent());
```

Components that are not available in test can be mocked like this to allow the route to start.

Adjusting routes for test

```
// Adjust routes
List<RouteDefinition> routes = context.getRouteDefinitions();

routes.get(0).adviceWith(context, new AdviceWithRouteBuilder() {
    @Override
    public void configure() throws Exception {
        // Replace "from" endpoint with direct:start
        replaceFromWith("direct:start");
        // Mock and skip result endpoint
        mockEndpoints("log:*");
    }
});
```

Camel's AdviceWith feature allows routes to be modified for test.

Starting the routes

```
// Start the integration
integration.run();
```

Here we start the Service Component and along with it the routes.

Sending a test message

```
// Send the test message
context.createProducerTemplate().sendBody("direct:start", "hello");
```

Here we send a message to a route in test.

294.5. RUNNING THE BUNDLE IN APACHE KARAF

Once the bundle has been built with **mvn install** it's ready to be deployed. To deploy the bundle on Apache Karaf perform the following steps on Karaf command line:

Deploying the bundle in Apache Karaf

```
# Add Camel feature repository
karaf@root> features:chooseurl camel 2.15-SNAPSHOT

# Install camel-scr feature
karaf@root> features:install camel-scr

# Install commons-lang, used in the example route to validate parameters
karaf@root> osgi:install mvn:commons-lang/commons-lang/2.6

# Install and start your bundle
karaf@root> osgi:install -s mvn:example/camel-scr-example/1.0-SNAPSHOT

# See how it's running
karaf@root> log:tail -n 10

Press ctrl-c to stop watching the log.
```

294.5.1. Overriding the default configuration

By default, Service Component's configuration PID equals the fully qualified name of its class. You can change the example bundle's properties with Karaf's **config:*** commands:

Override a property

```
# Override 'messageOk' property
karaf@root> config:propset -p example.CamelScrExample messageOk "This is better logging"
```

Or you can change the configuration by editing property files in Karaf's **etc** folder.

294.5.2. Using Camel SCR bundle as a template

Let's say you have a Camel SCR bundle that implements an integration pattern that you use frequently, say, **from** → **to**, with success/failure logging and redelivery which also happens to be the pattern our example route implements. You probably don't want to create a separate bundle for every instance. No worries, SCR has you covered.

Create a configuration PID for your Service Component, but add a tail with a dash and SCR will use that configuration to create a new instance of your component.

Creating a new Service Component instance

```
# Create a PID with a tail
karaf@root> config:edit example.CamelScrExample-anotherone

# Override some properties
karaf@root> config:propset camelContextId my-other-context
karaf@root> config:propset to "file://removeme?fileName=removemetoo.txt"
```

```
# Save the PID  
karaf@root> config:update
```

This will start a new CamelContext with your overridden properties. How convenient.

294.6. NOTES

When designing a Service Component to be a template you typically don't want it to start without a "tailed" configuration i.e. with the default configuration.

To prevent your Service Component from starting with the default configuration add **policy = ConfigurationPolicy.REQUIRE** to the class level `@Component` annotation.

CHAPTER 295. XML SECURITY DATAFORMAT

Available as of Camel version 2.0

The XMLSecurity Data Format facilitates encryption and decryption of XML payloads at the Document, Element, and Element Content levels (including simultaneous multi-node encryption/decryption using XPath). To sign messages using the XML Signature specification, please see the Camel XML Security component.

The encryption capability is based on formats supported using the Apache XML Security (Santuario) project. Symmetric encryption/decryption is currently supported using Triple-DES and AES (128, 192, and 256) encryption formats. Additional formats can be easily added later as needed. This capability allows Camel users to encrypt/decrypt payloads while being dispatched or received along a route.

Available as of Camel 2.9

The XMLSecurity Data Format supports asymmetric key encryption. In this encryption model a symmetric key is generated and used to perform XML content encryption or decryption. This "content encryption key" is then itself encrypted using an asymmetric encryption algorithm that leverages the recipient's public key as the "key encryption key". Use of an asymmetric key encryption algorithm ensures that only the holder of the recipient's private key can access the generated symmetric encryption key. Thus, only the private key holder can decode the message. The XMLSecurity Data Format handles all of the logic required to encrypt and decrypt the message content and encryption key(s) using asymmetric key encryption.

The XMLSecurity Data Format also has improved support for namespaces when processing the XPath queries that select content for encryption. A namespace definition mapping can be included as part of the data format configuration. This enables true namespace matching, even if the prefix values in the XPath query and the target xml document are not equivalent strings.

295.1. XMLSECURITY OPTIONS

The XML Security dataformat supports 13 options, which are listed below.

Name	Default	Java Type	Description
<code>xmlCipherAlgorithm</code>	TRIPLEDES	String	The cipher algorithm to be used for encryption/decryption of the XML message content. The available choices are: XMLCipher.TRIPEDES XMLCipher.AES_128 XMLCipher.AES_128_GCM XMLCipher.AES_192 XMLCipher.AES_192_GCM XMLCipher.AES_256 XMLCipher.AES_256_GCM XMLCipher.SEED_128 XMLCipher.CAMELLIA_128 XMLCipher.CAMELLIA_192 XMLCipher.CAMELLIA_256 The default value is XMLCipher.TRIPEDES
<code>passPhrase</code>		String	A String used as passPhrase to encrypt/decrypt content. The passPhrase has to be provided. If no passPhrase is specified, a default passPhrase is used. The passPhrase needs to be put together in conjunction with the appropriate encryption algorithm. For example using TRIPEDES the passPhrase can be a Only another 24 Byte key

Name	Default	Java Type	Description
passPhraseByte		byte[]	A byte used as passPhrase to encrypt/decrypt content. The passPhrase has to be provided. If no passPhrase is specified, a default passPhrase is used. The passPhrase needs to be put together in conjunction with the appropriate encryption algorithm. For example using TRIPLEDES the passPhase can be a Only another 24 Byte key
secureTag		String	The XPath reference to the XML Element selected for encryption/decryption. If no tag is specified, the entire payload is encrypted/decrypted.
secureTagContents	false	Boolean	A boolean value to specify whether the XML Element is to be encrypted or the contents of the XML Element false = Element Level true = Element Content Level
keyCipherAlgorithm	RSA_OAEP	String	The cipher algorithm to be used for encryption/decryption of the asymmetric key. The available choices are: XMLCipher.RSA_v1dot5 XMLCipher.RSA_OAEP XMLCipher.RSA_OAEP_11 The default value is XMLCipher.RSA_OAEP
recipientKeyAlias		String	The key alias to be used when retrieving the recipient's public or private key from a KeyStore when performing asymmetric key encryption or decryption.
keyOrTrustStoreParametersId		String	Refers to a KeyStore instance to lookup in the registry, which is used for configuration options for creating and loading a KeyStore instance that represents the sender's trustStore or recipient's keyStore.
keyPassword		String	The password to be used for retrieving the private key from the KeyStore. This key is used for asymmetric decryption.
digestAlgorithm	SHA1	String	The digest algorithm to use with the RSA OAEP algorithm. The available choices are: XMLCipher.SHA1 XMLCipher.SHA256 XMLCipher.SHA512 The default value is XMLCipher.SHA1
mgfAlgorithm	MGF1_SHA1	String	The MGF Algorithm to use with the RSA OAEP algorithm. The available choices are: EncryptionConstants.MGF1_SHA1 EncryptionConstants.MGF1_SHA256 EncryptionConstants.MGF1_SHA512 The default value is EncryptionConstants.MGF1_SHA1
addKeyValueForEncryptedKey	true	Boolean	Whether to add the public key used to encrypt the session key as a KeyValue in the EncryptedKey structure or not.

Name	Default	Java Type	Description
<code>contentTypeHeader</code>	<code>false</code>	<code>Boolean</code>	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example <code>application/xml</code> for data formats marshalling to XML, or <code>application/json</code> for data formats marshalling to JSON etc.

295.1.1. Key Cipher Algorithm

As of Camel 2.12.0, the default Key Cipher Algorithm is now `XMLCipher.RSA_OAEP` instead of `XMLCipher.RSA_v1dot5`. Usage of `XMLCipher.RSA_v1dot5` is discouraged due to various attacks. Requests that use RSA v1.5 as the key cipher algorithm will be rejected unless it has been explicitly configured as the key cipher algorithm.

295.2. MARSHAL

In order to encrypt the payload, the **marshal** processor needs to be applied on the route followed by the **secureXML()** tag.

295.3. UNMARSHAL

In order to decrypt the payload, the **unmarshal** processor needs to be applied on the route followed by the **secureXML()** tag.

295.4. EXAMPLES

Given below are several examples of how marshalling could be performed at the Document, Element, and Content levels.

295.4.1. Full Payload encryption/decryption

```
from("direct:start")
  .marshal().secureXML()
  .unmarshal().secureXML()
  .to("direct:end");
```

295.4.2. Partial Payload Content Only encryption/decryption

```
String tagXPath = "//cheesesites/italy/cheese";
boolean secureTagContent = true;
...
from("direct:start")
  .marshal().secureXML(tagXPath, secureTagContent)
  .unmarshal().secureXML(tagXPath, secureTagContent)
  .to("direct:end");
```

295.4.3. Partial Multi Node Payload Content Only encryption/decryption

■

```
String tagXPath = "//cheesesites/*/cheese";
boolean secureTagContent = true;
...
from("direct:start")
    .marshal().secureXML(tagXPath, secureTagContent)
    .unmarshal().secureXML(tagXPath, secureTagContent)
    .to("direct:end");
```

295.4.4. Partial Payload Content Only encryption/decryption with choice of passPhrase(password)

```
String tagXPath = "//cheesesites/italy/cheese";
boolean secureTagContent = true;
...
String passPhrase = "Just another 24 Byte key";
from("direct:start")
    .marshal().secureXML(tagXPath, secureTagContent, passPhrase)
    .unmarshal().secureXML(tagXPath, secureTagContent, passPhrase)
    .to("direct:end");
```

295.4.5. Partial Payload Content Only encryption/decryption with passPhrase(password) and Algorithm

```
import org.apache.xml.security.encryption.XMLCipher;
....
String tagXPath = "//cheesesites/italy/cheese";
boolean secureTagContent = true;
String passPhrase = "Just another 24 Byte key";
String algorithm= XMLCipher.TRIPLEDES;
from("direct:start")
    .marshal().secureXML(tagXPath, secureTagContent, passPhrase, algorithm)
    .unmarshal().secureXML(tagXPath, secureTagContent, passPhrase, algorithm)
    .to("direct:end");
```

295.4.6. Partial Payload Content with Namespace support

Java DSL

```
final Map<String, String> namespaces = new HashMap<String, String>();
namespaces.put("cust", "http://cheese.xmlsecurity.camel.apache.org");

final KeyStoreParameters tsParameters = new KeyStoreParameters();
tsParameters.setPassword("password");
tsParameters.setResource("sender.ts");

context.addRoutes(new RouteBuilder() {
    public void configure() {
        from("direct:start")
            .marshal().secureXML("//cust:cheesesites/italy", namespaces, true, "recipient",
                testCypherAlgorithm, XMLCipher.RSA_v1dot5, tsParameters)
            .to("mock:encrypted");
    }
})
```

Spring XML

A namespace prefix that is defined as part of the **camelContext** definition can be re-used in context within the data format **secureTag** attribute of the **secureXML** element.

```
<camelContext id="springXmlSecurityDataFormatTestCamelContext"
  xmlns="http://camel.apache.org/schema/spring"
  xmlns:cheese="http://cheese.xmlsecurity.camel.apache.org/">
  <route>
    <from uri="direct://start"/>
    <marshal>
      <secureXML secureTag="//cheese:cheesesites/italy"
        secureTagContents="true"/>
    </marshal>
    ...
  </route>
</camelContext>
```

295.4.7. Asymmetric Key Encryption

Spring XML Sender

```
<!-- trust store configuration -->
<camel:keyStoreParameters id="trustStoreParams" resource="./sender.ts" password="password"/>

<camelContext id="springXmlSecurityDataFormatTestCamelContext"
  xmlns="http://camel.apache.org/schema/spring"
  xmlns:cheese="http://cheese.xmlsecurity.camel.apache.org/">
  <route>
    <from uri="direct://start"/>
    <marshal>
      <secureXML secureTag="//cheese:cheesesites/italy"
        secureTagContents="true"
        xmlCipherAlgorithm="http://www.w3.org/2001/04/xmlenc#aes128-cbc"
        keyCipherAlgorithm="http://www.w3.org/2001/04/xmlenc#rsa-1_5"
        recipientKeyAlias="recipient"
        keyOrTrustStoreParametersId="trustStoreParams"/>
    </marshal>
    ...
  </route>
</camelContext>
```

Spring XML Recipient

```
<!-- key store configuration -->
<camel:keyStoreParameters id="keyStoreParams" resource="./recipient.ks" password="password" />

<camelContext id="springXmlSecurityDataFormatTestCamelContext"
  xmlns="http://camel.apache.org/schema/spring"
  xmlns:cheese="http://cheese.xmlsecurity.camel.apache.org/">
  <route>
    <from uri="direct://encrypted"/>
    <unmarshal>
      <secureXML secureTag="//cheese:cheesesites/italy"
        secureTagContents="true"
        xmlCipherAlgorithm="http://www.w3.org/2001/04/xmlenc#aes128-cbc"
        keyCipherAlgorithm="http://www.w3.org/2001/04/xmlenc#rsa-1_5"
        recipientKeyAlias="recipient"
      />
    </unmarshal>
  </route>
</camelContext>
```

```
keyOrTrustStoreParametersId="keyStoreParams"  
keyPassword="privateKeyPassword" />  
</unmarshal>  
...
```

295.5. DEPENDENCIES

This data format is provided within the **camel-xmlsecurity** component.

CHAPTER 296. SEDA COMPONENT

Available as of Camel version 1.1

The **seda:** component provides asynchronous [SEDA](#) behavior, so that messages are exchanged on a [BlockingQueue](#) and consumers are invoked in a separate thread from the producer.

Note that queues are only visible within a *single* CamelContext. If you want to communicate across **CamelContext** instances (for example, communicating between Web applications), see the [VM](#) component.

This component does not implement any kind of persistence or recovery, if the VM terminates while messages are yet to be processed. If you need persistence, reliability or distributed SEDA, try using either [JMS](#) or [ActiveMQ](#).

TIP:*Synchronous* The [Direct](#) component provides synchronous invocation of any consumers when a producer sends a message exchange.

296.1. URI FORMAT

```
seda:someName[?options]
```

Where **someName** can be any string that uniquely identifies the endpoint within the current CamelContext.

You can append query options to the URI in the following format: **?option=value&option=value&...**

296.2. OPTIONS

The SEDA component supports 6 options, which are listed below.

Name	Description	Default	Type
queueSize (advanced)	Sets the default maximum capacity of the SEDA queue (i.e., the number of messages it can hold).	1000	int
concurrentConsumers (consumer)	Sets the default number of concurrent threads processing exchanges.	1	int
defaultQueueFactory (advanced)	Sets the default queue factory.		BlockingQueueFactory
defaultBlockWhenFull (producer)	Whether a thread that sends messages to a full SEDA queue will block until the queue's capacity is no longer exhausted. By default, an exception will be thrown stating that the queue is full. By enabling this option, the calling thread will instead block and wait until the message can be accepted.	false	boolean

Name	Description	Default	Type
defaultOfferTimeout (producer)	Whether a thread that sends messages to a full SEDA queue will block until the queue's capacity is no longer exhausted. By default, an exception will be thrown stating that the queue is full. By enabling this option, where a configured timeout can be added to the block case. Utilizing the <code>.offer(timeout)</code> method of the underlining java queue		long
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The SEDA endpoint is configured using URI syntax:

```
seda:name
```

with the following path and query parameters:

296.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
name	Required Name of queue		String

296.2.2. Query Parameters (17 parameters):

Name	Description	Default	Type
size (common)	The maximum capacity of the SEDA queue (i.e., the number of messages it can hold). Will by default use the <code>defaultSize</code> set on the SEDA component.	1000	int
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN/ERROR level and ignored.	false	boolean

Name	Description	Default	Type
concurrentConsumers (consumer)	Number of concurrent threads processing exchanges.	1	int
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option <code>bridgeErrorHandler</code> is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN/ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the default exchange pattern when creating an exchange.		ExchangePattern
limitConcurrentConsumers (consumer)	Whether to limit the number of <code>concurrentConsumers</code> to the maximum of 500. By default, an exception will be thrown if an endpoint is configured with a greater number. You can disable that check by turning this option off.	true	boolean
multipleConsumers (consumer)	Specifies whether multiple consumers are allowed. If enabled, you can use SEDA for Publish-Subscribe messaging. That is, you can send a message to the SEDA queue and have each consumer receive a copy of the message. When enabled, this option should be specified on every consumer endpoint.	false	boolean
pollTimeout (consumer)	The timeout used when polling. When a timeout occurs, the consumer can check whether it is allowed to continue running. Setting a lower value allows the consumer to react more quickly upon shutdown.	1000	int
purgeWhenStopping (consumer)	Whether to purge the task queue when stopping the consumer/route. This allows to stop faster, as any pending messages on the queue is discarded.	false	boolean
blockWhenFull (producer)	Whether a thread that sends messages to a full SEDA queue will block until the queue's capacity is no longer exhausted. By default, an exception will be thrown stating that the queue is full. By enabling this option, the calling thread will instead block and wait until the message can be accepted.	false	boolean
discardIfNoConsumers (producer)	Whether the producer should discard the message (do not add the message to the queue), when sending to a queue with no active consumers. Only one of the options <code>discardIfNoConsumers</code> and <code>failIfNoConsumers</code> can be enabled at the same time.	false	boolean

Name	Description	Default	Type
failIfNoConsumers (producer)	Whether the producer should fail by throwing an exception, when sending to a queue with no active consumers. Only one of the options <code>discardIfNoConsumers</code> and <code>failIfNoConsumers</code> can be enabled at the same time.	false	boolean
offerTimeout (producer)	<code>offerTimeout</code> (in milliseconds) can be added to the block case when queue is full. You can disable timeout by using 0 or a negative value.		long
timeout (producer)	Timeout (in milliseconds) before a SEDA producer will stop waiting for an asynchronous task to complete. You can disable timeout by using 0 or a negative value.	30000	long
waitForTaskToComplete (producer)	Option to specify whether the caller should wait for the async task to complete or not before continuing. The following three options are supported: <code>Always</code> , <code>Never</code> or <code>IfReplyExpected</code> . The first two values are self-explanatory. The last value, <code>IfReplyExpected</code> , will only wait if the message is Request Reply based. The default option is <code>IfReplyExpected</code> .	IfReplyExpected	WaitForTaskToComplete
queue (advanced)	Define the queue instance which will be used by the endpoint. This option is only for rare use-cases where you want to use a custom queue instance.		BlockingQueue
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

296.3. CHOOSING BLOCKINGQUEUE IMPLEMENTATION

Available as of Camel 2.12

By default, the SEDA component always instantiates `LinkedBlockingQueue`, but you can use different implementation, you can reference your own `BlockingQueue` implementation, in this case the `size` option is not used

```
<bean id="arrayQueue" class="java.util.ArrayBlockingQueue">
  <constructor-arg index="0" value="10" ><!-- size -->
  <constructor-arg index="1" value="true" ><!-- fairness -->
</bean>

<!-- ... and later -->
<from>seda:array?queue=#arrayQueue</from>
```

Or you can reference a `BlockingQueueFactory` implementation, 3 implementations are provided `LinkedBlockingQueueFactory`, `ArrayBlockingQueueFactory` and `PriorityBlockingQueueFactory`:

```
<bean id="priorityQueueFactory"
class="org.apache.camel.component.seda.PriorityBlockingQueueFactory">
  <property name="comparator">
    <bean class="org.apache.camel.demo.MyExchangeComparator" />
  </property>
</bean>

<!-- ... and later -->
<from>seda:priority?queueFactory=#priorityQueueFactory&size=100</from>
```

296.4. USE OF REQUEST REPLY

The [SEDA](#) component supports using Request Reply, where the caller will wait for the Async route to complete. For instance:

```
from("mina:tcp://0.0.0.0:9876?textline=true&sync=true").to("seda:input");
from("seda:input").to("bean:processInput").to("bean:createResponse");
```

In the route above, we have a TCP listener on port 9876 that accepts incoming requests. The request is routed to the `seda:input` queue. As it is a Request Reply message, we wait for the response. When the consumer on the `seda:input` queue is complete, it copies the response to the original message response.

NOTE

until 2.2: Works only with 2 endpoints Using Request Reply over SEDA or [VM](#) only works with 2 endpoints. You **cannot** chain endpoints by sending to $A \rightarrow B \rightarrow C$ etc. Only between $A \rightarrow B$. The reason is the implementation logic is fairly simple. To support 3+ endpoints makes the logic much more complex to handle ordering and notification between the waiting threads properly. This has been improved in **Camel 2.3** onwards, which allows you to chain as many endpoints as you like.

296.5. CONCURRENT CONSUMERS

By default, the SEDA endpoint uses a single consumer thread, but you can configure it to use concurrent consumer threads. So instead of thread pools you can use:

```
from("seda:stageName?concurrentConsumers=5").process(...)
```

As for the difference between the two, note a *thread pool* can increase/shrink dynamically at runtime depending on load, whereas the number of concurrent consumers is always fixed.

296.6. THREAD POOLS

Be aware that adding a thread pool to a SEDA endpoint by doing something like:

```
from("seda:stageName").thread(5).process(...)
```

Can wind up with two **BlockQueues**: one from the SEDA endpoint, and one from the workqueue of the thread pool, which may not be what you want. Instead, you might wish to configure a [Direct](#) endpoint with a thread pool, which can process messages both synchronously and asynchronously. For example:

```
from("direct:stageName").thread(5).process(...)
```

You can also directly configure number of threads that process messages on a SEDA endpoint using the **concurrentConsumers** option.

296.7. SAMPLE

In the route below we use the SEDA queue to send the request to this async queue to be able to send a fire-and-forget message for further processing in another thread, and return a constant reply in this thread to the original caller.

Here we send a Hello World message and expects the reply to be OK.

The "Hello World" message will be consumed from the SEDA queue from another thread for further processing. Since this is from a unit test, it will be sent to a **mock** endpoint where we can do assertions in the unit test.

296.8. USING MULTIPLECONSUMERS

Available as of Camel 2.2

In this example we have defined two consumers and registered them as spring beans.

Since we have specified **multipleConsumers=true** on the seda foo endpoint we can have those two consumers receive their own copy of the message as a kind of pub-sub style messaging.

As the beans are part of an unit test they simply send the message to a mock endpoint, but notice how we can use `@Consume` to consume from the seda queue.

296.9. EXTRACTING QUEUE INFORMATION.

If needed, information such as queue size, etc. can be obtained without using JMX in this fashion:

```
SedaEndpoint seda = context.getEndpoint("seda:xxx");
int size = seda.getExchanges().size();
```

- [Async](#)

CHAPTER 297. JAVA OBJECT SERIALIZATION DATAFORMAT

Available as of Camel version 2.12

Serialization is a Data Format which uses the standard Java Serialization mechanism to unmarshal a binary payload into Java objects or to marshal Java objects into a binary blob.

For example the following uses Java serialization to unmarshal a binary file then send it as an ObjectMessage to ActiveMQ

```
from("file://foo/bar").
  unmarshal().serialization().
  to("activemq:Some.Queue");
```

297.1. OPTIONS

The Java Object Serialization dataformat supports 1 options, which are listed below.

Name	Default	Java Type	Description
<code>contentTypeHeader</code>	<code>false</code>	<code>Boolean</code>	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSon etc.

297.2. DEPENDENCIES

This data format is provided in `camel-core` so no additional dependencies is needed.

CHAPTER 298. SERVICE COMPONENT

Available as of Camel version 2.22

298.1. USING THE SERVICE ENDPOINT

298.2. URI FORMAT

```
service:serviceName:endpoint[?options]
```

298.3. OPTIONS

The Service component supports 3 options, which are listed below.

Name	Description	Default	Type
service (advanced)	Inject the service to use.		ServiceRegistry
serviceSelector (advanced)	Inject the service selector used to lookup the ServiceRegistry to use.		Selector
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Service endpoint is configured using URI syntax:

```
service:delegateUri
```

with the following path and query parameters:

298.3.1. Path Parameters (1 parameters):

Name	Description	Default	Type
delegateUri	Required The endpoint uri to expose as service		String

298.3.2. Query Parameters (4 parameters):

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer)	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		<code>ExceptionHandler</code>
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		<code>ExchangePattern</code>
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

298.4. SPRING BOOT AUTO-CONFIGURATION

The component supports 4 options, which are listed below.

Name	Description	Default	Type
camel.component.service.enabled	Whether to enable auto configuration of the service component. This is enabled by default.		Boolean
camel.component.service.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
camel.component.service.service	Inject the service to use. The option is a <code>org.apache.camel.cloud.ServiceRegistry</code> type.		String
camel.component.service.service-selector	Inject the service selector used to lookup the <code>ServiceRegistry</code> to use. The option is a <code>org.apache.camel.cloud.ServiceRegistry.Selector</code> type.		String

298.5. IMPLEMENTATIONS

Camel provide the following ServiceRegistry implementations:

- camel-consul
- camel-zookeeper
- camel-spring-cloud

298.6. SEE ALSO

- [Configuring Camel](#)
- [Component](#)
- [Endpoint](#)
- [Getting Started](#)

CHAPTER 299. SERVICENOW COMPONENT

Available as of Camel version 2.18

The ServiceNow component provides access to ServiceNow platform through their REST API.

NOTE

From Camel 2.18.1 the component supports multiple version of ServiceNow platform with default to Helsinki. Supported version are [Table 299.1, "API Mapping"](#) and [Table 299.2, "API Mapping"](#)

Maven users will need to add the following dependency to their pom.xml for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-servicenow</artifactId>
  <version>${camel-version}</version>
</dependency>
```

299.1. URI FORMAT

```
servicenow://instanceName?[options]
```

299.2. OPTIONS

The ServiceNow component supports 14 options, which are listed below.

Name	Description	Default	Type
instanceName (advanced)	The ServiceNow instance name		String
configuration (advanced)	The ServiceNow default configuration		ServiceNowConfiguration
apiUrl (producer)	The ServiceNow REST API url		String
userName (security)	ServiceNow user account name		String
password (security)	ServiceNow account password		String
oauthClientId (security)	OAuth2 ClientID		String

Name	Description	Default	Type
oauthClientSecret (security)	OAuth2 ClientSecret		String
oauthTokenUrl (security)	OAuth token Url		String
proxyHost (advanced)	The proxy host name		String
proxyPort (advanced)	The proxy port number		Integer
proxyUserName (security)	Username for proxy authentication		String
proxyPassword (security)	Password for proxy authentication		String
useGlobalSslContext Parameters (security)	Enable usage of global SSL context parameters.	false	boolean
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The ServiceNow endpoint is configured using URI syntax:

```
servicenow:instanceName
```

with the following path and query parameters:

299.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
instanceName	Required The ServiceNow instance name		String

299.2.2. Query Parameters (44 parameters):

Name	Description	Default	Type
display (producer)	Set this parameter to true to return only scorecards where the indicator Display field is selected. Set this parameter to all to return scorecards with any Display field value. This parameter is true by default.	true	String
displayValue (producer)	Return the display value (true), actual value (false), or both (all) for reference fields (default: false)	false	String
excludeReferenceLink (producer)	True to exclude Table API links for reference fields (default: false)		Boolean
favorites (producer)	Set this parameter to true to return only scorecards that are favorites of the querying user.		Boolean
includeAggregates (producer)	Set this parameter to true to always return all available aggregates for an indicator, including when an aggregate has already been applied. If a value is not specified, this parameter defaults to false and returns no aggregates.		Boolean
includeAvailableAggregates (producer)	Set this parameter to true to return all available aggregates for an indicator when no aggregate has been applied. If a value is not specified, this parameter defaults to false and returns no aggregates.		Boolean
includeAvailableBreakdowns (producer)	Set this parameter to true to return all available breakdowns for an indicator. If a value is not specified, this parameter defaults to false and returns no breakdowns.		Boolean
includeScoreNotes (producer)	Set this parameter to true to return all notes associated with the score. The note element contains the note text as well as the author and timestamp when the note was added.		Boolean
includeScores (producer)	Set this parameter to true to return all scores for a scorecard. If a value is not specified, this parameter defaults to false and returns only the most recent score value.		Boolean
inputDisplayValue (producer)	True to set raw value of input fields (default: false)		Boolean
key (producer)	Set this parameter to true to return only scorecards for key indicators.		Boolean

Name	Description	Default	Type
models (producer)	Defines both request and response models		String
perPage (producer)	Enter the maximum number of scorecards each query can return. By default this value is 10, and the maximum is 100.	10	Integer
release (producer)	The ServiceNow release to target, default to Helsinki See https://docs.servicenow.com	HELSEINKI	ServiceNowRelease
requestModels (producer)	Defines the request model		String
resource (producer)	The default resource, can be overridden by header CamelServiceNowResource		String
responseModels (producer)	Defines the response model		String
sortBy (producer)	Specify the value to use when sorting results. By default, queries sort records by value.		String
sortDir (producer)	Specify the sort direction, ascending or descending. By default, queries sort records in descending order. Use <code>sysparm_sortdir=asc</code> to sort in ascending order.		String
suppressAutoSysField (producer)	True to suppress auto generation of system fields (default: false)		Boolean
suppressPaginationHeader (producer)	Set this value to true to remove the Link header from the response. The Link header allows you to request additional pages of data when the number of records matching your query exceeds the query limit		Boolean
table (producer)	The default table, can be overridden by header CamelServiceNowTable		String
target (producer)	Set this parameter to true to return only scorecards that have a target.		Boolean
topLevelOnly (producer)	Gets only those categories whose parent is a catalog.		Boolean
apiVersion (advanced)	The ServiceNow REST API version, default latest		String

Name	Description	Default	Type
dateFormat (advanced)	The date format used for Json serialization/deserialization	yyyy-MM-dd	String
dateTimeFormat (advanced)	The date-time format used for Json serialization/deserialization	yyyy-MM-dd HH:mm:ss	String
httpClientPolicy (advanced)	To configure http-client		HTTPClientPolicy
mapper (advanced)	Sets Jackson's ObjectMapper to use for request/reply		ObjectMapper
proxyAuthorizationPolicy (advanced)	To configure proxy authentication		ProxyAuthorizationPolicy
retrieveTargetRecordOnImport (advanced)	Set this parameter to true to retrieve the target record when using import set api. The import set result is then replaced by the target record	false	Boolean
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
timeFormat (advanced)	The time format used for Json serialization/deserialization	HH:mm:ss	String
proxyHost (proxy)	The proxy host name		String
proxyPort (proxy)	The proxy port number		Integer
apiUrl (security)	The ServiceNow REST API url		String
oauthClientId (security)	OAuth2 ClientID		String
oauthClientSecret (security)	OAuth2 ClientSecret		String
oauthTokenUrl (security)	OAuth token Url		String

Name	Description	Default	Type
password (security)	Required ServiceNow account password, MUST be provided		String
proxyPassword (security)	Password for proxy authentication		String
proxyUserName (security)	Username for proxy authentication		String
sslContextParameters (security)	To configure security using SSLContextParameters. See http://camel.apache.org/camel-configuration-utilities.html		SSLContextParameters
userName (security)	Required ServiceNow user account name, MUST be provided		String

299.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 57 options, which are listed below.

Name	Description	Default	Type
camel.component.servicenow.api-url	The ServiceNow REST API url		String
camel.component.servicenow.configuration.api-url	The ServiceNow REST API url		String
camel.component.servicenow.configuration.api-version	The ServiceNow REST API version, default latest		String
camel.component.servicenow.configuration.date-format	The date format used for Json serialization/deserialization	yyyy-MM-dd	String
camel.component.servicenow.configuration.date-time-format	The date-time format used for Json serialization/deserialization	yyyy-MM-dd HH:mm:ss	String

Name	Description	Default	Type
<code>camel.component.servicenow.configuration.display</code>	Set this parameter to true to return only scorecards where the indicator Display field is selected. Set this parameter to all to return scorecards with any Display field value. This parameter is true by default.	true	String
<code>camel.component.servicenow.configuration.display-value</code>	Return the display value (true), actual value (false), or both (all) for reference fields (default: false)	false	String
<code>camel.component.servicenow.configuration.exclude-reference-link</code>	True to exclude Table API links for reference fields (default: false)		Boolean
<code>camel.component.servicenow.configuration.favorites</code>	Set this parameter to true to return only scorecards that are favorites of the querying user.		Boolean
<code>camel.component.servicenow.configuration.http-client-policy</code>	To configure http-client		HTTPClientPolicy
<code>camel.component.servicenow.configuration.include-aggregates</code>	Set this parameter to true to always return all available aggregates for an indicator, including when an aggregate has already been applied. If a value is not specified, this parameter defaults to false and returns no aggregates.		Boolean
<code>camel.component.servicenow.configuration.include-available-aggregates</code>	Set this parameter to true to return all available aggregates for an indicator when no aggregate has been applied. If a value is not specified, this parameter defaults to false and returns no aggregates.		Boolean
<code>camel.component.servicenow.configuration.include-available-breakdowns</code>	Set this parameter to true to return all available breakdowns for an indicator. If a value is not specified, this parameter defaults to false and returns no breakdowns.		Boolean
<code>camel.component.servicenow.configuration.include-score-notes</code>	Set this parameter to true to return all notes associated with the score. The note element contains the note text as well as the author and timestamp when the note was added.		Boolean

Name	Description	Default	Type
<code>camel.component.servicenow.configuration.include-scores</code>	Set this parameter to true to return all scores for a scorecard. If a value is not specified, this parameter defaults to false and returns only the most recent score value.		Boolean
<code>camel.component.servicenow.configuration.input-display-value</code>	True to set raw value of input fields (default: false)		Boolean
<code>camel.component.servicenow.configuration.key</code>	Set this parameter to true to return only scorecards for key indicators.		Boolean
<code>camel.component.servicenow.configuration.mapper</code>	Sets Jackson's ObjectMapper to use for request/reply		ObjectMapper
<code>camel.component.servicenow.configuration.models</code>	Defines both request and response models		Map
<code>camel.component.servicenow.configuration.oauth-client-id</code>	OAuth2 ClientID		String
<code>camel.component.servicenow.configuration.oauth-client-secret</code>	OAuth2 ClientSecret		String
<code>camel.component.servicenow.configuration.oauth-token-url</code>	OAuth token Url		String
<code>camel.component.servicenow.configuration.password</code>	ServiceNow account password, MUST be provided		String
<code>camel.component.servicenow.configuration.per-page</code>	Enter the maximum number of scorecards each query can return. By default this value is 10, and the maximum is 100.	10	Integer

Name	Description	Default	Type
<code>camel.component.servicenow.configuration.proxy-authorization-policy</code>	To configure proxy authentication		ProxyAuthorizationPolicy
<code>camel.component.servicenow.configuration.proxy-host</code>	The proxy host name		String
<code>camel.component.servicenow.configuration.proxy-password</code>	Password for proxy authentication		String
<code>camel.component.servicenow.configuration.proxy-port</code>	The proxy port number		Integer
<code>camel.component.servicenow.configuration.proxy-user-name</code>	Username for proxy authentication		String
<code>camel.component.servicenow.configuration.release</code>	The ServiceNow release to target, default to Helsinki See https://docs.servicenow.com		ServiceNowRelease
<code>camel.component.servicenow.configuration.request-models</code>	Defines the request model		Map
<code>camel.component.servicenow.configuration.resource</code>	The default resource, can be overridden by header CamelServiceNowResource		String
<code>camel.component.servicenow.configuration.response-models</code>	Defines the response model		Map

Name	Description	Default	Type
<code>camel.component.servicenow.configuration.retrieve-target-record-on-import</code>	Set this parameter to true to retrieve the target record when using import set api. The import set result is then replaced by the target record	false	Boolean
<code>camel.component.servicenow.configuration.sort-by</code>	Specify the value to use when sorting results. By default, queries sort records by value.		String
<code>camel.component.servicenow.configuration.sort-dir</code>	Specify the sort direction, ascending or descending. By default, queries sort records in descending order. Use <code>sysparm_sortdir=asc</code> to sort in ascending order.		String
<code>camel.component.servicenow.configuration.ssl-context-parameters</code>	To configure security using <code>SSLContextParameters</code> . See http://camel.apache.org/camel-configuration-utilities.html		<code>SSLContextParameters</code>
<code>camel.component.servicenow.configuration.suppress-auto-sys-field</code>	True to suppress auto generation of system fields (default: false)		Boolean
<code>camel.component.servicenow.configuration.suppress-pagination-header</code>	Set this value to true to remove the Link header from the response. The Link header allows you to request additional pages of data when the number of records matching your query exceeds the query limit		Boolean
<code>camel.component.servicenow.configuration.table</code>	The default table, can be overridden by header <code>CamelServiceNowTable</code>		String
<code>camel.component.servicenow.configuration.target</code>	Set this parameter to true to return only scorecards that have a target.		Boolean
<code>camel.component.servicenow.configuration.time-format</code>	The time format used for Json serialization/deserialization	HH:mm:ss	String

Name	Description	Default	Type
<code>camel.component.servicenow.configuration.top-level-only</code>	Gets only those categories whose parent is a catalog.		Boolean
<code>camel.component.servicenow.configuration.user-name</code>	ServiceNow user account name, MUST be provided		String
<code>camel.component.servicenow.enabled</code>	Enable servicenow component	true	Boolean
<code>camel.component.servicenow.instance-name</code>	The ServiceNow instance name		String
<code>camel.component.servicenow.oauth-client-id</code>	OAuth2 ClientID		String
<code>camel.component.servicenow.oauth-client-secret</code>	OAuth2 ClientSecret		String
<code>camel.component.servicenow.oauth-token-url</code>	OAuth token Url		String
<code>camel.component.servicenow.password</code>	ServiceNow account password		String
<code>camel.component.servicenow.proxy-host</code>	The proxy host name		String
<code>camel.component.servicenow.proxy-password</code>	Password for proxy authentication		String
<code>camel.component.servicenow.proxy-port</code>	The proxy port number		Integer

Name	Description	Default	Type
<code>camel.component.servicenow.proxy-user-name</code>	Username for proxy authentication		String
<code>camel.component.servicenow.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.component.servicenow.use-global-ssl-context-parameters</code>	Enable usage of global SSL context parameters.	false	Boolean
<code>camel.component.servicenow.user-name</code>	ServiceNow user account name		String

299.4. HEADERS

Name	Type	Service Now API Parameter	Endpoint option	Description
<code>CamelServiceNowResource</code>	String	-	-	The resource to access
<code>CamelServiceNowAction</code>	String	-	-	The action to perform
<code>CamelServiceNowActionSubject</code>	-	-	String	The subject to which the action should be applied
<code>CamelServiceNowModel</code>	Class	-	-	The data model

Name	Type	Service Now API Parameter	Endpoint option	Description

299.5. USAGE EXAMPLES:

Retrieve 10 Incidents

```
context.addRoutes(new RouteBuilder() {
    public void configure() {
        from("direct:servicenow")
            .to("servicenow:{{env:SERVICENOW_INSTANCE}}"
                + "?userName={{env:SERVICENOW_USERNAME}}"
                + "&password={{env:SERVICENOW_PASSWORD}}"
                + "&oauthClientId={{env:SERVICENOW_OAUTH2_CLIENT_ID}}"
                + "&oauthClientSecret={{env:SERVICENOW_OAUTH2_CLIENT_SECRET}}")
            .to("mock:servicenow");
    }
});
```

```
FluentProducerTemplate.on(context)
    .withHeader(ServiceNowConstants.RESOURCE, "table")
    .withHeader(ServiceNowConstants.ACTION, ServiceNowConstants.ACTION_RETRIEVE)
    .withHeader(ServiceNowConstants.SYSPARM_LIMIT.getId(), "10")
    .withHeader(ServiceNowConstants.TABLE, "incident")
    .withHeader(ServiceNowConstants.MODEL, Incident.class)
    .to("direct:servicenow")
    .send();
```

CHAPTER 300. SERVLET COMPONENT

Available as of Camel version 2.0

The **servlet**: component provides HTTP based endpoints for consuming HTTP requests that arrive at a HTTP endpoint that is bound to a published Servlet.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-servlet</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

NOTE

Stream

Servlet is stream based, which means the input it receives is submitted to Camel as a stream. That means you will only be able to read the content of the stream **once**. If you find a situation where the message body appears to be empty or you need to access the data multiple times (eg: doing multicasting, or redelivery error handling) you should use Stream caching or convert the message body to a **String** which is safe to be read multiple times.

300.1. URI FORMAT

```
servlet://relative_path[?options]
```

You can append query options to the URI in the following format: **?option=value&option=value&...**

300.2. OPTIONS

The Servlet component supports 9 options, which are listed below.

Name	Description	Default	Type
servletName (consumer)	Default name of servlet to use. The default name is CamelServlet.	CamelServlet	String
httpRegistry (consumer)	To use a custom org.apache.camel.component.servlet.HttpRegistry.		HttpRegistry

Name	Description	Default	Type
attachmentMultipartBinding (consumer)	Whether to automatic bind multipart/form-data as attachments on the Camel Exchange. The options <code>attachmentMultipartBinding=true</code> and <code>disableStreamCache=false</code> cannot work together. Remove <code>disableStreamCache</code> to use <code>AttachmentMultipartBinding</code> . This is turn off by default as this may require servlet specific configuration to enable this when using Servlet's.	false	boolean
fileNameExtWhitelist (consumer)	Whitelist of accepted filename extensions for accepting uploaded files. Multiple extensions can be separated by comma, such as <code>txt,xml</code> .		String
httpBinding (advanced)	To use a custom <code>HttpBinding</code> to control the mapping between Camel message and <code>HttpClient</code> .		<code>HttpBinding</code>
httpConfiguration (advanced)	To use the shared <code>HttpConfiguration</code> as base configuration.		<code>HttpConfiguration</code>
allowJavaSerializedObject (advanced)	Whether to allow java serialization when a request uses <code>context-type=application/x-java-serialized-object</code> . This is by default turned off. If you enable this then be aware that Java will deserialize the incoming data from the request to Java and that can be a potential security risk.	false	boolean
headerFilterStrategy (filter)	To use a custom <code>org.apache.camel.spi.HeaderFilterStrategy</code> to filter header to and from Camel message.		<code>HeaderFilterStrategy</code>
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Servlet endpoint is configured using URI syntax:

```
servlet:contextPath
```

with the following path and query parameters:

300.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
contextPath	Required The context-path to use		String

300.2.2. Query Parameters (22 parameters):

Name	Description	Default	Type
disableStreamCache (common)	Determines whether or not the raw input stream from Servlet is cached or not (Camel will read the stream into a in memory/overflow to file, Stream caching) cache. By default Camel will cache the Servlet input stream to support reading it multiple times to ensure it Camel can retrieve all data from the stream. However you can set this option to true when you for example need to access the raw stream, such as streaming it directly to a file or other persistent store. DefaultHttpBinding will copy the request input stream into a stream cache and put it into message body if this option is false to support reading the stream multiple times. If you use Servlet to bridge/proxy an endpoint then consider enabling this option to improve performance, in case you do not need to read the message payload multiple times. The http/http4 producer will by default cache the response body stream. If setting this option to true, then the producers will not cache the response body stream but use the response stream as-is as the message body.	false	boolean
headerFilterStrategy (common)	To use a custom HeaderFilterStrategy to filter header to and from Camel message.		HeaderFilterStrategy
httpBinding (common)	To use a custom HttpBinding to control the mapping between Camel message and HttpClient.		HttpBinding
async (consumer)	Configure the consumer to work in async mode	false	boolean
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean

Name	Description	Default	Type
chunked (consumer)	If this option is false the Servlet will disable the HTTP streaming and set the content-length header on the response	true	boolean
httpMethodRestrict (consumer)	Used to only allow consuming if the HttpMethod matches, such as GET/POST/PUT etc. Multiple methods can be specified separated by comma.		String
matchOnUriPrefix (consumer)	Whether or not the consumer should try to find a target consumer by matching the URI prefix if no exact match is found.	false	boolean
responseBufferSize (consumer)	To use a custom buffer size on the javax.servlet.ServletResponse.		Integer
servletName (consumer)	Name of the servlet to use	Camel Servlet	String
transferException (consumer)	If enabled and an Exchange failed processing on the consumer side, and if the caused Exception was send back serialized in the response as a application/x-java-serialized-object content type. On the producer side the exception will be deserialized and thrown as is, instead of the HttpOperationFailedException. The caused exception is required to be serialized. This is by default turned off. If you enable this then be aware that Java will deserialize the incoming data from the request to Java and that can be a potential security risk.	false	boolean
attachmentMultipartBinding (consumer)	Whether to automatic bind multipart/form-data as attachments on the Camel Exchange. The options attachmentMultipartBinding=true and disableStreamCache=false cannot work together. Remove disableStreamCache to use AttachmentMultipartBinding. This is turn off by default as this may require servlet specific configuration to enable this when using Servlet's.	false	boolean
eagerCheckContentAvailable (consumer)	Whether to eager check whether the HTTP requests has content if the content-length header is 0 or not present. This can be turned on in case HTTP clients do not send streamed data.	false	boolean

Name	Description	Default	Type
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
fileNameExtWhitelist (consumer)	Whitelist of accepted filename extensions for accepting uploaded files. Multiple extensions can be separated by comma, such as txt,xml.		String
optionsEnabled (consumer)	Specifies whether to enable HTTP OPTIONS for this Servlet consumer. By default OPTIONS is turned off.	false	boolean
traceEnabled (consumer)	Specifies whether to enable HTTP TRACE for this Servlet consumer. By default TRACE is turned off.	false	boolean
mapHttpMessageBody (advanced)	If this option is true then IN exchange Body of the exchange will be mapped to HTTP body. Setting this to false will avoid the HTTP mapping.	true	boolean
mapHttpMessageFormUrlEncodedBody (advanced)	If this option is true then IN exchange Form Encoded body of the exchange will be mapped to HTTP. Setting this to false will avoid the HTTP Form Encoded body mapping.	true	boolean
mapHttpMessageHeaders (advanced)	If this option is true then IN exchange Headers of the exchange will be mapped to HTTP headers. Setting this to false will avoid the HTTP Headers mapping.	true	boolean
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

300.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 13 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.servlet.allow-java-serialized-object</code>	Whether to allow java serialization when a request uses context-type=application/x-java-serialized-object. This is by default turned off. If you enable this then be aware that Java will deserialize the incoming data from the request to Java and that can be a potential security risk.	false	Boolean
<code>camel.component.servlet.attachment-multipart-binding</code>	Whether to automatic bind multipart/form-data as attachments on the Camel Exchange. The options attachmentMultipartBinding=true and disableStreamCache=false cannot work together. Remove disableStreamCache to use AttachmentMultipartBinding. This is turn off by default as this may require servlet specific configuration to enable this when using Servlet's.	false	Boolean
<code>camel.component.servlet.enabled</code>	Enable servlet component	true	Boolean
<code>camel.component.servlet.file-name-ext-whitelist</code>	Whitelist of accepted filename extensions for accepting uploaded files. Multiple extensions can be separated by comma, such as txt,xml.		String
<code>camel.component.servlet.header-filter-strategy</code>	To use a custom org.apache.camel.spi.HeaderFilterStrategy to filter header to and from Camel message. The option is a org.apache.camel.spi.HeaderFilterStrategy type.		String
<code>camel.component.servlet.http-binding</code>	To use a custom HttpBinding to control the mapping between Camel message and HttpClient. The option is a org.apache.camel.http.common.HttpBinding type.		String
<code>camel.component.servlet.http-configuration</code>	To use the shared HttpConfiguration as base configuration. The option is a org.apache.camel.http.common.HttpConfiguration type.		String
<code>camel.component.servlet.http-registry</code>	To use a custom org.apache.camel.component.servlet.HttpRegistry. The option is a org.apache.camel.component.servlet.HttpRegistry type.		String
<code>camel.component.servlet.mapping.context-path</code>	Context path used by the servlet component for automatic mapping.	/camel/*	String

Name	Description	Default	Type
<code>camel.component.servlet.mapping.enabled</code>	Enables the automatic mapping of the servlet component into the Spring web context.	true	Boolean
<code>camel.component.servlet.mapping.servlet-name</code>	The name of the Camel servlet.	CamelServlet	String
<code>camel.component.servlet.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.component.servlet.servlet-name</code>	Default name of servlet to use. The default name is CamelServlet.	CamelServlet	String

300.4. MESSAGE HEADERS

Camel will apply the same Message Headers as the [HTTP](#) component.

Camel will also populate **all request.parameter** and **request.headers**. For example, if a client request has the URL, <http://myserver/myserver?orderid=123>, the exchange will contain a header named **orderid** with the value 123.

300.5. USAGE

You can consume only **from** endpoints generated by the Servlet component. Therefore, it should be used only as input into your Camel routes. To issue HTTP requests against other HTTP endpoints, use the [HTTP Component](#).

300.6. PUTTING CAMEL JARS IN THE APP SERVER BOOT CLASSPATH

If you put the Camel JARs such as **camel-core**, **camel-servlet**, etc. in the boot classpath of your application server (eg usually in its lib directory), then mind that the servlet mapping list is now shared between multiple deployed Camel application in the app server.

Mind that putting Camel JARs in the boot classpath of the application server is generally not best practice!

So in those situations you **must** define a custom and unique servlet name in each of your Camel application, eg in the **web.xml** define:

```
<servlet>
  <servlet-name>MyServlet</servlet-name>
  <servlet-class>org.apache.camel.component.servlet.CamelHttpTransportServlet</servlet-class>
  <load-on-startup>1</load-on-startup>
```

```

</servlet>

<servlet-mapping>
  <servlet-name>MyServlet</servlet-name>
  <url-pattern>/*</url-pattern>
</servlet-mapping>

```

And in your Camel endpoints then include the servlet name as well

```

<route>
  <from uri="servlet://foo?servletName=MyServlet"/>
  ...
</route>

```

From **Camel 2.11** onwards Camel will detect this duplicate and fail to start the application. You can control to ignore this duplicate by setting the servlet init-parameter `ignoreDuplicateServletName` to true as follows:

```

<servlet>
  <servlet-name>CamelServlet</servlet-name>
  <display-name>Camel Http Transport Servlet</display-name>
  <servlet-class>org.apache.camel.component.servlet.CamelHttpTransportServlet</servlet-class>
  <init-param>
    <param-name>ignoreDuplicateServletName</param-name>
    <param-value>>true</param-value>
  </init-param>
</servlet>

```

But it is **strongly advised** to use unique **servlet-name** for each Camel application to avoid this duplication clash, as well any unforeseen side-effects.

300.7. SAMPLE

NOTE

From Camel 2.7 onwards it's easier to use [Servlet](#) in Spring web applications. See [Servlet Tomcat Example](#) for details.

In this sample, we define a route that exposes a HTTP service at <http://localhost:8080/camel/services/hello>.

First, you need to publish the [CamelHttpTransportServlet](#) through the normal Web Container, or OSGi Service. Use the **Web.xml** file to publish the [CamelHttpTransportServlet](#) as follows:

```

<web-app>

  <servlet>
    <servlet-name>CamelServlet</servlet-name>
    <display-name>Camel Http Transport Servlet</display-name>
    <servlet-class>org.apache.camel.component.servlet.CamelHttpTransportServlet</servlet-class>
  </servlet>

  <servlet-mapping>

```

```

<servlet-name>CamelServlet</servlet-name>
<url-pattern>/services/* </url-pattern>
</servlet-mapping>

</web-app>

```

Then you can define your route as follows:

```

from("servlet:hello?matchOnUriPrefix=true").process(new Processor() {
    public void process(Exchange exchange) throws Exception {
        String contentType = exchange.getIn().getHeader(Exchange.CONTENT_TYPE, String.class);
        String path = exchange.getIn().getHeader(Exchange.HTTP_URI, String.class);
        path = path.substring(path.lastIndexOf("/"));

        assertEquals("Get a wrong content type", CONTENT_TYPE, contentType);
        // assert camel http header
        String charsetEncoding =
exchange.getIn().getHeader(Exchange.HTTP_CHARACTER_ENCODING, String.class);
        assertEquals("Get a wrong charset name from the message heaer", "UTF-8", charsetEncoding);
        // assert exchange charset
        assertEquals("Get a wrong charset naem from the exchange property", "UTF-8",
exchange.getProperty(Exchange.CHARSET_NAME));
        exchange.getOut().setHeader(Exchange.CONTENT_TYPE, contentType + "; charset=UTF-8");
        exchange.getOut().setHeader("PATH", path);
        exchange.getOut().setBody("<b>Hello World</b>");
    }
});

```

NOTE

Specify the relative path for camel-servlet endpoint

Since we are binding the HTTP transport with a published servlet, and we don't know the servlet's application context path, the **camel-servlet** endpoint uses the relative path to specify the endpoint's URL. A client can access the **camel-servlet** endpoint through the servlet publish address: ("**http://localhost:8080/camel/services**") + **RELATIVE_PATH("/hello")**

300.7.1. Sample when using Spring 3.x

See [Servlet Tomcat Example](#).

300.7.2. Sample when using Spring 2.x

When using the Servlet component in a Camel/Spring application it's often required to load the Spring `ApplicationContext` *after* the Servlet component has started. This can be accomplished by using Spring's **ContextLoaderServlet** instead of **ContextLoaderListener**. In that case you'll need to start **ContextLoaderServlet** after [CamelHttpTransportServlet](#) like this:

```

<web-app>
<servlet>
    <servlet-name>CamelServlet</servlet-name>
    <servlet-class>
        org.apache.camel.component.servlet.CamelHttpTransportServlet

```

```

    </servlet-class>
    <load-on-startup>1</load-on-startup>
</servlet>
<servlet>
    <servlet-name>SpringApplicationContext</servlet-name>
    <servlet-class>
        org.springframework.web.context.ContextLoaderServlet
    </servlet-class>
    <load-on-startup>2</load-on-startup>
</servlet>
</web-app>

```

300.7.3. Sample when using OSGi

From **Camel 2.6.0**, you can publish the [CamelHttpTransportServlet](#) as an OSGi service with Blueprint like this:

```

<blueprint xmlns="http://www.osgi.org/xmlns/blueprint/v1.0.0"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="
        http://www.osgi.org/xmlns/blueprint/v1.0.0
        https://www.osgi.org/xmlns/blueprint/v1.0.0/blueprint.xsd">

    <bean id="camelServlet" class="org.apache.camel.component.servlet.CamelHttpTransportServlet"
/>

    <!--
        Enlist it in OSGi service registry.
        This will cause two things:
        1) As the pax web whiteboard extender is running the CamelServlet will
           be registered with the OSGi HTTP Service
        2) It will trigger the HttpRegistry in other bundles so the servlet is
           made known there too
    -->
    <service ref="camelServlet">
        <interfaces>
            <value>javax.servlet.Servlet</value>
            <value>org.apache.camel.http.common.CamelServlet</value>
        </interfaces>
        <service-properties>
            <entry key="alias" value="/camel/services" />
            <entry key="matchOnUriPrefix" value="true" />
            <entry key="servlet-name" value="CamelServlet" />
        </service-properties>
    </service>

</blueprint>

```

Then use this service in your Camel route like this:

```

<blueprint xmlns="http://www.osgi.org/xmlns/blueprint/v1.0.0"
    xmlns:ext="http://aries.apache.org/blueprint/xmlns/blueprint-ext/v1.0.0"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
    xsi:schemaLocation="
        http://www.osgi.org/xmlns/blueprint/v1.0.0

```

```

https://www.osgi.org/xmlns/blueprint/v1.0.0/blueprint.xsd">

  <reference id="servletref" ext:proxy-method="classes"
interface="org.apache.camel.http.common.CamelServlet">
  <reference-listener ref="httpRegistry" bind-method="register" unbind-method="unregister" />
</reference>

<bean id="httpRegistry" class="org.apache.camel.component.servlet.DefaultHttpRegistry" />

<bean id="servlet" class="org.apache.camel.component.servlet.ServletComponent">
  <property name="httpRegistry" ref="httpRegistry" />
</bean>

<bean id="servletProcessor" class="org.apache.camel.example.servlet.ServletProcessor" />

<camelContext xmlns="http://camel.apache.org/schema/blueprint">
  <route>
    <!-- Notice how we can use the servlet scheme which is that reference above -->
    <from uri="servlet://hello" />
    <process ref="servletProcessor" />
  </route>
</camelContext>

</blueprint>

```

For versions prior to Camel 2.6 you can use an **Activator** to publish the [CamelHttpTransportServlet](#) on the OSGi platform:

```

import java.util.Dictionary;
import java.util.Hashtable;

import org.apache.camel.component.servlet.CamelHttpTransportServlet;
import org.osgi.framework.BundleActivator;
import org.osgi.framework.BundleContext;
import org.osgi.framework.ServiceReference;
import org.osgi.service.http.HttpContext;
import org.osgi.service.http.HttpService;
import org.slf4j.Logger;
import org.slf4j.LoggerFactory;
import org.springframework.osgi.context.BundleContextAware;

public final class ServletActivator implements BundleActivator, BundleContextAware {
  private static final Logger LOG = LoggerFactory.getLogger(ServletActivator.class);
  private static boolean registerService;

  /**
   * HttpService reference.
   */
  private ServiceReference<?> httpServiceRef;

  /**
   * Called when the OSGi framework starts our bundle
   */
  public void start(BundleContext bc) throws Exception {
    registerServlet(bc);
  }
}

```

```

/**
 * Called when the OSGi framework stops our bundle
 */
public void stop(BundleContext bc) throws Exception {
    if (httpServiceRef != null) {
        bc.ungetService(httpServiceRef);
        httpServiceRef = null;
    }
}

protected void registerServlet(BundleContext bundleContext) throws Exception {
    httpServiceRef = bundleContext.getServiceReference(HttpService.class.getName());

    if (httpServiceRef != null && !registerService) {
        LOG.info("Register the servlet service");
        final HttpService httpService = (HttpService)bundleContext.getService(httpServiceRef);
        if (httpService != null) {
            // create a default context to share between registrations
            final HttpContext httpContext = httpService.createDefaultHttpContext();
            // register the hello world servlet
            final Dictionary<String, String> initParams = new Hashtable<String, String>();
            initParams.put("matchOnUriPrefix", "false");
            initParams.put("servlet-name", "CamelServlet");
            httpService.registerServlet("/camel/services", // alias
                new CamelHttpTransportServlet(), // register servlet
                initParams, // init params
                httpContext // http context
            );
            registerService = true;
        }
    }
}

public void setBundleContext(BundleContext bc) {
    try {
        registerServlet(bc);
    } catch (Exception e) {
        LOG.error("Cannot register the servlet, the reason is " + e);
    }
}
}

```

300.7.4. Usage with Spring-Boot

From **Camel 2.19.0** onwards, the `camel-servlet-starter` library binds automatically all the rest endpoints under the `/camel/*` context path. The following table summarizes the additional configuration properties available in the `camel-servlet-starter` library. The automatic mapping of the Camel servlet can also be disabled.

Spring-Boot Property	Default	Description
camel.component.servlet.mapping.enabled	true	Enables the automatic mapping of the servlet component into the Spring web context
camel.component.servlet.mapping.context-path	/camel /*	Context path used by the servlet component for automatic mapping
camel.component.servlet.mapping.servlet-name	Camel Servlet	The name of the Camel servlet

300.9. SERVLETLISTENER COMPONENT

Available as of Camel 2.11

This component is used for bootstrapping Camel applications in web applications. For example beforehand people would have to find their own way of bootstrapping Camel, or rely on 3rd party frameworks such as Spring to do it.

NOTE

Sidebar This component supports Servlet 2.x onwards, which mean it works also in older web containers; which is the goal of this component. Though Servlet 2.x requires to use a web.xml file as configuration. For Servlet 3.x containers you can use annotation driven configuration to bootstrap Camel using the `@WebListener`, and implement your own class, where you bootstrap Camel. Doing this still puts the challenge how to let end users easily configure Camel, which you get for free with the old school web.xml file.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-servletlistener</artifactId>
```

```

<version>x.x.x</version>
<!-- use the same version as your Camel core version -->
</dependency>

```

300.9.1. Using

You would need to choose one of the following implementations of the abstract class **org.apache.camel.component.servletlistener.CamelServletContextListener**.

- **JndiCamelServletContextListener** which uses the **JndiRegistry** to leverage JNDI for its registry.
- **SimpleCamelServletContextListener** which uses the **SimpleRegistry** to leverage a **java.util.Map** as its registry.

To use this you need to configure the **org.apache.camel.component.servletlistener.CamelServletContextListener** in the **WEB-INF/web.xml** file as shown below:

300.9.2. Options

The **org.apache.camel.component.servletlistener.CamelServletContextListener** supports the following options which can be configured as context-param in the web.xml file.

Option	Type	Description
propertyPlaceholder.XXX		To configure property placeholders in Camel. You should prefix the option with "propertyPlaceholder.", for example to configure the location, use propertyPlaceholder.location as name. You can configure all the options from the Properties component.
jmx.XXX		To configure JMX. You should prefix the option with "jmx.", for example to disable JMX, use jmx.disabled as name. You can configure all the options from org.apache.camel.spi.ManagementAgent . As well the options mentioned on the JMX page.
name	String	To configure the name of the CamelContext.
messageHistory	Boolean	Camel 2.12.2: Whether to enable or disable Message History (enabled by default).
streamCache	Boolean	Whether to enable Stream caching.
trace	Boolean	Whether to enable Tracer.
delayer	Long	To set a delay value for Delay Interceptor.
handleFault	Boolean	Whether to enable handle fault.

Option	Type	Description
errorHandlerRef	String	Refers to a context scoped Error Handler to be used.
autoStartup	Boolean	Whether to start all routes when starting Camel.
useMDCLogging	Boolean	Whether to use MDC logging.
useBreadcrumb	Boolean	Whether to use breadcrumb.
managementNamePattern	String	To set a custom naming pattern for JMX MBeans.
threadNamePattern	String	To set a custom naming pattern for threads.
properties.XXX		To set custom properties on CamelContext.getProperties . This is seldom in use.
routebuilder.XXX		To configure routes to be used. See below for more details.
CamelContextLifecycle		Refers to a FQN classname of an implementation of org.apache.camel.component.servletlistener.CamelContextLifecycle . Which allows to execute custom code before and after CamelContext has been started or stopped. See below for further details.
XXX		To set any option on CamelContext.

300.9.3. Examples

See [Servlet Tomcat No Spring Example](#) .

300.9.4. Accessing the created CamelContext

Available as of Camel 2.14/2.13.3/2.12.5

The created **CamelContext** is stored on the **ServletContext** as an attribute with the key "CamelContext". You can get hold of the CamelContext if you can get hold of the **ServletContext** as shown below:

```
ServletContext sc = ...
CamelContext camel = (CamelContext) sc.getAttribute("CamelContext");
```

300.9.5. Configuring routes

You need to configure which routes to use in the web.xml file. You can do this in a number of ways, though all the parameters must be prefixed with "routeBuilder".

300.9.5.1. Using a RouteBuilder class

By default Camel will assume the param-value is a FQN classname for a Camel RouteBuilder class, as shown below:

```
<context-param>
  <param-name>routeBuilder-MyRoute</param-name>
  <param-value>org.apache.camel.component.servletlistener.MyRoute</param-value>
</context-param>
```

You can specify multiple classes in the same param-value as shown below:

```
<context-param>
  <param-name>routeBuilder-routes</param-name>
  <!-- we can define multiple values separated by comma -->
  <param-value>
    org.apache.camel.component.servletlistener.MyRoute,
    org.apache.camel.component.servletlistener.routes.BarRouteBuilder
  </param-value>
</context-param>
```

The name of the parameter does not have a meaning at runtime. It just need to be unique and start with "routeBuilder". In the example above we have "routeBuilder-routes". But you could just as well have named it "routeBuilder.foo".

300.9.5.2. Using package scanning

You can also tell Camel to use package scanning, which mean it will look in the given package for all classes of RouteBuilder types and automatic adding them as Camel routes. To do that you need to prefix the value with "packagescan:" as shown below:

```
<context-param>
  <param-name>routeBuilder-MyRoute</param-name>
  <!-- define the routes using package scanning by prefixing with packagescan: -->
  <param-value>packagescan:org.apache.camel.component.servletlistener.routes</param-value>
</context-param>
```

300.9.5.3. Using a XML file

You can also define Camel routes using XML DSL, though as we are not using Spring or Blueprint the XML file can only contain Camel route(s).

In the web.xml you refer to the XML file which can be from "classpath", "file" or a "http" url, as shown below:

```
<context-param>
  <param-name>routeBuilder-MyRoute</param-name>
  <param-value>classpath:routes/myRoutes.xml</param-value>
</context-param>
```

And the XML file is:

routes/myRoutes.xml

```
<?xml version="1.0" encoding="UTF-8"?>
<!-- the xmlns="http://camel.apache.org/schema/spring" is needed -->
<routes xmlns="http://camel.apache.org/schema/spring">

  <route id="foo">
    <from uri="direct:foo"/>
    <to uri="mock:foo"/>
  </route>

  <route id="bar">
    <from uri="direct:bar"/>
    <to uri="mock:bar"/>
  </route>

</routes>
```

Notice that in the XML file the root tag is `<routes>` which must use the namespace "http://camel.apache.org/schema/spring". This namespace is having the spring in the name, but that is because of historical reasons, as Spring was the first and only XML DSL back in the time. At runtime no Spring JARs is needed. Maybe in Camel 3.0 the namespace can be renamed to a generic name.

300.9.5.4. Configuring propt placeholders

Here is a snippet of a web.xml configuration for setting up property placeholders to load **myproperties.properties** from the classpath

```
<!-- setup property placeholder to load properties from classpath -->
<!-- we do this by setting the param-name with propertyPlaceholder. as prefix and then any options
such as location, cache etc -->
<context-param>
  <param-name>propertyPlaceholder.location</param-name>
  <param-value>classpath:myproperties.properties</param-value>
</context-param>
<!-- for example to disable cache on properties component, you do -->
<context-param>
  <param-name>propertyPlaceholder.cache</param-name>
  <param-value>>false</param-value>
</context-param>
```

300.9.5.5. Configuring JMX

Here is a snippet of a web.xml configuration for configuring JMX, such as disabling JMX.

```
<!-- configure JMX by using names that is prefixed with jmx. -->
<!-- in this example we disable JMX -->
<context-param>
  <param-name>jmx.disabled</param-name>
  <param-value>>true</param-value>
</context-param>
```

JNDI or Simple as Camel Registry ^{^^^^^^^^^^^^^^^^^^^^^}^

This component uses either JNDI or Simple as the Registry.

This allows you to lookup [Beans](#) and other services in JNDI, and as well to bind and unbind your own [Beans](#).

This is done from Java code by implementing the

org.apache.camel.component.servletlistener.CamelContextLifecycle.

300.9.5.6. Using custom CamelContextLifecycle

In the code below we use the callbacks **beforeStart** and **afterStop** to enlist our custom bean in the Simple Registry, and as well to cleanup when we stop.

Then we need to register this class in the web.xml file as shown below, using the parameter name "CamelContextLifecycle". The value must be a FQN which refers to the class implementing the **org.apache.camel.component.servletlistener.CamelContextLifecycle** interface.

```
<context-param>
  <param-name>CamelContextLifecycle</param-name>
  <param-value>org.apache.camel.component.servletlistener.MyLifecycle</param-value>
</context-param>
```

As we enlisted our HelloBean [Bean](#) using the name "myBean" we can refer to this [Bean](#) in the Camel routes as shown below:

```
public class MyBeanRoute extends RouteBuilder {
  @Override
  public void configure() throws Exception {
    from("seda:foo").routeId("foo")
      .to("bean:myBean")
      .to("mock:foo");
  }
}
```

Important: If you use

org.apache.camel.component.servletlistener.JndiCamelServletContextListener then the

CamelContextLifecycle must use the **JndiRegistry** as well. And likewise if the servlet is

org.apache.camel.component.servletlistener.SimpleCamelServletContextListener then the

CamelContextLifecycle must use the **SimpleRegistry**

- [Servlet Tomcat Example](#)
- [Servlet Tomcat No Spring Example](#)

CHAPTER 301. SFTP COMPONENT

Available as of Camel version 1.1

This component provides access to remote file systems over the FTP and SFTP protocols.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-ftp</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

For more information you can look at [FTP component](#)

301.1. URI OPTIONS

The options below are exclusive for the FTPS component.

The SFTP component has no options.

The SFTP endpoint is configured using URI syntax:

```
sftp:host:port/directoryName
```

with the following path and query parameters:

301.1.1. Path Parameters (3 parameters):

Name	Description	Default	Type
host	Required Hostname of the FTP server		String
port	Port of the FTP server		int
directoryName	The starting directory		String

301.1.2. Query Parameters (117 parameters):

Name	Description	Default	Type
------	-------------	---------	------

Name	Description	Default	Type
charset (common)	This option is used to specify the encoding of the file. You can use this on the consumer, to specify the encodings of the files, which allow Camel to know the charset it should load the file content in case the file content is being accessed. Likewise when writing a file, you can use this option to specify which charset to write the file as well. Do mind that when writing the file Camel may have to read the message content into memory to be able to convert the data into the configured charset, so do not use this if you have big messages.		String
disconnect (common)	Whether or not to disconnect from remote FTP server right after use. Disconnect will only disconnect the current connection to the FTP server. If you have a consumer which you want to stop, then you need to stop the consumer/route instead.	false	boolean
doneFileName (common)	Producer: If provided, then Camel will write a 2nd done file when the original file has been written. The done file will be empty. This option configures what file name to use. Either you can specify a fixed name. Or you can use dynamic placeholders. The done file will always be written in the same folder as the original file. Consumer: If provided, Camel will only consume files if a done file exists. This option configures what file name to use. Either you can specify a fixed name. Or you can use dynamic placeholders. The done file is always expected in the same folder as the original file. Only \$file.name and \$file.name.noext is supported as dynamic placeholders.		String

Name	Description	Default	Type
fileName (common)	Use Expression such as File Language to dynamically set the filename. For consumers, it's used as a filename filter. For producers, it's used to evaluate the filename to write. If an expression is set, it take precedence over the CamelFileName header. (Note: The header itself can also be an Expression). The expression options support both String and Expression types. If the expression is a String type, it is always evaluated using the File Language. If the expression is an Expression type, the specified Expression type is used - this allows you, for instance, to use OGNL expressions. For the consumer, you can use it to filter filenames, so you can for instance consume today's file using the File Language syntax: mydata-\$date:now:yyyyMMdd.txt. The producers support the CamelOverruleFileName header which takes precedence over any existing CamelFileName header; the CamelOverruleFileName is a header that is used only once, and makes it easier as this avoids to temporary store CamelFileName and have to restore it afterwards.		String
jschLoggingLevel (common)	The logging level to use for JSCH activity logging. As JSCH is verbose at by default at INFO level the threshold is WARN by default.	WARN	LoggingLevel
separator (common)	Sets the path separator to be used. UNIX = Uses unix style path separator Windows = Uses windows style path separator Auto = (is default) Use existing path separator in file name	UNIX	PathSeparator
fastExistsCheck (common)	If set this option to be true, camel-ftp will use the list file directly to check if the file exists. Since some FTP server may not support to list the file directly, if the option is false, camel-ftp will use the old way to list the directory and check if the file exists. This option also influences readLock=changed to control whether it performs a fast check to update file information or not. This can be used to speed up the process if the FTP server has a lot of files.	false	boolean

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
delete (consumer)	If true, the file will be deleted after it is processed successfully.	false	boolean
moveFailed (consumer)	Sets the move failure expression based on Simple language. For example, to move files into a <code>.error</code> subdirectory use: <code>.error</code> . Note: When moving the files to the fail location Camel will handle the error and will not pick up the file again.		String
noop (consumer)	If true, the file is not moved or deleted in any way. This option is good for readonly data, or for ETL type requirements. If <code>noop=true</code> , Camel will set <code>idempotent=true</code> as well, to avoid consuming the same files over and over again.	false	boolean
preMove (consumer)	Expression (such as File Language) used to dynamically set the filename when moving it before processing. For example to move in-progress files into the order directory set this value to <code>order</code> .		String
preSort (consumer)	When pre-sort is enabled then the consumer will sort the file and directory names during polling, that was retrieved from the file system. You may want to do this in case you need to operate on the files in a sorted order. The pre-sort is executed before the consumer starts to filter, and accept files to process by Camel. This option is default=false meaning disabled.	false	boolean
recursive (consumer)	If a directory, will look for files in all the sub-directories as well.	false	boolean
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean

Name	Description	Default	Type
streamDownload (consumer)	Sets the download method to use when not using a local working directory. If set to true, the remote files are streamed to the route as they are read. When set to false, the remote files are loaded into memory before being sent into the route.	false	boolean
directoryMustExist (consumer)	Similar to startingDirectoryMustExist but this applies during polling recursive sub directories.	false	boolean
download (consumer)	Whether the FTP consumer should download the file. If this option is set to false, then the message body will be null, but the consumer will still trigger a Camel Exchange that has details about the file such as file name, file size, etc. It's just that the file will not be downloaded.	false	boolean
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
ignoreFileNotFoundOrPermissionError (consumer)	Whether to ignore when (trying to list files in directories or when downloading a file), which does not exist or due to permission error. By default when a directory or file does not exist or insufficient permission, then an exception is thrown. Setting this option to true allows to ignore that instead.	false	boolean
inProgressRepository (consumer)	A pluggable in-progress repository org.apache.camel.spi.IdempotentRepository. The in-progress repository is used to account the current in progress files being consumed. By default a memory based repository is used.		IdempotentRepository
localWorkDirectory (consumer)	When consuming, a local work directory can be used to store the remote file content directly in local files, to avoid loading the content into memory. This is beneficial, if you consume a very big remote file and thus can conserve memory.		String

Name	Description	Default	Type
onCompletionExceptionHandler (consumer)	To use a custom <code>org.apache.camel.spi.ExceptionHandler</code> to handle any thrown exceptions that happens during the file on completion process where the consumer does either a commit or rollback. The default implementation will log any exception at WARN level and ignore.		ExceptionHandler
pollStrategy (consumer)	A pluggable <code>org.apache.camel.PollingConsumerPollingStrategy</code> allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		PollingConsumerPollStrategy
processStrategy (consumer)	A pluggable <code>org.apache.camel.component.file.GenericFileProcessStrategy</code> allowing you to implement your own <code>readLock</code> option or similar. Can also be used when special conditions must be met before a file can be consumed, such as a special ready file exists. If this option is set then the <code>readLock</code> option does not apply.		GenericFileProcessStrategy
startingDirectoryMustExist (consumer)	Whether the starting directory must exist. Mind that the <code>autoCreate</code> option is default enabled, which means the starting directory is normally auto created if it doesn't exist. You can disable <code>autoCreate</code> and enable this to ensure the starting directory must exist. Will thrown an exception if the directory doesn't exist.	false	boolean
useList (consumer)	Whether to allow using LIST command when downloading a file. Default is true. In some use cases you may want to download a specific file and are not allowed to use the LIST command, and therefore you can set this option to false. Notice when using this option, then the specific file to download does not include meta-data information such as file size, timestamp, permissions etc, because those information is only possible to retrieve when LIST command is in use.	true	boolean

Name	Description	Default	Type
fileExist (producer)	What to do if a file already exists with the same name. Override, which is the default, replaces the existing file. Append - adds content to the existing file. Fail - throws a <code>GenericFileOperationException</code> , indicating that there is already an existing file. Ignore - silently ignores the problem and does not override the existing file, but assumes everything is okay. Move - option requires to use the <code>moveExisting</code> option to be configured as well. The option <code>eagerDeleteTargetFile</code> can be used to control what to do if an moving the file, and there exists already an existing file, otherwise causing the move operation to fail. The Move option will move any existing files, before writing the target file. <code>TryRename</code> is only applicable if <code>tempFileName</code> option is in use. This allows to try renaming the file from the temporary name to the actual name, without doing any exists check. This check may be faster on some file systems and especially FTP servers.	Override	GenericFileExist
flatten (producer)	Flatten is used to flatten the file name path to strip any leading paths, so it's just the file name. This allows you to consume recursively into sub-directories, but when you eg write the files to another directory they will be written in a single directory. Setting this to true on the producer enforces that any file name in <code>CamelFileName</code> header will be stripped for any leading paths.	false	boolean
jailStartingDirectory (producer)	Used for jailing (restricting) writing files to the starting directory (and sub) only. This is enabled by default to not allow Camel to write files to outside directories (to be more secured out of the box). You can turn this off to allow writing files to directories outside the starting directory, such as parent or root folders.	true	boolean
moveExisting (producer)	Expression (such as File Language) used to compute file name to use when <code>fileExist=Move</code> is configured. To move files into a backup subdirectory just enter backup. This option only supports the following File Language tokens: <code>file:name</code> , <code>file:name.ext</code> , <code>file:name.noext</code> , <code>file:onlyname</code> , <code>file:onlyname.noext</code> , <code>file:ext</code> , and <code>file:parent</code> . Notice the <code>file:parent</code> is not supported by the FTP component, as the FTP component can only move any existing files to a relative directory based on current dir as base.		String

Name	Description	Default	Type
tempFileName (producer)	The same as tempPrefix option but offering a more fine grained control on the naming of the temporary filename as it uses the File Language.		String
tempPrefix (producer)	This option is used to write the file using a temporary name and then, after the write is complete, rename it to the real name. Can be used to identify files being written and also avoid consumers (not using exclusive read locks) reading in progress files. Is often used by FTP when uploading big files.		String
allowNullBody (producer)	Used to specify if a null body is allowed during file writing. If set to true then an empty file will be created, when set to false, and attempting to send a null body to the file component, a GenericFileWriteException of 'Cannot write null body to file.' will be thrown. If the fileExist option is set to 'Override', then the file will be truncated, and if set to append the file will remain unchanged.	false	boolean
chmod (producer)	Allows you to set chmod on the stored file. For example chmod=640.		String
disconnectOnBatchComplete (producer)	Whether or not to disconnect from remote FTP server right after a Batch upload is complete. disconnectOnBatchComplete will only disconnect the current connection to the FTP server.	false	boolean
eagerDeleteTargetFile (producer)	Whether or not to eagerly delete any existing target file. This option only applies when you use fileExists=Override and the tempFileName option as well. You can use this to disable (set it to false) deleting the target file before the temp file is written. For example you may write big files and want the target file to exist during the temp file is being written. This ensure the target file is only deleted until the very last moment, just before the temp file is being renamed to the target filename. This option is also used to control whether to delete any existing files when fileExist=Move is enabled, and an existing file exists. If this option copyAndDeleteOnRenameFails false, then an exception will be thrown if an existing file existed, if its true, then the existing file is deleted before the move operation.	true	boolean

Name	Description	Default	Type
keepLastModified (producer)	Will keep the last modified timestamp from the source file (if any). Will use the Exchange.FILE_LAST_MODIFIED header to located the timestamp. This header can contain either a java.util.Date or long with the timestamp. If the timestamp exists and the option is enabled it will set this timestamp on the written file. Note: This option only applies to the file producer. You cannot use this option with any of the ftp producers.	false	boolean
moveExistingFileStrategy (producer)	Strategy (Custom Strategy) used to move file with special naming token to use when fileExist=Move is configured. By default, there is an implementation used if no custom strategy is provided		FileMoveExistingStrategy
sendNoop (producer)	Whether to send a noop command as a pre-write check before uploading files to the FTP server. This is enabled by default as a validation of the connection is still valid, which allows to silently re-connect to be able to upload the file. However if this causes problems, you can turn this option off.	true	boolean
autoCreate (advanced)	Automatically create missing directories in the file's pathname. For the file consumer, that means creating the starting directory. For the file producer, it means the directory the files should be written to.	true	boolean
bindAddress (advanced)	Specifies the address of the local interface against which the connection should bind.		String
bufferSize (advanced)	Write buffer sized in bytes.	131072	int
bulkRequests (advanced)	Specifies how many requests may be outstanding at any one time. Increasing this value may slightly improve file transfer speed but will increase memory usage.		Integer
compression (advanced)	To use compression. Specify a level from 1 to 10. Important: You must manually add the needed JSCH zlib JAR to the classpath for compression support.		int
connectTimeout (advanced)	Sets the connect timeout for waiting for a connection to be established Used by both FTPClient and JSCH	10000	int
maximumReconnectAttempts (advanced)	Specifies the maximum reconnect attempts Camel performs when it tries to connect to the remote FTP server. Use 0 to disable this behavior.		int

Name	Description	Default	Type
proxy (advanced)	To use a custom configured com.jcraft.jsch.Proxy. This proxy is used to consume/send messages from the target SFTP host.		Proxy
reconnectDelay (advanced)	Delay in millis Camel will wait before performing a reconnect attempt.		long
serverAliveCountMax (advanced)	Allows you to set the serverAliveCountMax of the sftp session	1	int
serverAliveInterval (advanced)	Allows you to set the serverAliveInterval of the sftp session		int
soTimeout (advanced)	Sets the so timeout Used only by FTPClient	30000 0	int
stepwise (advanced)	Sets whether we should stepwise change directories while traversing file structures when downloading files, or as well when uploading a file to a directory. You can disable this if you for example are in a situation where you cannot change directory on the FTP server due security reasons.	true	boolean
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
throwExceptionOnConnectFailed (advanced)	Should an exception be thrown if connection failed (exhausted) By default exception is not thrown and a WARN is logged. You can use this to enable exception being thrown and handle the thrown exception from the org.apache.camel.spi.PollingConsumerPollStrategy rollback method.	false	boolean
antExclude (filter)	Ant style filter exclusion. If both antInclude and antExclude are used, antExclude takes precedence over antInclude. Multiple exclusions may be specified in comma-delimited format.		String
antFilterCaseSensitive (filter)	Sets case sensitive flag on ant filter	true	boolean
antInclude (filter)	Ant style filter inclusion. Multiple inclusions may be specified in comma-delimited format.		String

Name	Description	Default	Type
eagerMaxMessagesPerPoll (filter)	Allows for controlling whether the limit from <code>maxMessagesPerPoll</code> is eager or not. If eager then the limit is during the scanning of files. Where as false would scan all files, and then perform sorting. Setting this option to false allows for sorting all files first, and then limit the poll. Mind that this requires a higher memory usage as all file details are in memory to perform the sorting.	true	boolean
exclude (filter)	Is used to exclude files, if filename matches the regex pattern (matching is case in-sensitive). Notice if you use symbols such as plus sign and others you would need to configure this using the <code>RAW()</code> syntax if configuring this as an endpoint uri. See more details at configuring endpoint uris		String
filter (filter)	Pluggable filter as a <code>org.apache.camel.component.file.GenericFileFilter</code> class. Will skip files if filter returns false in its <code>accept()</code> method.		GenericFileFilter
filterDirectory (filter)	Filters the directory based on Simple language. For example to filter on current date, you can use a simple date pattern such as <code>\$date:now:yyyMMdd</code>		String
filterFile (filter)	Filters the file based on Simple language. For example to filter on file size, you can use <code>\$file:size 5000</code>		String
idempotent (filter)	Option to use the Idempotent Consumer EIP pattern to let Camel skip already processed files. Will by default use a memory based <code>LRUCache</code> that holds 1000 entries. If <code>noop=true</code> then idempotent will be enabled as well to avoid consuming the same files over and over again.	false	Boolean
idempotentKey (filter)	To use a custom idempotent key. By default the absolute path of the file is used. You can use the File Language, for example to use the file name and file size, you can do: <code>idempotentKey=\$file:name-\$file:size</code>		String
idempotentRepository (filter)	A pluggable repository <code>org.apache.camel.spi.IdempotentRepository</code> which by default use <code>MemoryMessageIdRepository</code> if none is specified and idempotent is true.		IdempotentRepository

Name	Description	Default	Type
include (filter)	Is used to include files, if filename matches the regex pattern (matching is case in-sensitive). Notice if you use symbols such as plus sign and others you would need to configure this using the RAW() syntax if configuring this as an endpoint uri. See more details at configuring endpoint uris		String
maxDepth (filter)	The maximum depth to traverse when recursively processing a directory.	2147483647	int
maxMessagesPerPoll (filter)	To define a maximum messages to gather per poll. By default no maximum is set. Can be used to set a limit of e.g. 1000 to avoid when starting up the server that there are thousands of files. Set a value of 0 or negative to disabled it. Notice: If this option is in use then the File and FTP components will limit before any sorting. For example if you have 100000 files and use maxMessagesPerPoll=500, then only the first 500 files will be picked up, and then sorted. You can use the eagerMaxMessagesPerPoll option and set this to false to allow to scan all files first and then sort afterwards.		int
minDepth (filter)	The minimum depth to start processing when recursively processing a directory. Using minDepth=1 means the base directory. Using minDepth=2 means the first sub directory.		int
move (filter)	Expression (such as Simple Language) used to dynamically set the filename when moving it after processing. To move files into a .done subdirectory just enter .done.		String
exclusiveReadLockStrategy (lock)	Pluggable read-lock as a org.apache.camel.component.file.GenericFileExclusiveReadLockStrategy implementation.		GenericFileExclusiveReadLockStrategy

Name	Description	Default	Type
readLock (lock)	<p>Used by consumer, to only poll the files if it has exclusive read-lock on the file (i.e. the file is not in-progress or being written). Camel will wait until the file lock is granted. This option provides the build in strategies: none - No read lock is in use markerFile - Camel creates a marker file (fileName.camelLock) and then holds a lock on it. This option is not available for the FTP component changed - Changed is using file length/modification timestamp to detect whether the file is currently being copied or not. Will at least use 1 sec to determine this, so this option cannot consume files as fast as the others, but can be more reliable as the JDK IO API cannot always determine whether a file is currently being used by another process. The option readLockCheckInterval can be used to set the check frequency. fileLock - is for using java.nio.channels.FileLock. This option is not avail on Windows or the FTP component. This approach should be avoided when accessing a remote file system via a mount/share unless that file system supports distributed file locks. rename - rename is for using a try to rename the file as a test if we can get exclusive read-lock. idempotent - (only for file component) idempotent is for using a idempotentRepository as the read-lock. This allows to use read locks that supports clustering if the idempotent repository implementation supports that. idempotent-changed - (only for file component) idempotent-changed is for using a idempotentRepository and changed as the combined read-lock. This allows to use read locks that supports clustering if the idempotent repository implementation supports that. idempotent-rename - (only for file component) idempotent-rename is for using a idempotentRepository and rename as the combined read-lock. This allows to use read locks that supports clustering if the idempotent repository implementation supports that. Notice: The various read locks is not all suited to work in clustered mode, where concurrent consumers on different nodes is competing for the same files on a shared file system. The markerFile using a close to atomic operation to create the empty marker file, but its not guaranteed to work in a cluster. The fileLock may work better but then the file system need to support distributed file locks, and so on. Using the idempotent read lock can support clustering if the idempotent repository supports clustering, such as Hazelcast Component or Infinispan.</p>	none	String

Name	Description	Default	Type
readLockCheckInterval (lock)	Interval in millis for the read-lock, if supported by the read lock. This interval is used for sleeping between attempts to acquire the read lock. For example when using the changed read lock, you can set a higher interval period to cater for slow writes. The default of 1 sec. may be too fast if the producer is very slow writing the file. Notice: For FTP the default readLockCheckInterval is 5000. The readLockTimeout value must be higher than readLockCheckInterval, but a rule of thumb is to have a timeout that is at least 2 or more times higher than the readLockCheckInterval. This is needed to ensure that ample time is allowed for the read lock process to try to grab the lock before the timeout was hit.	1000	long
readLockDeleteOrphanLockFiles (lock)	Whether or not read lock with marker files should upon startup delete any orphan read lock files, which may have been left on the file system, if Camel was not properly shutdown (such as a JVM crash). If turning this option to false then any orphaned lock file will cause Camel to not attempt to pickup that file, this could also be due another node is concurrently reading files from the same shared directory.	true	boolean
readLockIdempotentReleaseAsync (lock)	Whether the delayed release task should be synchronous or asynchronous. See more details at the readLockIdempotentReleaseDelay option.	false	boolean
readLockIdempotentReleaseAsyncPoolSize (lock)	The number of threads in the scheduled thread pool when using asynchronous release tasks. Using a default of 1 core threads should be sufficient in almost all use-cases, only set this to a higher value if either updating the idempotent repository is slow, or there are a lot of files to process. This option is not in-use if you use a shared thread pool by configuring the readLockIdempotentReleaseExecutorService option. See more details at the readLockIdempotentReleaseDelay option.		int

Name	Description	Default	Type
readLockIdempotentReleaseDelay (lock)	Whether to delay the release task for a period of millis. This can be used to delay the release tasks to expand the window when a file is regarded as read-locked, in an active/active cluster scenario with a shared idempotent repository, to ensure other nodes cannot potentially scan and acquire the same file, due to race-conditions. By expanding the time-window of the release tasks helps prevents these situations. Note delaying is only needed if you have configured readLockRemoveOnCommit to true.		int
readLockIdempotentReleaseExecutorService (lock)	To use a custom and shared thread pool for asynchronous release tasks. See more details at the readLockIdempotentReleaseDelay option.		ScheduledExecutorService
readLockLoggingLevel (lock)	Logging level used when a read lock could not be acquired. By default a WARN is logged. You can change this level, for example to OFF to not have any logging. This option is only applicable for readLock of types: changed, fileLock, idempotent, idempotent-changed, idempotent-rename, rename.	DEBUG	LogLevel
readLockMarkerFile (lock)	Whether to use marker file with the changed, rename, or exclusive read lock types. By default a marker file is used as well to guard against other processes picking up the same files. This behavior can be turned off by setting this option to false. For example if you do not want to write marker files to the file systems by the Camel application.	true	boolean
readLockMinAge (lock)	This option is applied only for readLock=changed. It allows to specify a minimum age the file must be before attempting to acquire the read lock. For example use readLockMinAge=300s to require the file is at least 5 minutes old. This can speedup the changed read lock as it will only attempt to acquire files which are at least that given age.	0	long
readLockMinLength (lock)	This option is applied only for readLock=changed. It allows you to configure a minimum file length. By default Camel expects the file to contain data, and thus the default value is 1. You can set this option to zero, to allow consuming zero-length files.	1	long

Name	Description	Default	Type
readLockRemoveOnCommit (lock)	This option is applied only for readLock=idempotent. It allows to specify whether to remove the file name entry from the idempotent repository when processing the file is succeeded and a commit happens. By default the file is not removed which ensures that any race-condition do not occur so another active node may attempt to grab the file. Instead the idempotent repository may support eviction strategies that you can configure to evict the file name entry after X minutes - this ensures no problems with race conditions. See more details at the readLockIdempotentReleaseDelay option.	false	boolean
readLockRemoveOnRollback (lock)	This option is applied only for readLock=idempotent. It allows to specify whether to remove the file name entry from the idempotent repository when processing the file failed and a rollback happens. If this option is false, then the file name entry is confirmed (as if the file did a commit).	true	boolean
readLockTimeout (lock)	Optional timeout in millis for the read-lock, if supported by the read-lock. If the read-lock could not be granted and the timeout triggered, then Camel will skip the file. At next poll Camel, will try the file again, and this time maybe the read-lock could be granted. Use a value of 0 or lower to indicate forever. Currently fileLock, changed and rename support the timeout. Notice: For FTP the default readLockTimeout value is 20000 instead of 10000. The readLockTimeout value must be higher than readLockCheckInterval, but a rule of thumb is to have a timeout that is at least 2 or more times higher than the readLockCheckInterval. This is needed to ensure that ample time is allowed for the read lock process to try to grab the lock before the timeout was hit.	10000	long
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.		int

Name	Description	Default	Type
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then <code>backoffIdleThreshold</code> and/or <code>backoffErrorThreshold</code> must also be configured.		int
delay (scheduler)	Milliseconds before the next poll. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	500	long
greedy (scheduler)	If greedy is enabled, then the <code>ScheduledPollConsumer</code> will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	1000	long
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that.	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz2 component	none	ScheduledPollConsumer Scheduler
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz2, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for <code>initialDelay</code> and <code>delay</code> options.	MILLIS ECON DS	TimeUnit
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See <code>ScheduledExecutorService</code> in JDK for details.	true	boolean
shuffle (sort)	To shuffle the list of files (sort in random order)	false	boolean

Name	Description	Default	Type
sortBy (sort)	Built-in sort by using the File Language. Supports nested sorts, so you can have a sort by file name and as a 2nd group sort by modified date.		String
sorter (sort)	Pluggable sorter as a java.util.Comparator class.		Comparator
ciphers (security)	Set a comma separated list of ciphers that will be used in order of preference. Possible cipher names are defined by JCraft JSCH. Some examples include: aes128-ctr,aes128-cbc,3des-ctr,3des-cbc,blowfish-cbc,aes192-cbc,aes256-cbc. If not specified the default list from JSCH will be used.		String
keyPair (security)	Sets a key pair of the public and private key so to that the SFTP endpoint can do public/private key verification.		KeyPair
knownHosts (security)	Sets the known_hosts from the byte array, so that the SFTP endpoint can do host key verification.		byte[]
knownHostsFile (security)	Sets the known_hosts file, so that the SFTP endpoint can do host key verification.		String
knownHostsUri (security)	Sets the known_hosts file (loaded from classpath by default), so that the SFTP endpoint can do host key verification.		String
password (security)	Password to use for login		String
preferredAuthentications (security)	Set the preferred authentications which SFTP endpoint will used. Some example include:password,publickey. If not specified the default list from JSCH will be used.		String
privateKey (security)	Set the private key as byte so that the SFTP endpoint can do private key verification.		byte[]
privateKeyFile (security)	Set the private key file so that the SFTP endpoint can do private key verification.		String
privateKeyPassphrase (security)	Set the private key file passphrase so that the SFTP endpoint can do private key verification.		String
privateKeyUri (security)	Set the private key file (loaded from classpath by default) so that the SFTP endpoint can do private key verification.		String

Name	Description	Default	Type
strictHostKeyChecking (security)	Sets whether to use strict host key checking.	no	String
username (security)	Username to use for login		String
useUserKnownHostsFile (security)	If knownHostFile has not been explicit configured then use the host file from <code>System.getProperty(user.home)/.ssh/known_hosts</code>	true	boolean

CHAPTER 302. SHIRO SECURITY COMPONENT

Available as of Camel 2.5

The **shiro-security** component in Camel is a security focused component, based on the Apache Shiro security project.

Apache Shiro is a powerful and flexible open-source security framework that cleanly handles authentication, authorization, enterprise session management and cryptography. The objective of the Apache Shiro project is to provide the most robust and comprehensive application security framework available while also being very easy to understand and extremely simple to use.

This camel shiro-security component allows authentication and authorization support to be applied to different segments of a camel route.

Shiro security is applied on a route using a Camel Policy. A Policy in Camel utilizes a strategy pattern for applying interceptors on Camel Processors. It offering the ability to apply cross-cutting concerns (for example. security, transactions etc) on sections/segments of a camel route.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-shiro</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

302.1. SHIRO SECURITY BASICS

To employ Shiro security on a camel route, a ShiroSecurityPolicy object must be instantiated with security configuration details (including users, passwords, roles etc). This object must then be applied to a camel route. This ShiroSecurityPolicy Object may also be registered in the Camel registry (JNDI or ApplicationContextRegistry) and then utilized on other routes in the Camel Context.

Configuration details are provided to the ShiroSecurityPolicy using an Ini file (properties file) or an Ini object. The Ini file is a standard Shiro configuration file containing user/role details as shown below

```
[users]
# user 'ringo' with password 'starr' and the 'sec-level1' role
ringo = starr, sec-level1
george = harrison, sec-level2
john = lennon, sec-level3
paul = mccartney, sec-level3

[roles]
# 'sec-level3' role has all permissions, indicated by the
# wildcard '*'
sec-level3 = *

# The 'sec-level2' role can do anything with access of permission
# readonly (*) to help
sec-level2 = zone1:*
```

```
# The 'sec-level1' role can do anything with access of permission
# readonly
sec-level1 = zone1:readonly:*
```

302.2. INSTANTIATING A SHIROSECURITYPOLICY OBJECT

A ShiroSecurityPolicy object is instantiated as follows

```
private final String iniResourcePath = "classpath:shiro.ini";
private final byte[] passphrase = {
    (byte) 0x08, (byte) 0x09, (byte) 0x0A, (byte) 0x0B,
    (byte) 0x0C, (byte) 0x0D, (byte) 0x0E, (byte) 0x0F,
    (byte) 0x10, (byte) 0x11, (byte) 0x12, (byte) 0x13,
    (byte) 0x14, (byte) 0x15, (byte) 0x16, (byte) 0x17};
List<permission> permissionsList = new ArrayList<permission>();
Permission permission = new WildcardPermission("zone1:readwrite:*");
permissionsList.add(permission);

final ShiroSecurityPolicy securityPolicy =
    new ShiroSecurityPolicy(iniResourcePath, passphrase, true, permissionsList);
```

302.3. SHIROSECURITYPOLICY OPTIONS

Name	Default Value	Type	Description
iniResourcePath or ini	none	Resource String or Ini Object	A mandatory Resource String for the iniResourcePath or an instance of an Ini object must be passed to the security policy. Resources can be acquired from the file system, classpath, or URLs when prefixed with "file:", "classpath:", or "url:" respectively. For e.g "classpath:shiro.ini"
passPhrase	An AES 128 based key	byte[]	A passphrase to decrypt ShiroSecurityToken(s) sent along with Message Exchanges
alwaysReauthenticate	true	boolean	Setting to ensure re-authentication on every individual request. If set to false, the user is authenticated and locked such that only requests from the same user going forward are authenticated.

Name	Default Value	Type	Description
permissionsList	none	List<Permission>	A List of permissions required in order for an authenticated user to be authorized to perform further action i.e continue further on the route. If no Permissions list or Roles List (see below) is provided to the ShiroSecurityPolicy object, then authorization is deemed as not required. Note that the default is that authorization is granted if any of the Permission Objects in the list are applicable.
rolesList	none	List<String>	Camel 2.13: A List of roles required in order for an authenticated user to be authorized to perform further action i.e continue further on the route. If no roles list or permissions list (see above) is provided to the ShiroSecurityPolicy object, then authorization is deemed as not required. Note that the default is that authorization is granted if any of the roles in the list are applicable.
cipherService	AES	org.apache.shiro.crypto.CipherService	Shiro ships with AES & Blowfish based CipherServices. You may use one these or pass in your own Cipher implementation
base64	false	boolean	Camel 2.12: To use base64 encoding for the security token header, which allows transferring the header over JMS etc. This option must also be set on ShiroSecurityTokenInjector as well.
allPermissionsRequired	false	boolean	Camel 2.13: The default is that authorization is granted if any of the Permission Objects in the permissionsList parameter are applicable. Set this to true to require all of the Permissions to be met.
allRolesRequired	false	boolean	Camel 2.13: The default is that authorization is granted if any of the roles in the rolesList parameter are applicable. Set this to true to require all of the roles to be met.

302.4. APPLYING SHIRO AUTHENTICATION ON A CAMEL ROUTE

The ShiroSecurityPolicy, tests and permits incoming message exchanges containing a encrypted SecurityToken in the Message Header to proceed further following proper authentication. The SecurityToken object contains a Username/Password details that are used to determine where the user is a valid user.

protected RouteBuilder createRouteBuilder() throws Exception {

```

final ShiroSecurityPolicy securityPolicy =
    new ShiroSecurityPolicy("classpath:shiro.ini", passPhrase);

return new RouteBuilder() {
    public void configure() {
        onException(UnknownAccountException.class).
            to("mock:authenticationException");
        onException(IncorrectCredentialsException.class).
            to("mock:authenticationException");
        onException(LockedAccountException.class).
            to("mock:authenticationException");
        onException(AuthenticationException.class).
            to("mock:authenticationException");

        from("direct:secureEndpoint").
            to("log:incoming payload").
            policy(securityPolicy).
            to("mock:success");
    }
};
}

```

302.5. APPLYING SHIRO AUTHORIZATION ON A CAMEL ROUTE

Authorization can be applied on a camel route by associating a Permissions List with the ShiroSecurityPolicy. The Permissions List specifies the permissions necessary for the user to proceed with the execution of the route segment. If the user does not have the proper permission set, the request is not authorized to continue any further.

```

protected RouteBuilder createRouteBuilder() throws Exception {
    final ShiroSecurityPolicy securityPolicy =
        new ShiroSecurityPolicy("./src/test/resources/securityconfig.ini", passPhrase);

    return new RouteBuilder() {
        public void configure() {
            onException(UnknownAccountException.class).
                to("mock:authenticationException");
            onException(IncorrectCredentialsException.class).
                to("mock:authenticationException");
            onException(LockedAccountException.class).
                to("mock:authenticationException");
            onException(AuthenticationException.class).
                to("mock:authenticationException");

            from("direct:secureEndpoint").
                to("log:incoming payload").
                policy(securityPolicy).
                to("mock:success");
        }
    };
}

```

302.6. CREATING A SHIROSECURITYTOKEN AND INJECTING IT INTO A MESSAGE EXCHANGE

A ShiroSecurityToken object may be created and injected into a Message Exchange using a Shiro Processor called ShiroSecurityTokenInjector. An example of injecting a ShiroSecurityToken using a ShiroSecurityTokenInjector in the client is shown below

```
ShiroSecurityToken shiroSecurityToken = new ShiroSecurityToken("ringo", "starr");
ShiroSecurityTokenInjector shiroSecurityTokenInjector =
    new ShiroSecurityTokenInjector(shiroSecurityToken, passPhrase);

from("direct:client").
    process(shiroSecurityTokenInjector).
    to("direct:secureEndpoint");
```

302.7. SENDING MESSAGES TO ROUTES SECURED BY A SHIROSECURITYPOLICY

Messages and Message Exchanges sent along the camel route where the security policy is applied need to be accompanied by a SecurityToken in the Exchange Header. The SecurityToken is an encrypted object that holds a Username and Password. The SecurityToken is encrypted using AES 128 bit security by default and can be changed to any cipher of your choice.

Given below is an example of how a request may be sent using a ProducerTemplate in Camel along with a SecurityToken

```
@Test
public void testSuccessfulShiroAuthenticationWithNoAuthorization() throws Exception {
    //Incorrect password
    ShiroSecurityToken shiroSecurityToken = new ShiroSecurityToken("ringo", "stirr");

    // TestShiroSecurityTokenInjector extends ShiroSecurityTokenInjector
    TestShiroSecurityTokenInjector shiroSecurityTokenInjector =
        new TestShiroSecurityTokenInjector(shiroSecurityToken, passPhrase);

    successEndpoint.expectedMessageCount(1);
    failureEndpoint.expectedMessageCount(0);

    template.send("direct:secureEndpoint", shiroSecurityTokenInjector);

    successEndpoint.assertIsSatisfied();
    failureEndpoint.assertIsSatisfied();
}
```

302.8. SENDING MESSAGES TO ROUTES SECURED BY A SHIROSECURITYPOLICY (MUCH EASIER FROM CAMEL 2.12 ONWARDS)

From Camel 2.12 onwards its even easier as you can provide the subject in two different ways.

302.8.1. Using ShiroSecurityToken

You can send a message to a Camel route with a header of key **ShiroSecurityConstants.SHIRO_SECURITY_TOKEN** of the type **org.apache.camel.component.shiro.security.ShiroSecurityToken** that contains the username and password. For example:

```
ShiroSecurityToken shiroSecurityToken = new ShiroSecurityToken("ringo", "starr");

template.sendBodyAndHeader("direct:secureEndpoint", "Beatle Mania",
ShiroSecurityConstants.SHIRO_SECURITY_TOKEN, shiroSecurityToken);
```

You can also provide the username and password in two different headers as shown below:

```
Map<String, Object> headers = new HashMap<String, Object>();
headers.put(ShiroSecurityConstants.SHIRO_SECURITY_USERNAME, "ringo");
headers.put(ShiroSecurityConstants.SHIRO_SECURITY_PASSWORD, "starr");
template.sendBodyAndHeaders("direct:secureEndpoint", "Beatle Mania", headers);
```

When you use the username and password headers, then the **ShiroSecurityPolicy** in the Camel route will automatic transform those into a single header with key **ShiroSecurityConstants.SHIRO_SECURITY_TOKEN** with the token. Then token is either a **ShiroSecurityToken** instance, or a base64 representation as a String (the latter is when you have set `base64=true`).

CHAPTER 303. SIMPLE LANGUAGE

Available as of Camel version 1.1

The Simple Expression Language was a really simple language when it was created, but has since grown more powerful. It is primarily intended for being a really small and simple language for evaluating Expressions and Predicates without requiring any new dependencies or knowledge of [XPath](#); so it is ideal for testing in camel-core. The idea was to cover 95% of the common use cases when you need a little bit of expression based script in your Camel routes.

However for much more complex use cases you are generally recommended to choose a more expressive and powerful language such as:

- [SpEL](#)
- [Mvel](#)
- [Groovy](#)
- JavaScript
- [OGNL](#)
- one of the supported [Scripting Languages](#)

The simple language uses `#{body}` placeholders for complex expressions where the expression contains constant literals. The `#{ }` placeholders can be omitted if the expression is only the token itself.

TIP

Alternative syntax From Camel 2.5 onwards you can also use the alternative syntax which uses `$simple{ }` as placeholders. This can be used in situations to avoid clashes when using for example Spring property placeholder together with Camel.

303.1. SIMPLE LANGUAGE CHANGES IN CAMEL 2.9 ONWARDS

The [Simple](#) language have been improved from Camel 2.9 onwards to use a better syntax parser, which can do index precise error messages, so you know exactly what is wrong and where the problem is. For example if you have made a typo in one of the operators, then previously the parser would not be able to detect this, and cause the evaluation to be true. There are a few changes in the syntax which are no longer backwards compatible. When using [Simple](#) language as a Predicate then the literal text **must** be enclosed in either single or double quotes. For example: `"#{body} == 'Camel'"`. Notice how we have single quotes around the literal. The old style of using `"body"` and `"header.foo"` to refer to the message body and header is @deprecated, and it is encouraged to always use `#{ }` tokens for the built-in functions. The range operator now requires the range to be in single quote as well as shown: `"#{header.zip} between '30000..39999'"`.

To get the body of the in message: `"body"`, or `"in.body"` or `"#{body}"`.

A complex expression must use `#{ }` placeholders, such as: `"Hello #{in.header.name} how are you?"`.

You can have multiple functions in the same expression: `"Hello #{in.header.name} this is #{in.header.me} speaking"`.

However you can **not** nest functions in Camel 2.8.x or older (i.e. having another `#{ }` placeholder in an existing, is not allowed).

From **Camel 2.9** onwards you can nest functions.

303.2. SIMPLE LANGUAGE OPTIONS

The Simple language supports 2 options, which are listed below.

Name	Default	Java Type	Description
resultType		String	Sets the class name of the result type (type from output)
trim	true	Boolean	Whether to trim the value to remove leading and trailing whitespaces and line breaks

303.3. VARIABLES

Variable	Type	Description
camelId	String	Camel 2.10: the CamelContext name
camelContext. OGNL	Object	Camel 2.11: the CamelContext invoked using a Camel OGNL expression.
exchange	Exchange	Camel 2.16: the Exchange
exchange. OGNL	Object	Camel 2.16: the Exchange invoked using a Camel OGNL expression.
exchangeId	String	Camel 2.3: the exchange id
id	String	the input message id
body	Object	the input body
in.body	Object	the input body
body. OGNL	Object	Camel 2.3: the input body invoked using a Camel OGNL expression.
in.body. OGNL	Object	Camel 2.3: the input body invoked using a Camel OGNL expression.
bodyAs (type)	Type	Camel 2.3: Converts the body to the given type determined by its classname. The converted body can be null.

Variable	Type	Description
bodyAs (type). OGNL	Object	Camel 2.18: Converts the body to the given type determined by its classname and then invoke methods using a Camel OGNL expression. The converted body can be null.
mandatoryBodyAs(type)	Type	Camel 2.5: Converts the body to the given type determined by its classname, and expects the body to be not null.
mandatoryBodyAs(type). OGNL	Object	Camel 2.18: Converts the body to the given type determined by its classname and then invoke methods using a Camel OGNL expression.
out.body	Object	the output body
header.foo	Object	refer to the input foo header
header[foo]	Object	Camel 2.9.2: refer to the input foo header
headers.foo	Object	refer to the input foo header
headers[foo]	Object	Camel 2.9.2: refer to the input foo header
in.header.foo	Object	refer to the input foo header
in.header[foo]	Object	Camel 2.9.2: refer to the input foo header
in.headers.foo	Object	refer to the input foo header
in.headers[foo]	Object	Camel 2.9.2: refer to the input foo header
header.foo[bar]	Object	Camel 2.3: regard input foo header as a map and perform lookup on the map with bar as key

Variable	Type	Description
in.header.foo[bar]	Object	Camel 2.3: regard input foo header as a map and perform lookup on the map with bar as key
in.headers.foo[bar]	Object	Camel 2.3: regard input foo header as a map and perform lookup on the map with bar as key
header.foo. OGNL	Object	Camel 2.3: refer to the input foo header and invoke its value using a Camel OGNL expression.
in.header.foo. OGNL	Object	Camel 2.3: refer to the input foo header and invoke its value using a Camel OGNL expression.
in.headers.foo. OGNL	Object	Camel 2.3: refer to the input foo header and invoke its value using a Camel OGNL expression.
out.header.foo	Object	refer to the out header foo
out.header[foo]	Object	Camel 2.9.2: refer to the out header foo
out.headers.foo	Object	refer to the out header foo
out.headers[foo]	Object	Camel 2.9.2: refer to the out header foo
headerAs(key, type)	Type	Camel 2.5: Converts the header to the given type determined by its classname
headers	Map	Camel 2.9: refer to the input headers
in.headers	Map	Camel 2.9: refer to the input headers

Variable	Type	Description
property.foo	Object	Deprecated: refer to the foo property on the exchange
exchangeProperty.foo	Object	Camel 2.15: refer to the foo property on the exchange
property[foo]	Object	Deprecated: refer to the foo property on the exchange
exchangeProperty[foo]	Object	Camel 2.15: refer to the foo property on the exchange
property.foo. OGNL	Object	Deprecated: refer to the foo property on the exchange and invoke its value using a Camel OGNL expression.
exchangeProperty.foo. OGNL	Object	Camel 2.15: refer to the foo property on the exchange and invoke its value using a Camel OGNL expression.
sys.foo	String	refer to the system property
sysenv.foo	String	Camel 2.3: refer to the system environment
exception	Object	Camel 2.4: Refer to the exception object on the exchange, is null if no exception set on exchange. Will fallback and grab caught exceptions (Exchange.EXCEPTION_CAUGHT) if the Exchange has any.
exception. OGNL	Object	Camel 2.4: Refer to the exchange exception invoked using a Camel OGNL expression object
exception.message	String	Refer to the exception.message on the exchange, is null if no exception set on exchange. Will fallback and grab caught exceptions (Exchange.EXCEPTION_CAUGHT) if the Exchange has any.
exception.stacktrace	String	Camel 2.6. Refer to the exception.stacktrace on the exchange, is null if no exception set on exchange. Will fallback and grab caught exceptions (Exchange.EXCEPTION_CAUGHT) if the Exchange has any.

Variable	Type	Description
date:command_	Date	Evaluates to a Date object. Supported commands are: now for current timestamp, in.header.xxx or header.xxx to use the Date object in the IN header with the key xxx. out.header.xxx to use the Date object in the OUT header with the key xxx. property.xxx to use the Date object in the exchange property with the key xxx. file for the last modified timestamp of the file (available with a File consumer). Command accepts offsets such as: now-24h or in.header.xxx+1h or even now+1h30m-100 .
date:command:pattern_	String	Date formatting using java.text.SimpleDateFormat patterns.
date-with-timezone:command:timezone:pattern_	String	Date formatting using java.text.SimpleDateFormat timezones and patterns.
bean:_bean expression_	Object	Invoking a bean expression using the Bean language. Specifying a method name you must use dot as separator. We also support the ?method=methodname syntax that is used by the Bean component.
properties:_locations:key_	String	Deprecated (use properties-location instead) Camel 2.3: Lookup a property with the given key. The locations option is optional. See more at Using PropertyPlaceholder.
properties-location:_http://locationskey [locations:key] -	String	Camel 2.14.1: Lookup a property with the given key. The locations option is optional. See more at Using PropertyPlaceholder.
properties:key:default	String	Camel 2.14.1: Lookup a property with the given key. If the key does not exist or has no value, then an optional default value can be specified.
routeId	String	Camel 2.11: Returns the id of the current route the Exchange is being routed.

Variable	Type	Description
threadName	String	Camel 2.3: Returns the name of the current thread. Can be used for logging purpose.
ref:xxx	Object	Camel 2.6: To lookup a bean from the Registry with the given id.
type:name.field	Object	Camel 2.11: To refer to a type or field by its FQN name. To refer to a field you can append <code>.FIELD_NAME</code> . For example you can refer to the constant field from Exchange as: org.apache.camel.Exchange.FILE_NAME
null	null	Camel 2.12.3: represents a null
random_(value)_	Integer	*Camel 2.16.0:*returns a random Integer between 0 (included) and <i>value</i> (excluded)
random_(min,max)_	Integer	*Camel 2.16.0:*returns a random Integer between <i>min</i> (included) and <i>max</i> (excluded)
collate(group)	List	Camel 2.17: The collate function iterates the message body and groups the data into sub lists of specified size. This can be used with the Splitter EIP to split a message body and group/batch the splitted sub message into a group of N sub lists. This method works similar to the collate method in Groovy.
skip(number)	Iterator	Camel 2.19: The skip function iterates the message body and skips the first number of items. This can be used with the Splitter EIP to split a message body and skip the first N number of items.
messageHistory	String	Camel 2.17: The message history of the current exchange how it has been routed. This is similar to the route stack-trace message history the error handler logs in case of an unhandled exception.
messageHistory(false)	String	Camel 2.17: As messageHistory but without the exchange details (only includes the route stack-trace). This can be used if you do not want to log sensitive data from the message itself.

303.4. OGNL EXPRESSION SUPPORT

Available as of Camel 2.3

INFO:Camel's OGNL support is for invoking methods only. You cannot access fields. From **Camel 2.11.1** onwards we added special support for accessing the length field of Java arrays.

The [Simple](#) and [Bean](#) language now supports a Camel OGNL notation for invoking beans in a chain like fashion. Suppose the Message IN body contains a POJO which has a **getAddress()** method.

Then you can use Camel OGNL notation to access the address object:

```
simple("${body.address}")
simple("${body.address.street}")
simple("${body.address.zip}")
```

Camel understands the shorthand names for getters, but you can invoke any method or use the real name such as:

```
simple("${body.address}")
simple("${body.getAddress.getStreet}")
simple("${body.address.getZip}")
simple("${body.doSomething}")
```

You can also use the null safe operator (**?.**) to avoid NPE if for example the body does NOT have an address

```
simple("${body?.address?.street}")
```

It is also possible to index in **Map** or **List** types, so you can do:

```
simple("${body[foo].name}")
```

To assume the body is **Map** based and lookup the value with **foo** as key, and invoke the **getName** method on that value.

If the key has space, then you **must** enclose the key with quotes, for example 'foo bar':

```
simple("${body['foo bar'].name}")
```

You can access the **Map** or **List** objects directly using their key name (with or without dots) :

```
simple("${body[foo]}")
simple("${body[this.is.foo]}")
```

Suppose there was no value with the key **foo** then you can use the null safe operator to avoid the NPE as shown:

```
simple("${body[foo]?.name}")
```

You can also access **List** types, for example to get lines from the address you can do:

```
simple("${body.address.lines[0]}")
simple("${body.address.lines[1]}")
simple("${body.address.lines[2]}")
```

There is a special **last** keyword which can be used to get the last value from a list.

```
simple("${body.address.lines[last]}")
```

And to get the 2nd last you can subtract a number, so we can use **last-1** to indicate this:

```
simple("${body.address.lines[last-1]}")
```

And the 3rd last is of course:

```
simple("${body.address.lines[last-2]}")
```

And you can call the size method on the list with

```
simple("${body.address.lines.size}")
```

From **Camel 2.11.1** onwards we added support for the length field for Java arrays as well, eg:

```
String[] lines = new String[]{"foo", "bar", "cat"};
exchange.getIn().setBody(lines);
```

```
simple("There are ${body.length} lines")
```

And yes you can combine this with the operator support as shown below:

```
simple("${body.address.zip} > 1000")
```

303.5. OPERATOR SUPPORT

The parser is limited to only support a single operator.

To enable it the left value must be enclosed in ``${ }``. The syntax is:

```
`${leftValue} OP rightValue`
```

Where the **rightValue** can be a String literal enclosed in `' '`, **null**, a constant value or another expression enclosed in ``${ }``.

IMPORTANT

There **must** be spaces around the operator.

Camel will automatically type convert the rightValue type to the leftValue type, so it is able to eg. convert a string into a numeric so you can use `>` comparison for numeric values.

The following operators are supported:

Operator	Description
<code>==</code>	equals
<code>=~</code>	Camel 2.16: equals ignore case (will ignore case when comparing String values)
<code>></code>	greater than
<code>>=</code>	greater than or equals

Operator	Description
<	less than
≤	less than or equals
!=	not equals
contains	For testing if contains in a string based value
not contains	For testing if not contains in a string based value
~~	For testing if contains by ignoring case sensitivity in a string based value
regex	For matching against a given regular expression pattern defined as a String value
not regex	For not matching against a given regular expression pattern defined as a String value
in	For matching if in a set of values, each element must be separated by comma. If you want to include an empty value, then it must be defined using double comma, eg '„bronze,silver,gold', which is a set of four values with an empty value and then the three medals.
not in	For matching if not in a set of values, each element must be separated by comma. If you want to include an empty value, then it must be defined using double comma, eg '„bronze,silver,gold', which is a set of four values with an empty value and then the three medals.
is	For matching if the left hand side type is an instance of the value.
not is	For matching if the left hand side type is not an instance of the value.
range	For matching if the left hand side is within a range of values defined as numbers: from..to . From Camel 2.9 onwards the range values must be enclosed in single quotes.
not range	For matching if the left hand side is not within a range of values defined as numbers: from..to . From Camel 2.9 onwards the range values must be enclosed in single quotes.

Operator	Description
starts with	Camel 2.17.1, 2.18: For testing if the left hand side string starts with the right hand string.
ends with	Camel 2.17.1, 2.18: For testing if the left hand side string ends with the right hand string.

And the following unary operators can be used:

Operator	Description
++	Camel 2.9: To increment a number by one. The left hand side must be a function, otherwise parsed as literal.
--	Camel 2.9: To decrement a number by one. The left hand side must be a function, otherwise parsed as literal.
\	Camel 2.9.3 to 2.10.x To escape a value, eg \\$, to indicate a \$ sign. Special: Use \n for new line, \t for tab, and \r for carriage return. Notice: Escaping is not supported using the File Language . Notice: From Camel 2.11 onwards the escape character is no longer support, but replaced with the following three special escaping.
\n	Camel 2.11: To use newline character.
\t	Camel 2.11: To use tab character.
\r	Camel 2.11: To use carriage return character.
\}	Camel 2.18: To use the } character as text

And the following logical operators can be used to group expressions:

Operator	Description
and	deprecated use && instead. The logical and operator is used to group two expressions.
or	deprecated use instead. The logical or operator is used to group two expressions.

Operator	Description
&&	Camel 2.9: The logical and operator is used to group two expressions.
	Camel 2.9: The logical or operator is used to group two expressions.

IMPORTANT

Using and,or operators In **Camel 2.4 or older** the **and** or **or** can only be used **once** in a simple language expression. From **Camel 2.5** onwards you can use these operators multiple times.

The syntax for AND is:

```
${leftValue} OP rightValue and ${leftValue} OP rightValue
```

And the syntax for OR is:

```
${leftValue} OP rightValue or ${leftValue} OP rightValue
```

Some examples:

```
// exact equals match
simple("${in.header.foo} == 'foo'")
```

```
// ignore case when comparing, so if the header has value FOO this will match
simple("${in.header.foo} =~ 'foo'")
```

```
// here Camel will type convert '100' into the type of in.header.bar and if it is an Integer '100' will also
be converter to an Integer
simple("${in.header.bar} == '100'")
```

```
simple("${in.header.bar} == 100")
```

```
// 100 will be converter to the type of in.header.bar so we can do > comparison
simple("${in.header.bar} > 100")
```

303.5.1. Comparing with different types

When you compare with different types such as String and int, then you have to take a bit care. Camel will use the type from the left hand side as 1st priority. And fallback to the right hand side type if both values couldn't be compared based on that type.

This means you can flip the values to enforce a specific type. Suppose the bar value above is a String. Then you can flip the equation:

```
simple("100 < ${in.header.bar}")
```

which then ensures the int type is used as 1st priority.

This may change in the future if the Camel team improves the binary comparison operations to prefer numeric types over String based. It's most often the String type which causes problem when comparing with numbers.

```
// testing for null
simple("${in.header.baz} == null")

// testing for not null
simple("${in.header.baz} != null")
```

And a bit more advanced example where the right value is another expression

```
simple("${in.header.date} == ${date:now:yyyyMMdd}")

simple("${in.header.type} == ${bean:orderService?method=getOrderType}")
```

And an example with contains, testing if the title contains the word Camel

```
simple("${in.header.title} contains 'Camel'")
```

And an example with regex, testing if the number header is a 4 digit value:

```
simple("${in.header.number} regex '\\d{4}'")
```

And finally an example if the header equals any of the values in the list. Each element must be separated by comma, and no space around.

This also works for numbers etc, as Camel will convert each element into the type of the left hand side.

```
simple("${in.header.type} in 'gold,silver'")
```

And for all the last 3 we also support the negate test using not:

```
simple("${in.header.type} not in 'gold,silver'")
```

And you can test if the type is a certain instance, eg for instance a String

```
simple("${in.header.type} is 'java.lang.String'")
```

We have added a shorthand for all **java.lang** types so you can write it as:

```
simple("${in.header.type} is 'String'")
```

Ranges are also supported. The range interval requires numbers and both from and end are inclusive. For instance to test whether a value is between 100 and 199:

```
simple("${in.header.number} range 100..199")
```

Notice we use `..` in the range without spaces. It is based on the same syntax as Groovy.

From **Camel 2.9** onwards the range value must be in single quotes

```
simple("${in.header.number} range '100..199'")
```

303.5.2. Using Spring XML

As the Spring XML does not have all the power as the Java DSL with all its various builder methods, you have to resort to use some other languages for testing with simple operators. Now you can do this with the simple language. In the sample below we want to test if the header is a widget order:

```
<from uri="seda:orders">
  <filter>
    <simple>${in.header.type} == 'widget'</simple>
    <to uri="bean:orderService?method=handleWidget"/>
  </filter>
</from>
```

303.6. USING AND / OR

If you have two expressions you can combine them with the **and** or **or** operator.

TIP

Camel 2.9 onwards Use `&&` or `||` from Camel 2.9 onwards.

For instance:

```
simple("${in.header.title} contains 'Camel' and ${in.header.type} == 'gold'")
```

And of course the **or** is also supported. The sample would be:

```
simple("${in.header.title} contains 'Camel' or ${in.header.type} == 'gold'")
```

Notice: Currently **and** or **or** can only be used **once** in a simple language expression. This might change in the future.

So you **cannot** do:

```
simple("${in.header.title} contains 'Camel' and ${in.header.type} == 'gold' and ${in.header.number}
range 100..200")
```

303.7. SAMPLES

In the Spring XML sample below we filter based on a header value:

```
<from uri="seda:orders">
  <filter>
    <simple>${in.header.foo}</simple>
    <to uri="mock:fooOrders"/>
  </filter>
</from>
```

The Simple language can be used for the predicate test above in the Message Filter pattern, where we test if the in message has a **foo** header (a header with the key **foo** exists). If the expression evaluates to **true** then the message is routed to the **mock:fooOrders** endpoint, otherwise the message is dropped.

The same example in Java DSL:

```
from("seda:orders")
  .filter().simple("${in.header.foo}")
  .to("seda:fooOrders");
```

You can also use the simple language for simple text concatenations such as:

```
from("direct:hello")
  .transform().simple("Hello ${in.header.user} how are you?")
  .to("mock:reply");
```

Notice that we must use ``${}`` placeholders in the expression now to allow Camel to parse it correctly.

And this sample uses the date command to output current date.

```
from("direct:hello")
  .transform().simple("The today is ${date:now:yyyyMMdd} and it is a great day.")
  .to("mock:reply");
```

And in the sample below we invoke the bean language to invoke a method on a bean to be included in the returned string:

```
from("direct:order")
  .transform().simple("OrderId: ${bean:orderIdGenerator}")
  .to("mock:reply");
```

Where **orderIdGenerator** is the id of the bean registered in the Registry. If using Spring then it is the Spring bean id.

If we want to declare which method to invoke on the order id generator bean we must prepend **.methodName** such as below where we invoke the **generateId** method.

```
from("direct:order")
  .transform().simple("OrderId: ${bean:orderIdGenerator.generateId}")
  .to("mock:reply");
```

We can use the **?method=methodName** option that we are familiar with the [Bean](#) component itself:

```
from("direct:order")
  .transform().simple("OrderId: ${bean:orderIdGenerator?method=generateId}")
  .to("mock:reply");
```

And from Camel 2.3 onwards you can also convert the body to a given type, for example to ensure that it is a String you can do:

```
<transform>
  <simple>Hello ${bodyAs(String)} how are you?</simple>
</transform>
```

There are a few types which have a shorthand notation, so we can use **String** instead of **java.lang.String**. These are: **byte[]**, **String**, **Integer**, **Long**. All other types must use their FQN name, e.g. **org.w3c.dom.Document**.

It is also possible to lookup a value from a header **Map** in **Camel 2.3** onwards:

```
<transform>
  <simple>The gold value is ${header.type[gold]}</simple>
</transform>
```

In the code above we lookup the header with name **type** and regard it as a **java.util.Map** and we then lookup with the key **gold** and return the value. If the header is not convertible to Map an exception is thrown. If the header with name **type** does not exist **null** is returned.

From Camel 2.9 onwards you can nest functions, such as shown below:

```
<setHeader headerName="myHeader">
  <simple>${properties:${header.someKey}}</simple>
</setHeader>
```

303.8. REFERRING TO CONSTANTS OR ENUMS

Available as of Camel 2.11

Suppose you have an enum for customers

And in a Content Based Router we can use the [Simple](#) language to refer to this enum, to check the message which enum it matches.

303.9. USING NEW LINES OR TABS IN XML DSLS

Available as of Camel 2.9.3

From Camel 2.9.3 onwards it is easier to specify new lines or tabs in XML DSLs as you can escape the value now

```
<transform>
  <simple>The following text\nis on a new line</simple>
</transform>
```

303.10. LEADING AND TRAILING WHITESPACE HANDLING

Available as of Camel 2.10.0

From Camel 2.10.0 onwards, the trim attribute of the expression can be used to control whether the leading and trailing whitespace characters are removed or preserved. The default value is true, which removes the whitespace characters.

```
<setBody>
  <simple trim="false">You get some trailing whitespace characters. </simple>
</setBody>
```

303.11. SETTING RESULT TYPE

Available as of Camel 2.8

You can now provide a result type to the [Simple](#) expression, which means the result of the evaluation will be converted to the desired type. This is most useable to define types such as booleans, integers, etc.

For example to set a header as a boolean type you can do:

```
.setHeader("cool", simple("true", Boolean.class))
```

And in XML DSL

```
<setHeader headerName="cool">
  <!-- use resultType to indicate that the type should be a java.lang.Boolean -->
  <simple resultType="java.lang.Boolean">true</simple>
</setHeader>
```

303.12. CHANGING FUNCTION START AND END TOKENS

Available as of Camel 2.9.1

You can configure the function start and end tokens - ``${ }`` using the setters **changeFunctionStartToken** and **changeFunctionEndToken** on **SimpleLanguage**, using Java code. From Spring XML you can define a `<bean>` tag with the new changed tokens in the properties as shown below:

```
<!-- configure Simple to use custom prefix/suffix tokens -->
<bean id="simple" class="org.apache.camel.language.simple.SimpleLanguage">
  <property name="functionStartToken" value="["/>
  <property name="functionEndToken" value="]"/>
</bean>
```

In the example above we use `[]` as the changed tokens.

Notice by changing the start/end token you change those in all the Camel applications which share the same **camel-core** on their classpath. For example in an OSGi server this may affect many applications, where as a Web Application as a WAR file it only affects the Web Application.

303.13. LOADING SCRIPT FROM EXTERNAL RESOURCE

Available as of Camel 2.11

You can externalize the script and have Camel load it from a resource such as **"classpath:"**, **"file:"**, or **"http:"**.

This is done using the following syntax: **"resource:scheme:location"**, eg to refer to a file on the classpath you can do:

```
.setHeader("myHeader").simple("resource:classpath:mysimple.txt")
```

303.14. SETTING SPRING BEANS TO EXCHANGE PROPERTIES

Available as of Camel 2.6

You can set a spring bean into an exchange property as shown below:

```
<bean id="myBeanId" class="my.package.MyCustomClass" />
...
<route>
  ...
  <setProperty propertyName="monitoring.message">
    <simple>ref:myBeanId</simple>
  </setProperty>
  ...
</route>
```

303.15. DEPENDENCIES

The [Simple](#) language is part of **camel-core**.

CHAPTER 304. SIP COMPONENT

Available as of Camel version 2.5

The **sip** component in Camel is a communication component, based on the Jain SIP implementation (available under the JCP license).

Session Initiation Protocol (SIP) is an IETF-defined signaling protocol, widely used for controlling multimedia communication sessions such as voice and video calls over Internet Protocol (IP). The SIP protocol is an Application Layer protocol designed to be independent of the underlying transport layer; it can run on Transmission Control Protocol (TCP), User Datagram Protocol (UDP) or Stream Control Transmission Protocol (SCTP).

The Jain SIP implementation supports TCP and UDP only.

The Camel SIP component **only** supports the SIP Publish and Subscribe capability as described in the [RFC3903 - Session Initiation Protocol \(SIP\) Extension for Event](#)

This camel component supports both producer and consumer endpoints.

Camel SIP Producers (Event Publishers) and SIP Consumers (Event Subscribers) communicate event & state information to each other using an intermediary entity called a SIP Presence Agent (a stateful brokering entity).

For SIP based communication, a SIP Stack with a listener **must** be instantiated on both the SIP Producer and Consumer (using separate ports if using localhost). This is necessary in order to support the handshakes & acknowledgements exchanged between the SIP Stacks during communication.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-sip</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

304.1. URI FORMAT

The URI scheme for a sip endpoint is as follows:

```
sip://johndoe@localhost:99999[?options]
sips://johndoe@localhost:99999/[?options]
```

This component supports producer and consumer endpoints for both TCP and UDP.

You can append query options to the URI in the following format, **?option=value&option=value&...**

304.2. OPTIONS

The SIP Component offers an extensive set of configuration options & capability to create custom stateful headers needed to propagate state via the SIP protocol.

The SIP component has no options.

The SIP endpoint is configured using URI syntax:

```
sip:uri
```

with the following path and query parameters:

304.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
uri	Required URI of the SIP server to connect to (the username and password can be included such as: john:secretmyserver:9999)		URI

304.2.2. Query Parameters (44 parameters):

Name	Description	Default	Type
cacheConnections (common)	Should connections be cached by the SipStack to reduce cost of connection creation. This is useful if the connection is used for long running conversations.	false	boolean
contentSubType (common)	Setting for contentSubType can be set to any valid MimeSubType.	plain	String
contentType (common)	Setting for contentType can be set to any valid MimeType.	text	String
eventHeaderName (common)	Setting for a String based event type.		String
eventId (common)	Setting for a String based event Id. Mandatory setting unless a registry based FromHeader is specified		String
fromHost (common)	Hostname of the message originator. Mandatory setting unless a registry based FromHeader is specified		String
fromPort (common)	Port of the message originator. Mandatory setting unless a registry based FromHeader is specified		int
fromUser (common)	Username of the message originator. Mandatory setting unless a registry based custom FromHeader is specified.		String

Name	Description	Default	Type
msgExpiration (common)	The amount of time a message received at an endpoint is considered valid	3600	int
receiveTimeoutMillis (common)	Setting for specifying amount of time to wait for a Response and/or Acknowledgement can be received from another SIP stack	10000	long
stackName (common)	Name of the SIP Stack instance associated with an SIP Endpoint.	NAME_NOT_SET	String
toHost (common)	Hostname of the message receiver. Mandatory setting unless a registry based ToHeader is specified		String
toPort (common)	Portname of the message receiver. Mandatory setting unless a registry based ToHeader is specified		int
toUser (common)	Username of the message receiver. Mandatory setting unless a registry based custom ToHeader is specified.		String
transport (common)	Setting for choice of transport protocol. Valid choices are tcp or udp.	tcp	String
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
consumer (consumer)	This setting is used to determine whether the kind of header (FromHeader,ToHeader etc) that needs to be created for this endpoint	false	boolean
presenceAgent (consumer)	This setting is used to distinguish between a Presence Agent & a consumer. This is due to the fact that the SIP Camel component ships with a basic Presence Agent (for testing purposes only). Consumers have to set this flag to true.	false	boolean

Name	Description	Default	Type
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
addressFactory (advanced)	To use a custom AddressFactory		AddressFactory
callIdHeader (advanced)	A custom Header object containing call details. Must implement the type javax.sip.header.CallIdHeader		CallIdHeader
contactHeader (advanced)	An optional custom Header object containing verbose contact details (email, phone number etc). Must implement the type javax.sip.header.ContactHeader		ContactHeader
contentTypeHeader (advanced)	A custom Header object containing message content details. Must implement the type javax.sip.header.ContentTypeHeader		ContentTypeHeader
eventHeader (advanced)	A custom Header object containing event details. Must implement the type javax.sip.header.EventHeader		EventHeader
expiresHeader (advanced)	A custom Header object containing message expiration details. Must implement the type javax.sip.header.ExpiresHeader		ExpiresHeader
extensionHeader (advanced)	A custom Header object containing user/application specific details. Must implement the type javax.sip.header.ExtensionHeader		ExtensionHeader
fromHeader (advanced)	A custom Header object containing message originator settings. Must implement the type javax.sip.header.FromHeader		FromHeader
headerFactory (advanced)	To use a custom HeaderFactory		HeaderFactory
listeningPoint (advanced)	To use a custom ListeningPoint implementation		ListeningPoint

Name	Description	Default	Type
maxForwardsHeader (advanced)	A custom Header object containing details on maximum proxy forwards. This header places a limit on the viaHeaders possible. Must implement the type <code>javax.sip.header.MaxForwardsHeader</code>		MaxForwardsHeader
maxMessageSize (advanced)	Setting for maximum allowed Message size in bytes.	1048576	int
messageFactory (advanced)	To use a custom MessageFactory		MessageFactory
sipFactory (advanced)	To use a custom SipFactory to create the SipStack to be used		SipFactory
sipStack (advanced)	To use a custom SipStack		SipStack
sipUri (advanced)	To use a custom SipURI. If none configured, then the SipUri fallback to use the options <code>toUser</code> <code>toHost</code> : <code>toPort</code>		SipURI
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
toHeader (advanced)	A custom Header object containing message receiver settings. Must implement the type <code>javax.sip.header.ToHeader</code>		ToHeader
viaHeaders (advanced)	List of custom Header objects of the type <code>javax.sip.header.ViaHeader</code> . Each ViaHeader containing a proxy address for request forwarding. (Note this header is automatically updated by each proxy when the request arrives at its listener)		List
implementationDebugLogFile (logging)	Name of client debug log file to use for logging		String
implementationServerLogFile (logging)	Name of server log file to use for logging		String
implementationTraceLevel (logging)	Logging level for tracing	0	String

Name	Description	Default	Type
maxForwards (proxy)	Number of maximum proxy forwards		int
useRouterForAllUris (proxy)	This setting is used when requests are sent to the Presence Agent via a proxy.	false	boolean

304.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.component.sip.enabled	Enable sip component	true	Boolean
camel.component.sip.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

304.4. SENDING MESSAGES TO/FROM A SIP ENDPOINT

304.4.1. Creating a Camel SIP Publisher

In the example below, a SIP Publisher is created to send SIP Event publications to a user "agent@localhost:5152". This is the address of the SIP Presence Agent which acts as a broker between the SIP Publisher and Subscriber

- using a SIP Stack named client
- using a registry based eventHeader called evtHdrName
- using a registry based eventId called evtId
- from a SIP Stack with Listener set up as user2@localhost:3534
- The Event being published is EVENT_A
- A Mandatory Header called REQUEST_METHOD is set to Request.Publish thereby setting up the endpoint as a Event publisher"

```
producerTemplate.sendBodyAndHeader(
    "sip://agent@localhost:5152?
stackName=client&eventHeaderName=evtHdrName&eventId=evtId&fromUser=user2&fromHost=localhost&fromPort=3534",
```

```
"EVENT_A",
"REQUEST_METHOD",
Request.PUBLISH);
```

304.4.2. Creating a Camel SIP Subscriber

In the example below, a SIP Subscriber is created to receive SIP Event publications sent to a user "johndoe@localhost:5154"

- using a SIP Stack named Subscriber
- registering with a Presence Agent user called agent@localhost:5152
- using a registry based eventHeader called evtHdrName. The evtHdrName contains the Event which is set to "Event_A"
- using a registry based eventId called eventId

```
@Override
protected RouteBuilder createRouteBuilder() throws Exception {
    return new RouteBuilder() {
        @Override
        public void configure() throws Exception {
            // Create PresenceAgent
            from("sip://agent@localhost:5152?
stackName=PresenceAgent&presenceAgent=true&eventHeaderName=evtHdrName&eventId=")
                .to("mock:neverland");

            // Create Sip Consumer(Event Subscriber)
            from("sip://johndoe@localhost:5154?
stackName=Subscriber&toUser=agent&toHost=localhost&toPort=5152&eventHeaderName=evtHdrName&eventId=eventId")
                .to("log:ReceivedEvent?level=DEBUG")
                .to("mock:notification");
        }
    };
}
```

The Camel SIP component also ships with a Presence Agent that is meant to be used for Testing and Demo purposes only. An example of instantiating a Presence Agent is given above.

Note that the Presence Agent is set up as a user agent@localhost:5152 and is capable of communicating with both Publisher as well as Subscriber. It has a separate SIP stackName distinct from Publisher as well as Subscriber. While it is set up as a Camel Consumer, it does not actually send any messages along the route to the endpoint "mock:neverland".

CHAPTER 305. SIMPLE JMS BATCH COMPONENT

Available as of Camel version 2.16

SJMS Batch is a specialized component for highly performant, transactional batch consumption from a JMS queue. It can be thought of as a hybrid of a consumer-only component and an aggregator.

A common use case in Camel is to consume messages from a queue and aggregate them before sending the aggregated state to another endpoint. In order to ensure that data is not lost if the system performing the processing fails, it is typically consumed within a transaction from the queue, and once aggregated stored in a persistent **AggregationRepository**, such as the one found in the [JDBC Component](#).

The behavior of the aggregator pattern involves fetching data from the **AggregationRepository** before an incoming message is aggregated, and writing back the result afterwards. By nature, the reads and writes take progressively longer as the number of aggregated artifacts increases. A rough example of this using arbitrary time units that demonstrates the impact of this is as follows:

Item	Read Time	Write Time	Total Time
0	0	1	1
1	1	2	4
2	2	3	9
3	3	4	16
4	4	5	25
5	5	6	36
6	6	7	49
7	7	8	64
8	8	9	81
9	9	10	100

In contrast, consumption performance using the SJMS Batch component is linear. Each message is consumed and aggregated using an **AggregationStrategy** before the next one is fetched. As all of the consumption and aggregation is performed in a single JMS transaction no external storage is required to persist the intermediate state - this avoids the read and write costs described above. In practice, this yields multiple orders of magnitude higher throughput.

Once a completion condition is met, either by size or period since first message, the aggregated **Exchange** is passed into the route. During the processing of this **Exchange**, if an exception is thrown or the system shuts down, all of the original consumed messages end up back on the queue (or are placed on the dead-letter queue depending on the broker configuration).

Unlike using a regular aggregator, there is no facility for an aggregation condition, meaning that it is not possible to batch consume into multiple groups of messages. All consumed messages are aggregated together into a single batch.

Multiple JMS consumer support is available which allows you to consume in parallel using the one route, and at the same time use facilities like JMS message groups to group related messages.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-sjms</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

305.1. URI FORMAT

```
sjms:[queue:]destinationName[?options]
```

Where **destinationName** is a JMS queue. By default, the **destinationName** is interpreted as a queue name.

```
sjms:FOO.BAR
```

You can include the optional **queue:** prefix, if you prefer:

```
sjms:queue:FOO.BAR
```

Topic consumption is not supported, as there is no advantage to using batch consumption within that context. Topic messages are usually non-persistent, and loss is acceptable. If consumed within a transaction that fails, a topic message will likely not be redelivered by the broker. A plain [SJMS](#) consumer endpoint can be used in conjunction with a regular non-persistence backed aggregator in this scenario.

305.2. COMPONENT OPTIONS AND CONFIGURATIONS

The Simple JMS Batch component supports 5 options, which are listed below.

Name	Description	Default	Type
connectionFactory (advanced)	A ConnectionFactory is required to enable the SjsmsBatchComponent.		ConnectionFactory

Name	Description	Default	Type
asyncStartListener (advanced)	Whether to startup the consumer message listener asynchronously, when starting a route. For example if a JmsConsumer cannot get a connection to a remote JMS broker, then it may block while retrying and/or failover. This will cause Camel to block while starting routes. By setting this option to true, you will let routes startup, while the JmsConsumer connects to the JMS broker using a dedicated thread in asynchronous mode. If this option is used, then beware that if the connection could not be established, then an exception is logged at WARN level, and the consumer will not be able to receive messages; You can then restart the route to retry.	false	boolean
recoveryInterval (advanced)	Specifies the interval between recovery attempts, i.e. when a connection is being refreshed, in milliseconds. The default is 5000 ms, that is, 5 seconds.	5000	int
headerFilterStrategy (filter)	To use a custom org.apache.camel.spi.HeaderFilterStrategy to filter header to and from Camel message.		HeaderFilterStrategy
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Simple JMS Batch endpoint is configured using URI syntax:

```
sjms-batch:destinationName
```

with the following path and query parameters:

305.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
destinationName	Required The destination name. Only queues are supported, names may be prefixed by 'queue:'.		String

305.2.2. Query Parameters (23 parameters):

Name	Description	Default	Type
aggregationStrategy (consumer)	Required The aggregation strategy to use, which merges all the batched messages into a single message		AggregationStrategy
allowNullBody (consumer)	Whether to allow sending messages with no body. If this option is false and the message body is null, then an JMSEException is thrown.	true	boolean
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
completionInterval (consumer)	The completion interval in millis, which causes batches to be completed in a scheduled fixed rate every interval. The batch may be empty if the timeout triggered and there was no messages in the batch. Notice you cannot use both completion timeout and completion interval at the same time, only one can be configured.	1000	int
completionPredicate (consumer)	The completion predicate, which causes batches to be completed when the predicate evaluates as true. The predicate can also be configured using the simple language using the string syntax. You may want to set the option eagerCheckCompletion to true to let the predicate match the incoming message, as otherwise it matches the aggregated message.		String
completionSize (consumer)	The number of messages consumed at which the batch will be completed	200	int
completionTimeout (consumer)	The timeout in millis from receipt of the first first message when the batch will be completed. The batch may be empty if the timeout triggered and there was no messages in the batch. Notice you cannot use both completion timeout and completion interval at the same time, only one can be configured.	500	int
consumerCount (consumer)	The number of JMS sessions to consume from	1	int

Name	Description	Default	Type
eagerCheckCompletion (consumer)	Use eager completion checking which means that the completionPredicate will use the incoming Exchange. As opposed to without eager completion checking the completionPredicate will use the aggregated Exchange.	false	boolean
includeAllJMSXProperties (consumer)	Whether to include all JMSXxxx properties when mapping from JMS to Camel Message. Setting this to true will include properties such as JMSXAppID, and JMSXUserID etc. Note: If you are using a custom headerFilterStrategy then this option does not apply.	false	boolean
mapJmsMessage (consumer)	Specifies whether Camel should auto map the received JMS message to a suited payload type, such as javax.jms.TextMessage to a String etc. See section about how mapping works below for more details.	true	boolean
pollDuration (consumer)	The duration in milliseconds of each poll for messages. completionTimeOut will be used if it is shorter and a batch has started.	1000	int
sendEmptyMessageWhenIdle (consumer)	If using completion timeout or interval, then the batch may be empty if the timeout triggered and there was no messages in the batch. If this option is true and the batch is empty then an empty message is added to the batch so an empty message is routed.	false	boolean
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
asyncStartListener (advanced)	Whether to startup the consumer message listener asynchronously, when starting a route. For example if a JmsConsumer cannot get a connection to a remote JMS broker, then it may block while retrying and/or failover. This will cause Camel to block while starting routes. By setting this option to true, you will let routes startup, while the JmsConsumer connects to the JMS broker using a dedicated thread in asynchronous mode. If this option is used, then beware that if the connection could not be established, then an exception is logged at WARN level, and the consumer will not be able to receive messages; You can then restart the route to retry.	false	boolean

Name	Description	Default	Type
headerFilterStrategy (advanced)	To use a custom HeaderFilterStrategy to filter header to and from Camel message.		HeaderFilterStrategy
jmsKeyFormatStrategy (advanced)	Pluggable strategy for encoding and decoding JMS keys so they can be compliant with the JMS specification. Camel provides two implementations out of the box: default and passthrough. The default strategy will safely marshal dots and hyphens (. and -). The passthrough strategy leaves the key as is. Can be used for JMS brokers which do not care whether JMS header keys contain illegal characters. You can provide your own implementation of the org.apache.camel.component.jms.JmsKeyFormatStrategy and refer to it using the # notation.		JmsKeyFormatStrategy
keepAliveDelay (advanced)	The delay in millis between attempts to re-establish a valid session. If this is a positive value the SjsBatchConsumer will attempt to create a new session if it sees an IllegalStateException during message consumption. This delay value allows you to pause between attempts to prevent spamming the logs. If this is a negative value (default is -1) then the SjsBatchConsumer will behave as it always has before - that is it will bail out and the route will shut down if it sees an IllegalStateException.	-1	int
messageCreatedStrategy (advanced)	To use the given MessageCreatedStrategy which are invoked when Camel creates new instances of javax.jms.Message objects when Camel is sending a JMS message.		MessageCreatedStrategy
recoveryInterval (advanced)	Specifies the interval between recovery attempts, i.e. when a connection is being refreshed, in milliseconds. The default is 5000 ms, that is, 5 seconds.	5000	int
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
timeoutCheckerExecutorService (advanced)	If using the completionInterval option a background thread is created to trigger the completion interval. Set this option to provide a custom thread pool to be used rather than creating a new thread for every consumer.		ScheduledExecutorService

305.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 6 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.sjms-batch.async-start-listener</code>	Whether to startup the consumer message listener asynchronously, when starting a route. For example if a <code>JmsConsumer</code> cannot get a connection to a remote JMS broker, then it may block while retrying and/or failover. This will cause Camel to block while starting routes. By setting this option to true, you will let routes startup, while the <code>JmsConsumer</code> connects to the JMS broker using a dedicated thread in asynchronous mode. If this option is used, then beware that if the connection could not be established, then an exception is logged at WARN level, and the consumer will not be able to receive messages; You can then restart the route to retry.	false	Boolean
<code>camel.component.sjms-batch.connection-factory</code>	A <code>ConnectionFactory</code> is required to enable the <code>SjmsBatchComponent</code> . The option is a <code>javax.jms.ConnectionFactory</code> type.		String
<code>camel.component.sjms-batch.enabled</code>	Enable <code>sjms-batch</code> component	true	Boolean
<code>camel.component.sjms-batch.header-filter-strategy</code>	To use a custom <code>org.apache.camel.spi.HeaderFilterStrategy</code> to filter header to and from Camel message. The option is a <code>org.apache.camel.spi.HeaderFilterStrategy</code> type.		String
<code>camel.component.sjms-batch.recovery-interval</code>	Specifies the interval between recovery attempts, i.e. when a connection is being refreshed, in milliseconds. The default is 5000 ms, that is, 5 seconds.	5000	Integer
<code>camel.component.sjms-batch.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

The **completionSize** endpoint attribute is used in conjunction with **completionTimeout**, where the first condition to be met will cause the aggregated **Exchange** to be emitted down the route.

CHAPTER 306. SIMPLE JMS COMPONENT

Available as of Camel version 2.11

The Simple JMS Component, or SJMS, is a JMS client for use with Camel that uses well known best practices when it comes to JMS client creation and configuration. SJMS contains a brand new JMS client API written explicitly for Camel eliminating third party messaging implementations keeping it light and resilient. The following features is included:

- Standard Queue and Topic Support (Durable & Non-Durable)
- InOnly & InOut MEP Support
- Asynchronous Producer and Consumer Processing
- Internal JMS Transaction Support

Additional key features include:

- Pluggable Connection Resource Management
- Session, Consumer, & Producer Pooling & Caching Management
- Batch Consumers and Producers
- Transacted Batch Consumers & Producers
- Support for Customizable Transaction Commit Strategies (Local JMS Transactions only)

NOTE

Why the S in SJMS

S stands for Simple and Standard and Springless. Also camel-jms was already taken.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-sjms</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

306.1. URI FORMAT

```
sjms:[queue:|topic:]destinationName[?options]
```

Where **destinationName** is a JMS queue or topic name. By default, the **destinationName** is interpreted as a queue name. For example, to connect to the queue, **FOO.BAR** use:

```
sjms:FOO.BAR
```

You can include the optional **queue:** prefix, if you prefer:

```
sjms:queue:FOO.BAR
```

To connect to a topic, you *must* include the **topic:** prefix. For example, to connect to the topic, **Stocks.Prices**, use:

```
sjms:topic:Stocks.Prices
```

You append query options to the URI using the following format, **?option=value&option=value&...**

306.2. COMPONENT OPTIONS AND CONFIGURATIONS

The Simple JMS component supports 15 options, which are listed below.

Name	Description	Default	Type
connectionFactory (advanced)	A ConnectionFactory is required to enable the SjsmsComponent. It can be set directly or set set as part of a ConnectionResource.		ConnectionFactory
connectionResource (advanced)	A ConnectionResource is an interface that allows for customization and container control of the ConnectionFactory. See Pluggable Connection Resource Management for further details.		ConnectionResource
connectionCount (common)	The maximum number of connections available to endpoints started under this component	1	Integer
jmsKeyFormatStrategy (advanced)	Pluggable strategy for encoding and decoding JMS keys so they can be compliant with the JMS specification. Camel provides one implementation out of the box: default. The default strategy will safely marshal dots and hyphens (. and -). Can be used for JMS brokers which do not care whether JMS header keys contain illegal characters. You can provide your own implementation of the org.apache.camel.component.jms.JmsKeyFormatStrategy and refer to it using the # notation.		JmsKeyFormatStrategy
transactionCommit Strategy (transaction)	To configure which kind of commit strategy to use. Camel provides two implementations out of the box, default and batch.		TransactionCommit Strategy
destinationCreation Strategy (advanced)	To use a custom DestinationCreationStrategy.		DestinationCreation Strategy
timedTaskManager (advanced)	To use a custom TimedTaskManager		TimedTaskManager

Name	Description	Default	Type
messageCreatedStrategy (advanced)	To use the given MessageCreatedStrategy which are invoked when Camel creates new instances of javax.jms.Message objects when Camel is sending a JMS message.		MessageCreatedStrategy
connectionTestOnBorrow (advanced)	When using the default org.apache.camel.component.sjms.jms.ConnectionFactoryResource then should each javax.jms.Connection be tested (calling start) before returned from the pool.	true	boolean
connectionUsername (security)	The username to use when creating javax.jms.Connection when using the default org.apache.camel.component.sjms.jms.ConnectionFactoryResource.		String
connectionPassword (security)	The password to use when creating javax.jms.Connection when using the default org.apache.camel.component.sjms.jms.ConnectionFactoryResource.		String
connectionClientId (advanced)	The client ID to use when creating javax.jms.Connection when using the default org.apache.camel.component.sjms.jms.ConnectionFactoryResource.		String
connectionMaxWait (advanced)	The max wait time in millis to block and wait on free connection when the pool is exhausted when using the default org.apache.camel.component.sjms.jms.ConnectionFactoryResource.	5000	long
headerFilterStrategy (filter)	To use a custom org.apache.camel.spi.HeaderFilterStrategy to filter header to and from Camel message.		HeaderFilterStrategy
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Simple JMS endpoint is configured using URI syntax:

```
sjms:destinationType:destinationName
```

with the following path and query parameters:

306.2.1. Path Parameters (2 parameters):

Name	Description	Default	Type
destinationType	The kind of destination to use	queue	String
destinationName	Required DestinationName is a JMS queue or topic name. By default, the destinationName is interpreted as a queue name.		String

306.2.2. Query Parameters (34 parameters):

Name	Description	Default	Type
acknowledgmentMode (common)	The JMS acknowledgement name, which is one of: SESSION_TRANSACTED, CLIENT_ACKNOWLEDGE, AUTO_ACKNOWLEDGE, DUPS_OK_ACKNOWLEDGE	AUTO_ACKNOWLEDGE	SessionAcknowledgement Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
consumerCount (consumer)	Sets the number of consumer listeners used for this endpoint.	1	int
durableSubscriptionId (consumer)	Sets the durable subscription Id required for durable topics.		String
synchronous (consumer)	Sets whether synchronous processing should be strictly used or Camel is allowed to use asynchronous processing (if supported).	true	boolean
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern

Name	Description	Default	Type
messageSelector (consumer)	Sets the JMS Message selector syntax.		String
namedReplyTo (producer)	Sets the reply to destination name used for InOut producer endpoints. The type of the reply to destination can be determined by the starting prefix (topic: or queue:) in its name.		String
persistent (producer)	Flag used to enable/disable message persistence.	true	boolean
producerCount (producer)	Sets the number of producers used for this endpoint.	1	int
ttl (producer)	Flag used to adjust the Time To Live value of produced messages.	-1	long
allowNullBody (producer)	Whether to allow sending messages with no body. If this option is false and the message body is null, then an JMSEException is thrown.	true	boolean
prefillPool (producer)	Whether to prefill the producer connection pool on startup, or create connections lazy when needed.	true	boolean
responseTimeout (producer)	Sets the amount of time we should wait before timing out a InOut response.	5000	long
asyncStartListener (advanced)	Whether to startup the consumer message listener asynchronously, when starting a route. For example if a JmsConsumer cannot get a connection to a remote JMS broker, then it may block while retrying and/or failover. This will cause Camel to block while starting routes. By setting this option to true, you will let routes startup, while the JmsConsumer connects to the JMS broker using a dedicated thread in asynchronous mode. If this option is used, then beware that if the connection could not be established, then an exception is logged at WARN level, and the consumer will not be able to receive messages; You can then restart the route to retry.	false	boolean
asyncStopListener (advanced)	Whether to stop the consumer message listener asynchronously, when stopping a route.	false	boolean
connectionCount (advanced)	The maximum number of connections available to this endpoint		Integer

Name	Description	Default	Type
connectionFactory (advanced)	Initializes the connectionFactory for the endpoint, which takes precedence over the component's connectionFactory, if any		ConnectionFactory
connectionResource (advanced)	Initializes the connectionResource for the endpoint, which takes precedence over the component's connectionResource, if any		ConnectionResource
destinationCreationStrategy (advanced)	To use a custom DestinationCreationStrategy.		DestinationCreationStrategy
exceptionListener (advanced)	Specifies the JMS Exception Listener that is to be notified of any underlying JMS exceptions.		ExceptionListener
headerFilterStrategy (advanced)	To use a custom HeaderFilterStrategy to filter header to and from Camel message.		HeaderFilterStrategy
includeAllJMSXProperties (advanced)	Whether to include all JMSXxxx properties when mapping from JMS to Camel Message. Setting this to true will include properties such as JMSXAppID, and JMSXUserID etc. Note: If you are using a custom headerFilterStrategy then this option does not apply.	false	boolean
jmsKeyFormatStrategy (advanced)	Pluggable strategy for encoding and decoding JMS keys so they can be compliant with the JMS specification. Camel provides two implementations out of the box: default and passthrough. The default strategy will safely marshal dots and hyphens (. and -). The passthrough strategy leaves the key as is. Can be used for JMS brokers which do not care whether JMS header keys contain illegal characters. You can provide your own implementation of the org.apache.camel.component.jms.JmsKeyFormatStrategy and refer to it using the # notation.		JmsKeyFormatStrategy
mapJmsMessage (advanced)	Specifies whether Camel should auto map the received JMS message to a suited payload type, such as javax.jms.TextMessage to a String etc. See section about how mapping works below for more details.	true	boolean
messageCreatedStrategy (advanced)	To use the given MessageCreatedStrategy which are invoked when Camel creates new instances of javax.jms.Message objects when Camel is sending a JMS message.		MessageCreatedStrategy

Name	Description	Default	Type
errorHandlerLoggingLevel (logging)	Allows to configure the default errorHandler logging level for logging uncaught exceptions.	WARN	LogLevel
errorHandlerLogStackTrace (logging)	Allows to control whether stacktraces should be logged or not, by the default errorHandler.	true	boolean
transacted (transaction)	Specifies whether to use transacted mode	false	boolean
transactionBatchCount (transaction)	If transacted sets the number of messages to process before committing a transaction.	-1	int
transactionBatchTimeout (transaction)	Sets timeout (in millis) for batch transactions, the value should be 1000 or higher.	5000	long
transactionCommitStrategy (transaction)	Sets the commit strategy.		TransactionCommitStrategy
sharedJMSSession (transaction)	Specifies whether to share JMS session with other SJMS endpoints. Turn this off if your route is accessing to multiple JMS providers. If you need transaction against multiple JMS providers, use jms component to leverage XA transaction.	true	boolean

306.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 15 options, which are listed below.

Name	Description	Default	Type
camel.component.sjms.connection-client-id	The client ID to use when creating javax.jms.Connection when using the default org.apache.camel.component.sjms.jms.ConnectionFactoryResource.		String
camel.component.sjms.connection-count	The maximum number of connections available to endpoints started under this component	1	Integer

Name	Description	Default	Type
<code>camel.component.sjms.connection-factory</code>	A <code>ConnectionFactory</code> is required to enable the <code>SjmsComponent</code> . It can be set directly or set as part of a <code>ConnectionResource</code> . The option is a <code>javax.jms.ConnectionFactory</code> type.		String
<code>camel.component.sjms.connection-max-wait</code>	The max wait time in millis to block and wait on free connection when the pool is exhausted when using the default <code>org.apache.camel.component.sjms.jms.ConnectionFactoryResource</code> .	5000	Long
<code>camel.component.sjms.connection-password</code>	The password to use when creating <code>javax.jms.Connection</code> when using the default <code>org.apache.camel.component.sjms.jms.ConnectionFactoryResource</code> .		String
<code>camel.component.sjms.connection-resource</code>	A <code>ConnectionResource</code> is an interface that allows for customization and container control of the <code>ConnectionFactory</code> . See <code>Pluggable Connection Resource Management</code> for further details. The option is a <code>org.apache.camel.component.sjms.jms.ConnectionResource</code> type.		String
<code>camel.component.sjms.connection-test-on-borrow</code>	When using the default <code>org.apache.camel.component.sjms.jms.ConnectionFactoryResource</code> then should each <code>javax.jms.Connection</code> be tested (calling <code>start</code>) before returned from the pool.	true	Boolean
<code>camel.component.sjms.connection-username</code>	The username to use when creating <code>javax.jms.Connection</code> when using the default <code>org.apache.camel.component.sjms.jms.ConnectionFactoryResource</code> .		String
<code>camel.component.sjms.destination-creation-strategy</code>	To use a custom <code>DestinationCreationStrategy</code> . The option is a <code>org.apache.camel.component.sjms.jms.DestinationCreationStrategy</code> type.		String
<code>camel.component.sjms.enabled</code>	Enable <code>sjms</code> component	true	Boolean
<code>camel.component.sjms.header-filter-strategy</code>	To use a custom <code>org.apache.camel.spi.HeaderFilterStrategy</code> to filter header to and from Camel message. The option is a <code>org.apache.camel.spi.HeaderFilterStrategy</code> type.		String

Name	Description	Default	Type
<code>camel.component.sjms.jms-key-format-strategy</code>	Pluggable strategy for encoding and decoding JMS keys so they can be compliant with the JMS specification. Camel provides one implementation out of the box: default. The default strategy will safely marshal dots and hyphens (. and -). Can be used for JMS brokers which do not care whether JMS header keys contain illegal characters. You can provide your own implementation of the <code>org.apache.camel.component.jms.JmsKeyFormatStrategy</code> and refer to it using the # notation. The option is a <code>org.apache.camel.component.sjms.jms.JmsKeyFormatStrategy</code> type.		String
<code>camel.component.sjms.message-created-strategy</code>	To use the given <code>MessageCreatedStrategy</code> which are invoked when Camel creates new instances of <code>javax.jms.Message</code> objects when Camel is sending a JMS message. The option is a <code>org.apache.camel.component.sjms.jms.MessageCreatedStrategy</code> type.		String
<code>camel.component.sjms.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.component.sjms.transaction-commit-strategy</code>	To configure which kind of commit strategy to use. Camel provides two implementations out of the box, default and batch. The option is a <code>org.apache.camel.component.sjms.TransactionCommitStrategy</code> type.		String

Below is an example of how to configure the **SjmsComponent** with its required **ConnectionFactory** provider. It will create a single connection by default and store it using the components internal pooling APIs to ensure that it is able to service Session creation requests in a thread safe manner.

```
SjmsComponent component = new SjmsComponent();
component.setConnectionFactory(new ActiveMQConnectionFactory("tcp://localhost:61616"));
getContext().addComponent("sjms", component);
```

For a SJMS component that is required to support a durable subscription, you can override the default **ConnectionFactoryResource** instance and set the **clientId** property.

```
ConnectionFactoryResource connectionResource = new ConnectionFactoryResource();
connectionResource.setConnectionFactory(new ActiveMQConnectionFactory("tcp://localhost:61616"));
connectionResource.setClientId("myclient-id");
```

```
SjmsComponent component = new SjmsComponent();
component.setConnectionResource(connectionResource);
component.setMaxConnections(1);
```

306.4. PRODUCER USAGE

306.4.1. InOnly Producer - (Default)

The *InOnly* producer is the default behavior of the SJMS Producer Endpoint.

```
from("direct:start")
    .to("sjms:queue:bar");
```

306.4.2. InOut Producer

To enable *InOut* behavior append the **exchangePattern** attribute to the URI. By default it will use a dedicated TemporaryQueue for each consumer.

```
from("direct:start")
    .to("sjms:queue:bar?exchangePattern=InOut");
```

You can specify a **namedReplyTo** though which can provide a better monitor point.

```
from("direct:start")
    .to("sjms:queue:bar?exchangePattern=InOut&namedReplyTo=my.reply.to.queue");
```

306.5. CONSUMER USAGE

306.5.1. InOnly Consumer - (Default)

The *InOnly* consumer is the default Exchange behavior of the SJMS Consumer Endpoint.

```
from("sjms:queue:bar")
    .to("mock:result");
```

306.5.2. InOut Consumer

To enable *InOut* behavior append the **exchangePattern** attribute to the URI.

```
from("sjms:queue:in.out.test?exchangePattern=InOut")
    .transform(constant("Bye Camel"));
```

306.6. ADVANCED USAGE NOTES

306.6.1. Pluggable Connection Resource Management

SJMS provides JMS **Connection** resource management through built-in connection pooling. This eliminates the need to depend on third party API pooling logic. However there may be times that you are required to use an external Connection resource manager such as those provided by J2EE or OSGi

containers. For this SJMS provides an interface that can be used to override the internal SJMS Connection pooling capabilities. This is accomplished through the [ConnectionResource](#) interface.

The [ConnectionResource](#) provides methods for borrowing and returning Connections as needed is the contract used to provide [Connection](#) pools to the SJMS component. A user should use when it is necessary to integrate SJMS with an external connection pooling manager.

It is recommended though that for standard [ConnectionFactory](#) providers you use the [ConnectionFactoryResource](#) implementation that is provided with SJMS as-is or extend as it is optimized for this component.

Below is an example of using the pluggable ConnectionResource with the ActiveMQ **PooledConnectionFactory**:

```
public class AMQConnectionResource implements ConnectionResource {
    private PooledConnectionFactory pcf;

    public AMQConnectionResource(String connectString, int maxConnections) {
        super();
        pcf = new PooledConnectionFactory(connectString);
        pcf.setMaxConnections(maxConnections);
        pcf.start();
    }

    public void stop() {
        pcf.stop();
    }

    @Override
    public Connection borrowConnection() throws Exception {
        Connection answer = pcf.createConnection();
        answer.start();
        return answer;
    }

    @Override
    public Connection borrowConnection(long timeout) throws Exception {
        // SNIPPED...
    }

    @Override
    public void returnConnection(Connection connection) throws Exception {
        // Do nothing since there isn't a way to return a Connection
        // to the instance of PooledConnectionFactory
        log.info("Connection returned");
    }
}
```

Then pass in the **ConnectionResource** to the **SjmsComponent**:

```
CamelContext camelContext = new DefaultCamelContext();
AMQConnectionResource pool = new AMQConnectionResource("tcp://localhost:3333", 1);
SjmsComponent component = new SjmsComponent();
component.setConnectionResource(pool);
camelContext.addComponent("sjms", component);
```

To see the full example of its usage please refer to the [ConnectionResourceIT](#).

306.6.2. Batch Message Support

The `SjmsProducer` supports publishing a collection of messages by creating an Exchange that encapsulates a **List**. This `SjmsProducer` will take then iterate through the contents of the List and publish each message individually.

If when producing a batch of messages there is the need to set headers that are unique to each message you can use the SJMS `BatchMessage` class. When the `SjmsProducer` encounters a **BatchMessage** list it will iterate each **BatchMessage** and publish the included payload and headers.

Below is an example of using the `BatchMessage` class. First we create a list of **BatchMessage**:

```
List<BatchMessage<String>> messages = new ArrayList<BatchMessage<String>>();
for (int i = 1; i <= messageCount; i++) {
    String body = "Hello World " + i;
    BatchMessage<String> message = new BatchMessage<String>(body, null);
    messages.add(message);
}
```

Then publish the list:

```
template.sendBody("sjms:queue:batch.queue", messages);
```

306.6.3. Customizable Transaction Commit Strategies (Local JMS Transactions only)

SJMS provides a developer the means to create a custom and pluggable transaction strategy through the use of the `TransactionCommitStrategy` interface. This allows a user to define a unique set of circumstances that the `SessionTransactionSynchronization` will use to determine when to commit the Session. An example of its use is the `BatchTransactionCommitStrategy` which is detailed further in the next section.

306.6.4. Transacted Batch Consumers & Producers

The SJMS component has been designed to support the batching of local JMS transactions on both the Producer and Consumer endpoints. How they are handled on each is very different though.

The SJMS consumer endpoint is a straightforward implementation that will process X messages before committing them with the associated Session. To enable batched transaction on the consumer first enable transactions by setting the **transacted** parameter to true and then adding the **transactionBatchCount** and setting it to any value that is greater than 0. For example the following configuration will commit the Session every 10 messages:

```
sjms:queue:transacted.batch.consumer?transacted=true&transactionBatchCount=10
```

If an exception occurs during the processing of a batch on the consumer endpoint, the Session rollback is invoked causing the messages to be redelivered to the next available consumer. The counter is also reset to 0 for the `BatchTransactionCommitStrategy` for the associated Session as well. It is the responsibility of the user to ensure they put hooks in their processors of batch messages to watch for messages with the `JMSRedelivered` header set to true. This is the indicator that messages were rolled back at some point and that a verification of a successful processing should occur.

A transacted batch consumer also carries with it an instance of an internal timer that waits a default amount of time (5000ms) between messages before committing the open transactions on the Session. The default value of 5000ms (minimum of 1000ms) should be adequate for most use-cases but if further tuning is necessary simply set the **transactionBatchTimeout** parameter.

```
sjms:queue:transacted.batch.consumer?
transacted=true&transactionBatchCount=10&transactionBatchTimeout=2000
```

The minimal value that will be accepted is 1000ms as the amount of context switching may cause unnecessary performance impacts without gaining benefit.

The producer endpoint is handled much differently though. With the producer after each message is delivered to its destination the Exchange is closed and there is no longer a reference to that message. To make a available all the messages available for redelivery you simply enable transactions on a Producer Endpoint that is publishing BatchMessages. The transaction will commit at the conclusion of the exchange which includes all messages in the batch list. Nothing additional need be configured. For example:

```
List<BatchMessage<String>> messages = new ArrayList<BatchMessage<String>>();
for (int i = 1; i <= messageCount; i++) {
    String body = "Hello World " + i;
    BatchMessage<String> message = new BatchMessage<String>(body, null);
    messages.add(message);
}
```

Now publish the List with transactions enabled:

```
template.sendBody("sjms:queue:batch.queue?transacted=true", messages);
```

306.7. ADDITIONAL NOTES

306.7.1. Message Header Format

The SJMS Component uses the same header format strategy that is used in the Camel JMS Component. This pluggable strategy ensures that messages sent over the wire conform to the JMS Message spec.

For the **exchange.in.header** the following rules apply for the header keys:

- Keys starting with **JMS** or **JMSX** are reserved.
- **exchange.in.headers** keys must be literals and all be valid Java identifiers (do not use dots in the key name).
- Camel replaces dots & hyphens and the reverse when consuming JMS messages:
 - is replaced by *DOT* and the reverse replacement when Camel consumes the message.
 - is replaced by *HYPHEN* and the reverse replacement when Camel consumes the message. See also the option **jmsKeyFormatStrategy**, which allows use of your own custom strategy for formatting keys.

For the **exchange.in.header**, the following rules apply for the header values:

306.7.2. Message Content

To deliver content over the wire we must ensure that the body of the message that is being delivered adheres to the JMS Message Specification. Therefore, all that are produced must either be primitives or their counter objects (such as **Integer**, **Long**, **Character**). The types, **String**, **CharSequence**, **Date**, **BigDecimal** and **BigInteger** are all converted to their **toString()** representation. All other types are dropped.

306.7.3. Clustering

When using *InOut* with SJMS in a clustered environment you must either use *TemporaryQueue* destinations or use a unique named reply to destination per *InOut* producer endpoint. Message correlation is handled by the endpoint, not with message selectors at the broker. The *InOut* Producer Endpoint uses Java Concurrency Exchangers cached by the Message **JMSCorrelationID**. This provides a nice performance increase while reducing the overhead on the broker since all the messages are consumed from the destination in the order they are produced by the interested consumer.

Currently the only correlation strategy is to use the **JMSCorrelationId**. The *InOut* Consumer uses this strategy as well ensuring that all responses messages to the included **JMSReplyTo** destination also have the **JMSCorrelationId** copied from the request as well.

306.8. TRANSACTION SUPPORT

SJMS currently only supports the use of internal JMS Transactions. There is no support for the Camel Transaction Processor or the Java Transaction API (JTA).

306.8.1. Does Springless Mean I Can't Use Spring?

Not at all. Below is an example of the SJMS component using the Spring DSL:

```
<route
  id="inout.named.reply.to.producer.route">
  <from
    uri="direct:invoke.named.reply.to.queue" />
  <to
    uri="sjms:queue:named.reply.to.queue?
    namedReplyTo=my.response.queue&amp;exchangePattern=InOut" />
</route>
```

Springless refers to moving away from the dependency on the Spring JMS API. A new JMS client API is being developed from the ground up to power SJMS.

CHAPTER 307. SIMPLE JMS2 COMPONENT

Available as of Camel version 2.19

The Simple JMS 2.0 Component, or SJMS2, is a JMS client for use with Camel that uses well known best practices when it comes to JMS client creation and configuration. SJMS2 contains a brand new JMS 2.0 client API written explicitly for Camel eliminating third party messaging implementations keeping it light and resilient. The following features is included:

- Standard Queue and Topic Support (Durable & Non-Durable)
- InOnly & InOut MEP Support
- Asynchronous Producer and Consumer Processing
- Internal JMS Transaction Support

Additional key features include:

- Pluggable Connection Resource Management
- Session, Consumer, & Producer Pooling & Caching Management
- Batch Consumers and Producers
- Transacted Batch Consumers & Producers
- Support for Customizable Transaction Commit Strategies (Local JMS Transactions only)

NOTE

Why the S in SJMS

S stands for Simple and Standard and Springless. Also camel-jms was already taken.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-sjms2</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

307.1. URI FORMAT

```
sjms2:[queue:|topic:]destinationName[?options]
```

Where **destinationName** is a JMS queue or topic name. By default, the **destinationName** is interpreted as a queue name. For example, to connect to the queue, **FOO.BAR** use:

```
sjms2:FOO.BAR
```

You can include the optional **queue:** prefix, if you prefer:

```
sjms2:queue:FOO.BAR
```

To connect to a topic, you *must* include the **topic:** prefix. For example, to connect to the topic, **Stocks.Prices**, use:

```
sjms2:topic:Stocks.Prices
```

You append query options to the URI using the following format, **?option=value&option=value&...**

307.2. COMPONENT OPTIONS AND CONFIGURATIONS

The Simple JMS2 component supports 15 options, which are listed below.

Name	Description	Default	Type
connectionFactory (advanced)	A ConnectionFactory is required to enable the SjmsComponent. It can be set directly or set set as part of a ConnectionResource.		ConnectionFactory
connectionResource (advanced)	A ConnectionResource is an interface that allows for customization and container control of the ConnectionFactory. See Pluggable Connection Resource Management for further details.		ConnectionResource
connectionCount (common)	The maximum number of connections available to endpoints started under this component	1	Integer
jmsKeyFormatStrategy (advanced)	Pluggable strategy for encoding and decoding JMS keys so they can be compliant with the JMS specification. Camel provides one implementation out of the box: default. The default strategy will safely marshal dots and hyphens (. and -). Can be used for JMS brokers which do not care whether JMS header keys contain illegal characters. You can provide your own implementation of the org.apache.camel.component.jms.JmsKeyFormatStrategy and refer to it using the # notation.		JmsKeyFormatStrategy
transactionCommit Strategy (transaction)	To configure which kind of commit strategy to use. Camel provides two implementations out of the box, default and batch.		TransactionCommit Strategy
destinationCreation Strategy (advanced)	To use a custom DestinationCreationStrategy.		DestinationCreation Strategy
timedTaskManager (advanced)	To use a custom TimedTaskManager		TimedTaskManager

Name	Description	Default	Type
messageCreatedStrategy (advanced)	To use the given MessageCreatedStrategy which are invoked when Camel creates new instances of javax.jms.Message objects when Camel is sending a JMS message.		MessageCreatedStrategy
connectionTestOnBorrow (advanced)	When using the default org.apache.camel.component.sjms.jms.ConnectionFactoryResource then should each javax.jms.Connection be tested (calling start) before returned from the pool.	true	boolean
connectionUsername (security)	The username to use when creating javax.jms.Connection when using the default org.apache.camel.component.sjms.jms.ConnectionFactoryResource.		String
connectionPassword (security)	The password to use when creating javax.jms.Connection when using the default org.apache.camel.component.sjms.jms.ConnectionFactoryResource.		String
connectionClientId (advanced)	The client ID to use when creating javax.jms.Connection when using the default org.apache.camel.component.sjms.jms.ConnectionFactoryResource.		String
connectionMaxWait (advanced)	The max wait time in millis to block and wait on free connection when the pool is exhausted when using the default org.apache.camel.component.sjms.jms.ConnectionFactoryResource.	5000	long
headerFilterStrategy (filter)	To use a custom org.apache.camel.spi.HeaderFilterStrategy to filter header to and from Camel message.		HeaderFilterStrategy
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Simple JMS2 endpoint is configured using URI syntax:

```
sjms2:destinationType:destinationName
```

with the following path and query parameters:

307.2.1. Path Parameters (2 parameters):

Name	Description	Default	Type
destinationType	The kind of destination to use	queue	String
destinationName	Required DestinationName is a JMS queue or topic name. By default, the destinationName is interpreted as a queue name.		String

307.2.2. Query Parameters (37 parameters):

Name	Description	Default	Type
acknowledgementMode (common)	The JMS acknowledgement name, which is one of: SESSION_TRANSACTED, CLIENT_ACKNOWLEDGE, AUTO_ACKNOWLEDGE, DUPS_OK_ACKNOWLEDGE	AUTO_ACKNOWLEDGE	SessionAcknowledgement Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
consumerCount (consumer)	Sets the number of consumer listeners used for this endpoint.	1	int
durable (consumer)	Sets topic consumer to durable.	false	boolean
durableSubscriptionId (consumer)	Sets the durable subscription Id required for durable topics.		String
shared (consumer)	Sets the consumer to shared.	false	boolean
subscriptionId (consumer)	Sets the subscription Id, required for durable or shared topics.		String
synchronous (consumer)	Sets whether synchronous processing should be strictly used or Camel is allowed to use asynchronous processing (if supported).	true	boolean

Name	Description	Default	Type
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
messageSelector (consumer)	Sets the JMS Message selector syntax.		String
namedReplyTo (producer)	Sets the reply to destination name used for InOut producer endpoints.		String
persistent (producer)	Flag used to enable/disable message persistence.	true	boolean
producerCount (producer)	Sets the number of producers used for this endpoint.	1	int
ttl (producer)	Flag used to adjust the Time To Live value of produced messages.	-1	long
allowNullBody (producer)	Whether to allow sending messages with no body. If this option is false and the message body is null, then an <code>JMSEException</code> is thrown.	true	boolean
prefillPool (producer)	Whether to prefill the producer connection pool on startup, or create connections lazy when needed.	true	boolean
responseTimeout (producer)	Sets the amount of time we should wait before timing out a InOut response.	5000	long
asyncStartListener (advanced)	Whether to startup the consumer message listener asynchronously, when starting a route. For example if a <code>JmsConsumer</code> cannot get a connection to a remote JMS broker, then it may block while retrying and/or failover. This will cause Camel to block while starting routes. By setting this option to true, you will let routes startup, while the <code>JmsConsumer</code> connects to the JMS broker using a dedicated thread in asynchronous mode. If this option is used, then beware that if the connection could not be established, then an exception is logged at WARN level, and the consumer will not be able to receive messages; You can then restart the route to retry.	false	boolean

Name	Description	Default	Type
asyncStopListener (advanced)	Whether to stop the consumer message listener asynchronously, when stopping a route.	false	boolean
connectionCount (advanced)	The maximum number of connections available to this endpoint		Integer
connectionFactory (advanced)	Initializes the connectionFactory for the endpoint, which takes precedence over the component's connectionFactory, if any		ConnectionFactory
connectionResource (advanced)	Initializes the connectionResource for the endpoint, which takes precedence over the component's connectionResource, if any		ConnectionResource
destinationCreationStrategy (advanced)	To use a custom DestinationCreationStrategy.		DestinationCreationStrategy
exceptionListener (advanced)	Specifies the JMS Exception Listener that is to be notified of any underlying JMS exceptions.		ExceptionListener
headerFilterStrategy (advanced)	To use a custom HeaderFilterStrategy to filter header to and from Camel message.		HeaderFilterStrategy
includeAllJMSXProperties (advanced)	Whether to include all JMSXxxx properties when mapping from JMS to Camel Message. Setting this to true will include properties such as JMSXAppID, and JMSXUserID etc. Note: If you are using a custom headerFilterStrategy then this option does not apply.	false	boolean
jmsKeyFormatStrategy (advanced)	Pluggable strategy for encoding and decoding JMS keys so they can be compliant with the JMS specification. Camel provides two implementations out of the box: default and passthrough. The default strategy will safely marshal dots and hyphens (. and -). The passthrough strategy leaves the key as is. Can be used for JMS brokers which do not care whether JMS header keys contain illegal characters. You can provide your own implementation of the org.apache.camel.component.jms.JmsKeyFormatStrategy and refer to it using the # notation.		JmsKeyFormatStrategy
mapJmsMessage (advanced)	Specifies whether Camel should auto map the received JMS message to a suited payload type, such as javax.jms.TextMessage to a String etc. See section about how mapping works below for more details.	true	boolean

Name	Description	Default	Type
messageCreatedStrategy (advanced)	To use the given MessageCreatedStrategy which are invoked when Camel creates new instances of javax.jms.Message objects when Camel is sending a JMS message.		MessageCreatedStrategy
errorHandlerLoggingLevel (logging)	Allows to configure the default errorHandler logging level for logging uncaught exceptions.	WARN	LoggingLevel
errorHandlerLogStackTrace (logging)	Allows to control whether stacktraces should be logged or not, by the default errorHandler.	true	boolean
transacted (transaction)	Specifies whether to use transacted mode	false	boolean
transactionBatchCount (transaction)	If transacted sets the number of messages to process before committing a transaction.	-1	int
transactionBatchTimeout (transaction)	Sets timeout (in millis) for batch transactions, the value should be 1000 or higher.	5000	long
transactionCommitStrategy (transaction)	Sets the commit strategy.		TransactionCommitStrategy
sharedJMSSession (transaction)	Specifies whether to share JMS session with other SJMS endpoints. Turn this off if your route is accessing to multiple JMS providers. If you need transaction against multiple JMS providers, use jms component to leverage XA transaction.	true	boolean

307.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 16 options, which are listed below.

Name	Description	Default	Type
camel.component.sjms2.connection-client-id	The client ID to use when creating javax.jms.Connection when using the default org.apache.camel.component.sjms.jms.ConnectionFactoryResource.		String

Name	Description	Default	Type
<code>camel.component.sjms2.connection-count</code>	The maximum number of connections available to endpoints started under this component	1	Integer
<code>camel.component.sjms2.connection-factory</code>	A ConnectionFactory is required to enable the SjmsComponent. It can be set directly or set as part of a ConnectionResource. The option is a <code>javax.jms.ConnectionFactory</code> type.		String
<code>camel.component.sjms2.connection-max-wait</code>	The max wait time in millis to block and wait on free connection when the pool is exhausted when using the default <code>org.apache.camel.component.sjms.jms.ConnectionFactoryResource</code> .	5000	Long
<code>camel.component.sjms2.connection-password</code>	The password to use when creating <code>javax.jms.Connection</code> when using the default <code>org.apache.camel.component.sjms.jms.ConnectionFactoryResource</code> .		String
<code>camel.component.sjms2.connection-resource</code>	A ConnectionResource is an interface that allows for customization and container control of the ConnectionFactory. See Plugable Connection Resource Management for further details. The option is a <code>org.apache.camel.component.sjms.jms.ConnectionResource</code> type.		String
<code>camel.component.sjms2.connection-test-on-borrow</code>	When using the default <code>org.apache.camel.component.sjms.jms.ConnectionFactoryResource</code> then should each <code>javax.jms.Connection</code> be tested (calling <code>start</code>) before returned from the pool.	true	Boolean
<code>camel.component.sjms2.connection-username</code>	The username to use when creating <code>javax.jms.Connection</code> when using the default <code>org.apache.camel.component.sjms.jms.ConnectionFactoryResource</code> .		String
<code>camel.component.sjms2.destination-creation-strategy</code>	To use a custom DestinationCreationStrategy. The option is a <code>org.apache.camel.component.sjms.jms.DestinationCreationStrategy</code> type.		String
<code>camel.component.sjms2.enabled</code>	Enable sjms2 component	true	Boolean

Name	Description	Default	Type
<code>camel.component.sjms2.header-filter-strategy</code>	To use a custom <code>org.apache.camel.spi.HeaderFilterStrategy</code> to filter header to and from Camel message. The option is a <code>org.apache.camel.spi.HeaderFilterStrategy</code> type.		String
<code>camel.component.sjms2.jms-key-format-strategy</code>	Pluggable strategy for encoding and decoding JMS keys so they can be compliant with the JMS specification. Camel provides one implementation out of the box: <code>default</code> . The default strategy will safely marshal dots and hyphens (. and -). Can be used for JMS brokers which do not care whether JMS header keys contain illegal characters. You can provide your own implementation of the <code>org.apache.camel.component.jms.JmsKeyFormatStrategy</code> and refer to it using the # notation. The option is a <code>org.apache.camel.component.sjms.jms.JmsKeyFormatStrategy</code> type.		String
<code>camel.component.sjms2.message-created-strategy</code>	To use the given <code>MessageCreatedStrategy</code> which are invoked when Camel creates new instances of <code>javax.jms.Message</code> objects when Camel is sending a JMS message. The option is a <code>org.apache.camel.component.sjms.jms.MessageCreatedStrategy</code> type.		String
<code>camel.component.sjms2.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.component.sjms2.timed-task-manager</code>	To use a custom <code>TimedTaskManager</code> . The option is a <code>org.apache.camel.component.sjms.taskmanager.TimedTaskManager</code> type.		String
<code>camel.component.sjms2.transaction-commit-strategy</code>	To configure which kind of commit strategy to use. Camel provides two implementations out of the box, <code>default</code> and <code>batch</code> . The option is a <code>org.apache.camel.component.sjms.TransactionCommitStrategy</code> type.		String

Below is an example of how to configure the **Sjms2Component** with its required **ConnectionFactory** provider. It will create a single connection by default and store it using the component's internal pooling APIs to ensure that it is able to service Session creation requests in a thread safe manner.

```
Sjms2Component component = new Sjms2Component();
component.setConnectionFactory(new ActiveMQConnectionFactory("tcp://localhost:61616"));
getContext().addComponent("sjms2", component);
```

For a SJMS2 component that is required to support a durable subscription, you can override the default **ConnectionFactoryResource** instance and set the **clientId** property.

```
ConnectionFactoryResource connectionResource = new ConnectionFactoryResource();
connectionResource.setConnectionFactory(new
ActiveMQConnectionFactory("tcp://localhost:61616"));
connectionResource.setClientId("myclient-id");

Sjms2Component component = new Sjms2Component();
component.setConnectionFactory(connectionResource);
component.setMaxConnections(1);
```

307.4. PRODUCER USAGE

307.4.1. InOnly Producer - (Default)

The *InOnly* producer is the default behavior of the SJMS2 Producer Endpoint.

```
from("direct:start")
    .to("sjms2:queue:bar");
```

307.4.2. InOut Producer

To enable *InOut* behavior append the **exchangePattern** attribute to the URI. By default it will use a dedicated *TemporaryQueue* for each consumer.

```
from("direct:start")
    .to("sjms2:queue:bar?exchangePattern=InOut");
```

You can specify a **namedReplyTo** though which can provide a better monitor point.

```
from("direct:start")
    .to("sjms2:queue:bar?exchangePattern=InOut&namedReplyTo=my.reply.to.queue");
```

307.5. CONSUMER USAGE

307.5.1. Durable Shared Subscription

To create a durable subscription that can be shared between one or more consumers. Use a JMS 2.0 compliant connection factory and specify a common *subscriptionId*. Then set the subscription properties *durable* and *shared* to *true*.

```
from("sjms2:topic:foo?consumerCount=3&subscriptionId=bar&durable=true&shared=true")
    .to("mock:result");

from("sjms2:topic:foo?consumerCount=2&subscriptionId=bar&durable=true&shared=true")
    .to("mock:result");
```

307.5.2. InOnly Consumer - (Default)

The *InOnly* consumer is the default Exchange behavior of the SJMS2 Consumer Endpoint.

```
from("sjms2:queue:bar")
    .to("mock:result");
```

307.5.3. InOut Consumer

To enable *InOut* behavior append the **exchangePattern** attribute to the URI.

```
from("sjms2:queue:in.out.test?exchangePattern=InOut")
    .transform(constant("Bye Camel"));
```

307.6. ADVANCED USAGE NOTES

307.6.1. Pluggable Connection Resource Management

SJMS2 provides JMS **Connection** resource management through built-in connection pooling. This eliminates the need to depend on third party API pooling logic. However there may be times that you are required to use an external Connection resource manager such as those provided by J2EE or OSGi containers. For this SJMS2 provides an interface that can be used to override the internal SJMS2 Connection pooling capabilities. This is accomplished through the **ConnectionResource** interface.

The **ConnectionResource** provides methods for borrowing and returning Connections as needed is the contract used to provide **Connection** pools to the SJMS2 component. A user should use when it is necessary to integrate SJMS2 with an external connection pooling manager.

It is recommended though that for standard **ConnectionFactory** providers you use the **ConnectionFactoryResource** implementation that is provided with SJMS2 as-is or extend as it is optimized for this component.

Below is an example of using the pluggable ConnectionResource with the ActiveMQ **PooledConnectionFactory**:

```
public class AMQConnectionResource implements ConnectionResource {
    private PooledConnectionFactory pcf;

    public AMQConnectionResource(String connectString, int maxConnections) {
        super();
        pcf = new PooledConnectionFactory(connectString);
        pcf.setMaxConnections(maxConnections);
        pcf.start();
    }

    public void stop() {
        pcf.stop();
    }

    @Override
    public Connection borrowConnection() throws Exception {
        Connection answer = pcf.createConnection();
        answer.start();
        return answer;
    }
}
```

```

@Override
public Connection borrowConnection(long timeout) throws Exception {
    // SNIPPED...
}

@Override
public void returnConnection(Connection connection) throws Exception {
    // Do nothing since there isn't a way to return a Connection
    // to the instance of PooledConnectionFactory
    log.info("Connection returned");
}
}
}

```

Then pass in the **ConnectionResource** to the **Sjms2Component**:

```

CamelContext camelContext = new DefaultCamelContext();
AMQConnectionResource pool = new AMQConnectionResource("tcp://localhost:33333", 1);
Sjms2Component component = new Sjms2Component();
component.setConnectionResource(pool);
camelContext.addComponent("sjms2", component);

```

To see the full example of its usage please refer to the [ConnectionResourceIT](#).

307.6.2. Session, Consumer, & Producer Pooling & Caching Management

Coming soon ...

307.6.3. Batch Message Support

The **Sjms2Producer** supports publishing a collection of messages by creating an **Exchange** that encapsulates a **List**. This **Sjms2Producer** will take then iterate through the contents of the **List** and publish each message individually.

If when producing a batch of messages there is the need to set headers that are unique to each message you can use the **SJMS2 BatchMessage** class. When the **Sjms2Producer** encounters a **BatchMessage** list it will iterate each **BatchMessage** and publish the included payload and headers.

Below is an example of using the **BatchMessage** class. First we create a list of **BatchMessage**:

```

List<BatchMessage<String>> messages = new ArrayList<BatchMessage<String>>();
for (int i = 1; i <= messageCount; i++) {
    String body = "Hello World " + i;
    BatchMessage<String> message = new BatchMessage<String>(body, null);
    messages.add(message);
}

```

Then publish the list:

```

template.sendBody("sjms2:queue:batch.queue", messages);

```

307.6.4. Customizable Transaction Commit Strategies (Local JMS Transactions only)

SJMS2 provides a developer the means to create a custom and pluggable transaction strategy through the use of the [TransactionCommitStrategy](#) interface. This allows a user to define a unique set of circumstances that the [SessionTransactionSynchronization](#) will use to determine when to commit the Session. An example of its use is the [BatchTransactionCommitStrategy](#) which is detailed further in the next section.

307.6.5. Transacted Batch Consumers & Producers

The SJMS2 component has been designed to support the batching of local JMS transactions on both the Producer and Consumer endpoints. How they are handled on each is very different though.

The SJMS2 consumer endpoint is a straightforward implementation that will process X messages before committing them with the associated Session. To enable batched transaction on the consumer first enable transactions by setting the **transacted** parameter to true and then adding the **transactionBatchCount** and setting it to any value that is greater than 0. For example the following configuration will commit the Session every 10 messages:

```
sjms2:queue:transacted.batch.consumer?transacted=true&transactionBatchCount=10
```

If an exception occurs during the processing of a batch on the consumer endpoint, the Session rollback is invoked causing the messages to be redelivered to the next available consumer. The counter is also reset to 0 for the [BatchTransactionCommitStrategy](#) for the associated Session as well. It is the responsibility of the user to ensure they put hooks in their processors of batch messages to watch for messages with the `JMSRedelivered` header set to true. This is the indicator that messages were rolled back at some point and that a verification of a successful processing should occur.

A transacted batch consumer also carries with it an instance of an internal timer that waits a default amount of time (5000ms) between messages before committing the open transactions on the Session. The default value of 5000ms (minimum of 1000ms) should be adequate for most use-cases but if further tuning is necessary simply set the **transactionBatchTimeout** parameter.

```
sjms2:queue:transacted.batch.consumer?  
transacted=true&transactionBatchCount=10&transactionBatchTimeout=2000
```

The minimal value that will be accepted is 1000ms as the amount of context switching may cause unnecessary performance impacts without gaining benefit.

The producer endpoint is handled much differently though. With the producer after each message is delivered to its destination the Exchange is closed and there is no longer a reference to that message. To make a available all the messages available for redelivery you simply enable transactions on a Producer Endpoint that is publishing BatchMessages. The transaction will commit at the conclusion of the exchange which includes all messages in the batch list. Nothing additional need be configured. For example:

```
List<BatchMessage<String>> messages = new ArrayList<BatchMessage<String>>();  
for (int i = 1; i <= messageCount; i++) {  
    String body = "Hello World " + i;  
    BatchMessage<String> message = new BatchMessage<String>(body, null);  
    messages.add(message);  
}
```

Now publish the List with transactions enabled:

```
template.sendBody("sjms2:queue:batch.queue?transacted=true", messages);
```

307.7. ADDITIONAL NOTES

307.7.1. Message Header Format

The SJMS2 Component uses the same header format strategy that is used in the Camel JMS Component. This pluggable strategy ensures that messages sent over the wire conform to the JMS Message spec.

For the **exchange.in.header** the following rules apply for the header keys:

- Keys starting with **JMS** or **JMSX** are reserved.
- **exchange.in.headers** keys must be literals and all be valid Java identifiers (do not use dots in the key name).
- Camel replaces dots & hyphens and the reverse when consuming JMS messages:
 - is replaced by *DOT* and the reverse replacement when Camel consumes the message.
 - is replaced by *HYPHEN* and the reverse replacement when Camel consumes the message. See also the option **jmsKeyFormatStrategy**, which allows use of your own custom strategy for formatting keys.

For the **exchange.in.header**, the following rules apply for the header values:

307.7.2. Message Content

To deliver content over the wire we must ensure that the body of the message that is being delivered adheres to the JMS Message Specification. Therefore, all that are produced must either be primitives or their counter objects (such as **Integer**, **Long**, **Character**). The types, **String**, **CharSequence**, **Date**, **BigDecimal** and **BigInteger** are all converted to their **toString()** representation. All other types are dropped.

307.7.3. Clustering

When using *InOut* with SJMS2 in a clustered environment you must either use *TemporaryQueue* destinations or use a unique named reply to destination per *InOut* producer endpoint. Message correlation is handled by the endpoint, not with message selectors at the broker. The *InOut* Producer Endpoint uses Java Concurrency Exchangers cached by the Message **JMSCorrelationID**. This provides a nice performance increase while reducing the overhead on the broker since all the messages are consumed from the destination in the order they are produced by the interested consumer.

Currently the only correlation strategy is to use the **JMSCorrelationId**. The *InOut* Consumer uses this strategy as well ensuring that all responses messages to the included **JMSReplyTo** destination also have the **JMSCorrelationId** copied from the request as well.

307.8. TRANSACTION SUPPORT

SJMS2 currently only supports the use of internal JMS Transactions. There is no support for the Camel Transaction Processor or the Java Transaction API (JTA).

307.8.1. Does Springless Mean I Can't Use Spring?

Not at all. Below is an example of the SJMS2 component using the Spring DSL:

-

```
<route
  id="inout.named.reply.to.producer.route">
  <from
    uri="direct:invoke.named.reply.to.queue" />
  <to
    uri="sjms2:queue:named.reply.to.queue?
namedReplyTo=my.response.queue&exchangePattern=InOut" />
</route>
```

Springless refers to moving away from the dependency on the Spring JMS API. A new JMS client API is being developed from the ground up to power SJMS2.

CHAPTER 308. SLACK COMPONENT

Available as of Camel version 2.16

The **slack** component allows you to connect to an instance of [Slack](#) and delivers a message contained in the message body via a pre established [Slack incoming webhook](#).

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-slack</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

308.1. URI FORMAT

To send a message to a channel.

```
slack:#channel[?options]
```

To send a direct message to a slackuser.

```
slack:@username[?options]
```

308.2. OPTIONS

The Slack component supports 2 options, which are listed below.

Name	Description	Default	Type
webhookUrl (common)	The incoming webhook URL		String
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Slack endpoint is configured using URI syntax:

```
slack:channel
```

with the following path and query parameters:

308.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
channel	Required The channel name (syntax #name) or slackuser (syntax userName) to send a message directly to an user.		String

308.2.2. Query Parameters (26 parameters):

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
maxResults (consumer)	The Max Result for the poll	10	String
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean
serverUrl (consumer)	The Server URL of the Slack instance	https://slack.com	String
token (consumer)	The token to use		String
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
pollStrategy (consumer)	A pluggable org.apache.camel.PollingConsumerPollingStrategy allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		PollingConsumerPollStrategy

Name	Description	Default	Type
iconEmoji (producer)	Use a Slack emoji as an avatar		String
iconUrl (producer)	The avatar that the component will use when sending message to a channel or user.		String
username (producer)	This is the username that the bot will have when sending messages to a channel or user.		String
webhookUrl (producer)	The incoming webhook URL		String
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.		int
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.		int
delay (scheduler)	Milliseconds before the next poll. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	500	long
greedy (scheduler)	If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	1000	long
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that.	TRACE	LoggingLevel

Name	Description	Default	Type
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz2 component	none	ScheduledPollConsumerScheduler
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz2, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for initialDelay and delay options.	MILLISECONDS	TimeUnit
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.	true	boolean

308.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 3 options, which are listed below.

Name	Description	Default	Type
camel.component.slack.enabled	Enable slack component	true	Boolean
camel.component.slack.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
camel.component.slack.webhook-url	The incoming webhook URL		String

308.4. SLACKCOMPONENT

The SlackComponent with XML must be configured as a Spring or Blueprint bean that contains the incoming webhook url for the integration as a parameter.

```
<bean id="slack" class="org.apache.camel.component.slack.SlackComponent">
```

```
<property name="webhookUrl"
value="https://hooks.slack.com/services/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"/>
</bean>
```

For Java you can configure this using Java code.

308.5. EXAMPLE

A CamelContext with Blueprint could be as:

```
<?xml version="1.0" encoding="UTF-8"?>
<blueprint xmlns="http://www.osgi.org/xmlns/blueprint/v1.0.0" default-activation="lazy">

  <bean id="slack" class="org.apache.camel.component.slack.SlackComponent">
    <property name="webhookUrl"
value="https://hooks.slack.com/services/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"/>
  </bean>

  <camelContext xmlns="http://camel.apache.org/schema/blueprint">
    <route>
      <from uri="direct:test"/>
      <to uri="slack:#channel?iconEmoji=:camel:&username=CamelTest"/>
    </route>
  </camelContext>

</blueprint>
```

308.6. CONSUMER

You can use also a consumer for messages in channel

```
from("slack://general?token=RAW(<YOUR_TOKEN>)&maxResults=1")
.to("mock:result");
```

In this way you'll get the last message from general channel. The consumer will take track of the timestamp of the last message consumed and in the next poll it will check from that timestamp.

CHAPTER 309. SMPP COMPONENT

Available as of Camel version 2.2

This component provides access to an SMSC (Short Message Service Center) over the [SMPP](#) protocol to send and receive SMS. The [JSMPP](#) library is used for the protocol implementation.

The Camel component currently operates as an [ESME](#) (External Short Messaging Entity) and not as an SMSC itself.

Starting with *Camel 2.9* you are also able to execute `ReplaceSm`, `QuerySm`, `SubmitMulti`, `CancelSm` and `DataSm`.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-smpp</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

309.1. SMS LIMITATIONS

SMS is neither reliable or secure. Users who require reliable and secure delivery may want to consider using the XMPP or SIP components instead, combined with a smartphone app supporting the chosen protocol.

- **Reliability:** although the SMPP standard offers a range of feedback mechanisms to indicate errors, non-delivery and confirmation of delivery it is not uncommon for mobile networks to hide or simulate these responses. For example, some networks automatically send a delivery confirmation for every message even if the destination number is invalid or not switched on. Some networks silently drop messages if they think they are spam. Spam detection rules in the network may be very crude, sometimes more than 100 messages per day from a single sender may be considered spam.
- **Security:** there is basic encryption for the last hop from the radio tower down to the recipient handset. SMS messages are not encrypted or authenticated in any other part of the network. Some operators allow staff in retail outlets or call centres to browse through the SMS message histories of their customers. Message sender identity can be easily forged. Regulators and even the mobile telephone industry itself has cautioned against the use of SMS in two-factor authentication schemes and other purposes where security is important.

While the Camel component makes it as easy as possible to send messages to the SMS network, it can not offer an easy solution to these problems.

309.2. DATA CODING, ALPHABET AND INTERNATIONAL CHARACTER SETS

Data coding and alphabet can be specified on a per-message basis. Default values can be specified for the endpoint. It is important to understand the relationship between these options and the way the component acts when more than one value is set.

Data coding is an 8 bit field in the SMPP wire format.

Alphabet corresponds to bits 0–3 of the data coding field. For some types of message, where a message class is used (by setting bit 5 of the data coding field), the lower two bits of the data coding field are not interpreted as alphabet and only bits 2 and 3 impact the alphabet.

Furthermore, current version of the JSMPP library only seems to support bits 2 and 3, assuming that bits 0 and 1 are used for message class. This is why the Alphabet class in JSMPP doesn't support the value 3 (binary 0011) which indicates ISO-8859-1.

Although JSMPP provides a representation of the message class parameter, the Camel component doesn't currently provide a way to set it other than manually setting the corresponding bits in the data coding field.

When setting the data coding field in the outgoing message, the Camel component considers the following values and uses the first one it can find:

- the data coding specified in a header
- the alphabet specified in a header
- the data coding specified in the endpoint configuration (URI parameter)

Older versions of Camel had bugs in support for international character sets. This feature only worked when a single encoding was used for all messages and was troublesome when users wanted to change it on a per-message basis. Users who require this to work should ensure their version of Camel includes the fix for

JIRA Issues Macro: `com.atlassian.sal.api.net.ResponseStatusException: Unexpected response received. Status code: 404`

In addition to trying to send the data coding value to the SMSC, the Camel component also tries to analyze the message body, convert it to a Java String (Unicode) and convert that to a byte array in the corresponding alphabet. When deciding which alphabet to use in the byte array, the Camel SMPP component does not consider the data coding value (header or configuration), it only considers the specified alphabet (from either the header or endpoint parameter).

If some characters in the String can't be represented in the chosen alphabet, they may be replaced by the question mark (?) symbol. Users of the API may want to consider checking if their message body can be converted to ISO-8859-1 before passing it to the component and if not, setting the alphabet header to request UCS-2 encoding. If the alphabet and data coding options are not specified at all then the component may try to detect the required encoding and set the data coding for you.

The list of alphabet codes are specified in the SMPP specification v3.4, section 5.2.19. One notable limitation of the SMPP specification is that there is no alphabet code for explicitly requesting use of the GSM 3.38 (7 bit) character set. Choosing the value 0 for the alphabet selects the SMSC *default* alphabet, this usually means GSM 3.38 but it is not guaranteed. The SMPP gateway Nexmo [actually allows the default to be mapped to any other character set with a control panel option](#). It is suggested that users check with their SMSC operator to confirm exactly which character set is being used as the default.

309.3. MESSAGE SPLITTING AND THROTTLING

After transforming a message body from a String to a byte array, the Camel component is also responsible for splitting the message into parts (within the 140 byte SMS size limit) before passing it to JSMPP. This is completed automatically.

If the GSM 3.38 alphabet is used, the component will pack up to 160 characters into the 140 byte message body. If an 8 bit character set is used (e.g. ISO-8859-1 for western Europe) then 140 characters will be allowed within the 140 byte message body. If 16 bit UCS-2 encoding is used then just 70 characters fit into each 140 byte message.

Some SMSC providers implement throttling rules. Each part of a message that has been split may be counted separately by the provider's throttling mechanism. The Camel Throttler component can be useful for throttling messages in the SMPP route before handing them to the SMSC.

309.4. URI FORMAT

```
smpp://[username@]hostname[:port][?options]
smpps://[username@]hostname[:port][?options]
```

If no **username** is provided, then Camel will provide the default value **smppclient**.

If no **port** number is provided, then Camel will provide the default value **2775**.

Camel 2.3: If the protocol name is "smpps", camel-smpp will try to use SSLSocket to init a connection to the server.

You can append query options to the URI in the following format, **?option=value&option=value&...**

309.5. URI OPTIONS

The SMPP component supports 2 options, which are listed below.

Name	Description	Default	Type
configuration (advanced)	To use the shared SmppConfiguration as configuration.		SmppConfiguration
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The SMPP endpoint is configured using URI syntax:

```
smpp:host:port
```

with the following path and query parameters:

309.5.1. Path Parameters (2 parameters):

Name	Description	Default	Type
host	Hostname for the SMSC server to use.	localhost	String

Name	Description	Default	Type
port	Port number for the SMSC server to use.	2775	Integer

309.5.2. Query Parameters (38 parameters):

Name	Description	Default	Type
initialReconnectDelay (common)	Defines the initial delay in milliseconds after the consumer/producer tries to reconnect to the SMSC, after the connection was lost.	5000	long
maxReconnect (common)	Defines the maximum number of attempts to reconnect to the SMSC, if SMSC returns a negative bind response	2147483647	int
reconnectDelay (common)	Defines the interval in milliseconds between the reconnect attempts, if the connection to the SMSC was lost and the previous was not succeed.	5000	long
splittingPolicy (common)	You can specify a policy for handling long messages: ALLOW - the default, long messages are split to 140 bytes per message TRUNCATE - long messages are split and only the first fragment will be sent to the SMSC. Some carriers drop subsequent fragments so this reduces load on the SMPP connection sending parts of a message that will never be delivered. REJECT - if a message would need to be split, it is rejected with an SMPP NegativeResponseException and the reason code signifying the message is too long.	ALLOW	SmppSplittingPolicy
systemType (common)	This parameter is used to categorize the type of ESME (External Short Message Entity) that is binding to the SMSC (max. 13 characters).	cp	String
addressRange (consumer)	You can specify the address range for the SmppConsumer as defined in section 5.2.7 of the SMPP 3.4 specification. The SmppConsumer will receive messages only from SMSC's which target an address (MSISDN or IP address) within this range.		String

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
destAddr (producer)	Defines the destination SME address. For mobile terminated messages, this is the directory number of the recipient MS. Only for <code>SubmitSm</code> , <code>SubmitMulti</code> , <code>CancelSm</code> and <code>DataSm</code> .	1717	String
destAddrNpi (producer)	Defines the type of number (TON) to be used in the SME destination address parameters. Only for <code>SubmitSm</code> , <code>SubmitMulti</code> , <code>CancelSm</code> and <code>DataSm</code> . The following NPI values are defined: 0: Unknown 1: ISDN (E163/E164) 2: Data (X.121) 3: Telex (F.69) 6: Land Mobile (E.212) 8: National 9: Private 10: ERMES 13: Internet (IP) 18: WAP Client Id (to be defined by WAP Forum)		byte
destAddrTon (producer)	Defines the type of number (TON) to be used in the SME destination address parameters. Only for <code>SubmitSm</code> , <code>SubmitMulti</code> , <code>CancelSm</code> and <code>DataSm</code> . The following TON values are defined: 0: Unknown 1: International 2: National 3: Network Specific 4: Subscriber Number 5: Alphanumeric 6: Abbreviated		byte
lazySessionCreation (producer)	Sessions can be lazily created to avoid exceptions, if the SMSC is not available when the Camel producer is started. Camel will check the in message headers <code>'CamelSmppSystemId'</code> and <code>'CamelSmppPassword'</code> of the first exchange. If they are present, Camel will use these data to connect to the SMSC.	false	boolean

Name	Description	Default	Type
numberingPlanIndicator (producer)	Defines the numeric plan indicator (NPI) to be used in the SME. The following NPI values are defined: 0: Unknown 1: ISDN (E163/E164) 2: Data (X.121) 3: Telex (F.69) 6: Land Mobile (E.212) 8: National 9: Private 10: ERMES 13: Internet (IP) 18: WAP Client Id (to be defined by WAP Forum)		byte
priorityFlag (producer)	Allows the originating SME to assign a priority level to the short message. Only for SubmitSm and SubmitMulti. Four Priority Levels are supported: 0: Level 0 (lowest) priority 1: Level 1 priority 2: Level 2 priority 3: Level 3 (highest) priority		byte
protocolId (producer)	The protocol id		byte
registeredDelivery (producer)	Is used to request an SMSC delivery receipt and/or SME originated acknowledgements. The following values are defined: 0: No SMSC delivery receipt requested. 1: SMSC delivery receipt requested where final delivery outcome is success or failure. 2: SMSC delivery receipt requested where the final delivery outcome is delivery failure.		byte
replaceIfPresentFlag (producer)	Used to request the SMSC to replace a previously submitted message, that is still pending delivery. The SMSC will replace an existing message provided that the source address, destination address and service type match the same fields in the new message. The following replace if present flag values are defined: 0: Don't replace 1: Replace		byte
serviceType (producer)	The service type parameter can be used to indicate the SMS Application service associated with the message. The following generic service_types are defined: CMT: Cellular Messaging CPT: Cellular Paging VMN: Voice Mail Notification VMA: Voice Mail Alerting WAP: Wireless Application Protocol USSD: Unstructured Supplementary Services Data	CMT	String
sourceAddr (producer)	Defines the address of SME (Short Message Entity) which originated this message.	1616	String

Name	Description	Default	Type
sourceAddrNpi (producer)	Defines the numeric plan indicator (NPI) to be used in the SME originator address parameters. The following NPI values are defined: 0: Unknown 1: ISDN (E163/E164) 2: Data (X.121) 3: Telex (F.69) 6: Land Mobile (E.212) 8: National 9: Private 10: ERMES 13: Internet (IP) 18: WAP Client Id (to be defined by WAP Forum)		byte
sourceAddrTon (producer)	Defines the type of number (TON) to be used in the SME originator address parameters. The following TON values are defined: 0: Unknown 1: International 2: National 3: Network Specific 4: Subscriber Number 5: Alphanumeric 6: Abbreviated		byte
typeOfNumber (producer)	Defines the type of number (TON) to be used in the SME. The following TON values are defined: 0: Unknown 1: International 2: National 3: Network Specific 4: Subscriber Number 5: Alphanumeric 6: Abbreviated		byte
enquireLinkTimer (advanced)	Defines the interval in milliseconds between the confidence checks. The confidence check is used to test the communication path between an ESME and an SMSC.	5000	Integer
sessionStateListener (advanced)	You can refer to a <code>org.jsmpp.session.SessionStateListener</code> in the Registry to receive callbacks when the session state changed.		SessionStateListener
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
transactionTimer (advanced)	Defines the maximum period of inactivity allowed after a transaction, after which an SMPP entity may assume that the session is no longer active. This timer may be active on either communicating SMPP entity (i.e. SMSC or ESME).	10000	Integer
alphabet (codec)	Defines encoding of data according the SMPP 3.4 specification, section 5.2.19. 0: SMSC Default Alphabet 4: 8 bit Alphabet 8: UCS2 Alphabet		byte

Name	Description	Default	Type
dataCoding (codec)	Defines the data coding according the SMPP 3.4 specification, section 5.2.19. Example data encodings are: 0: SMSC Default Alphabet 3: Latin 1 (ISO-8859-1) 4: Octet unspecified (8-bit binary) 8: UCS2 (ISO/IEC-10646) 13: Extended Kanji JIS(X 0212-1990)		byte
encoding (codec)	Defines the encoding scheme of the short message user data. Only for SubmitSm, ReplaceSm and SubmitMulti.	ISO-8859-1	String
httpProxyHost (proxy)	If you need to tunnel SMPP through a HTTP proxy, set this attribute to the hostname or ip address of your HTTP proxy.		String
httpProxyPassword (proxy)	If your HTTP proxy requires basic authentication, set this attribute to the password required for your HTTP proxy.		String
httpProxyPort (proxy)	If you need to tunnel SMPP through a HTTP proxy, set this attribute to the port of your HTTP proxy.	3128	Integer
httpProxyUsername (proxy)	If your HTTP proxy requires basic authentication, set this attribute to the username required for your HTTP proxy.		String
proxyHeaders (proxy)	These headers will be passed to the proxy server while establishing the connection.		Map
password (security)	The password for connecting to SMSC server.		String
systemId (security)	The system id (username) for connecting to SMSC server.	smppclient	String
usingSSL (security)	Whether using SSL with the smpps protocol	false	boolean

309.6. SPRING BOOT AUTO-CONFIGURATION

The component supports 38 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.smpp.configuration.address-range</code>	You can specify the address range for the SmppConsumer as defined in section 5.2.7 of the SMPP 3.4 specification. The SmppConsumer will receive messages only from SMSC's which target an address (MSISDN or IP address) within this range.		String
<code>camel.component.smpp.configuration.alphabet</code>	Defines encoding of data according the SMPP 3.4 specification, section 5.2.19. 0: SMSC Default Alphabet 4: 8 bit Alphabet 8: UCS2 Alphabet		Byte
<code>camel.component.smpp.configuration.data-coding</code>	Defines the data coding according the SMPP 3.4 specification, section 5.2.19. Example data encodings are: 0: SMSC Default Alphabet 3: Latin 1 (ISO-8859-1) 4: Octet unspecified (8-bit binary) 8: UCS2 (ISO/IEC-10646) 13: Extended Kanji JIS(X 0212-1990)		Byte
<code>camel.component.smpp.configuration.dest-addr</code>	Defines the destination SME address. For mobile terminated messages, this is the directory number of the recipient MS. Only for SubmitSm, SubmitMulti, CancelSm and DataSm.	1717	String
<code>camel.component.smpp.configuration.dest-addr-npi</code>	Defines the type of number (TON) to be used in the SME destination address parameters. Only for SubmitSm, SubmitMulti, CancelSm and DataSm. The following NPI values are defined: 0: Unknown 1: ISDN (E163/E164) 2: Data (X.121) 3: Telex (F.69) 6: Land Mobile (E.212) 8: National 9: Private 10: ERMES 13: Internet (IP) 18: WAP Client Id (to be defined by WAP Forum)		Byte
<code>camel.component.smpp.configuration.dest-addr-ton</code>	Defines the type of number (TON) to be used in the SME destination address parameters. Only for SubmitSm, SubmitMulti, CancelSm and DataSm. The following TON values are defined: 0: Unknown 1: International 2: National 3: Network Specific 4: Subscriber Number 5: Alphanumeric 6: Abbreviated		Byte
<code>camel.component.smpp.configuration.encoding</code>	Defines the encoding scheme of the short message user data. Only for SubmitSm, ReplaceSm and SubmitMulti.	ISO-8859-1	String
<code>camel.component.smpp.configuration.enquire-link-timer</code>	Defines the interval in milliseconds between the confidence checks. The confidence check is used to test the communication path between an ESME and an SMSC.	5000	Integer

Name	Description	Default	Type
<code>camel.component.smpp.configurations.host</code>	Hostname for the SMSC server to use.	localhost	String
<code>camel.component.smpp.configurations.http-proxy-host</code>	If you need to tunnel SMPP through a HTTP proxy, set this attribute to the hostname or ip address of your HTTP proxy.		String
<code>camel.component.smpp.configurations.http-proxy-password</code>	If your HTTP proxy requires basic authentication, set this attribute to the password required for your HTTP proxy.		String
<code>camel.component.smpp.configurations.http-proxy-port</code>	If you need to tunnel SMPP through a HTTP proxy, set this attribute to the port of your HTTP proxy.	3128	Integer
<code>camel.component.smpp.configurations.http-proxy-username</code>	If your HTTP proxy requires basic authentication, set this attribute to the username required for your HTTP proxy.		String
<code>camel.component.smpp.configurations.initial-reconnect-delay</code>	Defines the initial delay in milliseconds after the consumer/producer tries to reconnect to the SMSC, after the connection was lost.	5000	Long
<code>camel.component.smpp.configurations.lazy-session-creation</code>	Sessions can be lazily created to avoid exceptions, if the SMSC is not available when the Camel producer is started. Camel will check the in message headers 'CamelSmppSystemId' and 'CamelSmppPassword' of the first exchange. If they are present, Camel will use these data to connect to the SMSC.	false	Boolean
<code>camel.component.smpp.configurations.max-reconnect</code>	Defines the maximum number of attempts to reconnect to the SMSC, if SMSC returns a negative bind response	2147483647	Integer
<code>camel.component.smpp.configurations.numbering-plan-indicator</code>	Defines the numeric plan indicator (NPI) to be used in the SME. The following NPI values are defined: 0: Unknown 1: ISDN (E163/E164) 2: Data (X.121) 3: Telex (F.69) 6: Land Mobile (E.212) 8: National 9: Private 10: ERMES 13: Internet (IP) 18: WAP Client Id (to be defined by WAP Forum)		Byte

Name	Description	Default	Type
<code>camel.component.smpp.configuration.password</code>	The password for connecting to SMSC server.		String
<code>camel.component.smpp.configuration.port</code>	Port number for the SMSC server to use.	2775	Integer
<code>camel.component.smpp.configuration.priority-flag</code>	Allows the originating SME to assign a priority level to the short message. Only for SubmitSm and SubmitMulti. Four Priority Levels are supported: 0: Level 0 (lowest) priority 1: Level 1 priority 2: Level 2 priority 3: Level 3 (highest) priority		Byte
<code>camel.component.smpp.configuration.protocol-id</code>	The protocol id		Byte
<code>camel.component.smpp.configuration.proxy-headers</code>	These headers will be passed to the proxy server while establishing the connection.		Map
<code>camel.component.smpp.configuration.reconnect-delay</code>	Defines the interval in milliseconds between the reconnect attempts, if the connection to the SMSC was lost and the previous was not succeed.	5000	Long
<code>camel.component.smpp.configuration.registered-delivery</code>	Is used to request an SMSC delivery receipt and/or SME originated acknowledgements. The following values are defined: 0: No SMSC delivery receipt requested. 1: SMSC delivery receipt requested where final delivery outcome is success or failure. 2: SMSC delivery receipt requested where the final delivery outcome is delivery failure.		Byte
<code>camel.component.smpp.configuration.replace-if-present-flag</code>	Used to request the SMSC to replace a previously submitted message, that is still pending delivery. The SMSC will replace an existing message provided that the source address, destination address and service type match the same fields in the new message. The following replace if present flag values are defined: 0: Don't replace 1: Replace		Byte

Name	Description	Default	Type
camel.component.smpp.configuration.service-type	The service type parameter can be used to indicate the SMS Application service associated with the message. The following generic service_types are defined: CMT: Cellular Messaging CPT: Cellular Paging VMN: Voice Mail Notification VMA: Voice Mail Alerting WAP: Wireless Application Protocol USSD: Unstructured Supplementary Services Data	CMT	String
camel.component.smpp.configuration.session-state-listener	You can refer to a <code>org.jsmpp.session.SessionStateListener</code> in the Registry to receive callbacks when the session state changed.		SessionStateListener
camel.component.smpp.configuration.source-addr	Defines the address of SME (Short Message Entity) which originated this message.	1616	String
camel.component.smpp.configuration.source-addr-npi	Defines the numeric plan indicator (NPI) to be used in the SME originator address parameters. The following NPI values are defined: 0: Unknown 1: ISDN (E163/E164) 2: Data (X.121) 3: Telex (F.69) 6: Land Mobile (E.212) 8: National 9: Private 10: ERMES 13: Internet (IP) 18: WAP Client Id (to be defined by WAP Forum)		Byte
camel.component.smpp.configuration.source-addr-ton	Defines the type of number (TON) to be used in the SME originator address parameters. The following TON values are defined: 0: Unknown 1: International 2: National 3: Network Specific 4: Subscriber Number 5: Alphanumeric 6: Abbreviated		Byte
camel.component.smpp.configuration.splitting-policy	You can specify a policy for handling long messages: ALLOW - the default, long messages are split to 140 bytes per message TRUNCATE - long messages are split and only the first fragment will be sent to the SMSC. Some carriers drop subsequent fragments so this reduces load on the SMPP connection sending parts of a message that will never be delivered. REJECT - if a message would need to be split, it is rejected with an SMPP NegativeResponseException and the reason code signifying the message is too long.		SmppSplittingPolicy
camel.component.smpp.configuration.system-id	The system id (username) for connecting to SMSC server.	smppclient	String

Name	Description	Default	Type
<code>camel.component.smpp.configurations.system-type</code>	This parameter is used to categorize the type of ESME (External Short Message Entity) that is binding to the SMSC (max. 13 characters).	cp	String
<code>camel.component.smpp.configurations.transaction-timer</code>	Defines the maximum period of inactivity allowed after a transaction, after which an SMPP entity may assume that the session is no longer active. This timer may be active on either communicating SMPP entity (i.e. SMSC or ESME).	10000	Integer
<code>camel.component.smpp.configurations.type-of-number</code>	Defines the type of number (TON) to be used in the SME. The following TON values are defined: 0: Unknown 1: International 2: National 3: Network Specific 4: Subscriber Number 5: Alphanumeric 6: Abbreviated		Byte
<code>camel.component.smpp.configurations.using-ssl</code>	Whether using SSL with the smpps protocol	false	Boolean
<code>camel.component.smpp.enabled</code>	Enable smpp component	true	Boolean
<code>camel.component.smpp.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

You can have as many of these options as you like.

```
smpp://smppclient@localhost:2775?
password=password&enquireLinkTimer=3000&transactionTimer=5000&systemType=consumer
```

309.7. PRODUCER MESSAGE HEADERS

The following message headers can be used to affect the behavior of the SMPP producer

Header	Type	Description
<code>CamelSmppDestAddress</code>	List/String	only for SubmitSm, SubmitMulti, CancelSm and DataSm Defines the destination SME address(es). For mobile terminated messages, this is the directory number of the recipient MS. It must be a List<String> for SubmitMulti and a String otherwise.

Header	Type	Description
Camel Smpp DestAddrTon	Byte	only for SubmitSm, SubmitMulti, CancelSm and DataSm Defines the type of number (TON) to be used in the SME destination address parameters. Use the sourceAddrTon URI option values defined above.
Camel Smpp DestAddrNpi	Byte	only for SubmitSm, SubmitMulti, CancelSm and DataSm Defines the numeric plan indicator (NPI) to be used in the SME destination address parameters. Use the URI option sourceAddrNpi values defined above.
Camel Smpp SourceAddr	String	Defines the address of SME (Short Message Entity) which originated this message.
Camel Smpp SourceAddrTon	Byte	Defines the type of number (TON) to be used in the SME originator address parameters. Use the sourceAddrTon URI option values defined above.
Camel Smpp SourceAddrNpi	Byte	Defines the numeric plan indicator (NPI) to be used in the SME originator address parameters. Use the URI option sourceAddrNpi values defined above.
Camel Smpp ServiceType	String	The service type parameter can be used to indicate the SMS Application service associated with the message. Use the URI option serviceType settings above.
Camel Smpp RegisteredDelivery	Byte	only for SubmitSm, ReplaceSm, SubmitMulti and DataSm Is used to request an SMSC delivery receipt and/or SME originated acknowledgements. Use the URI option registeredDelivery settings above.
Camel Smpp PriorityFlag	Byte	only for SubmitSm and SubmitMulti Allows the originating SME to assign a priority level to the short message. Use the URI option priorityFlag settings above.

Header	Type	Description
Camel Smpp ScheduleDeliveryTime	Date	only for SubmitSm, SubmitMulti and ReplaceSm This parameter specifies the scheduled time at which the message delivery should be first attempted. It defines either the absolute date and time or relative time from the current SMSC time at which delivery of this message will be attempted by the SMSC. It can be specified in either absolute time format or relative time format. The encoding of a time format is specified in chapter 7.1.1. in the smpp specification v3.4.
Camel Smpp ValidityPeriod	String /Date	only for SubmitSm, SubmitMulti and ReplaceSm The validity period parameter indicates the SMSC expiration time, after which the message should be discarded if not delivered to the destination. If it's provided as Date , it's interpreted as absolute time. Camel 2.9.1 onwards: It can be defined in absolute time format or relative time format if you provide it as String as specified in chapter 7.1.1 in the smpp specification v3.4.
Camel Smpp ReplaceIfPresentFlag	Byte	only for SubmitSm and SubmitMulti The replace if present flag parameter is used to request the SMSC to replace a previously submitted message, that is still pending delivery. The SMSC will replace an existing message provided that the source address, destination address and service type match the same fields in the new message. The following values are defined: 0 , Don't replace and 1 , Replace
Camel Smpp Alphabet / Camel Smpp DataCoding	Byte	Camel 2.5 For SubmitSm, SubmitMulti and ReplaceSm (Prior to Camel 2.9 use CamelSmppDataCoding instead of CamelSmppAlphabet .) The data coding according to the SMPP 3.4 specification, section 5.2.19. Use the URI option alphabet settings above.
Camel Smpp OptionalParameters	Map<String, String>	Deprecated and will be removed in Camel 2.13.0/3.0.0 Camel 2.10.5 and 2.11.1 onwards and only for SubmitSm, SubmitMulti and DataSm The optional parameters send back by the SMSC.
Camel Smpp OptionalParameter	Map<Short, Object>	Camel 2.10.7 and 2.11.2 onwards and only for SubmitSm, SubmitMulti and DataSm The optional parameter which are send to the SMSC. The value is converted in the following way: String → org.jsmpp.bean.OptionalParameter.COctetString , byte[] → org.jsmpp.bean.OptionalParameter.OctetString , Byte → org.jsmpp.bean.OptionalParameter.Byte , Integer → org.jsmpp.bean.OptionalParameter.Int , Short → org.jsmpp.bean.OptionalParameter.Short , null → org.jsmpp.bean.OptionalParameter.Null

Header	Type	Description
CamelSmpEncoding	String	Camel 2.14.1 and Camel 2.15.0 onwards and* only for SubmitSm, SubmitMulti and DataSm*. Specifies the encoding (character set name) of the bytes in the message body. If the message body is a string then this is not relevant because Java Strings are always Unicode. If the body is a byte array then this header can be used to indicate that it is ISO-8859-1 or some other value. Default value is specified by the endpoint configuration parameter <i>encoding</i>
CamelSmpSplittingPolicy	String	Camel 2.14.1 and Camel 2.15.0 onwards and* only for SubmitSm, SubmitMulti and DataSm*. Specifies the policy for message splitting for this exchange. Possible values are described in the endpoint configuration parameter <i>splittingPolicy</i>

The following message headers are used by the SMPP producer to set the response from the SMSC in the message header

Header	Type	Description
CamelSmpId	List<String>/String	The id to identify the submitted short message(s) for later use. From Camel 2.9.0: In case of a ReplaceSm, QuerySm, CancelSm and DataSm this header vaule is a String . In case of a SubmitSm or SubmitMultiSm this header vaule is a List<String> .
CamelSmpSentMessageCount	Integer	From Camel 2.9 onwards only for SubmitSm and SubmitMultiSm The total number of messages which has been sent.
CamelSmpError	Map<String, List<Map<String, Object>>>	From Camel 2.9 onwards only for SubmitMultiSm The errors which occurred by sending the short message(s) the form Map<String, List<Map<String, Object>>> (messageID : (destAddr : address, error : errorCode)).
CamelSmpOptionalParameters	Map<String, String>	Deprecated and will be removed in Camel 2.13.0/3.0.0 From Camel 2.11.1 onwards only for DataSm The optional parameters which are returned from the SMSC by sending the message.

Header	Type	Description
Camel SmpptOptionalParameter	Map<Short, Object>	From Camel 2.10.7, 2.11.2 onwards only for DataSm The optional parameter which are returned from the SMSC by sending the message. The key is the Short code for the optional parameter. The value is converted in the following way: org.jsmpp.bean.OptionalParameter.COctetString → String , org.jsmpp.bean.OptionalParameter.OctetString → byte[] , org.jsmpp.bean.OptionalParameter.Byte → Byte , org.jsmpp.bean.OptionalParameter.Int → Integer , org.jsmpp.bean.OptionalParameter.Short → Short , org.jsmpp.bean.OptionalParameter.Null → null

309.8. CONSUMER MESSAGE HEADERS

The following message headers are used by the SMPP consumer to set the request data from the SMSC in the message header

Header	Type	Description
Camel SmpptSequenceNumber	Integer	only for AlertNotification, DeliverSm and DataSm A sequence number allows a response PDU to be correlated with a request PDU. The associated SMPP response PDU must preserve this field.
Camel SmpptCommandId	Integer	only for AlertNotification, DeliverSm and DataSm The command id field identifies the particular SMPP PDU. For the complete list of defined values see chapter 5.1.2.1 in the smpp specification v3.4.
Camel SmpptSourceAddr	String	only for AlertNotification, DeliverSm and DataSm Defines the address of SME (Short Message Entity) which originated this message.
Camel SmpptSourceAddrNpi	Byte	only for AlertNotification and DataSm Defines the numeric plan indicator (NPI) to be used in the SME originator address parameters. Use the URI option sourceAddrNpi values defined above.
Camel SmpptSourceAddrTon	Byte	only for AlertNotification and DataSm Defines the type of number (TON) to be used in the SME originator address parameters. Use the sourceAddrTon URI option values defined above.

Header	Type	Description
Camel Smpp Esme Addr	String	only for AlertNotification Defines the destination ESME address. For mobile terminated messages, this is the directory number of the recipient MS.
Camel Smpp Esme AddrN pi	Byte	only for AlertNotification Defines the numeric plan indicator (NPI) to be used in the ESME originator address parameters. Use the URI option sourceAddrNpi values defined above.
Camel Smpp Esme AddrTon	Byte	only for AlertNotification Defines the type of number (TON) to be used in the ESME originator address parameters. Use the sourceAddrTon URI option values defined above.
Camel Smpp Id	String	only for smsc DeliveryReceipt and DataSm The message ID allocated to the message by the SMSC when originally submitted.
Camel Smpp Delivered	Integer	only for smsc DeliveryReceipt Number of short messages delivered. This is only relevant where the original message was submitted to a distribution list. The value is padded with leading zeros if necessary.
Camel Smpp Done Date	Date	only for smsc DeliveryReceipt The time and date at which the short message reached it's final state. The format is as follows: YYMMDDhhmm.
Camel Smpp Status	DeliveryReceiptState	only for smsc DeliveryReceipt: The final status of the message. The following values are defined: DELIVRD: Message is delivered to destination, EXPIRED: Message validity period has expired, DELETED: Message has been deleted, UNDELIV: Message is undeliverable, ACCEPTD: Message is in accepted state (i.e. has been manually read on behalf of the subscriber by customer service), UNKNOWN: Message is in invalid state, REJECTD: Message is in a rejected state
Camel Smpp CommandStatus	Integer	only for DataSm The Command status of the message.
Camel Smpp Error	String	only for smsc DeliveryReceipt Where appropriate this may hold a Network specific error code or an SMSC error code for the attempted delivery of the message. These errors are Network or SMSC specific and are not included here.

Header	Type	Description
Camel Smpp SubmittedDate	Date	only for smsc DeliveryReceipt The time and date at which the short message was submitted. In the case of a message which has been replaced, this is the date that the original message was replaced. The format is as follows: YYMMDDhhmm.
Camel Smpp Submitted	Integer	only for smsc DeliveryReceipt Number of short messages originally submitted. This is only relevant when the original message was submitted to a distribution list. The value is padded with leading zeros if necessary.
Camel Smpp DestAddr	String	only for DeliverSm and DataSm: Defines the destination SME address. For mobile terminated messages, this is the directory number of the recipient MS.
Camel Smpp ScheduledDeliveryTime	String	only for DeliverSm: This parameter specifies the scheduled time at which the message delivery should be first attempted. It defines either the absolute date and time or relative time from the current SMSC time at which delivery of this message will be attempted by the SMSC. It can be specified in either absolute time format or relative time format. The encoding of a time format is specified in Section 7.1.1. in the smpp specification v3.4.
Camel Smpp ValidityPeriod	String	only for DeliverSm The validity period parameter indicates the SMSC expiration time, after which the message should be discarded if not delivered to the destination. It can be defined in absolute time format or relative time format. The encoding of absolute and relative time format is specified in Section 7.1.1 in the smpp specification v3.4.
Camel Smpp ServiceType	String	only for DeliverSm and DataSm The service type parameter indicates the SMS Application service associated with the message.
Camel Smpp RegisteredDelivery	Byte	only for DataSm Is used to request an delivery receipt and/or SME originated acknowledgements. Same values as in Producer header list above.
Camel Smpp DestAddrNpi	Byte	only for DataSm Defines the numeric plan indicator (NPI) in the destination address parameters. Use the URI option sourceAddrNpi values defined above.

Header	Type	Description
Camel Smpp DestAddrTon	Byte	only for DataSm Defines the type of number (TON) in the destination address parameters. Use the sourceAddrTon URI option values defined above.
Camel Smpp MessageType	String	Camel 2.6 onwards: Identifies the type of an incoming message: AlertNotification: an SMSC alert notification, DataSm: an SMSC data short message, DeliveryReceipt: an SMSC delivery receipt, DeliverSm: an SMSC deliver short message
Camel Smpp OptionalParameters	Map<String, Object>	Deprecated and will be removed in Camel 2.13.0/3.0.0 Camel 2.10.5 onwards and only for DeliverSm The optional parameters send back by the SMSC.
Camel Smpp OptionalParameter	Map<Short, Object>	Camel 2.10.7, 2.11.2 onwards and only for DeliverSm The optional parameters send back by the SMSC. The key is the Short code for the optional parameter. The value is converted in the following way: org.jsmpp.bean.OptionalParameter.COctetString → String , org.jsmpp.bean.OptionalParameter.OctetString → byte[] , org.jsmpp.bean.OptionalParameter.Byte → Byte , org.jsmpp.bean.OptionalParameter.Int → Integer , org.jsmpp.bean.OptionalParameter.Short → Short , org.jsmpp.bean.OptionalParameter.Null → null

TIP

JSMPP library See the documentation of the [JSMPP Library](#) for more details about the underlying library.

309.9. EXCEPTION HANDLING

This component supports the general Camel exception handling capabilities

When an error occurs sending a message with `SubmitSm` (the default action), the `org.apache.camel.component.smpp.SmppException` is thrown with a nested exception, `org.jsmpp.extra.NegativeResponseException`. Call `NegativeResponseException.getCommandStatus()` to obtain the exact SMPP negative response code, the values are explained in the SMPP specification 3.4, section 5.1.3.

Camel 2.8 onwards: When the SMPP consumer receives a **DeliverSm** or **DataSm** short message and the processing of these messages fails, you can also throw a **ProcessRequestException** instead of handle the failure. In this case, this exception is forwarded to the underlying [JSMPP library](#) which will return the included error code to the SMSC. This feature is useful to e.g. instruct the SMSC to resend the short message at a later time. This could be done with the following lines of code:

```

from("smpp://smppclient@localhost:2775?
password=password&enquireLinkTimer=3000&transactionTimer=5000&systemType=consumer")
  .doTry()
    .to("bean:dao?method=updateSmsState")
  .doCatch(Exception.class)
    .throwException(new ProcessRequestException("update of sms state failed", 100))
  .end();

```

Please refer to the [SMPP specification](#) for the complete list of error codes and their meanings.

309.10. SAMPLES

A route which sends an SMS using the Java DSL:

```

from("direct:start")
  .to("smpp://smppclient@localhost:2775?
password=password&enquireLinkTimer=3000&transactionTimer=5000&systemType=producer");

```

A route which sends an SMS using the Spring XML DSL:

```

<route>
  <from uri="direct:start"/>
  <to uri="smpp://smppclient@localhost:2775?
password=password&enquireLinkTimer=3000&transactionTimer=5000&systemType=producer"/>
</route>

```

A route which receives an SMS using the Java DSL:

```

from("smpp://smppclient@localhost:2775?
password=password&enquireLinkTimer=3000&transactionTimer=5000&systemType=consumer")
  .to("bean:foo");

```

A route which receives an SMS using the Spring XML DSL:

```

<route>
  <from uri="smpp://smppclient@localhost:2775?
password=password&enquireLinkTimer=3000&transactionTimer=5000&systemType=consumer"/>
  <to uri="bean:foo"/>
</route>

```

TIP

SMSC simulator If you need an SMSC simulator for your test, you can use the simulator provided by [Logica](#).

309.11. DEBUG LOGGING

This component has log level **DEBUG**, which can be helpful in debugging problems. If you use log4j, you can add the following line to your configuration:

```
log4j.logger.org.apache.camel.component.smpp=DEBUG
```

309.12. SEE ALSO

- [Configuring Camel](#)
- [Component](#)
- [Endpoint](#)
- [Getting Started](#)

CHAPTER 310. SNMP COMPONENT

Available as of Camel version 2.1

The `snmp:` component gives you the ability to poll SNMP capable devices or receiving traps

Maven users will need to add the following dependency to their `pom.xml` for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-snmp</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

310.1. URI FORMAT

```
snmp://hostname[:port][?Options]
```

The component supports polling OID values from an SNMP enabled device and receiving traps.

You can append query options to the URI in the following format, **?option=value&option=value&...**

310.2. SNMP PRODUCER

Available from 2.18 release

It can also be used to request information using GET method.

The response body type is `org.apache.camel.component.snmp.SnmpMessage`

310.3. OPTIONS

The SNMP component has no options.

The SNMP endpoint is configured using URI syntax:

```
snmp:host:port
```

with the following path and query parameters:

310.3.1. Path Parameters (2 parameters):

Name	Description	Default	Type
host	Required Hostname of the SNMP enabled device		String
port	Required Port number of the SNMP enabled device		Integer

310.3.2. Query Parameters (35 parameters):

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
delay (consumer)	Sets update rate in seconds	60000	long
oids (consumer)	Defines which values you are interested in. Please have a look at the Wikipedia to get a better understanding. You may provide a single OID or a coma separated list of OIDs. Example: oids=1.3.6.1.2.1.1.3.0,1.3.6.1.2.1.25.3.2.1.5.1,1.3.6.1.2.1.25.3.5.1.1,1.3.6.1.2.1.43.5.1.1.11.1		String
protocol (consumer)	Here you can select which protocol to use. You can use either udp or tcp.	udp	String
retries (consumer)	Defines how often a retry is made before canceling the request.	2	int
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean
snmpCommunity (consumer)	Sets the community octet string for the snmp request.	public	String
snmpContextEngineId (consumer)	Sets the context engine ID field of the scoped PDU.		String
snmpContextName (consumer)	Sets the context name field of this scoped PDU.		String
snmpVersion (consumer)	Sets the snmp version for the request. The value 0 means SNMPv1, 1 means SNMPv2c, and the value 3 means SNMPv3	0	int
timeout (consumer)	Sets the timeout value for the request in millis.	1500	int

Name	Description	Default	Type
treeList (consumer)	Sets the flag whether the scoped PDU will be displayed as the list if it has child elements in its tree	false	boolean
type (consumer)	Which operation to perform such as poll, trap, etc.		SnmpActionType
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
pollStrategy (consumer)	A pluggable org.apache.camel.PollingConsumerPollingStrategy allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		PollingConsumerPollStrategy
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.		int
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.		int
greedy (scheduler)	If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	1000	long

Name	Description	Default	Type
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that.	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz2 component	none	ScheduledPollConsumer Scheduler
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz2, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for initialDelay and delay options.	MILLIS ECON DS	TimeUnit
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.	true	boolean
authenticationPassphrase (security)	The authentication passphrase. If not null, authenticationProtocol must also be not null. RFC3414 11.2 requires passphrases to have a minimum length of 8 bytes. If the length of authenticationPassphrase is less than 8 bytes an IllegalArgumentException is thrown.		String
authenticationProtocol (security)	Authentication protocol to use if security level is set to enable authentication The possible values are: MD5, SHA1		String
privacyPassphrase (security)	The privacy passphrase. If not null, privacyProtocol must also be not null. RFC3414 11.2 requires passphrases to have a minimum length of 8 bytes. If the length of authenticationPassphrase is less than 8 bytes an IllegalArgumentException is thrown.		String
privacyProtocol (security)	The privacy protocol ID to be associated with this user. If set to null, this user only supports unencrypted messages.		String

Name	Description	Default	Type
securityLevel (security)	Sets the security level for this target. The supplied security level must be supported by the security model dependent information associated with the security name set for this target. The value 1 means: No authentication and no encryption. Anyone can create and read messages with this security level The value 2 means: Authentication and no encryption. Only the one with the right authentication key can create messages with this security level, but anyone can read the contents of the message. The value 3 means: Authentication and encryption. Only the one with the right authentication key can create messages with this security level, and only the one with the right encryption/decryption key can read the contents of the message.	3	int
securityName (security)	Sets the security name to be used with this target.		String

310.4. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.component.snmp.enabled	Enable snmp component	true	Boolean
camel.component.snmp.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

310.5. THE RESULT OF A POLL

Given the situation, that I poll for the following OIDs:

OIDs

```
1.3.6.1.2.1.1.3.0
1.3.6.1.2.1.25.3.2.1.5.1
1.3.6.1.2.1.25.3.5.1.1.1
1.3.6.1.2.1.43.5.1.1.11.1
```

The result will be the following:

Result of toString conversion

```
<?xml version="1.0" encoding="UTF-8"?>
<snmp>
  <entry>
    <oid>1.3.6.1.2.1.1.3.0</oid>
    <value>6 days, 21:14:28.00</value>
  </entry>
  <entry>
    <oid>1.3.6.1.2.1.25.3.2.1.5.1</oid>
    <value>2</value>
  </entry>
  <entry>
    <oid>1.3.6.1.2.1.25.3.5.1.1.1</oid>
    <value>3</value>
  </entry>
  <entry>
    <oid>1.3.6.1.2.1.43.5.1.1.11.1</oid>
    <value>6</value>
  </entry>
  <entry>
    <oid>1.3.6.1.2.1.1.1.0</oid>
    <value>My Very Special Printer Of Brand Unknown</value>
  </entry>
</snmp>
```

As you maybe recognized there is one more result than requested...1.3.6.1.2.1.1.0.

This one is filled in by the device automatically in this special case. So it may absolutely happen, that you receive more than you requested...be prepared.

OID starting with dot representation

```
.1.3.6.1.4.1.6527.3.1.2.21.2.1.50
```

As you may notice, default snmpVersion is 0 which means **version1** in the endpoint if it is not set explicitly. Make sure you explicitly set snmpVersion which is not default value, of course in a case of where you are able to query SNMP tables with different versions. Other possible values are **version2c** and **version3**.

310.6. EXAMPLES

Polling a remote device:

```
snmp:192.168.178.23:161?protocol=udp&type=POLL&oids=1.3.6.1.2.1.1.5.0
```

Setting up a trap receiver (**Note that no OID info is needed here!**):

```
snmp:127.0.0.1:162?protocol=udp&type=TRAP
```

From Camel 2.10.0, you can get the community of SNMP TRAP with message header 'securityName', peer address of the SNMP TRAP with message header 'peerAddress'.

Routing example in Java: (converts the SNMP PDU to XML String)

```
from("snmp:192.168.178.23:161?protocol=udp&type=POLL&oids=1.3.6.1.2.1.1.5.0").  
  convertBodyTo(String.class).  
  to("activemq:snmp.states");
```

310.7. SEE ALSO

CHAPTER 311. SOAP DATAFORMAT

Available as of Camel version 2.3

SOAP is a Data Format which uses JAXB2 and JAX-WS annotations to marshal and unmarshal SOAP payloads. It provides the basic features of Apache CXF without need for the CXF Stack.

Supported SOAP versions

SOAP 1.1 is supported by default. SOAP 1.2 is supported from Camel 2.11 onwards.

Namespace prefix mapping

See [JAXB](#) for details how you can control namespace prefix mappings when marshalling using SOAP data format.

311.1. SOAP OPTIONS

The SOAP dataformat supports 7 options, which are listed below.

Name	Default	Java Type	Description
<code>contextPath</code>		String	Package name where your JAXB classes are located.
<code>encoding</code>		String	To overrule and use a specific encoding
<code>elementNameStrategyRef</code>		String	Refers to an element strategy to lookup from the registry. An element name strategy is used for two purposes. The first is to find a xml element name for a given object and soap action when marshaling the object into a SOAP message. The second is to find an Exception class for a given soap fault name. The following three element strategy class name is provided out of the box. QNameStrategy - Uses a fixed qName that is configured on instantiation. Exception lookup is not supported TypeNameStrategy - Uses the name and namespace from the XMLType annotation of the given type. If no namespace is set then package-info is used. Exception lookup is not supported ServiceInterfaceStrategy - Uses information from a webservice interface to determine the type name and to find the exception class for a SOAP fault All three classes is located in the package name org.apache.camel.dataformat.soap.name If you have generated the web service stub code with cxf-codegen or a similar tool then you probably will want to use the ServiceInterfaceStrategy. In the case you have no annotated service interface you should use QNameStrategy or TypeNameStrategy.
<code>version</code>	1.1	String	SOAP version should either be 1.1 or 1.2. Is by default 1.1

Name	Default	Java Type	Description
<code>namespacePrefixRef</code>		String	When marshalling using JAXB or SOAP then the JAXB implementation will automatic assign namespace prefixes, such as ns2, ns3, ns4 etc. To control this mapping, Camel allows you to refer to a map which contains the desired mapping.
<code>schema</code>		String	To validate against an existing schema. You can use the prefix classpath:, file: or http: to specify how the resource should be resolved. You can separate multiple schema files by using the ',' character.
<code>contentTypeHeader</code>	false	Boolean	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON etc.

311.2. SPRING BOOT AUTO-CONFIGURATION

The component supports 8 options, which are listed below.

Name	Description	Default	Type
<code>camel.dataformat.soapjaxb.content-type-header</code>	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON etc.	false	Boolean
<code>camel.dataformat.soapjaxb.context-path</code>	Package name where your JAXB classes are located.		String

Name	Description	Default	Type
camel.dataformat.soapjaxb.element-name-strategy-ref	Refers to an element strategy to lookup from the registry. An element name strategy is used for two purposes. The first is to find a xml element name for a given object and soap action when marshaling the object into a SOAP message. The second is to find an Exception class for a given soap fault name. The following three element strategy class name is provided out of the box. QNameStrategy - Uses a fixed qName that is configured on instantiation. Exception lookup is not supported TypeNameStrategy - Uses the name and namespace from the XMLType annotation of the given type. If no namespace is set then package-info is used. Exception lookup is not supported ServiceInterfaceStrategy - Uses information from a webservice interface to determine the type name and to find the exception class for a SOAP fault All three classes is located in the package name org.apache.camel.dataformat.soap.name If you have generated the web service stub code with cxf-codegen or a similar tool then you probably will want to use the ServiceInterfaceStrategy. In the case you have no annotated service interface you should use QNameStrategy or TypeNameStrategy.		String
camel.dataformat.soapjaxb.enabled	Enable soapjaxb dataformat	true	Boolean
camel.dataformat.soapjaxb.encoding	To overrule and use a specific encoding		String
camel.dataformat.soapjaxb.namespace-prefix-ref	When marshalling using JAXB or SOAP then the JAXB implementation will automatic assign namespace prefixes, such as ns2, ns3, ns4 etc. To control this mapping, Camel allows you to refer to a map which contains the desired mapping.		String
camel.dataformat.soapjaxb.schema	To validate against an existing schema. Your can use the prefix classpath:, file: or http: to specify how the resource should by resolved. You can separate multiple schema files by using the ',' character.		String
camel.dataformat.soapjaxb.version	SOAP version should either be 1.1 or 1.2. Is by default 1.1	1.1	String

ND

311.3. ELEMENTNAMESTRATEGY

An element name strategy is used for two purposes. The first is to find a xml element name for a given object and soap action when marshaling the object into a SOAP message. The second is to find an Exception class for a given soap fault name.

Strategy	Usage
QNameStrategy	Uses a fixed qName that is configured on instantiation. Exception lookup is not supported
TypeNameStrategy	Uses the name and namespace from the @XMLType annotation of the given type. If no namespace is set then package-info is used. Exception lookup is not supported
ServiceInterfaceStrategy	Uses information from a webservice interface to determine the type name and to find the exception class for a SOAP fault

If you have generated the web service stub code with cxf-codegen or a similar tool then you probably will want to use the ServiceInterfaceStrategy. In the case you have no annotated service interface you should use QNameStrategy or TypeNameStrategy.

311.4. USING THE JAVA DSL

The following example uses a named DataFormat of soap which is configured with the package com.example.customerservice to initialize the [JAXBContext](#). The second parameter is the ElementNameStrategy. The route is able to marshal normal objects as well as exceptions. (Note the below just sends a SOAP Envelope to a queue. A web service provider would actually need to be listening to the queue for a SOAP call to actually occur, in which case it would be a one way SOAP request. If you need request reply then you should look at the next example.)

```
SoapJaxbDataFormat soap = new SoapJaxbDataFormat("com.example.customerservice", new
ServiceInterfaceStrategy(CustomerService.class));
from("direct:start")
.marshall(soap)
.to("jms:myQueue");
```

TIP

See also As the SOAP dataformat inherits from the [JAXB](#) dataformat most settings apply here as well

311.4.1. Using SOAP 1.2

Available as of Camel 2.11

```
SoapJaxbDataFormat soap = new SoapJaxbDataFormat("com.example.customerservice", new
ServiceInterfaceStrategy(CustomerService.class));
```

```
soap.setVersion("1.2");
from("direct:start")
  .marshal(soap)
  .to("jms:myQueue");
```

When using XML DSL there is a version attribute you can set on the <soapjaxb> element.

```
<!-- Defining a ServiceInterfaceStrategy for retrieving the element name when marshalling -->
<bean id="myNameStrategy"
class="org.apache.camel.dataformat.soap.name.ServiceInterfaceStrategy">
  <constructor-arg value="com.example.customerservice.CustomerService"/>
  <constructor-arg value="true"/>
</bean>
```

And in the Camel route

```
<route>
  <from uri="direct:start"/>
  <marshal>
    <soapjaxb contentPath="com.example.customerservice" version="1.2"
elementNameStrategyRef="myNameStrategy"/>
  </marshal>
  <to uri="jms:myQueue"/>
</route>
```

311.5. MULTI-PART MESSAGES

Available as of Camel 2.8.1

Multi-part SOAP messages are supported by the ServiceInterfaceStrategy. The ServiceInterfaceStrategy must be initialized with a service interface definition that is annotated in accordance with JAX-WS 2.2 and meets the requirements of the Document Bare style. The target method must meet the following criteria, as per the JAX-WS specification: 1) it must have at most one **in** or **in/out** non-header parameter, 2) if it has a return type other than **void** it must have no **in/out** or **out** non-header parameters, 3) if it has a return type of **void** it must have at most one **in/out** or **out** non-header parameter.

The ServiceInterfaceStrategy should be initialized with a boolean parameter that indicates whether the mapping strategy applies to the request parameters or response parameters.

```
ServiceInterfaceStrategy strat = new
ServiceInterfaceStrategy(com.example.customerservice.multipart.MultiPartCustomerService.class,
true);
SoapJaxbDataFormat soapDataFormat = new
SoapJaxbDataFormat("com.example.customerservice.multipart", strat);
```

311.5.1. Multi-part Request

The payload parameters for a multi-part request are initialized using a **BeanInvocation** object that reflects the signature of the target operation. The camel-soap DataFormat maps the content in the **BeanInvocation** to fields in the SOAP header and body in accordance with the JAX-WS mapping when the **marshal()** processor is invoked.

```

BeanInvocation beanInvocation = new BeanInvocation();

// Identify the target method
beanInvocation.setMethod(MultiPartCustomerService.class.getMethod("getCustomersByName",
    GetCustomersByName.class, com.example.customerservice.multipart.Product.class));

// Populate the method arguments
GetCustomersByName getCustomersByName = new GetCustomersByName();
getCustomersByName.setName("Dr. Multipart");

Product product = new Product();
product.setName("Multiuse Product");
product.setDescription("Useful for lots of things.");

Object[] args = new Object[] {getCustomersByName, product};

// Add the arguments to the bean invocation
beanInvocation.setArgs(args);

// Set the bean invocation object as the message body
exchange.getIn().setBody(beanInvocation);

```

311.5.2. Multi-part Response

A multi-part soap response may include an element in the soap body and will have one or more elements in the soap header. The camel-soap DataFormat will unmarshal the element in the soap body (if it exists) and place it onto the body of the out message in the exchange. Header elements will **not** be marshaled into their JAXB mapped object types. Instead, these elements are placed into the camel out message header **org.apache.camel.dataformat.soap.UNMARSHALLED_HEADER_LIST**. The elements will appear either as element instance values, or as JAXBElement values, depending upon the setting for the **ignoreJAXBElement** property. This property is inherited from camel-jaxb.

You can also have the camel-soap DataFormat ignore header content all-together by setting the **ignoreUnmarshalledHeaders** value to **true**.

311.5.3. Holder Object mapping

JAX-WS specifies the use of a type-parameterized **javax.xml.ws.Holder** object for **In/Out** and **Out** parameters. A **Holder** object may be used when building the **BeanInvocation**, or you may use an instance of the parameterized-type directly. The camel-soap DataFormat marshals Holder values in accordance with the JAXB mapping for the class of the **Holder's value**. **No mapping is provided for Holder** objects in an unmarshalled response.

311.6. EXAMPLES

311.6.1. Webservice client

The following route supports marshalling the request and unmarshalling a response or fault.

```

String WS_URI = "cxf://http://myserver/customerservice?
serviceClass=com.example.customerservice&dataFormat=MESSAGE";
SoapJaxbDataFormat soapDF = new SoapJaxbDataFormat("com.example.customerservice", new
ServiceInterfaceStrategy(CustomerService.class));

```

```

from("direct:customerServiceClient")
  .onException(Exception.class)
  .handled(true)
  .unmarshal(soapDF)
  .end()
  .marshal(soapDF)
  .to(WS_URI)
  .unmarshal(soapDF);

```

The below snippet creates a proxy for the service interface and makes a SOAP call to the above route.

```

import org.apache.camel.Endpoint;
import org.apache.camel.component.bean.ProxyHelper;
...

Endpoint startEndpoint = context.getEndpoint("direct:customerServiceClient");
ClassLoader classLoader = Thread.currentThread().getContextClassLoader();
// CustomerService below is the service endpoint interface, *not* the javax.xml.ws.Service subclass
CustomerService proxy = ProxyHelper.createProxy(startEndpoint, classLoader,
CustomerService.class);
GetCustomersByNameResponse response = proxy.getCustomersByName(new
GetCustomersByName());

```

311.6.2. Webservice Server

Using the following route sets up a webservice server that listens on jms queue customerServiceQueue and processes requests using the class CustomerServiceImpl. The customerServiceImpl of course should implement the interface CustomerService. Instead of directly instantiating the server class it could be defined in a spring context as a regular bean.

```

SoapJaxbDataFormat soapDF = new SoapJaxbDataFormat("com.example.customerservice", new
ServiceInterfaceStrategy(CustomerService.class));
CustomerService serverBean = new CustomerServiceImpl();
from("jms://queue:customerServiceQueue")
  .onException(Exception.class)
  .handled(true)
  .marshal(soapDF)
  .end()
  .unmarshal(soapDF)
  .bean(serverBean)
  .marshal(soapDF);

```

311.7. DEPENDENCIES

To use the SOAP dataformat in your camel routes you need to add the following dependency to your pom.

```

<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-soap</artifactId>
  <version>2.3.0</version>
</dependency>

```

CHAPTER 312. SOLR COMPONENT

Available as of Camel version 2.9

The Solr component allows you to interface with an [Apache Lucene Solr](#) server (based on SolrJ 3.5.0).

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-solr</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

312.1. URI FORMAT

NOTE: solrs and solrCloud are new added since **Camel 2.14**.

```
solr://host[:port]/solr?[options]
solrs://host[:port]/solr?[options]
solrCloud://host[:port]/solr?[options]
```

312.2. SOLR OPTIONS

The Solr component has no options.

The Solr endpoint is configured using URI syntax:

```
solr:url
```

with the following path and query parameters:

312.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
url	Required Hostname and port for the solr server		String

312.2.2. Query Parameters (13 parameters):

Name	Description	Default	Type
allowCompression (producer)	Server side must support gzip or deflate for this to have any effect		Boolean

Name	Description	Default	Type
connectionTimeout (producer)	connectionTimeout on the underlying HttpConnectionManager		Integer
defaultMaxConnectionsPerHost (producer)	maxConnectionsPerHost on the underlying HttpConnectionManager		Integer
followRedirects (producer)	indicates whether redirects are used to get to the Solr server		Boolean
maxRetries (producer)	Maximum number of retries to attempt in the event of transient errors		Integer
maxTotalConnections (producer)	maxTotalConnection on the underlying HttpConnectionManager		Integer
requestHandler (producer)	Set the request handler to be used		String
soTimeout (producer)	Read timeout on the underlying HttpConnectionManager. This is desirable for queries, but probably not for indexing		Integer
streamingQueueSize (producer)	Set the queue size for the StreamingUpdateSolrServer	10	int
streamingThreadCount (producer)	Set the number of threads for the StreamingUpdateSolrServer	2	int
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
collection (solrCloud)	Set the collection name which the solrCloud server could use		String
zkHost (solrCloud)	Set the ZooKeeper host information which the solrCloud could use, such as zkhost=localhost:8123.		String

312.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.solr.enabled</code>	Enable solr component	true	Boolean
<code>camel.component.solr.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

312.4. MESSAGE OPERATIONS

The following Solr operations are currently supported. Simply set an exchange header with a key of "SolrOperation" and a value set to one of the following. Some operations also require the message body to be set.

- the INSERT operations use the [CommonsHttpSolrServer](#)
- the INSERT_STREAMING operations use the [StreamingUpdateSolrServer](#) (**Camel 2.9.2**)

Operation	Message body	Description
INSERT/INSERT_STREAMING	n/a	adds an index using message headers (must be prefixed with "SolrField.")
INSERT/INSERT_STREAMING	File	adds an index using the given File (using ContentStreamUpdateRequest)
INSERT/INSERT_STREAMING	SolrInputDocument	Camel 2.9.2 updates index based on the given SolrInputDocument
INSERT/INSERT_STREAMING	String XML	Camel 2.9.2 updates index based on the given XML (must follow SolrInputDocument format)

Operation	Message body	Description
ADD_BEAN	bean instance	adds an index based on values in an annotated bean
ADD_BEANS	collection<bean>	Camel 2.15 adds index based on a collection of annotated bean
DELETE_BY_ID	index id to delete	delete a record by ID
DELETE_BY_QUERY	query string	delete a record by a query
COMMIT	n/a	performs a commit on any pending index changes
ROLLBACK	n/a	performs a rollback on any pending index changes
OPTIMIZE	n/a	performs a commit on any pending index changes and then runs the optimize command

312.5. EXAMPLE

Below is a simple INSERT, DELETE and COMMIT example

```

from("direct:insert")
  .setHeader(SolrConstants.OPERATION, constant(SolrConstants.OPERATION_INSERT))
  .setHeader(SolrConstants.FIELD + "id", body())
  .to("solr://localhost:8983/solr");

from("direct:delete")
  .setHeader(SolrConstants.OPERATION, constant(SolrConstants.OPERATION_DELETE_BY_ID))
  .to("solr://localhost:8983/solr");

from("direct:commit")
  .setHeader(SolrConstants.OPERATION, constant(SolrConstants.OPERATION_COMMIT))
  .to("solr://localhost:8983/solr");

<route>
  <from uri="direct:insert"/>
  <setHeader headerName="SolrOperation">

```

```

    <constant>INSERT</constant>
  </setHeader>
  <setHeader headerName="SolrField.id">
    <simple>${body}</simple>
  </setHeader>
  <to uri="solr://localhost:8983/solr"/>
</route>
<route>
  <from uri="direct:delete"/>
  <setHeader headerName="SolrOperation">
    <constant>DELETE_BY_ID</constant>
  </setHeader>
  <to uri="solr://localhost:8983/solr"/>
</route>
<route>
  <from uri="direct:commit"/>
  <setHeader headerName="SolrOperation">
    <constant>COMMIT</constant>
  </setHeader>
  <to uri="solr://localhost:8983/solr"/>
</route>

```

A client would simply need to pass a body message to the insert or delete routes and then call the commit route.

```

template.sendBody("direct:insert", "1234");
template.sendBody("direct:commit", null);
template.sendBody("direct:delete", "1234");
template.sendBody("direct:commit", null);

```

312.6. QUERYING SOLR

Currently, this component doesn't support querying data natively (may be added later). For now, you can query Solr using [HTTP](#) as follows:

```

//define the route to perform a basic query
from("direct:query")
  .recipientList(simple("http://localhost:8983/solr/select?q=${body}"))
  .convertBodyTo(String.class);
...
//query for an id of '1234' (url encoded)
String responseXml = (String) template.requestBody("direct:query", "id%3A1234");

```

CHAPTER 313. APACHE SPARK COMPONENT

Available as of Camel version 2.17

This documentation page covers the [Apache Spark](#) component for the Apache Camel. The main purpose of the Spark integration with Camel is to provide a bridge between Camel connectors and Spark tasks. In particular Camel connector provides a way to route message from various transports, dynamically choose a task to execute, use incoming message as input data for that task and finally deliver the results of the execution back to the Camel pipeline.

313.1. SUPPORTED ARCHITECTURAL STYLES

Spark component can be used as a driver application deployed into an application server (or executed as a fat jar).

Spark component can also be submitted as a job directly into the Spark cluster.

While Spark component is primary designed to work as a *long running job* serving as an bridge between Spark cluster and the other endpoints, you can also use it as a *fire-once* short job.

313.2. RUNNING SPARK IN OSGI SERVERS

Currently the Spark component doesn't support execution in the OSGi container. Spark has been designed to be executed as a fat jar, usually submitted as a job to a cluster. For those reasons running Spark in an OSGi server is at least challenging and is not support by Camel as well.

313.3. URI FORMAT

Currently the Spark component supports only producers - it intended to invoke a Spark job and return results. You can call RDD, data frame or Hive SQL job.

Spark URI format

```
spark:{rdd|dataframe|hive}
```

313.3.1. Spark options

The Apache Spark component supports 3 options, which are listed below.

Name	Description	Default	Type
rdd (producer)	RDD to compute against.		JavaRDDLike
rddCallback (producer)	Function performing action against an RDD.		RddCallback
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Apache Spark endpoint is configured using URI syntax:

```
spark:endpointType
```

with the following path and query parameters:

313.3.2. Path Parameters (1 parameters):

Name	Description	Default	Type
endpointType	Required Type of the endpoint (rdd, dataframe, hive).		EndpointType

313.3.3. Query Parameters (6 parameters):

Name	Description	Default	Type
collect (producer)	Indicates if results should be collected or counted.	true	boolean
dataFrame (producer)	DataFrame to compute against.		Dataset
dataFrameCallback (producer)	Function performing action against an DataFrame.		DataFrameCallback
rdd (producer)	RDD to compute against.		JavaRDDLike
rddCallback (producer)	Function performing action against an RDD.		RddCallback
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

313.4. SPRING BOOT AUTO-CONFIGURATION

The component supports 4 options, which are listed below.

Name	Description	Default	Type
camel.component.spark.enabled	Enable spark component	true	Boolean
camel.component.spark.rdd	RDD to compute against. The option is a <code>org.apache.spark.api.java.JavaRDDLike</code> type.		String
camel.component.spark.rdd-callback	Function performing action against an RDD. The option is a <code>org.apache.camel.component.spark.RddCallback</code> type.		String
camel.component.spark.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

RDD jobs

To invoke an RDD job, use the following URI:

Spark RDD producer

```
spark:rdd?rdd=#testFileRdd&rddCallback=#transformation
```

Where **rdd** option refers to the name of an RDD instance (subclass of **org.apache.spark.api.java.JavaRDDLike**) from a Camel registry, while **rddCallback** refers to the implementation of **org.apache.camel.component.spark.RddCallback** interface (also from a registry). RDD callback provides a single method used to apply incoming messages against the given RDD. Results of callback computations are saved as a body to an exchange.

Spark RDD callback

```
public interface RddCallback<T> {
    T onRdd(JavaRDDLike rdd, Object... payloads);
}
```

The following snippet demonstrates how to send message as an input to the job and return results:

Calling spark job

```
String pattern = "job input";
long linesCount = producerTemplate.requestBody("spark:rdd?
rdd=#myRdd&rddCallback=#countLinesContaining", pattern, long.class);
```

The RDD callback for the snippet above registered as Spring bean could look as follows:

Spark RDD callback

```
@Bean
RddCallback<Long> countLinesContaining() {
    return new RddCallback<Long>() {
        Long onRdd(JavaRDDLike rdd, Object... payloads) {
            String pattern = (String) payloads[0];
            return rdd.filter({line -> line.contains(pattern)}).count();
        }
    }
}
```

The RDD definition in Spring could look as follows:

Spark RDD definition

```
@Bean
JavaRDDLike myRdd(JavaSparkContext sparkContext) {
    return sparkContext.textFile("testRDD.txt");
}
```

313.4.1. Void RDD callbacks

If your RDD callback doesn't return any value back to a Camel pipeline, you can either return **null** value or use **VoidRddCallback** base class:

Spark RDD definition

```
@Bean
```

```
RddCallback<Void> rddCallback() {
    return new VoidRddCallback() {
        @Override
        public void doOnRdd(JavaRDDLike rdd, Object... payloads) {
            rdd.saveAsTextFile(output.getAbsolutePath());
        }
    };
}
```

313.4.2. Converting RDD callbacks

If you know what type of the input data will be sent to the RDD callback, you can use **ConvertingRddCallback** and let Camel to automatically convert incoming messages before inserting those into the callback:

Spark RDD definition

```
@Bean
RddCallback<Long> rddCallback(CamelContext context) {
    return new ConvertingRddCallback<Long>(context, int.class, int.class) {
        @Override
        public Long doOnRdd(JavaRDDLike rdd, Object... payloads) {
            return rdd.count() * (int) payloads[0] * (int) payloads[1];
        }
    };
};
```

313.4.3. Annotated RDD callbacks

Probably the easiest way to work with the RDD callbacks is to provide class with method marked with **@RddCallback** annotation:

Annotated RDD callback definition

```
import static
org.apache.camel.component.spark.annotations.AnnotatedRddCallback.annotatedRddCallback;

@Bean
RddCallback<Long> rddCallback() {
    return annotatedRddCallback(new MyTransformation());
}

...

import org.apache.camel.component.spark.annotation.RddCallback;

public class MyTransformation {

    @RddCallback
    long countLines(JavaRDD<String> textFile, int first, int second) {
        return textFile.count() * first * second;
    }
}
```

```
    }
}
```

If you will pass CamelContext to the annotated RDD callback factory method, the created callback will be able to convert incoming payloads to match the parameters of the annotated method:

Body conversions for annotated RDD callbacks

```
import static
org.apache.camel.component.spark.annotations.AnnotatedRddCallback.annotatedRddCallback;

@Bean
RddCallback<Long> rddCallback(CamelContext camelContext) {
    return annotatedRddCallback(new MyTransformation(), camelContext);
}

...

import org.apache.camel.component.spark.annotation.RddCallback;

public class MyTransformation {

    @RddCallback
    long countLines(JavaRDD<String> textFile, int first, int second) {
        return textFile.count() * first * second;
    }

}

...

// Convert String "10" to integer
long result = producerTemplate.requestBody("spark:rdd?rdd=#rdd&rddCallback=#rddCallback"
Arrays.asList(10, "10"), long.class);
```

313.5. DATAFRAME JOBS

Instead of working with RDDs Spark component can work with DataFrames as well.

To invoke an DataFrame job, use the following URI:

Spark RDD producer

```
spark:dataframe?dataFrame=#testDataFrame&dataFrameCallback=#transformation
```

Where **dataFrame** option refers to the name of an DataFrame instance (**instances of org.apache.spark.sql.Dataset and org.apache.spark.sql.Row**) from a Camel registry, while **dataFrameCallback** refers to the implementation of **org.apache.camel.component.spark.DataFrameCallback** interface (also from a registry). DataFrame callback provides a single method used to apply incoming messages against the given DataFrame. Results of callback computations are saved as a body to an exchange.

Spark RDD callback

```
public interface DataFrameCallback<T> {
    T onDataFrame(Dataset<Row> dataFrame, Object... payloads);
}
```

The following snippet demonstrates how to send message as an input to a job and return results:

Calling spark job

```
String model = "Micra";
long linesCount = producerTemplate.requestBody("spark:dataFrame?
dataFrame=#cars&dataFrameCallback=#findCarWithModel", model, long.class);
```

The DataFrame callback for the snippet above registered as Spring bean could look as follows:

Spark RDD callback

```
@Bean
RddCallback<Long> findCarWithModel() {
    return new DataFrameCallback<Long>() {
        @Override
        public Long onDataFrame(Dataset<Row> dataFrame, Object... payloads) {
            String model = (String) payloads[0];
            return dataFrame.where(dataFrame.col("model").eqNullSafe(model)).count();
        }
    };
}
```

The DataFrame definition in Spring could look as follows:

Spark RDD definition

```
@Bean
Dataset<Row> cars(HiveContext hiveContext) {
    Dataset<Row> jsonCars = hiveContext.read().json("/var/data/cars.json");
    jsonCars.registerTempTable("cars");
    return jsonCars;
}
```

313.6. HIVE JOBS

Instead of working with RDDs or DataFrame Spark component can also receive Hive SQL queries as payloads. To send Hive query to Spark component, use the following URI:

Spark RDD producer

```
spark:hive
```

The following snippet demonstrates how to send message as an input to a job and return results:

Calling spark job

```
long carsCount = template.requestBody("spark:hive?collect=false", "SELECT * FROM cars",  
Long.class);  
List<Row> cars = template.requestBody("spark:hive", "SELECT * FROM cars", List.class);
```

The table we want to execute query against should be registered in a HiveContext before we query it. For example in Spring such registration could look as follows:

Spark RDD definition

```
@Bean  
Dataset<Row> cars(HiveContext hiveContext) {  
    jsonCars = hiveContext.read().json("/var/data/cars.json");  
    jsonCars.registerTempTable("cars");  
    return jsonCars;  
}
```

313.7. SEE ALSO

- [Configuring Camel](#)
- [Component](#)
- [Endpoint](#)
- [Getting Started](#)

CHAPTER 314. SPARK REST COMPONENT

Available as of Camel version 2.14

The Spark-rest component allows to define REST endpoints using the [Spark REST Java library](#) using the Rest DSL.

INFO: Spark Java requires Java 8 runtime.

Maven users will need to add the following dependency to their pom.xml for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-spark-rest</artifactId>
  <version>${camel-version}</version>
</dependency>
```

314.1. URI FORMAT

```
spark-rest://verb:path?[options]
```

314.2. URI OPTIONS

The Spark Rest component supports 12 options, which are listed below.

Name	Description	Default	Type
port (consumer)	Port number. Will by default use 4567	4567	int
ipAddress (consumer)	Set the IP address that Spark should listen on. If not called the default address is '0.0.0.0'.	0.0.0.0	String
minThreads (advanced)	Minimum number of threads in Spark thread-pool (shared globally)		int
maxThreads (advanced)	Maximum number of threads in Spark thread-pool (shared globally)		int
timeOutMillis (advanced)	Thread idle timeout in millis where threads that has been idle for a longer period will be terminated from the thread pool		int
keystoreFile (security)	Configures connection to be secure to use the keystore file		String
keystorePassword (security)	Configures connection to be secure to use the keystore password		String

Name	Description	Default	Type
truststoreFile (security)	Configures connection to be secure to use the truststore file		String
truststorePassword (security)	Configures connection to be secure to use the truststore password		String
sparkConfiguration (advanced)	To use the shared SparkConfiguration		SparkConfiguration
sparkBinding (advanced)	To use a custom SparkBinding to map to/from Camel message.		SparkBinding
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Spark Rest endpoint is configured using URI syntax:

```
spark-rest:verb:path
```

with the following path and query parameters:

314.2.1. Path Parameters (2 parameters):

Name	Description	Default	Type
verb	Required get, post, put, patch, delete, head, trace, connect, or options.		String
path	Required The content path which support Spark syntax.		String

314.2.2. Query Parameters (11 parameters):

Name	Description	Default	Type
accept (consumer)	Accept type such as: 'text/xml', or 'application/json'. By default we accept all kinds of types.		String

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
disableStreamCache (consumer)	Determines whether or not the raw input stream from Spark <code>HttpRequest#getContent()</code> is cached or not (Camel will read the stream into a in light-weight memory based Stream caching) cache. By default Camel will cache the Netty input stream to support reading it multiple times to ensure Camel can retrieve all data from the stream. However you can set this option to true when you for example need to access the raw stream, such as streaming it directly to a file or other persistent store. Mind that if you enable this option, then you cannot read the Netty stream multiple times out of the box, and you would need manually to reset the reader index on the Spark raw stream.	false	boolean
mapHeaders (consumer)	If this option is enabled, then during binding from Spark to Camel Message then the headers will be mapped as well (eg added as header to the Camel Message as well). You can turn off this option to disable this. The headers can still be accessed from the <code>org.apache.camel.component.sparkrest.SparkMessage</code> message with the method <code>getRequest()</code> that returns the Spark HTTP request instance.	true	boolean
transferException (consumer)	If enabled and an Exchange failed processing on the consumer side, and if the caused Exception was send back serialized in the response as a <code>application/x-java-serialized-object</code> content type. This is by default turned off. If you enable this then be aware that Java will deserialize the incoming data from the request to Java and that can be a potential security risk.	false	boolean
urlDecodeHeaders (consumer)	If this option is enabled, then during binding from Spark to Camel Message then the header values will be URL decoded (eg <code>%20</code> will be a space character.)	false	boolean

Name	Description	Default	Type
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
matchOnUriPrefix (advanced)	Whether or not the consumer should try to find a target consumer by matching the URI prefix if no exact match is found.	false	boolean
sparkBinding (advanced)	To use a custom SparkBinding to map to/from Camel message.		SparkBinding
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

314.3. PATH USING SPARK SYNTAX

The path option is defined using a Spark REST syntax where you define the REST context path using support for parameters and splat. See more details at the [Spark Java Route](#) documentation.

The following is a Camel route using a fixed path

```
from("spark-rest:get:hello")
  .transform().constant("Bye World");
```

And the following route uses a parameter which is mapped to a Camel header with the key "me".

```
from("spark-rest:get:hello/:me")
  .transform().simple("Bye ${header.me}");
```

314.4. MAPPING TO CAMEL MESSAGE

The Spark Request object is mapped to a Camel Message as a **org.apache.camel.component.sparkrest.SparkMessage** which has access to the raw Spark request using the `getRequest` method. By default the Spark body is mapped to Camel message body, and any HTTP headers / Spark parameters is mapped to Camel Message headers. There is special support for the Spark splat syntax, which is mapped to the Camel message header with key `splat`.

For example the given route below uses Spark splat (the asterisk sign) in the context path which we can access as a header from the Simple language to construct a response message.

```
from("spark-rest:get:/hello/*/to/*")
  .transform().simple("Bye big ${header.splat[1]} from ${header.splat[0]}");
```

314.5. REST DSL

Apache Camel provides a new Rest DSL that allow to define the REST services in a nice REST style. For example we can define a REST hello service as shown below:

```
return new RouteBuilder() {
    @Override
    public void configure() throws Exception {
        rest("/hello/{me}").get()
            .route().transform().simple("Bye ${header.me}");
    }
};
```

```
<camelContext xmlns="http://camel.apache.org/schema/spring">
  <rest uri="/hello/{me}">
    <get>
      <route>
        <transform>
          <simple>Bye ${header.me}</simple>
        </transform>
      </route>
    </get>
  </rest>
</camelContext>
```

See more details at the Rest DSL.

314.6. MORE EXAMPLES

There is a **camel-example-spark-rest-tomcat** example in the Apache Camel distribution, that demonstrates how to use camel-spark-rest in a web application that can be deployed on Apache Tomcat, or similar web containers.

CHAPTER 315. SPEL LANGUAGE

Available as of Camel version 2.7

Camel allows [Spring Expression Language \(SpEL\)](#) to be used as an Expression or Predicate in the DSL or XML Configuration.

NOTE

It is recommended to use SpEL in Spring runtimes. However from Camel 2.21 onwards you can use SpEL in other runtimes (there may be functionality SpEL cannot do when not running in a Spring runtime)

315.1. VARIABLES

The following variables are available in expressions and predicates written in SpEL:

Variable	Type	Description
this	Exchange	the Exchange is the root object
exchange	Exchange	the Exchange object
exception	Throwable	the Exchange exception (if any)
exchangeId	String	the exchange id
fault	Message	the Fault message (if any)
body	Object	The IN message body.
request	Message	the exchange.in message
response	Message	the exchange.out message (if any)
properties	Map	the exchange properties
property(name)	Object	the property by the given name

Variable	Type	Description
property(name, type)	Type	the property by the given name as the given type

315.2. OPTIONS

The SpEL language supports 1 options, which are listed below.

Name	Default	Java Type	Description
trim	true	Boolean	Whether to trim the value to remove leading and trailing whitespaces and line breaks

315.3. SAMPLES

315.3.1. Expression templating

SpEL expressions need to be surrounded by `#{ }` delimiters since expression templating is enabled. This allows you to combine SpEL expressions with regular text and use this as extremely lightweight template language.

For example if you construct the following route:

```
from("direct:example")
  .setBody(spel("Hello #{request.body}! What a beautiful #{request.headers['dayOrNight']}"))
  .to("mock:result");
```

In the route above, notice `spel` is a static method which we need to import from **org.apache.camel.language.spel.SpelExpression.spel**, as we use `spel` as an Expression passed in as a parameter to the **setBody** method. Though if we use the fluent API we can do this instead:

```
from("direct:example")
  .setBody().spel("Hello #{request.body}! What a beautiful #{request.headers['dayOrNight']}")
  .to("mock:result");
```

Notice we now use the **spel** method from the **setBody()** method. And this does not require us to static import the `spel` method from **org.apache.camel.language.spel.SpelExpression.spel**.

And sent a message with the string "World" in the body, and a header "dayOrNight" with value "day":

```
template.sendBodyAndHeader("direct:example", "World", "dayOrNight", "day");
```

The output on **mock:result** will be *"Hello World! What a beautiful day"*

315.3.2. Bean integration

You can reference beans defined in the Registry (most likely an **ApplicationContext**) in your SpEL expressions. For example if you have a bean named "foo" in your **ApplicationContext** you can invoke the "bar" method on this bean like this:

```
#{@foo.bar == 'xyz'}
```

315.3.3. SpEL in enterprise integration patterns

You can use SpEL as an expression for [Recipient List](#) or as a predicate inside a [Message Filter](#):

```
<route>
  <from uri="direct:foo"/>
  <filter>
    <spel>#{request.headers['foo'] == 'bar'}</spel>
    <to uri="direct:bar"/>
  </filter>
</route>
```

And the equivalent in Java DSL:

```
from("direct:foo")
  .filter().spel("#{request.headers['foo'] == 'bar'}")
  .to("direct:bar");
```

315.4. LOADING SCRIPT FROM EXTERNAL RESOURCE

Available as of Camel 2.11

You can externalize the script and have Camel load it from a resource such as **"classpath:"**, **"file:"**, or **"http:"**.

This is done using the following syntax: **"resource:scheme:location"**, eg to refer to a file on the classpath you can do:

```
.setHeader("myHeader").spel("resource:classpath:myspel.txt")
```

CHAPTER 316. SPLUNK COMPONENT

Available as of Camel version 2.13

The Splunk component provides access to [Splunk](#) using the Splunk provided [client](#) api, and it enables you to publish and search for events in Splunk.

Maven users will need to add the following dependency to their pom.xml for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-splunk</artifactId>
  <version>${camel-version}</version>
</dependency>
```

316.1. URI FORMAT

```
splunk://[endpoint]?[options]
```

316.2. PRODUCER ENDPOINTS:

Endpoint	Description
stream	Streams data to a named index or the default if not specified. When using stream mode be aware of that Splunk has some internal buffer (about 1MB or so) before events gets to the index. If you need realtime, better use submit or tcp mode.
submit	submit mode. Uses Splunk rest api to publish events to a named index or the default if not specified.
tcp	tcp mode. Streams data to a tcp port, and requires a open receiver port in Splunk.

When publishing events the message body should contain a SplunkEvent. See comment under message body.

Example

```
from("direct:start").convertBodyTo(SplunkEvent.class)
  .to("splunk://submit?
username=user&password=123&index=myindex&sourceType=someSourceType&source=mySource"
)...
```

In this example a converter is required to convert to a SplunkEvent class.

316.3. CONSUMER ENDPOINTS:

Endpoint	Description
normal	Performs normal search and requires a search query in the search option.
savedsearch	Performs search based on a search query saved in splunk and requires the name of the query in the savedSearch option.

Example

```
from("splunk://normal?delay=5s&username=user&password=123&initEarliestTime=-10s&search=search index=myindex sourcetype=someSourcetype")
.to("direct:search-result");
```

camel-splunk creates a route exchange per search result with a SplunkEvent in the body.

316.4. URI OPTIONS

The Splunk component supports 2 options, which are listed below.

Name	Description	Default	Type
splunkConfigurationFactory (advanced)	To use the SplunkConfigurationFactory		SplunkConfigurationFactory
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Splunk endpoint is configured using URI syntax:

```
splunk:name
```

with the following path and query parameters:

316.4.1. Path Parameters (1 parameters):

Name	Description	Default	Type
name	Required Name has no purpose		String

316.4.2. Query Parameters (42 parameters):

Name	Description	Default	Type
app (common)	Splunk app		String
connectionTimeout (common)	Timeout in MS when connecting to Splunk server	5000	int
host (common)	Splunk host.	localhost	String
owner (common)	Splunk owner		String
port (common)	Splunk port	8089	int
scheme (common)	Splunk scheme	https	String
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
count (consumer)	A number that indicates the maximum number of entities to return.		int
earliestTime (consumer)	Earliest time of the search time window.		String
initEarliestTime (consumer)	Initial start offset of the first search		String
latestTime (consumer)	Latest time of the search time window.		String
savedSearch (consumer)	The name of the query saved in Splunk to run		String
search (consumer)	The Splunk query to run		String
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean

Name	Description	Default	Type
streaming (consumer)	Sets streaming mode. Streaming mode sends exchanges as they are received, rather than in a batch.		Boolean
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
pollStrategy (consumer)	A pluggable org.apache.camel.PollingConsumerPollingStrategy allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		PollingConsumerPollStrategy
eventHost (producer)	Override the default Splunk event host field		String
index (producer)	Splunk index to write to		String
raw (producer)	Should the payload be inserted raw	false	boolean
source (producer)	Splunk source argument		String
sourceType (producer)	Splunk sourcetype argument		String
tcpReceiverPort (producer)	Splunk tcp receiver port		int
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.		int

Name	Description	Default	Type
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then <code>backoffIdleThreshold</code> and/or <code>backoffErrorThreshold</code> must also be configured.		int
delay (scheduler)	Milliseconds before the next poll. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	500	long
greedy (scheduler)	If greedy is enabled, then the <code>ScheduledPollConsumer</code> will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	1000	long
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that.	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz2 component	none	ScheduledPollConsumer Scheduler
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz2, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for <code>initialDelay</code> and <code>delay</code> options.	MILLIS ECON DS	TimeUnit
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See <code>ScheduledExecutorService</code> in JDK for details.	true	boolean

Name	Description	Default	Type
password (security)	Password for Splunk		String
sslProtocol (security)	Set the ssl protocol to use	TLSv1.2	SSLSecurityProtocol
username (security)	Username for Splunk		String
useSunHttpsHandler (security)	Use sun.net.www.protocol.https.Handler Https handler to establish the Splunk Connection. Can be useful when running in application servers to avoid app. server https handling.	false	boolean

316.5. SPRING BOOT AUTO-CONFIGURATION

The component supports 3 options, which are listed below.

Name	Description	Default	Type
camel.component.splunk.enabled	Enable splunk component	true	Boolean
camel.component.splunk.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
camel.component.splunk.splunk-configuration-factory	To use the SplunkConfigurationFactory. The option is a org.apache.camel.component.splunk.SplunkConfigurationFactory type.		String

316.6. MESSAGE BODY

Splunk operates on data in key/value pairs. The SplunkEvent class is a placeholder for such data, and should be in the message body for the producer. Likewise it will be returned in the body per search result for the consumer.

As of Camel 2.16.0 you can send raw data to Splunk by setting the raw option on the producer endpoint. This is useful for eg. json/xml and other payloads where Splunk has build in support.

316.7. USE CASES

Search Twitter for tweets with music and publish events to Splunk

```

    from("twitter://search?
type=polling&keywords=music&delay=10&consumerKey=abc&consumerSecret=def&accessToken=hij&
ccessTokenSecret=xxx")
        .convertBodyTo(SplunkEvent.class)
        .to("splunk://submit?username=foo&password=bar&index=camel-
tweets&sourceType=twitter&source=music-tweets");

```

To convert a Tweet to a SplunkEvent you could use a converter like

```

@Converter
public class Tweet2SplunkEvent {
    @Converter
    public static SplunkEvent convertTweet(Status status) {
        SplunkEvent data = new SplunkEvent("twitter-message", null);
        //data.addPair("source", status.getSource());
        data.addPair("from_user", status.getUser().getScreenName());
        data.addPair("in_reply_to", status.getInReplyToScreenName());
        data.addPair(SplunkEvent.COMMON_START_TIME, status.getCreatedAt());
        data.addPair(SplunkEvent.COMMON_EVENT_ID, status.getId());
        data.addPair("text", status.getText());
        data.addPair("retweet_count", status.getRetweetCount());
        if (status.getPlace() != null) {
            data.addPair("place_country", status.getPlace().getCountry());
            data.addPair("place_name", status.getPlace().getName());
            data.addPair("place_street", status.getPlace().getStreetAddress());
        }
        if (status.getGeoLocation() != null) {
            data.addPair("geo_latitude", status.getGeoLocation().getLatitude());
            data.addPair("geo_longitude", status.getGeoLocation().getLongitude());
        }
        return data;
    }
}

```

Search Splunk for tweets

```

    from("splunk://normal?username=foo&password=bar&initEarliestTime=-2m&search=search
index=camel-tweets sourcetype=twitter")
        .log("${body}");

```

316.8. OTHER COMMENTS

Splunk comes with a variety of options for leveraging machine generated data with prebuilt apps for analyzing and displaying this.

For example the jmx app. could be used to publish jmx attributes, eg. route and jvm metrics to Splunk, and displaying this on a dashboard.

- [Configuring Camel](#)
- [Component](#)
- [Endpoint](#)

- Getting Started

CHAPTER 317. SPRING SUPPORT

Apache Camel is designed to work nicely with the [Spring Framework](#) in a number of ways.

- Camel uses Spring Transactions as the default transaction handling in components like [JMS](#) and [JPA](#)
- Camel works with Spring 2 XML processing with the Xml Configuration
- Camel Spring XML Schema's is defined at [Xml Reference](#)
- Camel supports a powerful version of [Spring Remoting](#) which can use powerful routing between the client and server side along with using all of the available Components for the transport
- Camel provides powerful Bean Integration with any bean defined in a Spring ApplicationContext
- Camel integrates with various Spring helper classes; such as providing Type Converter support for Spring Resources etc
- Allows Spring to dependency inject Component instances or the CamelContext instance itself and auto-expose Spring beans as components and endpoints.
- Allows you to reuse the Spring Testing framework to simplify your unit and integration testing using [Enterprise Integration Patterns](#) and Camel's powerful [Mock](#) and [Test](#) endpoints
- From **Camel 2.15** onwards Camel supports Spring Boot using the **camel-spring-boot** component.

317.1. USING SPRING TO CONFIGURE THE CAMELCONTEXT

You can configure a CamelContext inside any spring.xml using the [CamelContextFactoryBean](#). This will automatically start the CamelContext along with any referenced Routes along any referenced Component and Endpoint instances.

- Adding Camel schema
- Configure Routes in two ways:
 - Using Java Code
 - Using Spring XML

317.2. ADDING CAMEL SCHEMA

For Camel 1.x you need to use the following namespace:

```
http://activemq.apache.org/camel/schema/spring
```

with the following schema location:

```
http://activemq.apache.org/camel/schema/spring/camel-spring.xsd
```

You need to add Camel to the **schemaLocation** declaration

```
http://camel.apache.org/schema/spring http://camel.apache.org/schema/spring/camel-spring.xsd
```

So the XML file looks like this:

```
<beans xmlns="http://www.springframework.org/schema/beans"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="
    http://www.springframework.org/schema/beans
    http://www.springframework.org/schema/beans/spring-beans.xsd
    http://camel.apache.org/schema/spring http://camel.apache.org/schema/spring/camel-
    spring.xsd">
```

317.2.1. Using camel: namespace

Or you can refer to camel XSD in the XML declaration:

```
xmlns:camel="http://camel.apache.org/schema/spring"
```

- i. so the declaration is:

```
<beans xmlns="http://www.springframework.org/schema/beans"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xmlns:camel="http://camel.apache.org/schema/spring"
  xsi:schemaLocation="
    http://www.springframework.org/schema/beans
    http://www.springframework.org/schema/beans/spring-beans.xsd
    http://camel.apache.org/schema/spring http://camel.apache.org/schema/spring/camel-
    spring.xsd">
```

- i. and then use the camel: namespace prefix, and you can omit the inline namespace declaration:

```
<camel:camelContext id="camel5">
  <camel:package>org.apache.camel.spring.example</camel:package>
</camel:camelContext>
```

317.2.2. Advanced configuration using Spring

See more details at [Advanced configuration of CamelContext using Spring](#)

Using Java Code

You can use Java Code to define your RouteBuilder implementations. These can be defined as beans in spring and then referenced in your camel context e.g.

317.2.3. Using <package>

Camel also provides a powerful feature that allows for the automatic discovery and initialization of routes in given packages. This is configured by adding tags to the camel context in your spring context definition, specifying the packages to be recursively searched for RouteBuilder implementations. To use this feature in 1.X, requires a <package></package> tag specifying a comma separated list of packages that should be searched e.g.

```
<camelContext xmlns="http://camel.apache.org/schema/spring">
  <package>org.apache.camel.spring.config.scan.route</package>
</camelContext>
```

WARNING: Use caution when specifying the package name as **org.apache.camel** or a sub package of this. This causes Camel to search in its own packages for your routes which could cause problems.

INFO: *Will ignore already instantiated classes*. The `<package>` and `<packageScan>` will skip any classes which has already been created by Spring etc. So if you define a route builder as a spring bean tag then that class will be skipped. You can include those beans using `<routeBuilder ref="theBeanId"/>` or the `<contextScan>` feature.

317.2.4. Using `<packageScan>`

In Camel 2.0 this has been extended to allow selective inclusion and exclusion of discovered route classes using Ant like path matching. In spring this is specified by adding a `<packageScan/>` tag. The tag must contain one or more 'package' elements (similar to 1.x), and optionally one or more 'includes' or 'excludes' elements specifying patterns to be applied to the fully qualified names of the discovered classes. e.g.

```
<camelContext xmlns="http://camel.apache.org/schema/spring">
  <packageScan>
    <package>org.example.routes</package>
    <excludes>**. *Excluded*</excludes>
    <includes>**. *</includes>
  </packageScan>
</camelContext>
```

Exclude patterns are applied before the include patterns. If no include or exclude patterns are defined then all the Route classes discovered in the packages will be returned.

In the above example, camel will scan all the 'org.example.routes' package and any subpackages for RouteBuilder classes. Say the scan finds two RouteBuilders, one in org.example.routes called 'MyRoute' and another 'MyExcludedRoute' in a subpackage 'excluded'. The fully qualified names of each of the classes are extracted (org.example.routes.MyRoute, org.example.routes.excluded.MyExcludedRoute) and the include and exclude patterns are applied.

The exclude pattern ***.*Excluded** is going to match the fqcn 'org.example.routes.excluded.MyExcludedRoute' and veto camel from initializing it.

Under the covers, this is using Spring's [AntPatternMatcher](#) implementation, which matches as follows

- ? matches one character
- * matches zero or more characters
- ** matches zero or more segments of a fully qualified name

For example:

***.*Excluded** would match org.simple.Excluded, org.apache.camel.SomeExcludedRoute or org.example.RouteWhichIsExcluded

***.??cluded** would match org.simple.IncludedRoute, org.simple.Excluded but not match org.simple.PrecludedRoute

317.2.5. Using contextScan

Available as of Camel 2.4

You can allow Camel to scan the container context, e.g. the Spring **ApplicationContext** for route builder instances. This allow you to use the Spring **<component-scan>** feature and have Camel pickup any RouteBuilder instances which was created by Spring in its scan process.

This allows you to just annotate your routes using the Spring **@Component** and have those routes included by Camel

```
@Component
public class MyRoute extends SpringRouteBuilder {

    @Override
    public void configure() throws Exception {
        from("direct:start").to("mock:result");
    }
}
```

You can also use the ANT style for inclusion and exclusion, as mentioned above in the **<packageScan>** documentation.

317.3. HOW DO I IMPORT ROUTES FROM OTHER XML FILES

Available as of Camel 2.3

When defining routes in Camel using [Xml Configuration](#) you may want to define some routes in other XML files. For example you may have many routes and it may help to maintain the application if some of the routes are in separate XML files. You may also want to store common and reusable routes in other XML files, which you can simply import when needed.

In **Camel 2.3** it is now possible to define routes outside **<camelContext/>** which you do in a new **<routeContext/>** tag.

Notice: When you use **<routeContext>** then they are separated, and cannot reuse existing **<onException>**, **<intercept>**, **<dataFormats>** and similar cross cutting functionality defined in the **<camelContext>**. In other words the **<routeContext>** is currently isolated. This may change in Camel 3.x.

For example we could have a file named **myCoolRoutes.xml** which contains a couple of routes as shown:

myCoolRoutes.xml

Then in your XML file which contains the CamelContext you can use Spring to import the **myCoolRoute.xml** file.

And then inside **<camelContext/>** you can refer to the **<routeContext/>** by its id as shown below:

Also notice that you can mix and match, having routes inside CamelContext and also externalized in RouteContext.

You can have as many **<routeContextRef/>** as you like.

Reusable routes

The routes defined in `<routeContext/>` can be reused by multiple `<camelContext/>`. However its only the definition which is reused. At runtime each CamelContext will create its own instance of the route based on the definition.

317.3.1. Test time exclusion.

At test time it is often desirable to be able to selectively exclude matching routes from being initialized that are not applicable or useful to the test scenario. For instance you might a spring context file `routes-context.xml` and three Route builders `RouteA`, `RouteB` and `RouteC` in the `'org.example.routes'` package. The `packageScan` definition would discover all three of these routes and initialize them.

Say `RouteC` is not applicable to our test scenario and generates a lot of noise during test. It would be nice to be able to exclude this route from this specific test. The `SpringTestSupport` class has been modified to allow this. It provides two methods (`excludedRoute` and `excludedRoutes`) that may be overridden to exclude a single class or an array of classes.

```
public class RouteAandRouteBOnlyTest extends SpringTestSupport {
    @Override
    protected Class excludeRoute() {
        return RouteC.class;
    }
}
```

In order to hook into the `camelContext` initialization by spring to exclude the `MyExcludedRouteBuilder.class` we need to intercept the spring context creation. When overriding `createApplicationContext` to create the spring context, we call the `getRouteExcludingApplicationContext()` method to provide a special parent spring context that takes care of the exclusion.

```
@Override
protected AbstractXmlApplicationContext createApplicationContext() {
    return new ClassPathXmlApplicationContext(new String[] {"routes-context.xml"},
        getRouteExcludingApplicationContext());
}
```

`RouteC` will now be excluded from initialization. Similarly, in another test that is testing only `RouteC`, we could exclude `RouteB` and `RouteA` by overriding

```
@Override
protected Class[] excludeRoutes() {
    return new Class[]{RouteA.class, RouteB.class};
}
```

317.4. USING SPRING XML

You can use Spring 2.0 XML configuration to specify your Xml Configuration for Routes such as in the following [example](#).

317.5. CONFIGURING COMPONENTS AND ENDPOINTS

You can configure your Component or Endpoint instances in your Spring XML as follows in [this example](#).

Which allows you to configure a component using some name (`activemq` in the above example), then

you can refer to the component using `activemq:[queue:]topic:destinationName`. This works by the SpringCamelContext lazily fetching components from the spring context for the scheme name you use for Endpoint URIs.

For more detail see [Configuring Endpoints and Components](#).

317.6. CAMELCONTEXTAWARE

If you want to be injected with the CamelContext in your POJO just implement the [CamelContextAware interface](#); then when Spring creates your POJO the CamelContext will be injected into your POJO. Also see the [Bean Integration](#) for further injections.

317.7. INTEGRATION TESTING

To avoid a hung route when testing using Spring Transactions see the note about Spring Integration Testing under Transactional Client.

317.8. SEE ALSO

- [Spring JMS Tutorial](#)

CHAPTER 318. SPRING BATCH COMPONENT

Available as of Camel version 2.10

The **spring-batch**: component and support classes provide integration bridge between Camel and [Spring Batch](#) infrastructure.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-spring-batch</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

318.1. URI FORMAT

```
spring-batch:jobName[?options]
```

Where **jobName** represents the name of the Spring Batch job located in the Camel registry. Alternatively if a JobRegistry is provided it will be used to locate the job instead.

WARNING: This component can only be used to define producer endpoints, which means that you cannot use the Spring Batch component in a **from()** statement.

318.2. OPTIONS

The Spring Batch component supports 3 options, which are listed below.

Name	Description	Default	Type
jobLauncher (producer)	Explicitly specifies a JobLauncher to be used.		JobLauncher
jobRegistry (producer)	Explicitly specifies a JobRegistry to be used.		JobRegistry
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Spring Batch endpoint is configured using URI syntax:

```
spring-batch:jobName
```

with the following path and query parameters:

318.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
jobName	Required The name of the Spring Batch job located in the registry.		String

318.2.2. Query Parameters (4 parameters):

Name	Description	Default	Type
jobFromHeader (producer)	Explicitly defines if the jobName should be taken from the headers instead of the URI.	false	boolean
jobLauncher (producer)	Explicitly specifies a JobLauncher to be used.		JobLauncher
jobRegistry (producer)	Explicitly specifies a JobRegistry to be used.		JobRegistry
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

318.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 4 options, which are listed below.

Name	Description	Default	Type
camel.component.spring-batch.enabled	Enable spring-batch component	true	Boolean
camel.component.spring-batch.job-launcher	Explicitly specifies a JobLauncher to be used. The option is a <code>org.springframework.batch.core.launch.JobLauncher</code> type.		String
camel.component.spring-batch.job-registry	Explicitly specifies a JobRegistry to be used. The option is a <code>org.springframework.batch.core.configuration.JobRegistry</code> type.		String

Name	Description	Default	Type
<code>camel.component.spring-batch.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

318.4. USAGE

When Spring Batch component receives the message, it triggers the job execution. The job will be executed using the `org.springframework.batch.core.launch.JobLauncher` instance resolved according to the following algorithm:

- if **JobLauncher** is manually set on the component, then use it.
- if **jobLauncherRef** option is set on the component, then search Camel Registry for the **JobLauncher** with the given name. **Deprecated and will be removed in Camel 3.0!**
- if there is **JobLauncher** registered in the Camel Registry under **jobLauncher** name, then use it.
- if none of the steps above allow to resolve the **JobLauncher** and there is exactly one **JobLauncher** instance in the Camel Registry, then use it.

All headers found in the message are passed to the **JobLauncher** as job parameters. **String**, **Long**, **Double** and **java.util.Date** values are copied to the `org.springframework.batch.core.JobParametersBuilder` - other data types are converted to Strings.

318.5. EXAMPLES

Triggering the Spring Batch job execution:

```
from("direct:startBatch").to("spring-batch:myJob");
```

Triggering the Spring Batch job execution with the **JobLauncher** set explicitly.

```
from("direct:startBatch").to("spring-batch:myJob?jobLauncherRef=myJobLauncher");
```

Starting from the Camel **2.11.1 JobExecution** instance returned by the **JobLauncher** is forwarded by the **SpringBatchProducer** as the output message. You can use the **JobExecution** instance to perform some operations using the Spring Batch API directly.

```
from("direct:startBatch").to("spring-batch:myJob").to("mock:JobExecutions");
...
MockEndpoint mockEndpoint = ...;
JobExecution jobExecution =
mockEndpoint.getExchanges().get(0).getIn().getBody(JobExecution.class);
BatchStatus currentJobStatus = jobExecution.getStatus();
```

318.6. SUPPORT CLASSES

Apart from the Component, Camel Spring Batch provides also support classes, which can be used to hook into Spring Batch infrastructure.

318.6.1. CamelItemReader

CamelItemReader can be used to read batch data directly from the Camel infrastructure.

For example the snippet below configures Spring Batch to read data from JMS queue.

```
<bean id="camelReader"
class="org.apache.camel.component.spring.batch.support.CamelItemReader">
  <constructor-arg ref="consumerTemplate"/>
  <constructor-arg value="jms:dataQueue"/>
</bean>

<batch:job id="myJob">
  <batch:step id="step">
    <batch:tasklet>
      <batch:chunk reader="camelReader" writer="someWriter" commit-interval="100"/>
    </batch:tasklet>
  </batch:step>
</batch:job>
```

318.6.2. CamelItemWriter

CamelItemWriter has similar purpose as **CamelItemReader**, but it is dedicated to write chunk of the processed data.

For example the snippet below configures Spring Batch to read data from JMS queue.

```
<bean id="camelwriter" class="org.apache.camel.component.spring.batch.support.CamelItemWriter">
  <constructor-arg ref="producerTemplate"/>
  <constructor-arg value="jms:dataQueue"/>
</bean>

<batch:job id="myJob">
  <batch:step id="step">
    <batch:tasklet>
      <batch:chunk reader="someReader" writer="camelwriter" commit-interval="100"/>
    </batch:tasklet>
  </batch:step>
</batch:job>
```

318.6.3. CamelItemProcessor

CamelItemProcessor is the implementation of Spring Batch **org.springframework.batch.item.ItemProcessor** interface. The latter implementation relays on [Request Reply pattern](#) to delegate the processing of the batch item to the Camel infrastructure. The item to process is sent to the Camel endpoint as the body of the message.

For example the snippet below performs simple processing of the batch item using the [Direct endpoint](#) and the [Simple expression language](#).

```

<camel:camelContext>
  <camel:route>
    <camel:from uri="direct:processor"/>
    <camel:setExchangePattern pattern="InOut"/>
    <camel:setBody>
      <camel:simple>Processed ${body}</camel:simple>
    </camel:setBody>
  </camel:route>
</camel:camelContext>

<bean id="camelProcessor"
class="org.apache.camel.component.spring.batch.support.CamelItemProcessor">
  <constructor-arg ref="producerTemplate"/>
  <constructor-arg value="direct:processor"/>
</bean>

<batch:job id="myJob">
  <batch:step id="step">
    <batch:tasklet>
      <batch:chunk reader="someReader" writer="someWriter" processor="camelProcessor" commit-
interval="100"/>
    </batch:tasklet>
  </batch:step>
</batch:job>

```

318.6.4. CamelJobExecutionListener

CamelJobExecutionListener is the implementation of the **org.springframework.batch.core.JobExecutionListener** interface sending job execution events to the Camel endpoint.

The **org.springframework.batch.core.JobExecution** instance produced by the Spring Batch is sent as a body of the message. To distinguish between before- and after-callbacks **SPRING_BATCH_JOB_EVENT_TYPE** header is set to the **BEFORE** or **AFTER** value.

The example snippet below sends Spring Batch job execution events to the JMS queue.

```

<bean id="camelJobExecutionListener"
class="org.apache.camel.component.spring.batch.support.CamelJobExecutionListener">
  <constructor-arg ref="producerTemplate"/>
  <constructor-arg value="jms:batchEventsBus"/>
</bean>

<batch:job id="myJob">
  <batch:step id="step">
    <batch:tasklet>
      <batch:chunk reader="someReader" writer="someWriter" commit-interval="100"/>
    </batch:tasklet>
  </batch:step>
  <batch:listeners>
    <batch:listener ref="camelJobExecutionListener"/>
  </batch:listeners>
</batch:job>

```

318.7. SPRING CLOUD

Available as of Camel 2.19

Spring Cloud component

Maven users will need to add the following dependency to their **pom.xml** in order to use this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-spring-cloud</artifactId>
  <version>${camel.version}</version> <!-- use the same version as your Camel core version -->
</dependency>
```

camel-spring-cloud jar comes with the **spring.factories** file, so as soon as you add that dependency into your classpath, Spring Boot will automatically auto-configure Camel for you.

318.7.1. Camel Spring Cloud Starter

Available as of Camel 2.19

To use the starter, add the following to your spring boot pom.xml file:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-spring-cloud-starter</artifactId>
  <version>${camel.version}</version> <!-- use the same version as your Camel core version -->
</dependency>
```

318.8. SPRING CLOUD CONSUL

Available as of Camel 2.22

318.9. SPRING CLOUD ZOOKEEPER

Available as of Camel 2.22

318.10. SPRING CLOUD NETFLIX

Available as of Camel 2.19

The Spring Cloud Netflix component bridges Camel Cloud and Spring Cloud Netflix so you can leverage Spring Cloud Netflix service discovery and load balance features in Camel and/or you can use Camel Service Discovery implementations as ServerList source for Spring Cloud Netflix's Ribbon load balancer.

Maven users will need to add the following dependency to their **pom.xml** in order to use this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-spring-cloud-netflix</artifactId>
```

```
<version>${camel.version}</version>  
<!-- use the same version as your Camel core version -->  
</dependency>
```

camel-spring-cloud-netflix jar comes with the **spring.factories** file, so as soon as you add that dependency into your classpath, Spring Boot will automatically auto-configure Camel for you.

You can disable Camel Spring Cloud Netflix with the following properties:

```
# Enable/Disable the whole integration, default true  
camel.cloud.netflix = true  
  
# Enable/Disable the integration with Ribbon, default true  
camel.cloud.netflix.ribbon = true
```

318.11. SPRING CLOUD NETFLIX STARTER

Available as of Camel 2.19

To use the starter, add the following to your spring boot pom.xml file:

```
<dependency>  
  <groupId>org.apache.camel</groupId>  
  <artifactId>camel-spring-cloud-netflix-starter</artifactId>  
  <version>${camel.version}</version>  
  <!-- use the same version as your Camel core version -->  
</dependency>
```

CHAPTER 319. SPRING EVENT COMPONENT

Available as of Camel version 1.4

The **spring-event**: component provides access to the Spring **ApplicationEvent** objects. This allows you to publish **ApplicationEvent** objects to a Spring **ApplicationContext** or to consume them. You can then use [Enterprise Integration Patterns](#) to process them such as [Message Filter](#).

319.1. URI FORMAT

```
spring-event://default[?options]
```

Note, at the moment there are no options for this component. That can easily change in future releases, so please check back.

319.2. SPRING EVENT OPTIONS

The Spring Event component has no options.

The Spring Event endpoint is configured using URI syntax:

```
spring-event:name
```

with the following path and query parameters:

319.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
name	Name of endpoint		String

319.2.2. Query Parameters (4 parameters):

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean

Name	Description	Default	Type
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

319.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 4 options, which are listed below.

Name	Description	Default	Type
camel.component.spring-event.enabled	Enable spring-event component	true	Boolean
camel.component.spring-event.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
camel.language.spel.enabled	Enable spel language	true	Boolean
camel.language.spel.trim	Whether to trim the value to remove leading and trailing whitespaces and line breaks	true	Boolean

319.4. SEE ALSO

- [Configuring Camel](#)
- [Component](#)
- [Endpoint](#)
- [Getting Started](#)

CHAPTER 320. SPRING INTEGRATION COMPONENT

Available as of Camel version 1.4

The `spring-integration` component provides a bridge for Camel components to talk to [spring integration endpoints](#).

Maven users will need to add the following dependency to their `pom.xml` for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-spring-integration</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

320.1. URI FORMAT

```
spring-integration:defaultChannelName[?options]
```

Where `defaultChannelName` represents the default channel name which is used by the Spring Integration Spring context. It will equal to the `inputChannel` name for the Spring Integration consumer and the `outputChannel` name for the Spring Integration provider.

You can append query options to the URI in the following format, `?option=value&option=value&...`

320.2. OPTIONS

The Spring Integration component has no options.

The Spring Integration endpoint is configured using URI syntax:

```
spring-integration:defaultChannel
```

with the following path and query parameters:

320.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
<code>defaultChannel</code>	Required The default channel name which is used by the Spring Integration Spring context. It will equal to the <code>inputChannel</code> name for the Spring Integration consumer and the <code>outputChannel</code> name for the Spring Integration provider.		String

320.2.2. Query Parameters (7 parameters):

Name	Description	Default	Type
inOut (common)	The exchange pattern that the Spring integration endpoint should use. If <code>inOut=true</code> then a reply channel is expected, either from the Spring Integration Message header or configured on the endpoint.	false	boolean
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
inputChannel (consumer)	The Spring integration input channel name that this endpoint wants to consume from Spring integration.		String
exceptionHandler (consumer)	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		<code>ExceptionHandler</code>
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		<code>ExchangePattern</code>
outputChannel (producer)	The Spring integration output channel name that is used to send messages to Spring integration.		String
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

320.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.component.spring-integration.enabled	Enable spring-integration component	true	Boolean

Name	Description	Default	Type
<code>camel.component.spring-integration.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

320.4. USAGE

The Spring integration component is a bridge that connects Camel endpoints with Spring integration endpoints through the Spring integration's input channels and output channels. Using this component, we can send Camel messages to Spring Integration endpoints or receive messages from Spring integration endpoints in a Camel routing context.

320.5. EXAMPLES

320.5.1. Using the Spring integration endpoint

You can set up a Spring integration endpoint using a URI, as follows:

Or directly using a Spring integration channel name:

320.5.2. The Source and Target adapter

Spring integration also provides the Spring integration's source and target adapters, which can route messages from a Spring integration channel to a Camel endpoint or from a Camel endpoint to a Spring integration channel.

This example uses the following namespaces:

You can bind your source or target to a Camel endpoint as follows:

320.6. SEE ALSO

- [Configuring Camel](#)
- [Component](#)
- [Endpoint](#)
- [Getting Started](#)

320.7. SPRING JAVA CONFIG

Spring started life using XML Config to wire beans together. However some folks don't like using XML and would rather use Java code which led to the creation of Guice along with the Spring JavaConfig project.

You can use either the XML or Java config approaches with Camel; its your choice really on which you prefer.

320.7.1. Using Spring Java Config

To use Spring Java Config in your Camel project the easiest thing to do is add the following to your pom.xml

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-spring-javaconfig</artifactId>
  <version>${camel-version}</version>
</dependency>
```

This will then add the dependencies on the Spring JavaConfig library along with some helper classes for configuring Camel inside Spring.

Note that this library is totally optional; you could just wire Camel together yourself with Java Config.

320.7.2. Configuration

The most common case of using JavaConfig with Camel would be to create configuration with defined list of routes to be used by router.

```
@Configuration
public class MyRouteConfiguration extends CamelConfiguration {

    @Autowired
    private MyRouteBuilder myRouteBuilder;

    @Autowired
    private MyAnotherRouteBuilder myAnotherRouteBuilder;

    @Override
    public List<RouteBuilder> routes() {
        return Arrays.asList(myRouteBuilder, myAnotherRouteBuilder);
    }
}
```

Starting from Camel 2.13.0 you can skip the `routes()` definition, and fall back to the `RouteBuilder` instances located in the Spring context.

```
@Configuration
@ComponentScan("com.example.routes")
public class MyRouteConfiguration extends CamelConfiguration {
}
```

320.7.3. Testing

Since **Camel 2.11.0** you can use the **CamelSpringJUnit4ClassRunner** with **CamelSpringDelegatingTestContextLoader**. This is the recommended way to test Java Config and Camel integration.

If you wish to create a collection of **RouteBuilder** instances then derive from the **CamelConfiguration** helper class and implement the **routes()** method. Keep in mind that (starting from the Camel 2.13.0) if you don't override **routes()** method, then **CamelConfiguration** will use all **RouteBuilder** instances available in the Spring context.

The following [example using Java Config](#) demonstrates how to test Java Config integration with Camel 2.10 and lower. Keep in mind that **JavaConfigContextLoader** is deprecated and could be removed in the future versions of Camel on the behalf of the **CamelSpringDelegatingTestContextLoader**.

The **@ContextConfiguration** annotation tells the Spring Testing framework to load the **ContextConfig** class as the configuration to use. This class derives from **SingleRouteCamelConfiguration** which is a helper Spring Java Config class which will configure the CamelContext for us and then register the RouteBuilder we create.

CHAPTER 321. SPRING LDAP COMPONENT

Available as of Camel version 2.11

The `spring-ldap:` component provides a Camel wrapper for [Spring LDAP](#).

Maven users will need to add the following dependency to their `pom.xml` for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-spring-ldap</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

321.1. URI FORMAT

```
spring-ldap:springLdapTemplate[?options]
```

Where `springLdapTemplate` is the name of the [Spring LDAP Template bean](#). In this bean, you configure the URL and the credentials for your LDAP access.

321.2. OPTIONS

The Spring LDAP component has no options.

The Spring LDAP endpoint is configured using URI syntax:

```
spring-ldap:templateName
```

with the following path and query parameters:

321.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
<code>templateName</code>	Required Name of the Spring LDAP Template bean		String

321.2.2. Query Parameters (3 parameters):

Name	Description	Default	Type
<code>operation</code> (producer)	Required The LDAP operation to be performed.		LdapOperation
<code>scope</code> (producer)	The scope of the search operation.	subtree	String

Name	Description	Default	Type
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

321.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.component.spring-ldap.enabled	Enable spring-ldap component	true	Boolean
camel.component.spring-ldap.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

321.4. USAGE

The component supports producer endpoint only. An attempt to create a consumer endpoint will result in an **UnsupportedOperationException**.

The body of the message must be a map (an instance of **java.util.Map**). Unless a base DN is specified by in the configuration of your ContextSource, this map must contain at least an entry with the key **dn** (not needed for function_driven operation) that specifies the root node for the LDAP operation to be performed. Other entries of the map are operation-specific (see below).

The body of the message remains unchanged for the **bind** and **unbind** operations. For the **search** and **function_driven** operations, the body is set to the result of the search, see <http://static.springsource.org/spring-ldap/site/apidocs/org/springframework/ldap/core/LdapTemplate.html#search%28java.lang.String,%20ja>

321.4.1. Search

The message body must have an entry with the key **filter**. The value must be a **String** representing a valid LDAP filter, see

http://en.wikipedia.org/wiki/Lightweight_Directory_Access_Protocol#Search_and_Compare.

321.4.2. Bind

The message body must have an entry with the key **attributes**. The value must be an instance of [javax.naming.directory.Attributes](http://en.wikipedia.org/wiki/Lightweight_Directory_Access_Protocol#Search_and_Compare) This entry specifies the LDAP node to be created.

321.4.3. Unbind

No further entries necessary, the node with the specified **dn** is deleted.

321.4.4. Authenticate

The message body must have entries with the keys **filter** and **password**. The values must be an instance of **String** representing a valid LDAP filter and a user password, respectively.

321.4.5. Modify Attributes

The message body must have an entry with the key **modificationItems**. The value must be an instance of any array of type [javax.naming.directory.ModificationItem](#)

321.4.6. Function-Driven

The message body must have entries with the keys **function** and **request**. The **function** value must be of type **java.util.function.BiFunction<L, Q, S>**. The **L** type parameter must be of type **org.springframework.ldap.core.LdapOperations**. The **request** value must be the same type as the **Q** type parameter in the **function** and it must encapsulate the parameters expected by the `LdapTemplate` method being invoked within the **function**. The **S** type parameter represents the response type as returned by the `LdapTemplate` method being invoked. This operation allows dynamic invocation of `LdapTemplate` methods that are not covered by the operations mentioned above.

Key definitions

In order to avoid spelling errors, the following constants are defined in **org.apache.camel.springldap.SpringLdapProducer**:

- `public static final String DN = "dn"`
- `public static final String FILTER = "filter"`
- `public static final String ATTRIBUTES = "attributes"`
- `public static final String PASSWORD = "password";`
- `public static final String MODIFICATION_ITEMS = "modificationItems";`
- `public static final String FUNCTION = "function";`
- `public static final String REQUEST = "request";`

CHAPTER 322. SPRING REDIS COMPONENT

Available as of Camel version 2.11

This component allows sending and receiving messages from [Redis](#). Redis is advanced key-value store where keys can contain strings, hashes, lists, sets and sorted sets. In addition it provides pub/sub functionality for inter-app communications.

Camel provides a producer for executing commands, consumer for subscribing to pub/sub messages and an idempotent repository for filtering out duplicate messages.

INFO:**Prerequisites** In order to use this component, you must have a Redis server running.

322.1. URI FORMAT

```
spring-redis://host:port[?options]
```

You can append query options to the URI in the following format, **?options=value&option2=value&...**

322.2. URI OPTIONS

The Spring Redis component has no options.

The Spring Redis endpoint is configured using URI syntax:

```
spring-redis:host:port
```

with the following path and query parameters:

322.2.1. Path Parameters (2 parameters):

Name	Description	Default	Type
host	Required The host where Redis server is running.		String
port	Required Redis server port number		Integer

322.2.2. Query Parameters (10 parameters):

Name	Description	Default	Type
channels (common)	List of topic names or name patterns to subscribe to. Multiple names can be separated by comma.		String
command (common)	Default command, which can be overridden by message header. Notice the consumer only supports the following commands: PSUBSCRIBE and SUBSCRIBE	SET	Command

Name	Description	Default	Type
connectionFactory (common)	Reference to a pre-configured RedisConnectionFactory instance to use.		RedisConnectionFactory
redisTemplate (common)	Reference to a pre-configured RedisTemplate instance to use.		RedisTemplate
serializer (common)	Reference to a pre-configured RedisSerializer instance to use.		RedisSerializer
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
listenerContainer (consumer)	Reference to a pre-configured RedisMessageListenerContainer instance to use.		RedisMessageListenerContainer
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

322.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.component.spring-redis.enabled	Enable spring-redis component	true	Boolean

Name	Description	Default	Type
<code>camel.component.spring-redis.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

322.4. USAGE

See also the unit tests available at <https://github.com/apache/camel/tree/master/components/camel-spring-redis/src/test/java/org/apache/camel/component/redis>.

322.4.1. Message headers evaluated by the Redis producer

The producer issues commands to the server and each command has different set of parameters with specific types. The result from the command execution is returned in the message body.

Hash Commands	Description	Parameters	Result
HSET	Set the string value of a hash field	CamelRedis.Key (String), CamelRedis.Field (String), CamelRedis.Value (Object)	void
HGET	Get the value of a hash field	CamelRedis.Key (String), CamelRedis.Field (String)	String
HSETNX	Set the value of a hash field, only if the field does not exist	CamelRedis.Key (String), CamelRedis.Field (String), CamelRedis.Value (Object)	void
HMSET	Set multiple hash fields to multiple values	CamelRedis.Key (String), CamelRedis.Values (Map<String, Object>)	void

Hash Commands	Description	Parameters	Result
HMGET	Get the values of all the given hash fields	CamelRedis.Key (String), CamelRedis.Fields (Collection<String>)	Collection<Object>
HINCRBY	Increment the integer value of a hash field by the given number	CamelRedis.Key (String), CamelRedis.Field (String), CamelRedis.Value (Long)	Long
HEXISTS	Determine if a hash field exists	CamelRedis.Key (String), CamelRedis.Field (String)	Boolean
HDEL	Delete one or more hash fields	CamelRedis.Key (String), CamelRedis.Field (String)	void
HLEN	Get the number of fields in a hash	CamelRedis.Key (String)	Long
HKEYS	Get all the fields in a hash	CamelRedis.Key (String)	Set<String>
HVALS	Get all the values in a hash	CamelRedis.Key (String)	Collection<Object>
HGETALL	Get all the fields and values in a hash	CamelRedis.Key (String)	Map<String, Object>

List Commands	Description	Parameters	Result
R PUSH	Append one or multiple values to a list	CamelRedis.Key (String), CamelRedis.Value (Object)	Long

List Commands	Description	Parameters	Result
RPUSHX	Append a value to a list, only if the list exists	CamelRedis.Key (String), CamelRedis.Value (Object)	Long
LPUSH	Prepend one or multiple values to a list	CamelRedis.Key (String), CamelRedis.Value (Object)	Long
LLEN	Get the length of a list	CamelRedis.Key (String)	Long
LRange	Get a range of elements from a list	CamelRedis.Key (String), CamelRedis.Start (Long), CamelRedis.End (Long)	List<Object>
LTRIM	Trim a list to the specified range	CamelRedis.Key (String), CamelRedis.Start (Long), CamelRedis.End (Long)	void
LINDEX	Get an element from a list by its index	CamelRedis.Key (String), CamelRedis.Index (Long)	String
LINSERT	Insert an element before or after another element in a list	CamelRedis.Key (String), CamelRedis.Value (Object), CamelRedis.Pivot (String), CamelRedis.Position (String)	Long
LSET	Set the value of an element in a list by its index	CamelRedis.Key (String), CamelRedis.Value (Object), CamelRedis.Index (Long)	void

List Commands	Description	Parameters	Result
LREM	Remove elements from a list	CamelRedis.Key (String), CamelRedis.Value (Object), CamelRedis.Count (Long)	Long
LPOP	Remove and get the first element in a list	CamelRedis.Key (String)	Object
RPOP	Remove and get the last element in a list	CamelRedis.Key (String)	String
RPOPLPUSH	Remove the last element in a list, append it to another list and return it	CamelRedis.Key (String), CamelRedis.Destination (String)	Object
BRPOPLPUSH	Pop a value from a list, push it to another list and return it; or block until one is available	CamelRedis.Key (String), CamelRedis.Destination (String), CamelRedis.Timeout (Long)	Object
BLPOP	Remove and get the first element in a list, or block until one is available	CamelRedis.Key (String), CamelRedis.Timeout (Long)	Object
BRPOP	Remove and get the last element in a list, or block until one is available	CamelRedis.Key (String), CamelRedis.Timeout (Long)	String

Set Commands	Description	Parameters	Result
SADD	Add one or more members to a set	CamelRedis.Key (String), CamelRedis.Value (Object)	Boolean
SMEMBERS	Get all the members in a set	CamelRedis.Key (String)	Set<Object>
SREM	Remove one or more members from a set	CamelRedis.Key (String), CamelRedis.Value (Object)	Boolean
SPOP	Remove and return a random member from a set	CamelRedis.Key (String)	String
SMOVE	Move a member from one set to another	CamelRedis.Key (String), CamelRedis.Value (Object), CamelRedis.Destination (String)	Boolean
SCARD	Get the number of members in a set	CamelRedis.Key (String)	Long
SISMEMBER	Determine if a given value is a member of a set	CamelRedis.Key (String), CamelRedis.Value (Object)	Boolean
SINTER	Intersect multiple sets	CamelRedis.Key (String), CamelRedis.Keys (String)	Set<Object>

Set Commands	Description	Parameters	Result
SINTERSTORE	Intersect multiple sets and store the resulting set in a key	CamelRedis.Key (String), CamelRedis.Keys (String), CamelRedis.Destination (String)	void
SUNION	Add multiple sets	CamelRedis.Key (String), CamelRedis.Keys (String)	Set<Object>
SUNIONSTORE	Add multiple sets and store the resulting set in a key	CamelRedis.Key (String), CamelRedis.Keys (String), CamelRedis.Destination (String)	void
SDIFF	Subtract multiple sets	CamelRedis.Key (String), CamelRedis.Keys (String)	Set<Object>
SDIFFSTORE	Subtract multiple sets and store the resulting set in a key	CamelRedis.Key (String), CamelRedis.Keys (String), CamelRedis.Destination (String)	void
SRANDMEMBER	Get one or multiple random members from a set	CamelRedis.Key (String)	String

Ordered set Commands	Description	Parameters	Result
----------------------	-------------	------------	--------

Ordered set Commands	Description	Parameters	Result
ZADD	Add one or more members to a sorted set, or update its score if it already exists	CamelRedis.Key (String), CamelRedis.Value (Object), CamelRedis.Score (Double)	Boolean
ZRANGE	Return a range of members in a sorted set, by index	CamelRedis.Key (String), CamelRedis.Start (Long), CamelRedis.End (Long), CamelRedis.WithScore (Boolean)	Object
ZREM	Remove one or more members from a sorted set	CamelRedis.Key (String), CamelRedis.Value (Object)	Boolean
ZINCRBY	Increment the score of a member in a sorted set	CamelRedis.Key (String), CamelRedis.Value (Object), CamelRedis.Increment (Double)	Double
ZRANK	Determine the index of a member in a sorted set	CamelRedis.Key (String), CamelRedis.Value (Object)	Long
ZREVRANK	Determine the index of a member in a sorted set, with scores ordered from high to low	CamelRedis.Key (String), CamelRedis.Value (Object)	Long

Ordered set Commands	Description	Parameters	Result
ZREVRANGE	Return a range of members in a sorted set, by index, with scores ordered from high to low	CamelRedis.Key (String), CamelRedis.Start (Long), CamelRedis.End (Long), CamelRedis.WithScore (Boolean)	Object
ZCARD	Get the number of members in a sorted set	CamelRedis.Key (String)	Long
ZCOUNT	Count the members in a sorted set with scores within the given values	CamelRedis.Key (String), CamelRedis.Min (Double), CamelRedis.Max (Double)	Long
ZRANGEBYSCORE	Return a range of members in a sorted set, by score	CamelRedis.Key (String), CamelRedis.Min (Double), CamelRedis.Max (Double)	Set<Object>
ZREVRANGEBYSCORE	Return a range of members in a sorted set, by score, with scores ordered from high to low	CamelRedis.Key (String), CamelRedis.Min (Double), CamelRedis.Max (Double)	Set<Object>
ZREMRANGEBYRANK	Remove all members in a sorted set within the given indexes	CamelRedis.Key (String), CamelRedis.Start (Long), CamelRedis.End (Long)	void

Ordered set Commands	Description	Parameters	Result
ZREMRANGEBYSCORE	Remove all members in a sorted set within the given scores	CamelRedis.Key (String), CamelRedis.Start (Long), CamelRedis.End (Long)	void
ZUNIONSTORE	Add multiple sorted sets and store the resulting sorted set in a new key	CamelRedis.Key (String), CamelRedis.Keys (String), CamelRedis.Destination (String)	void
ZINTERSTORE	Intersect multiple sorted sets and store the resulting sorted set in a new key	CamelRedis.Key (String), CamelRedis.Keys (String), CamelRedis.Destination (String)	void

String Commands	Description	Parameters	Result
SET	Set the string value of a key	CamelRedis.Key (String), CamelRedis.Value (Object)	void
GET	Get the value of a key	CamelRedis.Key (String)	Object
STRLEN	Get the length of the value stored in a key	CamelRedis.Key (String)	Long
APPEND	Append a value to a key	CamelRedis.Key (String), CamelRedis.Value (String)	Integer

String Commands	Description	Parameters	Result
SETBIT	Sets or clears the bit at offset in the string value stored at key	CamelRedis.Key (String), CamelRedis.Offset (Long), CamelRedis.Value (Boolean)	void
GETBIT	Returns the bit value at offset in the string value stored at key	CamelRedis.Key (String), CamelRedis.Offset (Long)	Boolean
SETRANGE	Overwrite part of a string at key starting at the specified offset	CamelRedis.Key (String), CamelRedis.Value (Object), CamelRedis.Offset (Long)	void
GETRANGE	Get a substring of the string stored at a key	CamelRedis.Key (String), CamelRedis.Start (Long), CamelRedis.End (Long)	String
SETNX	Set the value of a key, only if the key does not exist	CamelRedis.Key (String), CamelRedis.Value (Object)	Boolean
SETEX	Set the value and expiration of a key	CamelRedis.Key (String), CamelRedis.Value (Object), CamelRedis.Timeout (Long), SECONDS	void
DECRBY	Decrement the integer value of a key by the given number	CamelRedis.Key (String), CamelRedis.Value (Long)	Long

String Commands	Description	Parameters	Result
DECR	Decrement the integer value of a key by one	CamelRedis.Key (String),	Long
INCRBY	Increment the integer value of a key by the given amount	CamelRedis.Key (String), CamelRedis.Value (Long)	Long
INCR	Increment the integer value of a key by one	CamelRedis.Key (String)	Long
MGET	Get the values of all the given keys	CamelRedis.Fields (Collection<String>)	List<Object>
MSET	Set multiple keys to multiple values	CamelRedis.Values(Map<String, Object>)	void
MSETNX	Set multiple keys to multiple values, only if none of the keys exist	CamelRedis.Key (String), CamelRedis.Value (Object)	void
GETSET	Set the string value of a key and return its old value	CamelRedis.Key (String), CamelRedis.Value (Object)	Object

Key Commands	Description	Parameters	Result
EXISTS	Determine if a key exists	CamelRedis.Key (String)	Boolean
DEL	Delete a key	CamelRedis.Keys (String)	void
TYPE	Determine the type stored at key	CamelRedis.Key (String)	DataType

Key Commands	Description	Parameters	Result
KEYS	Find all keys matching the given pattern	CamelRedis.Pa ttern (String)	Collection<String>
RANDOMKEY	Return a random key from the keyspace	CamelRedis.Pa ttern (String), CamelRedis.Va lue (String)	String
RENAME	Rename a key	CamelRedis.Ke y (String)	void
RENAMENX	Rename a key, only if the new key does not exist	CamelRedis.Ke y (String), CamelRedis.Va lue (String)	Boolean
EXPIRE	Set a key's time to live in seconds	CamelRedis.Ke y (String), CamelRedis.Ti meout (Long)	Boolean
SORT	Sort the elements in a list, set or sorted set	CamelRedis.Ke y (String)	List<Object>
PERSIST	Remove the expiration from a key	CamelRedis.Ke y (String)	Boolean
EXPIREAT	Set the expiration for a key as a UNIX timestamp	CamelRedis.Ke y (String), CamelRedis.Ti mestamp (Long)	Boolean
PEXPIRE	Set a key's time to live in milliseconds	CamelRedis.Ke y (String), CamelRedis.Ti meout (Long)	Boolean
PEXPIREAT	Set the expiration for a key as a UNIX timestamp specified in milliseconds	CamelRedis.Ke y (String), CamelRedis.Ti mestamp (Long)	Boolean

Key Commands	Description	Parameters	Result
--------------	-------------	------------	--------

TTL	Get the time to live for a key	CamelRedis.Key (String)	Long
MOVE	Move a key to another database	CamelRedis.Key (String), CamelRedis.Db (Integer)	Boolean

Other Command	Description	Parameters	Result
---------------	-------------	------------	--------

MULTI	Mark the start of a transaction block	none	void
DISCARD	Discard all commands issued after MULTI	none	void
EXEC	Execute all commands issued after MULTI	none	void
WATCH	Watch the given keys to determine execution of the MULTI/EXEC block	CamelRedis.Keys (String)	void
UNWATCH	Forget about all watched keys	none	void

Other Command	Description	Parameters	Result
ECHO	Echo the given string	CamelRedis.Value (String)	String
PING	Ping the server	none	String
QUIT	Close the connection	none	void
PUBLISH	Post a message to a channel	CamelRedis.Channel (String), CamelRedis.Message (Object)	void

322.5. DEPENDENCIES

Maven users will need to add the following dependency to their pom.xml.

pom.xml

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-spring-redis</artifactId>
  <version>${camel-version}</version>
</dependency>
```

where **`${camel-version}`** must be replaced by the actual version of Camel (2.11 or higher).

322.6. SEE ALSO

- [Configuring Camel](#)

- [Endpoint](#)
- [Getting Started](#)

CHAPTER 323. SPRING SECURITY

Available as of Camel 2.3

The **camel-spring-security** component provides role-based authorization for Camel routes. It leverages the authentication and user services provided by [Spring Security](#) (formerly Acegi Security) and adds a declarative, role-based policy system to control whether a route can be executed by a given principal.

If you are not familiar with the Spring Security authentication and authorization system, please review the current reference documentation on the SpringSource web site linked above.

323.1. CREATING AUTHORIZATION POLICIES

Access to a route is controlled by an instance of a **SpringSecurityAuthorizationPolicy** object. A policy object contains the name of the Spring Security authority (role) required to run a set of endpoints and references to Spring Security **AuthenticationManager** and **AccessDecisionManager** objects used to determine whether the current principal has been assigned that role. Policy objects may be configured as Spring beans or by using an `<authorizationPolicy>` element in Spring XML.

The `<authorizationPolicy>` element may contain the following attributes:

Name	Default Value	Description
id	null	The unique Spring bean identifier which is used to reference the policy in routes (required)
access	null	The Spring Security authority name that is passed to the access decision manager (required)
authenticationManager	authenticationManager	The name of the Spring Security AuthenticationManager object in the context
accessDecisionManager	accessDecisionManager	The name of the Spring Security AccessDecisionManager object in the context
authenticationAdapter	Default Authentication Adapter	Camel 2.4 The name of acamel-spring-securityAuthenticationAdapter object in the context that is used to convert a javax.security.auth.Subject into a Spring Security Authentication instance.

Name	Default Value	Description
<code>useThreadSecurityContext</code>	<code>true</code>	If a <code>javax.security.auth.Subject</code> cannot be found in the In message header under <code>Exchange.AUTHENTICATION</code> , check the Spring Security <code>SecurityContextHolder</code> for an <code>Authentication</code> object.
<code>alwaysAuthenticate</code>	<code>false</code>	If set to true, the <code>SpringSecurityAuthorizationPolicy</code> will always call <code>AuthenticationManager.authenticate()</code> each time the policy is accessed.

323.2. CONTROLLING ACCESS TO CAMEL ROUTES

A Spring Security `AuthenticationManager` and `AccessDecisionManager` are required to use this component. Here is an example of how to configure these objects in Spring XML using the Spring Security namespace:

Now that the underlying security objects are set up, we can use them to configure an authorization policy and use that policy to control access to a route:

In this example, the endpoint `mock:end` will not be executed unless a Spring Security `Authentication` object that has been or can be authenticated and contains the `ROLE_ADMIN` authority can be located by the `admin` `SpringSecurityAuthorizationPolicy`.

323.3. AUTHENTICATION

The process of obtaining security credentials that are used for authorization is not specified by this component. You can write your own processors or components which get authentication information from the exchange depending on your needs. For example, you might create a processor that gets credentials from an HTTP request header originating in the `Jetty` component. No matter how the credentials are collected, they need to be placed in the In message or the `SecurityContextHolder` so the Camel `Spring Security` component can access them:

```
import javax.security.auth.Subject;
import org.apache.camel.*;
import org.apache.commons.codec.binary.Base64;
import org.springframework.security.authentication.*;

public class MyAuthService implements Processor {
    public void process(Exchange exchange) throws Exception {
        // get the username and password from the HTTP header
        // http://en.wikipedia.org/wiki/Basic_access_authentication
        String userpass = new
String(Base64.decodeBase64(exchange.getIn().getHeader("Authorization", String.class)));
        String[] tokens = userpass.split(":");

        // create an Authentication object
        UsernamePasswordAuthenticationToken authToken = new
UsernamePasswordAuthenticationToken(tokens[0], tokens[1]);
```

```

// wrap it in a Subject
Subject subject = new Subject();
subject.getPrincipals().add(authToken);

// place the Subject in the In message
exchange.getIn().setHeader(Exchange.AUTHENTICATION, subject);

// you could also do this if useThreadSecurityContext is set to true
// SecurityContextHolder.getContext().setAuthentication(authToken);
}
}

```

The **SpringSecurityAuthorizationPolicy** will automatically authenticate the **Authentication** object if necessary.

There are two issues to be aware of when using the **SecurityContextHolder** instead of or in addition to the **Exchange.AUTHENTICATION** header. First, the context holder uses a thread-local variable to hold the **Authentication** object. Any routes that cross thread boundaries, like **seda** or **jms**, will lose the **Authentication** object. Second, the Spring Security system appears to expect that an **Authentication** object in the context is already authenticated and has roles (see the Technical Overview [section 5.3.1](#) for more details).

The default behavior of **camel-spring-security** is to look for a **Subject** in the **Exchange.AUTHENTICATION** header. This **Subject** must contain at least one principal, which must be a subclass of **org.springframework.security.core.Authentication**. You can customize the mapping of **Subject** to **Authentication** object by providing an implementation of the **org.apache.camel.component.spring.security.AuthenticationAdapter** to your **<authorizationPolicy>** bean. This can be useful if you are working with components that do not use Spring Security but do provide a **Subject**. At this time, only the **CXF** component populates the **Exchange.AUTHENTICATION** header.

323.4. HANDLING AUTHENTICATION AND AUTHORIZATION ERRORS

If authentication or authorization fails in the **SpringSecurityAuthorizationPolicy**, a **CamelAuthorizationException** will be thrown. This can be handled using Camel's standard exception handling methods, like the Exception Clause. The **CamelAuthorizationException** will have a reference to the ID of the policy which threw the exception so you can handle errors based on the policy as well as the type of exception:

```

<onException>
  <exception>org.springframework.security.authentication.AccessDeniedException</exception>
  <choice>
    <when>
      <simple>${exception.policyId} == 'user'</simple>
      <transform>
        <constant>You do not have ROLE_USER access!</constant>
      </transform>
    </when>
    <when>
      <simple>${exception.policyId} == 'admin'</simple>
      <transform>
        <constant>You do not have ROLE_ADMIN access!</constant>
      </transform>
    </when>
  </choice>
</onException>

```

```
</when>  
</choice>  
</onException>
```

323.5. DEPENDENCIES

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>  
  <groupId>org.apache.camel</groupId>  
  <artifactId>camel-spring-security</artifactId>  
  <version>2.4.0</version>  
</dependency>
```

This dependency will also pull in **org.springframework.security:spring-security-core:3.0.3.RELEASE** and **org.springframework.security:spring-security-config:3.0.3.RELEASE**.

- [Components](#)

CHAPTER 324. SPRING WEBSERVICE COMPONENT

Available as of Camel version 2.6

IMPORTANT

The Camel WebService, **camel-spring-ws**, component is **not** supported on the Red Hat JBoss Enterprise Application Platform (JBoss EAP) container. If you need to implement a JAX-WS endpoint on the JBoss EAP container, the recommended approach is to use the **webservice** subsystem built into the JBoss EAP container. This approach automatically gives you enterprise level qualities of service (including management, security, and so on). If you subsequently need to integrate the JAX-WS endpoint with a Camel route, you can pass the resulting **EndpointImpl** bean to the Camel route, after the initial payload processing.

The **spring-ws:** component allows you to integrate with [Spring Web Services](#). It offers both *client*-side support, for accessing web services, and *server*-side support for creating your own contract-first web services.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-spring-ws</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

INFO:*Dependencies* As of Camel 2.8 this component ships with Spring-WS 2.0.x which (like the rest of Camel) requires Spring 3.0.x. Earlier Camel versions shipped Spring-WS 1.5.9 which is compatible with Spring 2.5.x and 3.0.x. In order to run earlier versions of **camel-spring-ws** on Spring 2.5.x you need to add the **spring-webmvc** module from Spring 2.5.x. In order to run Spring-WS 1.5.9 on Spring 3.0.x you need to exclude the OXM module from Spring 3.0.x as this module is also included in Spring-WS 1.5.9 (see [this post](#))

324.1. URI FORMAT

The URI scheme for this component is as follows

```
spring-ws:[mapping-type:]address[?options]
```

To expose a web service **mapping-type** needs to be set to any of the following:

Mapping type	Description
root name	Offers the option to map web service requests based on the qualified name of the root element contained in the message.
soap action	Used to map web service requests based on the SOAP action specified in the header of the message.

Mapping type	Description
uri	In order to map web service requests that target a specific URI.
xpathresult	Used to map web service requests based on the evaluation of an XPath expression against the incoming message. The result of the evaluation should match the XPath result specified in the endpoint URI.
beanname	Allows you to reference an org.apache.camel.component.spring.ws.bean.CamelEndpointDispatcher object in order to integrate with existing (legacy) endpoint mappings like PayloadRootQNameEndpointMapping , SoapActionEndpointMapping , etc

As a consumer the **address** should contain a value relevant to the specified mapping-type (e.g. a SOAP action, XPath expression). As a producer the address should be set to the URI of the web service your calling upon.

You can append query **options** to the URI in the following format, **?option=value&option=value&...**

324.2. OPTIONS

The Spring WebService component supports 2 options, which are listed below.

Name	Description	Default	Type
useGlobalSslContext Parameters (security)	Enable usage of global SSL context parameters.	false	boolean
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Spring WebService endpoint is configured using URI syntax:

```
spring-ws:type:lookupKey:webServiceEndpointUri
```

with the following path and query parameters:

324.2.1. Path Parameters (3 parameters):

Name	Description	Default	Type
type	Endpoint mapping type if endpoint mapping is used. rootqname - Offers the option to map web service requests based on the qualified name of the root element contained in the message. soapaction - Used to map web service requests based on the SOAP action specified in the header of the message. uri - In order to map web service requests that target a specific URI. xpathresult - Used to map web service requests based on the evaluation of an XPath expression against the incoming message. The result of the evaluation should match the XPath result specified in the endpoint URI. beanname - Allows you to reference an org.apache.camel.component.spring.ws.bean.CamelEndpointDispatcher object in order to integrate with existing (legacy) endpoint mappings like PayloadRootQNameEndpointMapping, SoapActionEndpointMapping, etc		EndpointMapping Type
lookupKey	Endpoint mapping key if endpoint mapping is used		String
webServiceEndpointUri	The default Web Service endpoint uri to use for the producer.		String

324.2.2. Query Parameters (22 parameters):

Name	Description	Default	Type
messageFilter (common)	Option to provide a custom MessageFilter. For example when you want to process your headers or attachments by your own.		MessageFilter
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean

Name	Description	Default	Type
endpointDispatcher (consumer)	Spring org.springframework.ws.server.endpoint.MessageEndpoint for dispatching messages received by Spring-WS to a Camel endpoint, to integrate with existing (legacy) endpoint mappings like PayloadRootQNameEndpointMapping, SoapActionEndpointMapping, etc.		CamelEndpointDispatcher
endpointMapping (consumer)	Reference to an instance of org.apache.camel.component.spring.ws.bean.CamelEndpointMapping in the Registry/ApplicationContext. Only one bean is required in the registry to serve all Camel/Spring-WS endpoints. This bean is auto-discovered by the MessageDispatcher and used to map requests to Camel endpoints based on characteristics specified on the endpoint (like root QName, SOAP action, etc)		CamelSpringWSEndpointMapping
expression (consumer)	The XPath expression to use when option type=xpathresult. Then this option is required to be configured.		String
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option errorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
allowResponseAttachmentOverride (producer)	Option to override soap response attachments in in/out exchange with attachments from the actual service layer. If the invoked service appends or rewrites the soap attachments this option when set to true, allows the modified soap attachments to be overwritten in in/out message attachments	false	boolean
allowResponseHeaderOverride (producer)	Option to override soap response header in in/out exchange with header info from the actual service layer. If the invoked service appends or rewrites the soap header this option when set to true, allows the modified soap header to be overwritten in in/out message headers	false	boolean
faultAction (producer)	Signifies the value for the faultAction response WS-Addressing Fault Action header that is provided by the method.		URI

Name	Description	Default	Type
faultTo (producer)	Signifies the value for the faultAction response WS-Addressing FaultTo header that is provided by the method.		URI
messageFactory (producer)	Option to provide a custom WebServiceMessageFactory. For example when you want Apache Axiom to handle web service messages instead of SAAJ.		WebServiceMessageFactory
messageIdStrategy (producer)	Option to provide a custom MessageIdStrategy to control generation of unique message ids.		MessageIdStrategy
messageSender (producer)	Option to provide a custom WebServiceMessageSender. For example to perform authentication or use alternative transports		WebServiceMessageSender
outputAction (producer)	Signifies the value for the response WS-Addressing Action header that is provided by the method.		URI
replyTo (producer)	Signifies the value for the replyTo response WS-Addressing ReplyTo header that is provided by the method.		URI
soapAction (producer)	SOAP action to include inside a SOAP request when accessing remote web services		String
timeout (producer)	Sets the socket read timeout (in milliseconds) while invoking a webservice using the producer, see <code>URLConnection.setReadTimeout()</code> and <code>CommonsHttpMessageSender.setReadTimeout()</code> . This option works when using the built-in message sender implementations: <code>CommonsHttpMessageSender</code> and <code>URLConnectionMessageSender</code> . One of these implementations will be used by default for HTTP based services unless you customize the Spring WS configuration options supplied to the component. If you are using a non-standard sender, it is assumed that you will handle your own timeout configuration. The built-in message sender <code>HttpComponentsMessageSender</code> is considered instead of <code>CommonsHttpMessageSender</code> which has been deprecated, see <code>HttpComponentsMessageSender.setReadTimeout()</code> .		int

Name	Description	Default	Type
webServiceTemplate (producer)	Option to provide a custom WebServiceTemplate. This allows for full control over client-side web services handling; like adding a custom interceptor or specifying a fault resolver, message sender or message factory.		WebServiceTemplate
wsAddressingAction (producer)	WS-Addressing 1.0 action header to include when accessing web services. The To header is set to the address of the web service as specified in the endpoint URI (default Spring-WS behavior).		URI
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
sslContextParameters (security)	To configure security using SSLContextParameters		SSLContextParameters

324.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 3 options, which are listed below.

Name	Description	Default	Type
camel.component.spring-ws.enabled	Enable spring-ws component	true	Boolean
camel.component.spring-ws.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
camel.component.spring-ws.use-global-ssl-context-parameters	Enable usage of global SSL context parameters.	false	Boolean

324.3.1. Message headers

Name	Type	Description
Camel SpringWebServiceEndpointUri	String	URI of the web service your accessing as a client, overrides <i>address</i> part of the endpoint URI
Camel SpringWebServiceSoapAction	String	Header to specify the SOAP action of the message, overrides soapAction option if present
CamelSpringWebServiceSoapHeader	Source	Camel 2.11.1: Use this header to specify/access the SOAP headers of the message.
Camel SpringWebServiceAddressingAction	URI	Use this header to specify the WS-Addressing action of the message, overrides wsAddressingAction option if present
CamelSpringWebServiceAddressingFaultTo	URI	Use this header to specify the WS-Addressing FaultTo , overrides <i>faultTo</i> option if present
CamelSpringWebServiceAddressingReplyTo	URI	Use this header to specify the WS-Addressing ReplyTo , overrides <i>replyTo</i> option if present

Name	Type	Description
CamelSpringWebServiceAddressingOutputAction	URI	Use this header to specify the WS-Addressing Action , overrides outputAction option if present
CamelSpringWebServiceAddressingFaultAction	URI	Use this header to specify the WS-Addressing Fault Action , overrides faultAction option if present

324.4. ACCESSING WEB SERVICES

To call a web service at <http://foo.com/bar> simply define a route:

```
from("direct:example").to("spring-ws:http://foo.com/bar")
```

And sent a message:

```
template.requestBody("direct:example", "<foobar xmlns='http://foo.com'><msg>test message</msg></foobar>");
```

Remember if it's a SOAP service you're calling you don't have to include SOAP tags. Spring-WS will perform the XML-to-SOAP marshaling.

324.5. SENDING SOAP AND WS-ADDRESSING ACTION HEADERS

When a remote web service requires a SOAP action or use of the WS-Addressing standard you define your route as:

```
from("direct:example")
.to("spring-ws:http://foo.com/bar?soapAction=http://foo.com&wsAddressingAction=http://bar.com")
```

Optionally you can override the endpoint options with header values:

```
template.requestBodyAndHeader("direct:example",
"<foobar xmlns='http://foo.com'><msg>test message</msg></foobar>",
SpringWebserviceConstants.SPRING_WS_SOAP_ACTION, "http://baz.com");
```

324.6. USING SOAP HEADERS

Available as of Camel 2.11.1

You can provide the SOAP header(s) as a Camel Message header when sending a message to a spring-ws endpoint, for example given the following SOAP header in a String

```
String body = ...
String soapHeader = "<h:Header xmlns:h=\"http://www.webserviceX.NET^\">
<h:MessageID>1234567890</h:MessageID><h:Nested><h:NestedID>1111</h:NestedID>
</h:Nested></h:Header>";
```

We can set the body and header on the Camel Message as follows:

```
exchange.getIn().setBody(body);
exchange.getIn().setHeader(SpringWebserviceConstants.SPRING_WS_SOAP_HEADER,
soapHeader);
```

And then send the Exchange to a **spring-ws** endpoint to call the Web Service.

Likewise the spring-ws consumer will also enrich the Camel Message with the SOAP header.

For an example see this [unit test](#).

324.7. THE HEADER AND ATTACHMENT PROPAGATION

Spring WS Camel supports propagation of the headers and attachments into Spring-WS WebServiceMessage response since version **2.10.3**. The endpoint will use so called "hook" the MessageFilter (default implementation is provided by BasicMessageFilter) to propagate the exchange headers and attachments into WebServiceMessage response. Now you can use

```
exchange.getOut().getHeaders().put("myCustom", "myHeaderValue")
exchange.getIn().addAttachment("myAttachment", new DataHandler(...))
```

Note: If the exchange header in the pipeline contains text, it generates QName(key)=value attribute in the soap header. Recommended is to create a QName class directly and put into any key into header.

324.8. HOW TO TRANSFORM THE SOAP HEADER USING A STYLESHEET

The header transformation filter (HeaderTransformationMessageFilter.java) can be used to transform the soap header for a soap request. If you want to use the header transformation filter, see the below example:

```
<bean id="headerTransformationFilter"
class="org.apache.camel.component.spring.ws.filter.impl.HeaderTransformationMessageFilter">
  <constructor-arg index="0" value="org/apache/camel/component/spring/ws/soap-header-
transform.xslt"/>
</bean>
```

Use the bead defined above in the camel endpoint

```
<route>
  <from uri="direct:stockQuoteWebserviceHeaderTransformation"/>
  <to uri="spring-ws:http://localhost?>
```

```
webServiceTemplate=#webServiceTemplate&soapAction=http://www.stockquotes.edu/GetQuote&
&messageFilter=#headerTransformationFilter"/>
</route>
```

324.9. HOW TO USE MTOM ATTACHMENTS

The `BasicMessageFilter` provides all required information for Apache Axiom in order to produce MTOM message. If you want to use Apache Camel Spring WS within Apache Axiom, here is an example: - Simply define the `messageFactory` as is bellow and Spring-WS will use MTOM strategy to populate your SOAP message with optimized attachments.

```
<bean id="axiomMessageFactory"
class="org.springframework.ws.soap.axiom.AxiomSoapMessageFactory">
<property name="payloadCaching" value="false" />
<property name="attachmentCaching" value="true" />
<property name="attachmentCacheThreshold" value="1024" />
</bean>
```

- Add into your `pom.xml` the following dependencies

```
<dependency>
<groupId>org.apache.ws.commons.axiom</groupId>
<artifactId>axiom-api</artifactId>
<version>1.2.13</version>
</dependency>
<dependency>
<groupId>org.apache.ws.commons.axiom</groupId>
<artifactId>axiom-impl</artifactId>
<version>1.2.13</version>
<scope>runtime</scope>
</dependency>
```

- Add your attachment into the pipeline, for example using a `Processor` implementation.

```
private class Attachement implements Processor {
public void process(Exchange exchange) throws Exception
{ exchange.getOut().copyFrom(exchange.getIn()); File file = new File("testAttachment.txt");
exchange.getOut().addAttachment("test", new DataHandler(new FileDataSource(file))); }
}
```

- Define endpoint (producer) as usual, for example like this:

```
from("direct:send")
.process(new Attachement())
.to("spring-ws:http://localhost:8089/mySoapService?
soapAction=mySoap&messageFactory=axiomMessageFactory");
```

- Now, your producer will generate MTOM message with optimized attachments.

324.10. THE CUSTOM HEADER AND ATTACHMENT FILTERING

If you need to provide your custom processing of either headers or attachments, extend existing `BasicMessageFilter` and override the appropriate methods or write a brand new implementation of the

MessageFilter interface.

To use your custom filter, add this into your spring context:

You can specify either a global a or a local message filter as follows: a) the global custom filter that provides the global configuration for all Spring-WS endpoints

```
<bean id="messageFilter" class="your.domain.myMessageFiler" scope="singleton" />
```

or b) the local messageFilter directly on the endpoint as follows:

```
to("spring-ws:http://yourdomain.com?messageFilter=#myEndpointSpecificMessageFilter");
```

For more information see [CAMEL-5724](#)

If you want to create your own MessageFilter, consider overriding the following methods in the default implementation of MessageFilter in class BasicMessageFilter:

```
protected void doProcessSoapHeader(Message inOrOut, SoapMessage soapMessage)
{your code /*no need to call super*/}
```

```
protected void doProcessSoapAttachements(Message inOrOut, SoapMessage response)
{ your code /*no need to call super*/}
```

324.11. USING A CUSTOM MESSAGESENDER AND MESSAGEFACTORY

A custom message sender or factory in the registry can be referenced like this:

```
from("direct:example")
.to("spring-ws:http://foo.com/bar?
messageFactory=#messageFactory&messageSender=#messageSender")
```

Spring configuration:

```
<!-- authenticate using HTTP Basic Authentication -->
<bean id="messageSender"
class="org.springframework.ws.transport.http.HttpComponentsMessageSender">
  <property name="credentials">
    <bean class="org.apache.commons.httpclient.UsernamePasswordCredentials">
      <constructor-arg index="0" value="admin"/>
      <constructor-arg index="1" value="secret"/>
    </bean>
  </property>
</bean>

<!-- force use of Sun SAAJ implementation, http://static.springsource.org/spring-
ws/sites/1.5/faq.html#saaj-jboss -->
<bean id="messageFactory" class="org.springframework.ws.soap.saaj.SaajSoapMessageFactory">
  <property name="messageFactory">
    <bean
class="com.sun.xml.messaging.saaj.soap.ver1_1.SOAPMessageFactory1_1Impl"></bean>
  </property>
</bean>
```

324.12. EXPOSING WEB SERVICES

In order to expose a web service using this component you first need to set-up a [MessageDispatcher](#) to look for endpoint mappings in a Spring XML file. If you plan on running inside a servlet container you probably want to use a **MessageDispatcherServlet** configured in **web.xml**.

By default the **MessageDispatcherServlet** will look for a Spring XML named **/WEB-INF/spring-ws-servlet.xml**. To use Camel with Spring-WS the only mandatory bean in that XML file is **CamelEndpointMapping**. This bean allows the **MessageDispatcher** to dispatch web service requests to your routes.

web.xml

```
<web-app>
  <servlet>
    <servlet-name>spring-ws</servlet-name>
    <servlet-class>org.springframework.ws.transport.http.MessageDispatcherServlet</servlet-class>
    <load-on-startup>1</load-on-startup>
  </servlet>
  <servlet-mapping>
    <servlet-name>spring-ws</servlet-name>
    <url-pattern>/*</url-pattern>
  </servlet-mapping>
</web-app>
```

spring-ws-servlet.xml

```
<bean id="endpointMapping"
class="org.apache.camel.component.spring.ws.bean.CamelEndpointMapping" />

<bean id="wsdl" class="org.springframework.ws.wsdl.wsdl11.DefaultWsdl11Definition">
  <property name="schema">
    <bean class="org.springframework.xml.xsd.SimpleXsdSchema">
      <property name="xsd" value="/WEB-INF/foobar.xsd"/>
    </bean>
  </property>
  <property name="portTypeName" value="FooBar"/>
  <property name="locationUri" value="/" />
  <property name="targetNamespace" value="http://example.com/" />
</bean>
```

More information on setting up Spring-WS can be found in [Writing Contract-First Web Services](#).

Basically paragraph 3.6 "Implementing the Endpoint" is handled by this component (specifically paragraph 3.6.2 "Routing the Message to the Endpoint" is where **CamelEndpointMapping** comes in). Also don't forget to check out the Spring Web Services Example included in the Camel distribution.

324.13. ENDPOINT MAPPING IN ROUTES

With the XML configuration in-place you can now use Camel's DSL to define what web service requests are handled by your endpoint:

The following route will receive all web service requests that have a root element named "GetFoo" within the <http://example.com/> namespace.

```
from("spring-ws:rootqname:{http://example.com}/GetFoo?endpointMapping=#endpointMapping")
  .convertBodyTo(String.class).to(mock:example)
```

The following route will receive web service requests containing the <http://example.com/GetFoo> SOAP action.

```
from("spring-ws:soapaction:http://example.com/GetFoo?endpointMapping=#endpointMapping")
  .convertBodyTo(String.class).to(mock:example)
```

The following route will receive all requests sent to <http://example.com/foobar>.

```
from("spring-ws:uri:http://example.com/foobar?endpointMapping=#endpointMapping")
  .convertBodyTo(String.class).to(mock:example)
```

The route below will receive requests that contain the element `<foobar>abc</foobar>` anywhere inside the message (and the default namespace).

```
from("spring-ws:xpathresult:abc?expression=//foobar&endpointMapping=#endpointMapping")
  .convertBodyTo(String.class).to(mock:example)
```

324.14. ALTERNATIVE CONFIGURATION, USING EXISTING ENDPOINT MAPPINGS

For every endpoint with mapping-type **beanname** one bean of type **CamelEndpointDispatcher** with a corresponding name is required in the Registry/Application Context. This bean acts as a bridge between the Camel endpoint and an existing **endpoint mapping** like **PayloadRootQNameEndpointMapping**.

NOTE: The use of the **beanname** mapping-type is primarily meant for (legacy) situations where you're already using Spring-WS and have endpoint mappings defined in a Spring XML file. The **beanname** mapping-type allows you to wire your Camel route into an existing endpoint mapping. When you're starting from scratch it's recommended to define your endpoint mappings as Camel URI's (as illustrated above with **endpointMapping**) since it requires less configuration and is more expressive. Alternatively you could use vanilla Spring-WS with the help of annotations.

An example of a route using **beanname**:

```
<camelContext xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="spring-ws:beanname:QuoteEndpointDispatcher" />
    <to uri="mock:example" />
  </route>
</camelContext>

<bean id="legacyEndpointMapping"
class="org.springframework.ws.server.endpoint.mapping.PayloadRootQNameEndpointMapping">
  <property name="mappings">
    <props>
      <prop key="{http://example.com}/GetFuture">FutureEndpointDispatcher</prop>
      <prop key="{http://example.com}/GetQuote">QuoteEndpointDispatcher</prop>
    </props>
  </property>
</bean>
```

```
<bean id="QuoteEndpointDispatcher"  
class="org.apache.camel.component.spring.ws.bean.CamelEndpointDispatcher" />  
<bean id="FutureEndpointDispatcher"  
class="org.apache.camel.component.spring.ws.bean.CamelEndpointDispatcher" />
```

324.15. POJO (UN)MARSHALLING

Camel's pluggable data formats offer support for pojo/xml marshalling using libraries such as JAXB, XStream, JibX, Castor and XMLBeans. You can use these data formats in your route to send and receive pojo's, to and from web services.

When *accessing* web services you can marshal the request and unmarshal the response message:

```
JaxbDateFormat jaxb = new JaxbDateFormat(false);  
jaxb.setContextPath("com.example.model");  
  
from("direct:example").marshal(jaxb).to("spring-ws:http://foo.com/bar").unmarshal(jaxb);
```

Similarly when *providing* web services, you can unmarshal XML requests to POJO's and marshal the response message back to XML:

```
from("spring-ws:rootqname:{http://example.com/}GetFoo?  
endpointMapping=#endpointMapping").unmarshal(jaxb)  
.to("mock:example").marshal(jaxb);
```

324.16. SEE ALSO

- [Configuring Camel](#)
- [Component](#)
- [Endpoint](#)
- [Getting Started](#)

CHAPTER 325. SQL COMPONENT

Available as of Camel version 1.4

The **sql**: component allows you to work with databases using JDBC queries. The difference between this component and **JDBC** component is that in case of SQL the query is a property of the endpoint and it uses message payload as parameters passed to the query.

This component uses **spring-jdbc** behind the scenes for the actual SQL handling.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-sql</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

The SQL component also supports:

- JDBC-based repository for the Idempotent Consumer EIP pattern. See [Section 325.13, “Using the JDBC-based idempotent repository”](#).
- JDBC-based repository for the Aggregator EIP pattern. See [Section 325.14, “Using the JDBC-based aggregation repository”](#).

325.1. URI FORMAT

WARNING:From Camel 2.11 onwards this component can create both consumer (e.g. **from()**) and producer endpoints (e.g. **to()**). In previous versions, it could only act as a producer.

INFO:This component can be used as a [Transactional Client](#).

The SQL component uses the following endpoint URI notation:

```
sql:select * from table where id=# order by name[?options]
```

From Camel 2.11 onwards you can use named parameters by using ``#name_of_the_parameter`` style as shown:

```
sql:select * from table where id=:#myId order by name[?options]
```

When using named parameters, Camel will lookup the names from, in the given precedence:

1. From message body if its a **java.util.Map**
2. From message headers

If a named parameter cannot be resolved, then an exception is thrown.

From **Camel 2.14** onward you can use Simple expressions as parameters as shown:

```
sql:select * from table where id=:${property.myId} order by name[?options]
```

Notice that the standard `?` symbol that denotes the parameters to an SQL query is substituted with the `#` symbol, because the `?` symbol is used to specify options for the endpoint. The `?` symbol replacement can be configured on endpoint basis.

From **Camel 2.17** onwards you can externalize your SQL queries to files in the classpath or file system as shown:

```
sql:classpath:sql/myquery.sql[?options]
```

And the `myquery.sql` file is in the classpath and is just a plain text

```
-- this is a comment
select *
from table
where
  id = :#${property.myId}
order by
  name
```

In the file you can use multilines and format the SQL as you wish. And also use comments such as the dash line.

You can append query options to the URI in the following format, **?option=value&option=value&...**

325.2. OPTIONS

The SQL component supports 3 options, which are listed below.

Name	Description	Default	Type
dataSource (common)	Sets the DataSource to use to communicate with the database.		DataSource
usePlaceholder (advanced)	Sets whether to use placeholder and replace all placeholder characters with sign in the SQL queries. This option is default true	true	boolean
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The SQL endpoint is configured using URI syntax:

```
sql:query
```

with the following path and query parameters:

325.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
query	Required Sets the SQL query to perform. You can externalize the query by using file: or classpath: as prefix and specify the location of the file.		String

325.2.2. Query Parameters (45 parameters):

Name	Description	Default	Type
allowNamedParameters (common)	Whether to allow using named parameters in the queries.	true	boolean
dataSource (common)	Sets the DataSource to use to communicate with the database.		DataSource
dataSourceRef (common)	Deprecated Sets the reference to a DataSource to lookup from the registry, to use for communicating with the database.		String
outputClass (common)	Specify the full package and class name to use as conversion when outputType=SelectOne or SelectList.		String
outputHeader (common)	Store the query result in a header instead of the message body. By default, outputHeader == null and the query result is stored in the message body, any existing content in the message body is discarded. If outputHeader is set, the value is used as the name of the header to store the query result and the original message body is preserved.		String
outputType (common)	Make the output of consumer or producer to SelectList as List of Map, or SelectOne as single Java object in the following way: a) If the query has only single column, then that JDBC Column object is returned. (such as SELECT COUNT() FROM PROJECT will return a Long object. b) If the query has more than one column, then it will return a Map of that result. c) If the outputClass is set, then it will convert the query result into an Java bean object by calling all the setters that match the column names. It will assume your class has a default constructor to create instance with. d) If the query resulted in more than one rows, it throws an non-unique result exception.	Select List	SqlOutputType

Name	Description	Default	Type
separator (common)	The separator to use when parameter values is taken from message body (if the body is a String type), to be inserted at # placeholders. Notice if you use named parameters, then a Map type is used instead. The default value is comma.	,	char
breakBatchOnConsumeFail (consumer)	Sets whether to break batch if onConsume failed.	false	boolean
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
expectedUpdateCount (consumer)	Sets an expected update count to validate when using onConsume.	-1	int
maxMessagesPerPoll (consumer)	Sets the maximum number of messages to poll		int
onConsume (consumer)	After processing each row then this query can be executed, if the Exchange was processed successfully, for example to mark the row as processed. The query can have parameter.		String
onConsumeBatchComplete (consumer)	After processing the entire batch, this query can be executed to bulk update rows etc. The query cannot have parameters.		String
onConsumeFailed (consumer)	After processing each row then this query can be executed, if the Exchange failed, for example to mark the row as failed. The query can have parameter.		String
routeEmptyResultSet (consumer)	Sets whether empty resultset should be allowed to be sent to the next hop. Defaults to false. So the empty resultset will be filtered out.	false	boolean
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean

Name	Description	Default	Type
transacted (consumer)	Enables or disables transaction. If enabled then if processing an exchange failed then the consumer break out processing any further exchanges to cause a rollback eager	false	boolean
useIterator (consumer)	Sets how resultset should be delivered to route. Indicates delivery as either a list or individual object. defaults to true.	true	boolean
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
pollStrategy (consumer)	A pluggable org.apache.camel.PollingConsumerPollingStrategy allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		PollingConsumerPollStrategy
processingStrategy (consumer)	Allows to plugin to use a custom org.apache.camel.component.sql.SqlProcessingStrategy to execute queries when the consumer has processed the rows/batch.		SqlProcessingStrategy
batch (producer)	Enables or disables batch mode	false	boolean
noop (producer)	If set, will ignore the results of the SQL query and use the existing IN message as the OUT message for the continuation of processing	false	boolean
useMessageBodyForSql (producer)	Whether to use the message body as the SQL and then headers for parameters. If this option is enabled then the SQL in the uri is not used.	false	boolean
alwaysPopulateStatement (advanced)	If enabled then the populateStatement method from org.apache.camel.component.sql.SqlPrepareStatementStrategy is always invoked, also if there is no expected parameters to be prepared. When this is false then the populateStatement is only invoked if there is 1 or more expected parameters to be set; for example this avoids reading the message body/headers for SQL queries with no parameters.	false	boolean

Name	Description	Default	Type
parametersCount (advanced)	If set greater than zero, then Camel will use this count value of parameters to replace instead of querying via JDBC metadata API. This is useful if the JDBC vendor could not return correct parameters count, then user may override instead.		int
placeholder (advanced)	Specifies a character that will be replaced to in SQL query. Notice, that it is simple String.replaceAll() operation and no SQL parsing is involved (quoted strings will also change).	#	String
prepareStatementStrategy (advanced)	Allows to plugin to use a custom org.apache.camel.component.sql.SqlPreparedStatementStrategy to control preparation of the query and prepared statement.		SqlPreparedStatementStrategy
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
templateOptions (advanced)	Configures the Spring JdbcTemplate with the key/values from the Map		Map
usePlaceholder (advanced)	Sets whether to use placeholder and replace all placeholder characters with sign in the SQL queries. This option is default true	true	boolean
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.		int
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.		int
delay (scheduler)	Milliseconds before the next poll. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	500	long

Name	Description	Default	Type
greedy (scheduler)	If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	1000	long
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that.	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz2 component	none	ScheduledPollConsumer Scheduler
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz2, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for initialDelay and delay options.	MILLIS ECON DS	TimeUnit
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.	true	boolean

325.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 4 options, which are listed below.

Name	Description	Default	Type
camel.component.sql.data-source	Sets the DataSource to use to communicate with the database. The option is a javax.sql.DataSource type.		String

Name	Description	Default	Type
<code>camel.component.sql.enabled</code>	Enable sql component	true	Boolean
<code>camel.component.sql.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.component.sql.use-placeholder</code>	Sets whether to use placeholder and replace all placeholder characters with sign in the SQL queries. This option is default true	true	Boolean

325.4. TREATMENT OF THE MESSAGE BODY

The SQL component tries to convert the message body to an object of `java.util.Iterator` type and then uses this iterator to fill the query parameters (where each query parameter is represented by a `#` symbol (or configured placeholder) in the endpoint URI). If the message body is not an array or collection, the conversion results in an iterator that iterates over only one object, which is the body itself.

For example, if the message body is an instance of `java.util.List`, the first item in the list is substituted into the first occurrence of `#` in the SQL query, the second item in the list is substituted into the second occurrence of `#`, and so on.

If `batch` is set to `true`, then the interpretation of the inbound message body changes slightly – instead of an iterator of parameters, the component expects an iterator that contains the parameter iterators; the size of the outer iterator determines the batch size.

From Camel 2.16 onwards you can use the option `useMessageBodyForSql` that allows to use the message body as the SQL statement, and then the SQL parameters must be provided in a header with the key `SqlConstants.SQL_PARAMETERS`. This allows the SQL component to work more dynamic as the SQL query is from the message body.

325.5. RESULT OF THE QUERY

For `select` operations, the result is an instance of `List<Map<String, Object>>` type, as returned by the `JdbcTemplate.queryForList()` method. For `update` operations, a `NULL` body is returned as the `update` operation is only set as a header and never as a body.

NOTE

See [Header values](#) for more information on the `update` operation.

By default, the result is placed in the message body. If the `outputHeader` parameter is set, the result is placed in the header. This is an alternative to using a full message enrichment pattern to add headers, it provides a concise syntax for querying a sequence or some other small value into a header. It is convenient to use `outputHeader` and `outputType` together:

```

from("jms:order.inbox")
  .to("sql:select order_seq.nextval from dual?outputHeader=OrderId&outputType=SelectOne")
  .to("jms:order.booking");

```

325.6. USING STREAMLIST

From *Camel 2.18* onwards the producer supports `outputType=StreamList` that uses an iterator to stream the output of the query. This allows to process the data in a streaming fashion which for example can be used by the Splitter EIP to process each row one at a time, and load data from the database as needed.

```

from("direct:withSplitModel")
  .to("sql:select * from projects order by id?
outputType=StreamList&outputClass=org.apache.camel.component.sql.ProjectModel")
  .to("log:stream")
  .split(body()).streaming()
    .to("log:row")
    .to("mock:result")
  .end();

```

325.7. HEADER VALUES

When performing **update** operations, the SQL Component stores the update count in the following message headers:

Header	Description
Camel SqlUpdateCount	The number of rows updated for update operations, returned as an Integer object. This header is not provided when using <code>outputType=StreamList</code> .
Camel SqlRowCount	The number of rows returned for select operations, returned as an Integer object. This header is not provided when using <code>outputType=StreamList</code> .
Camel SqlQuery	Camel 2.8: Query to execute. This query takes precedence over the query specified in the endpoint URI. Note that query parameters in the header <i>are</i> represented by a ? instead of a # symbol

When performing **insert** operations, the SQL Component stores the rows with the generated keys and number of these rown in the following message headers (**Available as of Camel 2.12.4, 2.13.1**):

Header	Description
CamelSqlGeneratedKeysRowCount	The number of rows in the header that contains generated keys.
CamelSqlGeneratedKeyRows	Rows that contains the generated keys (a list of maps of keys).

325.8. GENERATED KEYS

*Available as of Camel 2.12.4, 2.13.1 and 2.14 *

If you insert data using SQL INSERT, then the RDBMS may support auto generated keys. You can instruct the SQL producer to return the generated keys in headers. To do that set the header **CamelSqlRetrieveGeneratedKeys=true**. Then the generated keys will be provided as headers with the keys listed in the table above.

You can see more details in this [unit test](#).

325.9. DATASOURCE

You can now set a reference to a **DataSource** in the URI directly:

```
sql:select * from table where id=# order by name?dataSource=myDS
```

325.10. SAMPLE

In the sample below we execute a query and retrieve the result as a **List** of rows, where each row is a **Map<String, Object** and the key is the column name.

First, we set up a table to use for our sample. As this is based on an unit test, we do it in java:

The SQL script **createAndPopulateDatabase.sql** we execute looks like as described below:

Then we configure our route and our **sql** component. Notice that we use a **direct** endpoint in front of the **sql** endpoint. This allows us to send an exchange to the **direct** endpoint with the URI, **direct:simple**, which is much easier for the client to use than the long **sql:** URI. Note that the **DataSource** is looked up in the registry, so we can use standard Spring XML to configure our **DataSource**.

And then we fire the message into the **direct** endpoint that will route it to our **sql** component that queries the database.

We could configure the **DataSource** in Spring XML as follows:

```
<jee:jndi-lookup id="myDS" jndi-name="jdbc/myDataSource"/>
```

325.10.1. Using named parameters

Available as of Camel 2.11

In the given route below, we want to get all the projects from the projects table. Notice the SQL query has 2 named parameters, `:#lic` and `:#min`.

Camel will then lookup for these parameters from the message body or message headers. Notice in the example above we set two headers with constant value for the named parameters:

```
from("direct:projects")
  .setHeader("lic", constant("ASF"))
  .setHeader("min", constant(123))
  .to("sql:select * from projects where license = :#lic and id > :#min order by id")
```

Though if the message body is a `java.util.Map` then the named parameters will be taken from the body.

```
from("direct:projects")
  .to("sql:select * from projects where license = :#lic and id > :#min order by id")
```

325.11. USING EXPRESSION PARAMETERS IN PRODUCERS

Available as of Camel 2.14

In the given route below, we want to get all the project from the database. It uses the body of the exchange for defining the license and uses the value of a property as the second parameter.

```
from("direct:projects")
  .setBody(constant("ASF"))
  .setProperty("min", constant(123))
  .to("sql:select * from projects where license = :#${body} and id > :#${property.min} order by id")
```

325.11.1. Using expression parameters in consumers

Available as of Camel 2.23

When using the SQL component as consumer, you can now also use expression parameters (simple language) to build dynamic query parameters, such as calling a method on a bean to retrieve an id, date or something.

For example in the sample below we call the `nextId` method on the bean `myIdGenerator`:

```
from("sql:select * from projects where id = :#${bean:myIdGenerator.nextId}")
  .to("mock:result");
```

And the bean has the following method:

```
public static class MyIdGenerator {
    private int id = 1;
```

```
public int nextId() {
    return id++;
}
```

Notice that there is no existing **Exchange** with message body and headers, so the simple expression you can use in the consumer are most useable for calling bean methods as in this example.

325.12. USING IN QUERIES WITH DYNAMIC VALUES

Available as of Camel 2.17

From Camel 2.17 onwards the SQL producer allows to use SQL queries with IN statements where the IN values is dynamic computed. For example from the message body or a header etc.

To use IN you need to:

- prefix the parameter name with **in:**
- add () around the parameter

An example explains this better. The following query is used:

```
-- this is a comment
select *
from projects
where project in (:#in:names)
order by id
```

In the following route:

```
from("direct:query")
    .to("sql:classpath:sql/selectProjectsIn.sql")
    .to("log:query")
    .to("mock:query");
```

Then the IN query can use a header with the key names with the dynamic values such as:

```
// use an array
template.requestBodyAndHeader("direct:query", "Hi there!", "names", new String[]{"Camel", "AMQ"});

// use a list
List<String> names = new ArrayList<String>();
names.add("Camel");
names.add("AMQ");

template.requestBodyAndHeader("direct:query", "Hi there!", "names", names);

// use a string separated values with comma
template.requestBodyAndHeader("direct:query", "Hi there!", "names", "Camel,AMQ");
```

The query can also be specified in the endpoint instead of being externalized (notice that externalizing makes maintaining the SQL queries easier)

```
from("direct:query")
```

```
.to("sql:select * from projects where project in (:#in:names) order by id")
.to("log:query")
.to("mock:query");
```

325.13. USING THE JDBC-BASED IDEMPOTENT REPOSITORY

Available as of Camel 2.7 In this section we will use the JDBC based idempotent repository.

TIP:*Abstract class* From Camel 2.9 onwards there is an abstract class

org.apache.camel.processor.idempotent.jdbc.AbstractJdbcMessageIdRepository you can extend to build custom JDBC idempotent repository.

First we have to create the database table which will be used by the idempotent repository. For **Camel 2.7**, we use the following schema:

```
CREATE TABLE CAMEL_MESSAGEPROCESSED ( processorName VARCHAR(255),
messageld VARCHAR(100) )
```

In **Camel 2.8**, we added the createdAt column:

```
CREATE TABLE CAMEL_MESSAGEPROCESSED ( processorName VARCHAR(255),
messageld VARCHAR(100), createdAt TIMESTAMP )
```

WARNING:The SQL Server **TIMESTAMP** type is a fixed-length binary-string type. It does not map to any of the JDBC time types: **DATE**, **TIME**, or **TIMESTAMP**.

Customize the JdbcMessageIdRepository

Starting with **Camel 2.9.1** you have a few options to tune the

org.apache.camel.processor.idempotent.jdbc.JdbcMessageIdRepository for your needs:

Parameter	Default Value	Description
createTableIfNotExists	true	Defines whether or not Camel should try to create the table if it doesn't exist.
tableExistsString	SELECT 1 FROM CAMEL_MESSAGEPROCESSED WHERE 1=0	This query is used to figure out whether the table already exists or not. It must throw an exception to indicate the table doesn't exist.

Parameter	Default Value	Description
createString	CREATE TABLE CAMEL_MESSAGES (processorName VARCHAR(255), messageId VARCHAR(100), createdAt TIMESTAMP)	The statement which is used to create the table.
queryString	SELECT COUNT(*) FROM CAMEL_MESSAGES WHERE processorName = ? AND messageId = ?	The query which is used to figure out whether the message already exists in the repository (the result is not equals to '0'). It takes two parameters. This first one is the processor name (String) and the second one is the message id (String).

Parameter	Default Value	Description
insertString	INSERT INTO CAMEL_MESSAGES PROCESORNAME, MESSAGEID, CREATEDAT) VALUES (?, ?, ?)	The statement which is used to add the entry into the table. It takes three parameter. The first one is the processor name (String), the second one is the message id (String) and the third one is the timestamp (java.sql.Timestamp) when this entry was added to the repository.
deleteString	DELETE FROM CAMEL_MESSAGES WHERE PROCESORNAME = ? AND MESSAGEID = ?	The statement which is used to delete the entry from the database. It takes two parameter. This first one is the processor name (String) and the second one is the message id (String).

325.14. USING THE JDBC-BASED AGGREGATION REPOSITORY

Available as of Camel 2.6

INFO: Using `JdbcAggregationRepository` in Camel 2.6

In Camel 2.6, the `JdbcAggregationRepository` is provided in the **camel-jdbc-aggregator** component. From Camel 2.7 onwards, the **JdbcAggregationRepository** is provided in the **camel-sql** component.

JdbcAggregationRepository is an **AggregationRepository** which on the fly persists the aggregated messages. This ensures that you will not lose messages, as the default aggregator will use an in memory only **AggregationRepository**. The **JdbcAggregationRepository** allows together with Camel to provide persistent support for the Aggregator.

Only when an Exchange has been successfully processed it will be marked as complete which happens when the **confirm** method is invoked on the **AggregationRepository**. This means if the same Exchange fails again it will be kept retried until it success.

You can use option **maximumRedeliveries** to limit the maximum number of redelivery attempts for a given recovered Exchange. You must also set the **deadLetterUri** option so Camel knows where to send the Exchange when the **maximumRedeliveries** was hit.

You can see some examples in the unit tests of camel-sql, for example [this test](#).

325.14.1. Database

To be operational, each aggregator uses two table: the aggregation and completed one. By convention the completed has the same name as the aggregation one suffixed with "**_COMPLETED**". The name must be configured in the Spring bean with the **RepositoryName** property. In the following example aggregation will be used.

The table structure definition of both table are identical: in both case a String value is used as key (**id**) whereas a Blob contains the exchange serialized in byte array.

However one difference should be remembered: the **id** field does not have the same content depending on the table.

In the aggregation table **id** holds the correlation Id used by the component to aggregate the messages. In the completed table, **id** holds the id of the exchange stored in corresponding the blob field.

Here is the SQL query used to create the tables, just replace "**aggregation**" with your aggregator repository name.

```
CREATE TABLE aggregation (
  id varchar(255) NOT NULL,
  exchange blob NOT NULL,
  constraint aggregation_pk PRIMARY KEY (id)
);
CREATE TABLE aggregation_completed (
  id varchar(255) NOT NULL,
  exchange blob NOT NULL,
  constraint aggregation_completed_pk PRIMARY KEY (id)
);
```

325.15. STORING BODY AND HEADERS AS TEXT

Available as of Camel 2.11

You can configure the **JdbcAggregationRepository** to store message body and select(ed) headers as String in separate columns. For example to store the body, and the following two headers **companyName** and **accountName** use the following SQL:

```
CREATE TABLE aggregationRepo3 (
  id varchar(255) NOT NULL,
  exchange blob NOT NULL,
  body varchar(1000),
  companyName varchar(1000),
  accountName varchar(1000),
  constraint aggregationRepo3_pk PRIMARY KEY (id)
);
CREATE TABLE aggregationRepo3_completed (
```

```

id varchar(255) NOT NULL,
exchange blob NOT NULL,
body varchar(1000),
companyName varchar(1000),
accountName varchar(1000),
constraint aggregationRepo3_completed_pk PRIMARY KEY (id)
);

```

And then configure the repository to enable this behavior as shown below:

```

<bean id="repo3"
class="org.apache.camel.processor.aggregate.jdbc.JdbcAggregationRepository">
  <property name="repositoryName" value="aggregationRepo3"/>
  <property name="transactionManager" ref="txManager3"/>
  <property name="dataSource" ref="dataSource3"/>
  <!-- configure to store the message body and following headers as text in the repo -->
  <property name="storeBodyAsText" value="true"/>
  <property name="headersToStoreAsText">
    <list>
      <value>companyName</value>
      <value>accountName</value>
    </list>
  </property>
</bean>

```

325.15.1. Codec (Serialization)

Because they can contain any type of payload, Exchanges are not serializable by design. It is converted into a byte array to be stored in a database BLOB field. All those conversions are handled by the **JdbcCodec** class. One detail of the code requires your attention: the **ClassLoadingAwareObjectInputStream**.

The **ClassLoadingAwareObjectInputStream** has been reused from the [Apache ActiveMQ](#) project. It wraps an **ObjectInputStream** and use it with the **ContextClassLoader** rather than the **currentThread** one. The benefit is to be able to load classes exposed by other bundles. This allows the exchange body and headers to have custom types object references.

325.15.2. Transaction

A Spring **PlatformTransactionManager** is required to orchestrate transactions.

325.15.2.1. Service (Start/Stop)

The **start** method verifies the connection of the database and the presence of the required tables. If anything is wrong it will fail during starting.

325.15.3. Aggregator configuration

Depending on the targeted environment, the aggregator might need some configuration. As you already know, each aggregator should have its own repository (with the corresponding pair of table created in the database) and a data source. If the default lobHandler is not adapted to your database system, it can be injected with the **lobHandler** property.

Here is the declaration for Oracle:

```

<bean id="lobHandler" class="org.springframework.jdbc.support.lob.OracleLobHandler">
  <property name="nativeJdbcExtractor" ref="nativeJdbcExtractor"/>
</bean>
<bean id="nativeJdbcExtractor"
  class="org.springframework.jdbc.support.nativejdbc.CommonsDbcpNativeJdbcExtractor"/>
<bean id="repo"
  class="org.apache.camel.processor.aggregate.jdbc.JdbcAggregationRepository">
  <property name="transactionManager" ref="transactionManager"/>
  <property name="repositoryName" value="aggregation"/>
  <property name="dataSource" ref="dataSource"/>
  <!-- Only with Oracle, else use default -->
  <property name="lobHandler" ref="lobHandler"/>
</bean>

```

==== Optimistic locking

From **Camel 2.12** onwards you can turn on **optimisticLocking** and use this JDBC based aggregation repository in a clustered environment where multiple Camel applications shared the same database for the aggregation repository. If there is a race condition there JDBC driver will throw a vendor specific exception which the **JdbcAggregationRepository** can react upon. To know which caused exceptions from the JDBC driver is regarded as an optimistic locking error we need a mapper to do this. Therefore there is a **org.apache.camel.processor.aggregate.jdbc.JdbcOptimisticLockingExceptionMapper** allows you to implement your custom logic if needed. There is a default implementation **org.apache.camel.processor.aggregate.jdbc.DefaultJdbcOptimisticLockingExceptionMapper** which works as follows:

The following check is done:

- If the caused exception is an **SQLException** then the SQLState is checked if starts with 23.
- If the caused exception is a **DataIntegrityViolationException**
- If the caused exception class name has "ConstraintViolation" in its name.
- Optional checking for FQN class name matches if any class names has been configured

You can in addition add FQN classnames, and if any of the caused exception (or any nested) equals any of the FQN class names, then its an optimistic locking error.

Here is an example, where we define 2 extra FQN class names from the JDBC vendor:

```

<bean id="repo"
  class="org.apache.camel.processor.aggregate.jdbc.JdbcAggregationRepository">
  <property name="transactionManager" ref="transactionManager"/>
  <property name="repositoryName" value="aggregation"/>
  <property name="dataSource" ref="dataSource"/>
  <property name="jdbcOptimisticLockingExceptionMapper" ref="myExceptionMapper"/>
</bean>
<!-- use the default mapper with extraFQN class names from our JDBC driver -->
<bean id="myExceptionMapper"
  class="org.apache.camel.processor.aggregate.jdbc.DefaultJdbcOptimisticLockingExceptionMapper">
  <property name="classNames">
    <util:set>
      <value>com.foo.sql.MyViolationExceptoion</value>
      <value>com.foo.sql.MyOtherViolationExceptoion</value>
    </util:set>
  </property>
</bean>

```

```

</util:set>
</property>
</bean>

```

325.16. PROPAGATION BEHAVIOR

JdbcAggregationRepository uses two distinct *transaction templates* from Spring-TX. One is read-only and one is used for read-write operations.

However, when using **JdbcAggregationRepository** within a route that itself uses `<transacted />` and there's common **PlatformTransactionManager** used, there may be a need to configure *propagation behavior* used by transaction templates inside **JdbcAggregationRepository**.

Here's a way to do it:

```

<bean id="repo"
class="org.apache.camel.processor.aggregate.jdbc.JdbcAggregationRepository">
  <property name="propagationBehaviorName" value="PROPAGATION_NESTED" />
</bean>

```

Propagation is specified by constants of **org.springframework.transaction.TransactionDefinition** interface, so **propagationBehaviorName** is convenient setter that allows to use names of the constants.

325.17. POSTGRESQL CASE

There's special database that may cause problems with optimistic locking used by **JdbcAggregationRepository**. PostgreSQL marks connection as invalid in case of data integrity violation exception (the one with `SQLState=23505`). This makes the connection effectively unusable within nested transaction. Details can be found [in this document](#).

org.apache.camel.processor.aggregate.jdbc.PostgresAggregationRepository extends **JdbcAggregationRepository** and uses special `INSERT .. ON CONFLICT ..` statement to provide optimistic locking behavior.

This statement is (with default aggregation table definition):

```

INSERT INTO aggregation (id, exchange) values (?, ?) ON CONFLICT DO NOTHING

```

Details can be found [in PostgreSQL documentation](#).

When this clause is used, **java.sql.PreparedStatement.executeUpdate()** call returns **0** instead of throwing `SQLException` with `SQLState=23505`. Further handling is exactly the same as with generic **JdbcAggregationRepository**, but without marking PostgreSQL connection as invalid.

325.18. CAMEL SQL STARTER

A starter module is available to spring-boot users. When using the starter, the **DataSource** can be directly configured using spring-boot properties.

```

# Example for a mysql datasource
spring.datasource.url=jdbc:mysql://localhost/test
spring.datasource.username=dbuser

```

```
spring.datasource.password=dbpass  
spring.datasource.driver-class-name=com.mysql.jdbc.Driver
```

To use this feature, add the following dependencies to your spring boot pom.xml file:

```
<dependency>  
  <groupId>org.apache.camel</groupId>  
  <artifactId>camel-sql-starter</artifactId>  
  <version>${camel.version}</version> <!-- use the same version as your Camel core version -->  
</dependency>  
  
<dependency>  
  <groupId>org.springframework.boot</groupId>  
  <artifactId>spring-boot-starter-jdbc</artifactId>  
  <version>${spring-boot-version}</version>  
</dependency>
```

You should also include the specific database driver, if needed.

CHAPTER 326. SQL STORED PROCEDURE COMPONENT

Available as of Camel version 2.17

The **sql-stored**: component allows you to work with databases using JDBC Stored Procedure queries. This component is an extension to the [SQL Component](#) but specialized for calling stored procedures.

This component uses **spring-jdbc** behind the scenes for the actual SQL handling.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-sql</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

326.1. URI FORMAT

The SQL component uses the following endpoint URI notation:

```
sql-stored:template[?options]
```

Where template is the stored procedure template, where you declare the name of the stored procedure and the IN, INOUT, and OUT arguments.

You can also refer to the template in a external file on the file system or classpath such as:

```
sql-stored:classpath:sql/myprocedure.sql[?options]
```

Where sql/myprocedure.sql is a plain text file in the classpath with the template, as show:

```
SUBNUMBERS(
  INTEGER ${headers.num1},
  INTEGER ${headers.num2},
  INOUT INTEGER ${headers.num3} out1,
  OUT INTEGER out2
)
```

You can append query options to the URI in the following format, **?option=value&option=value&...**

326.2. OPTIONS

The SQL Stored Procedure component supports 2 options, which are listed below.

Name	Description	Default	Type
dataSource (producer)	Sets the DataSource to use to communicate with the database.		DataSource

Name	Description	Default	Type
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The SQL Stored Procedure endpoint is configured using URI syntax:

```
sql-stored:template
```

with the following path and query parameters:

326.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
template	Required Sets the StoredProcedure template to perform		String

326.2.2. Query Parameters (7 parameters):

Name	Description	Default	Type
batch (producer)	Enables or disables batch mode	false	boolean
dataSource (producer)	Sets the DataSource to use to communicate with the database.		DataSource
function (producer)	Whether this call is for a function.	false	boolean
noop (producer)	If set, will ignore the results of the template and use the existing IN message as the OUT message for the continuation of processing	false	boolean
outputHeader (producer)	Store the template result in a header instead of the message body. By default, outputHeader == null and the template result is stored in the message body, any existing content in the message body is discarded. If outputHeader is set, the value is used as the name of the header to store the template result and the original message body is preserved.		String

Name	Description	Default	Type
useMessageBodyForTemplate (producer)	Whether to use the message body as the template and then headers for parameters. If this option is enabled then the template in the uri is not used.	false	boolean
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

326.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 3 options, which are listed below.

Name	Description	Default	Type
camel.component.sql-stored.data-source	Sets the DataSource to use to communicate with the database. The option is a javax.sql.DataSource type.		String
camel.component.sql-stored.enabled	Enable sql-stored component	true	Boolean
camel.component.sql-stored.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

326.4. DECLARING THE STORED PROCEDURE TEMPLATE

The template is declared using a syntax that would be similar to a Java method signature. The name of the stored procedure, and then the arguments enclosed in parenthesis. An example explains this well:

```
<to uri="sql-stored:STOREDSAMPLE(INTEGER ${headers.num1},INTEGER
${headers.num2},INOUT INTEGER ${headers.num3} result1,OUT INTEGER result2)"/>
```

The arguments are declared by a type and then a mapping to the Camel message using simple expression. So, in this example the first two parameters are IN values of INTEGER type, mapped to the message headers. The third parameter is INOUT, meaning it accepts an INTEGER and then returns a different INTEGER result. The last parameter is the OUT value, also an INTEGER type.

In SQL term the stored procedure could be declared as:

```
CREATE PROCEDURE STOREDSAMPLE(VALUE1 INTEGER, VALUE2 INTEGER, INOUT
RESULT1 INTEGER, OUT RESULT2 INTEGER)
```

326.4.1. IN Parameters

IN parameters take four parts separated by a space: parameter name, SQL type (with scale), type name and value source.

Parameter name is optional and will be auto generated if not provided. It must be given between quotes(').

SQL type is required and can be an integer (positive or negative) or reference to integer field in some class. If SQL type contains a dot then component tries resolve that class and read the given field. For example SQL type **com.Foo.INTEGER** is read from the field INTEGER of class **com.Foo**. If the type doesn't contain comma then class to resolve the integer value will be **java.sql.Types**. Type can be postfixed by scale for example DECIMAL(10) would mean **java.sql.Types.DECIMAL** with scale 10.

Type name is optional and must be given between quotes(').

Value source is required. Value source populates the parameter value from the Exchange. It can be either a Simple expression or header location i.e. **:#<header name>**. For example Simple expression **#{header.val}** would mean that parameter value will be read from the header "val". Header location expression **:#val** would have identical effect.

```
<to uri="sql-stored:MYFUNC('param1' org.example.Types.INTEGER(10) #{header.srcValue})"/>
```

URI means that the stored procedure will be called with parameter name "param1", it's SQL type is read from field INTEGER of class **org.example.Types** and scale will be set to 10. Input value for the parameter is passed from the header "srcValue".

```
<to uri="sql-stored:MYFUNC('param1' 100 'mytypename' #{header.srcValue})"/>
```

URI is identical to previous on except SQL-type is 100 and type name is "mytypename".

Actual call will be done using `org.springframework.jdbc.core.SqlParameter`.

326.4.2. OUT Parameters

OUT parameters work similarly IN parameters and contain three parts: SQL type(with scale), type name and output parameter name.

SQL type works the same as IN parameters.

Type name is optional and also works the same as IN parameters.

Output parameter name is used for the OUT parameter name, as well as the header name where the result will be stored.

```
<to uri="sql-stored:MYFUNC(OUT org.example.Types.DECIMAL(10) outheader1)"/>
```

URI means that OUT parameter's name is "outheader1" and result will be but into header "outheader1".

```
<to uri="sql-stored:MYFUNC(OUT org.example.Types.NUMERIC(10) 'mytype' outheader1)"/>
```

This is identical to previous one but type name will be "mytype".

Actual call will be done using `org.springframework.jdbc.core.SqlOutParameter`.

326.4.3. INOUT Parameters

INOUT parameters are a combination of all of the above. They receive a value from the exchange, as well as store a result as a message header. The only caveat is that the IN parameter's "name" is skipped. Instead, the OUT parameter's "name" defines both the SQL parameter name, as well as the result header name.

```
<to uri="sql-stored:MYFUNC(INOUT DECIMAL(10) ${headers.inheader} outheader)"/>
```

Actual call will be done using `org.springframework.jdbc.core.SqlInOutParameter`.

326.5. CAMEL SQL STARTER

A starter module is available to spring-boot users. When using the starter, the **DataSource** can be directly configured using spring-boot properties.

```
# Example for a mysql datasource
spring.datasource.url=jdbc:mysql://localhost/test
spring.datasource.username=dbuser
spring.datasource.password=dbpass
spring.datasource.driver-class-name=com.mysql.jdbc.Driver
```

To use this feature, add the following dependencies to your spring boot pom.xml file:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-sql-starter</artifactId>
  <version>${camel.version}</version> <!-- use the same version as your Camel core version -->
</dependency>

<dependency>
  <groupId>org.springframework.boot</groupId>
  <artifactId>spring-boot-starter-jdbc</artifactId>
  <version>${spring-boot-version}</version>
</dependency>
```

You should also include the specific database driver, if needed.

326.6. SEE ALSO

- [SQL Component](#)

CHAPTER 327. SSH COMPONENT

Available as of Camel version 2.10

The SSH component enables access to SSH servers such that you can send an SSH command, and process the response.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-ssh</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

327.1. URI FORMAT

```
ssh:[username[:password]@]host[:port][?options]
```

327.2. OPTIONS

The SSH component supports 15 options, which are listed below.

Name	Description	Default	Type
configuration (advanced)	To use the shared SSH configuration		SshConfiguration
host (common)	Sets the hostname of the remote SSH server.		String
port (common)	Sets the port number for the remote SSH server.		int
username (security)	Sets the username to use in logging into the remote SSH server.		String
password (security)	Sets the password to use in connecting to remote SSH server. Requires keyPairProvider to be set to null.		String
pollCommand (common)	Sets the command string to send to the remote SSH server during every poll cycle. Only works with camel-ssh component being used as a consumer, i.e. from(ssh://...). You may need to end your command with a newline, and that must be URL encoded %OA		String
keyPairProvider (security)	Sets the KeyPairProvider reference to use when connecting using Certificates to the remote SSH Server.		KeyPairProvider

Name	Description	Default	Type
keyType (security)	Sets the key type to pass to the KeyPairProvider as part of authentication. KeyPairProvider.loadKey(...) will be passed this value. Defaults to ssh-rsa.		String
timeout (common)	Sets the timeout in milliseconds to wait in establishing the remote SSH server connection. Defaults to 30000 milliseconds.		long
certFilename (security)	Deprecated Sets the resource path of the certificate to use for Authentication.		String
certResource (security)	Sets the resource path of the certificate to use for Authentication. Will use ResourceHelperKeyPairProvider to resolve file based certificate, and depends on keyType setting.		String
channelType (advanced)	Sets the channel type to pass to the Channel as part of command execution. Defaults to exec.		String
shellPrompt (advanced)	Sets the shellPrompt to be dropped when response is read after command execution		String
sleepForShellPrompt (advanced)	Sets the sleep period in milliseconds to wait reading response from shell prompt. Defaults to 100 milliseconds.		long
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The SSH endpoint is configured using URI syntax:

```
ssh:host:port
```

with the following path and query parameters:

327.2.1. Path Parameters (2 parameters):

Name	Description	Default	Type
host	Required Sets the hostname of the remote SSH server.		String
port	Sets the port number for the remote SSH server.	22	int

327.2.2. Query Parameters (31 parameters):

Name	Description	Default	Type
failOnUnknownHost (common)	Specifies whether a connection to an unknown host should fail or not. This value is only checked when the property <code>knownHosts</code> is set.	false	boolean
knownHostsResource (common)	Sets the resource path for a <code>known_hosts</code> file		String
timeout (common)	Sets the timeout in milliseconds to wait in establishing the remote SSH server connection. Defaults to 30000 milliseconds.	30000	long
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
pollCommand (consumer)	Sets the command string to send to the remote SSH server during every poll cycle. Only works with <code>camel-ssh</code> component being used as a consumer, i.e. <code>from(ssh://...)</code> You may need to end your command with a newline, and that must be URL encoded <code>%0A</code>		String
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean
exceptionHandler (consumer)	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		<code>ExceptionHandler</code>
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		<code>ExchangePattern</code>
pollStrategy (consumer)	A pluggable <code>org.apache.camel.PollingConsumerPollingStrategy</code> allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		<code>PollingConsumerPollStrategy</code>

Name	Description	Default	Type
channelType (advanced)	Sets the channel type to pass to the Channel as part of command execution. Defaults to exec.	exec	String
shellPrompt (advanced)	Sets the shellPrompt to be dropped when response is read after command execution		String
sleepForShellPrompt (advanced)	Sets the sleep period in milliseconds to wait reading response from shell prompt. Defaults to 100 milliseconds.	100	long
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.		int
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.		int
delay (scheduler)	Milliseconds before the next poll. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	500	long
greedy (scheduler)	If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	1000	long
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that.	TRACE	LoggingLevel

Name	Description	Default	Type
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz2 component	none	ScheduledPollConsumerScheduler
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz2, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for initialDelay and delay options.	MILLISECONDS	TimeUnit
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.	true	boolean
certResource (security)	Sets the resource path of the certificate to use for Authentication. Will use ResourceHelperKeyPairProvider to resolve file based certificate, and depends on keyType setting.		String
keyPairProvider (security)	Sets the KeyPairProvider reference to use when connecting using Certificates to the remote SSH Server.		KeyPairProvider
keyType (security)	Sets the key type to pass to the KeyPairProvider as part of authentication. KeyPairProvider.loadKey(...) will be passed this value. Defaults to ssh-rsa.	ssh-rsa	String
password (security)	Sets the password to use in connecting to remote SSH server. Requires keyPairProvider to be set to null.		String
username (security)	Sets the username to use in logging into the remote SSH server.		String

327.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 30 options, which are listed below.

Name	Description	Default	Type
camel.component.ssh.cert-resource	Sets the resource path of the certificate to use for Authentication. Will use ResourceHelperKeyPairProvider to resolve file based certificate, and depends on keyType setting.		String
camel.component.ssh.channel-type	Sets the channel type to pass to the Channel as part of command execution. Defaults to exec.		String
camel.component.ssh.configuration.cert-resource	Sets the resource path of the certificate to use for Authentication. Will use ResourceHelperKeyPairProvider to resolve file based certificate, and depends on keyType setting.		String
camel.component.ssh.configuration.channel-type	Sets the channel type to pass to the Channel as part of command execution. Defaults to exec.	exec	String
camel.component.ssh.configuration.fail-on-unknown-host	Specifies whether a connection to an unknown host should fail or not. This value is only checked when the property knownHosts is set.	false	Boolean
camel.component.ssh.configuration.host	Sets the hostname of the remote SSH server.		String
camel.component.ssh.configuration.key-pair-provider	Sets the KeyPairProvider reference to use when connecting using Certificates to the remote SSH Server.		KeyPairProvider
camel.component.ssh.configuration.key-type	Sets the key type to pass to the KeyPairProvider as part of authentication. KeyPairProvider.loadKey(...) will be passed this value. Defaults to ssh-rsa.	ssh-rsa	String
camel.component.ssh.configuration.known-hosts-resource	Sets the resource path for a known_hosts file		String
camel.component.ssh.configuration.password	Sets the password to use in connecting to remote SSH server. Requires keyPairProvider to be set to null.		String

Name	Description	Default	Type
<code>camel.component.ssh.configuration.poll-command</code>	Sets the command string to send to the remote SSH server during every poll cycle. Only works with camel-ssh component being used as a consumer, i.e. from(ssh://...) You may need to end your command with a newline, and that must be URL encoded %0A		String
<code>camel.component.ssh.configuration.port</code>	Sets the port number for the remote SSH server.	22	Integer
<code>camel.component.ssh.configuration.shell-prompt</code>	Sets the shellPrompt to be dropped when response is read after command execution		String
<code>camel.component.ssh.configuration.sleep-for-shell-prompt</code>	Sets the sleep period in milliseconds to wait reading response from shell prompt. Defaults to 100 milliseconds.	100	Long
<code>camel.component.ssh.configuration.timeout</code>	Sets the timeout in milliseconds to wait in establishing the remote SSH server connection. Defaults to 30000 milliseconds.	30000	Long
<code>camel.component.ssh.configuration.username</code>	Sets the username to use in logging into the remote SSH server.		String
<code>camel.component.ssh.enabled</code>	Enable ssh component	true	Boolean
<code>camel.component.ssh.host</code>	Sets the hostname of the remote SSH server.		String
<code>camel.component.ssh.key-pair-provider</code>	Sets the KeyPairProvider reference to use when connecting using Certificates to the remote SSH Server. The option is a org.apache.sshd.common.keyprovider.KeyPairProvider type.		String
<code>camel.component.ssh.key-type</code>	Sets the key type to pass to the KeyPairProvider as part of authentication. KeyPairProvider.loadKey(...) will be passed this value. Defaults to ssh-rsa.		String
<code>camel.component.ssh.password</code>	Sets the password to use in connecting to remote SSH server. Requires keyPairProvider to be set to null.		String

Name	Description	Default	Type
<code>camel.component.ssh.poll-command</code>	Sets the command string to send to the remote SSH server during every poll cycle. Only works with camel-ssh component being used as a consumer, i.e. <code>from(ssh://...)</code> . You may need to end your command with a newline, and that must be URL encoded <code>%0A</code>		String
<code>camel.component.ssh.port</code>	Sets the port number for the remote SSH server.		Integer
<code>camel.component.ssh.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.component.ssh.shell-prompt</code>	Sets the shellPrompt to be dropped when response is read after command execution		String
<code>camel.component.ssh.sleep-for-shell-prompt</code>	Sets the sleep period in milliseconds to wait reading response from shell prompt. Defaults to 100 milliseconds.		Long
<code>camel.component.ssh.timeout</code>	Sets the timeout in milliseconds to wait in establishing the remote SSH server connection. Defaults to 30000 milliseconds.		Long
<code>camel.component.ssh.username</code>	Sets the username to use in logging into the remote SSH server.		String
<code>camel.component.ssh.cert-filename</code>	Sets the resource path of the certificate to use for Authentication.		String
<code>camel.component.ssh.configuration.cert-filename</code>	@deprecated As of version 2.11, replaced by <code>{@link #setCertResource(String)}</code>		String

327.4. USAGE AS A PRODUCER ENDPOINT

When the SSH Component is used as a Producer (`.to("ssh://...")`), it will send the message body as the command to execute on the remote SSH server.

Here is an example of this within the XML DSL. Note that the command has an XML encoded newline (`
`).

```
<route id="camel-example-ssh-producer">
  <from uri="direct:exampleSshProducer"/>
  <setBody>
    <constant>features:list&#10;</constant>
  </setBody>
```

```
<to uri="ssh://karaf:karaf@localhost:8101"/>
<log message="${body}"/>
</route>
```

327.5. AUTHENTICATION

The SSH Component can authenticate against the remote SSH server using one of two mechanisms: Public Key certificate or username/password. Configuring how the SSH Component does authentication is based on how and which options are set.

1. First, it will look to see if the **certResource** option has been set, and if so, use it to locate the referenced Public Key certificate and use that for authentication.
2. If **certResource** is not set, it will look to see if a **keyPairProvider** has been set, and if so, it will use that to for certificate based authentication.
3. If neither **certResource** nor **keyPairProvider** are set, it will use the **username** and **password** options for authentication. Even though the **username** and **password** are provided in the endpoint configuration and headers set with **SshConstants.USERNAME_HEADER** (**CamelSshUsername**) and **SshConstants.PASSWORD_HEADER** (**CamelSshPassword**), the endpoint configuration is surpassed and credentials set in the headers are used.

The following route fragment shows an SSH polling consumer using a certificate from the classpath.

In the XML DSL,

```
<route>
  <from uri="ssh://scott@localhost:8101?
certResource=classpath:test_rsa&useFixedDelay=true&delay=5000&pollCommand=feat
ures:list%0A"/>
  <log message="${body}"/>
</route>
```

In the Java DSL,

```
from("ssh://scott@localhost:8101?
certResource=classpath:test_rsa&useFixedDelay=true&delay=5000&pollCommand=features:list%0A"
)
.log("${body}");
```

An example of using Public Key authentication is provided in [examples/camel-example-ssh-security](#).

Certificate Dependencies

You will need to add some additional runtime dependencies if you use certificate based authentication. The dependency versions shown are as of Camel 2.11, you may need to use later versions depending what version of Camel you are using.

```
<dependency>
  <groupId>org.apache.sshd</groupId>
  <artifactId>sshd-core</artifactId>
  <version>0.8.0</version>
</dependency>
<dependency>
  <groupId>org.bouncycastle</groupId>
```

```
<artifactId>bcpkg-jdk15on</artifactId>
<version>1.47</version>
</dependency>
<dependency>
  <groupId>org.bouncycastle</groupId>
  <artifactId>bcpkix-jdk15on</artifactId>
  <version>1.47</version>
</dependency>
```

327.6. EXAMPLE

See the **examples/camel-example-ssh** and **examples/camel-example-ssh-security** in the Camel distribution.

327.7. SEE ALSO

- [Configuring Camel](#)
- [Component](#)
- [Endpoint](#)
- [Getting Started](#)

CHAPTER 328. STAX COMPONENT

Available as of Camel version 2.9

The StAX component allows messages to be process through a SAX [ContentHandler](#). Another feature of this component is to allow to iterate over JAXB records using StAX, for example using the Splitter EIP.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-stax</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

328.1. URI FORMAT

```
stax:content-handler-class
```

example:

```
stax:org.superbiz.FooContentHandler
```

From **Camel 2.11.1** onwards you can lookup a **org.xml.sax.ContentHandler** bean from the Registry using the # syntax as shown:

```
stax:#myHandler
```

328.2. OPTIONS

The StAX component has no options.

The StAX endpoint is configured using URI syntax:

```
stax:contentHandlerClass
```

with the following path and query parameters:

328.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
contentHandlerClass	Required The FQN class name for the ContentHandler implementation to use.		String

328.2.2. Query Parameters (1 parameters):

Name	Description	Default	Type
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

328.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.component.stax.enabled	Enable stax component	true	Boolean
camel.component.stax.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

328.4. USAGE OF A CONTENT HANDLER AS STAX PARSER

The message body after the handling is the handler itself.

Here an example:

```
from("file:target/in")
  .to("stax:org.superbiz.handler.CountingHandler")
  // CountingHandler implements org.xml.sax.ContentHandler or extends
  org.xml.sax.helpers.DefaultHandler
  .process(new Processor() {
    @Override
    public void process(Exchange exchange) throws Exception {
      CountingHandler handler = exchange.getIn().getBody(CountingHandler.class);
      // do some great work with the handler
    }
  });
```

328.5. ITERATE OVER A COLLECTION USING JAXB AND STAX

First we suppose you have JAXB objects.

For instance a list of records in a wrapper object:

```
import java.util.ArrayList;
import java.util.List;
import javax.xml.bind.annotation.XmlAccessType;
import javax.xml.bind.annotation.XmlAccessorType;
```

```

import javax.xml.bind.annotation.XmlElement;
import javax.xml.bind.annotation.XmlRootElement;

@XmlAccessorType(XmlAccessType.FIELD)
@XmlRootElement(name = "records")
public class Records {
    @XmlElement(required = true)
    protected List<Record> record;

    public List<Record> getRecord() {
        if (record == null) {
            record = new ArrayList<Record>();
        }
        return record;
    }
}

```

and

```

import javax.xml.bind.annotation.XmlAccessType;
import javax.xml.bind.annotation.XmlAccessorType;
import javax.xml.bind.annotation.XmlAttribute;
import javax.xml.bind.annotation.XmlType;

@XmlAccessorType(XmlAccessType.FIELD)
@XmlType(name = "record", propOrder = { "key", "value" })
public class Record {
    @XmlAttribute(required = true)
    protected String key;

    @XmlAttribute(required = true)
    protected String value;

    public String getKey() {
        return key;
    }

    public void setKey(String key) {
        this.key = key;
    }

    public String getValue() {
        return value;
    }

    public void setValue(String value) {
        this.value = value;
    }
}

```

Then you get a XML file to process:

```

<?xml version="1.0" encoding="UTF-8" standalone="yes"?>
<records>
  <record value="v0" key="0"/>

```

```

<record value="v1" key="1"/>
<record value="v2" key="2"/>
<record value="v3" key="3"/>
<record value="v4" key="4"/>
<record value="v5" key="5"/>
</record>

```

The StAX component provides an **StAXBuilder** which can be used when iterating XML elements with the Camel Splitter

```

from("file:target/in")
  .split(stax(Record.class)).streaming()
  .to("mock:records");

```

Where **stax** is a static method on **org.apache.camel.component.stax.StAXBuilder** which you can static import in the Java code. The stax builder is by default namespace aware on the XMLReader it uses. From **Camel 2.11.1** onwards you can turn this off by setting the boolean parameter to false, as shown below:

```

from("file:target/in")
  .split(stax(Record.class, false)).streaming()
  .to("mock:records");

```

328.5.1. The previous example with XML DSL

The example above could be implemented as follows in XML DSL

328.6. SEE ALSO

- [Component](#)
- [Endpoint](#)
- [Getting Started](#)

CHAPTER 329. STOMP COMPONENT

Available as of Camel version 2.12

The **stomp:** component is used for communicating with [Stomp](#) compliant message brokers, like [Apache ActiveMQ](#) or [ActiveMQ Apollo](#)

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-stomp</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

329.1. URI FORMAT

```
stomp:queue:destination[?options]
```

Where **destination** is the name of the queue.

329.2. OPTIONS

The Stomp component supports 8 options, which are listed below.

Name	Description	Default	Type
configuration (advanced)	To use the shared stomp configuration		StompConfigurati on
brokerURL (common)	The URI of the Stomp broker to connect to		String
login (security)	The username		String
passcode (security)	The password		String
host (common)	The virtual host		String
useGlobalSslCont ext Parameters (security)	Enable usage of global SSL context parameters.	false	boolean
headerFilterStrat egy (filter)	To use a custom org.apache.camel.spi.HeaderFilterStrategy to filter header to and from Camel message.		HeaderFilterStrate gy

Name	Description	Default	Type
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Stomp endpoint is configured using URI syntax:

```
stomp:destination
```

with the following path and query parameters:

329.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
destination	Required Name of the queue		String

329.2.2. Query Parameters (10 parameters):

Name	Description	Default	Type
brokerURL (common)	Required The URI of the Stomp broker to connect to	tcp://localhost:61613	String
host (common)	The virtual host name		String
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean

Name	Description	Default	Type
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
headerFilterStrategy (advanced)	To use a custom HeaderFilterStrategy to filter header to and from Camel message.		HeaderFilterStrategy
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
login (security)	The username		String
passcode (security)	The password		String
sslContextParameters (security)	To configure security using SSLContextParameters		SSLContextParameters

329.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 13 options, which are listed below.

Name	Description	Default	Type
camel.component.stomp.broker-uri	The URI of the Stomp broker to connect to		String
camel.component.stomp.configuration.broker-uri	The URI of the Stomp broker to connect to	tcp://localhost:61613	String
camel.component.stomp.configuration.host	The virtual host name		String

Name	Description	Default	Type
<code>camel.component.stomp.configuration.login</code>	The username		String
<code>camel.component.stomp.configuration.passcode</code>	The password		String
<code>camel.component.stomp.configuration.ssl-context-parameters</code>	To configure security using <code>SSLContextParameters</code>		<code>SSLContextParameters</code>
<code>camel.component.stomp.enabled</code>	Enable stomp component	true	Boolean
<code>camel.component.stomp.header-filter-strategy</code>	To use a custom <code>org.apache.camel.spi.HeaderFilterStrategy</code> to filter header to and from Camel message. The option is a <code>org.apache.camel.spi.HeaderFilterStrategy</code> type.		String
<code>camel.component.stomp.host</code>	The virtual host		String
<code>camel.component.stomp.login</code>	The username		String
<code>camel.component.stomp.passcode</code>	The password		String
<code>camel.component.stomp.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.component.stomp.use-global-ssl-context-parameters</code>	Enable usage of global SSL context parameters.	false	Boolean

You can append query options to the URI in the following format, **?option=value&option=value&...**

329.4. SAMPLES

Sending messages:

```
from("direct:foo").to("stomp:queue:test");
```

Consuming messages:

```
from("stomp:queue:test").transform(body().convertToString()).to("mock:result")
```

329.5. ENDPOINTS

Camel supports the Message Endpoint pattern using the [Endpoint](#) interface. Endpoints are usually created by a Component and Endpoints are usually referred to in the DSL via their URIs.

From an Endpoint you can use the following methods

* [createProducer\(\)](#) will create a [Producer](#) for sending message exchanges to the endpoint * [createConsumer\(\)](#) implements the Event Driven Consumer pattern for consuming message exchanges from the endpoint via a [Processor](#) when creating a [Consumer](#) * [createPollingConsumer\(\)](#) implements the Polling Consumer pattern for consuming message exchanges from the endpoint via a [PollingConsumer](#)

329.6. SEE ALSO

- [Configuring Camel](#)
- [Message Endpoint pattern](#)
- [URIs](#)
- [Writing Components](#)

CHAPTER 330. STREAM COMPONENT

Available as of Camel version 1.3

The **stream:** component provides access to the **System.in**, **System.out** and **System.err** streams as well as allowing streaming of file and URL.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-stream</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

330.1. URI FORMAT

```
stream:in[?options]
stream:out[?options]
stream:err[?options]
stream:header[?options]
```

In addition, the **file** and **url** endpoint URIs are supported:

```
stream:file?fileName=/foo/bar.txt
stream:url[?options]
```

If the **stream:header** URI is specified, the **stream** header is used to find the stream to write to. This option is available only for stream producers (that is, it cannot appear in **from()**).

You can append query options to the URI in the following format, **?option=value&option=value&...**

330.2. OPTIONS

The Stream component has no options.

The Stream endpoint is configured using URI syntax:

```
stream:kind
```

with the following path and query parameters:

330.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
kind	Required Kind of stream to use such as System.in or System.out.		String

330.2.2. Query Parameters (22 parameters):

Name	Description	Default	Type
encoding (common)	You can configure the encoding (is a charset name) to use text-based streams (for example, message body is a String object). If not provided, Camel uses the JVM default Charset.		String
fileName (common)	When using the stream:file URI format, this option specifies the filename to stream to/from.		String
url (common)	When using the stream:url URI format, this option specifies the URL to stream to/from. The input/output stream will be opened using the JDK URLConnection facility.		String
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
fileWatcher (consumer)	To use JVM file watcher to listen for file change events to support re-loading files that may be overwritten, somewhat like tail --retry	false	boolean
groupLines (consumer)	To group X number of lines in the consumer. For example to group 10 lines and therefore only spit out an Exchange with 10 lines, instead of 1 Exchange per line.		int
groupStrategy (consumer)	Allows to use a custom GroupStrategy to control how to group lines.		GroupStrategy
initialPromptDelay (consumer)	Initial delay in milliseconds before showing the message prompt. This delay occurs only once. Can be used during system startup to avoid message prompts being written while other logging is done to the system out.	2000	long
promptDelay (consumer)	Optional delay in milliseconds before showing the message prompt.		long
promptMessage (consumer)	Message prompt to use when reading from stream:in; for example, you could set this to Enter a command:		String

Name	Description	Default	Type
retry (consumer)	Will retry opening the stream if it's overwritten, somewhat like tail --retry. If reading from files then you should also enable the fileWatcher option, to make it work reliable.	false	boolean
scanStream (consumer)	To be used for continuously reading a stream such as the unix tail command.	false	boolean
scanStreamDelay (consumer)	Delay in milliseconds between read attempts when using scanStream.		long
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
autoCloseCount (producer)	Number of messages to process before closing stream on Producer side. Never close stream by default (only when Producer is stopped). If more messages are sent, the stream is reopened for another autoCloseCount batch.		int
closeOnDone (producer)	This option is used in combination with Splitter and streaming to the same file. The idea is to keep the stream open and only close when the Splitter is done, to improve performance. Mind this requires that you only stream to the same file, and not 2 or more files.	false	boolean
delay (producer)	Initial delay in milliseconds before producing the stream.		long
connectTimeout (advanced)	Sets a specified timeout value, in milliseconds, to be used when opening a communications link to the resource referenced by this URLConnection. If the timeout expires before the connection can be established, a java.net.SocketTimeoutException is raised. A timeout of zero is interpreted as an infinite timeout.		int
httpHeaders (advanced)	Optional http headers to use in request when using HTTP URL.		Map

Name	Description	Default	Type
readTimeout (advanced)	Sets the read timeout to a specified timeout, in milliseconds. A non-zero value specifies the timeout when reading from Input stream when a connection is established to a resource. If the timeout expires before there is data available for read, a <code>java.net.SocketTimeoutException</code> is raised. A timeout of zero is interpreted as an infinite timeout.		int
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

330.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.component.stream.enabled	Enable stream component	true	Boolean
camel.component.stream.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

330.4. MESSAGE CONTENT

The **stream:** component supports either **String** or **byte[]** for writing to streams. Just add either **String** or **byte[]** content to the **message.in.body**. Messages sent to the **stream:** producer in binary mode are not followed by the newline character (as opposed to the **String** messages). Message with **null** body will not be appended to the output stream.

The special **stream:header** URI is used for custom output streams. Just add a **java.io.OutputStream** object to **message.in.header** in the key **header**.

See samples for an example.

330.5. SAMPLES

In the following sample we route messages from the **direct:in** endpoint to the **System.out** stream:

```
// Route messages to the standard output.
from("direct:in").to("stream:out");

// Send String payload to the standard output.
// Message will be followed by the newline.
template.sendBody("direct:in", "Hello Text World");
```

```
// Send byte[] payload to the standard output.  
// No newline will be added after the message.  
template.sendBody("direct:in", "Hello Bytes World".getBytes());
```

The following sample demonstrates how the header type can be used to determine which stream to use. In the sample we use our own output stream, **MyOutputStream**.

The following sample demonstrates how to continuously read a file stream (analogous to the UNIX **tail** command):

```
from("stream:file?fileName=/server/logs/server.log&scanStream=true&scanStreamDelay=1000")  
  .to("bean:logService?method=parseLogLine");
```

One gotcha with `scanStream` (pre Camel 2.7) or `scanStream + retry` is the file will be re-opened and scanned with each iteration of `scanStreamDelay`. Until NIO2 is available we cannot reliably detect when a file is deleted/recreated.

If you want to re-load the file if it rollover/rewritten then you should also turn on the **fileWatcher** and **retry** options.

```
from("stream:file?  
fileName=/server/logs/server.log&scanStream=true&scanStreamDelay=1000&retry=true&fileWatcher=true")  
  .to("bean:logService?method=parseLogLine");
```

CHAPTER 331. STRING ENCODING DATAFORMAT

Available as of Camel version 2.12

The String Data Format is a textual based format that supports encoding.

331.1. OPTIONS

The String Encoding dataformat supports 2 options, which are listed below.

Name	Default	Java Type	Description
<code>charset</code>		String	Sets an encoding to use. Will by default use the JVM platform default charset.
<code>contentTypeHeader</code>	false	Boolean	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON etc.

331.2. MARSHAL

In this example we marshal the file content to String object in UTF-8 encoding.

```
from("file://data.csv").marshal().string("UTF-8").to("jms://myqueue");
```

331.3. UNMARSHAL

In this example we unmarshal the payload from the JMS queue to a String object using UTF-8 encoding, before its processed by the newOrder processor.

```
from("jms://queue/order").unmarshal().string("UTF-8").processRef("newOrder");
```

331.4. DEPENDENCIES

This data format is provided in **camel-core** so no additional dependencies is needed.

CHAPTER 332. STRING TEMPLATE COMPONENT

Available as of Camel version 1.2

The **string-template**: component allows you to process a message using a [String Template](#). This can be ideal when using Templating to generate responses for requests.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-stringtemplate</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

332.1. URI FORMAT

```
string-template:templateName[?options]
```

Where **templateName** is the classpath-local URI of the template to invoke; or the complete URL of the remote template.

You can append query options to the URI in the following format, **?option=value&option=value&...**

332.2. OPTIONS

The String Template component supports 2 options, which are listed below.

Name	Description	Default	Type
allowContextMapAll (producer)	Sets whether the context map should allow access to all details. By default only the message body and headers can be accessed. This option can be enabled for full access to the current Exchange and CamelContext. Doing so imposes a potential security risk as this opens access to the full power of CamelContext API.	false	boolean
allowTemplateFromHeader (producer)	Whether to allow to use resource template from header or not (default false). Enabling this option has security ramifications. For example, if the header contains untrusted or user derived content, this can ultimately impact on the confidentiality and integrity of your end application, so use this option with caution.	false	boolean

The String Template endpoint is configured using URI syntax:

```
string-template:resourceUri
```

with the following path and query parameters:

332.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
resourceUri	Required Path to the resource. You can prefix with: classpath, file, http, ref, or bean. classpath, file and http loads the resource using these protocols (classpath is default). ref will lookup the resource in the registry. bean will call a method on a bean to be used as the resource. For bean you can specify the method name after dot, eg bean:myBean.myMethod.		String

332.2.2. Query Parameters (6 parameters):

Name	Description	Default	Type
allowContextMapAll (producer)	Sets whether the context map should allow access to all details. By default only the message body and headers can be accessed. This option can be enabled for full access to the current Exchange and CamelContext. Doing so imposes a potential security risk as this opens access to the full power of CamelContext API.	false	boolean
allowTemplateFromHeader (producer)	Whether to allow to use resource template from header or not (default false). Enabling this option has security ramifications. For example, if the header contains untrusted or user derived content, this can ultimately impact on the confidentiality and integrity of your end application, so use this option with caution.	false	boolean
contentCache (producer)	Sets whether to use resource content cache or not	false	boolean
delimiterStart (producer)	The variable start delimiter	<	char
delimiterStop (producer)	The variable end delimiter	>	char
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

332.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.string-template.enabled</code>	Enable string-template component	true	Boolean
<code>camel.component.string-template.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

332.4. HEADERS

Camel will store a reference to the resource in the message header with key, **`org.apache.camel.stringtemplate.resource`**. The Resource is an **`org.springframework.core.io.Resource`** object.

332.5. HOT RELOADING

The string template resource is by default hot-reloadable for both file and classpath resources (expanded jar). If you set **`contentCache=true`**, Camel loads the resource only once and hot-reloading is not possible. This scenario can be used in production when the resource never changes.

332.6. STRINGTEMPLATE ATTRIBUTES

Since Camel 2.14, you can define the custom context map by setting the message header "**`CamelStringTemplateVariableMap`**" just like the below code.

```
Map<String, Object> variableMap = new HashMap<String, Object>();
Map<String, Object> headersMap = new HashMap<String, Object>();
headersMap.put("name", "Willem");
variableMap.put("headers", headersMap);
variableMap.put("body", "Monday");
variableMap.put("exchange", exchange);
exchange.getIn().setHeader("CamelStringTemplateVariableMap", variableMap);
```

332.7. SAMPLES

For example you could use a string template as follows in order to formulate a response to a message:

```
from("activemq:My.Queue").
to("string-template:com/acme/MyResponse.tm");
```

332.8. THE EMAIL SAMPLE

In this sample we want to use a string template to send an order confirmation email. The email template is laid out in **StringTemplate** as: This example works for **camel 2.11.0**. If your camel version is less than 2.11.0, the variables should be started and ended with \$.

```
Dear <headers.lastName>, <headers.firstName>
```

```
Thanks for the order of <headers.item>.
```

```
Regards Camel Riders Bookstore  
<body>
```

And the java code is as follows:

332.9. SEE ALSO

- [Configuring Camel](#)
- [Component](#)
- [Endpoint](#)
- [Getting Started](#)

CHAPTER 333. STUB COMPONENT

Available as of Camel version 2.10

The **stub:** component provides a simple way to stub out any physical endpoints while in development or testing, allowing you for example to run a route without needing to actually connect to a specific [SMTP](#) or [Http](#) endpoint. Just add **stub:** in front of any endpoint URI to stub out the endpoint.

Internally the Stub component creates [VM](#) endpoints. The main difference between [Stub](#) and [VM](#) is that [VM](#) will validate the URI and parameters you give it, so putting `vm:` in front of a typical URI with query arguments will usually fail. Stub won't though, as it basically ignores all query parameters to let you quickly stub out one or more endpoints in your route temporarily.

333.1. URI FORMAT

```
stub:someUri
```

Where **someUri** can be any URI with any query parameters.

333.2. OPTIONS

The Stub component supports 6 options, which are listed below.

Name	Description	Default	Type
queueSize (advanced)	Sets the default maximum capacity of the SEDA queue (i.e., the number of messages it can hold).	1000	int
concurrentConsumers (consumer)	Sets the default number of concurrent threads processing exchanges.	1	int
defaultQueueFactory (advanced)	Sets the default queue factory.		BlockingQueueFactory
defaultBlockWhenFull (producer)	Whether a thread that sends messages to a full SEDA queue will block until the queue's capacity is no longer exhausted. By default, an exception will be thrown stating that the queue is full. By enabling this option, the calling thread will instead block and wait until the message can be accepted.	false	boolean
defaultOfferTimeout (producer)	Whether a thread that sends messages to a full SEDA queue will block until the queue's capacity is no longer exhausted. By default, an exception will be thrown stating that the queue is full. By enabling this option, where a configured timeout can be added to the block case. Utilizing the <code>.offer(timeout)</code> method of the underlying java queue		long

Name	Description	Default	Type
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Stub endpoint is configured using URI syntax:

```
stub:name
```

with the following path and query parameters:

333.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
name	Required Name of queue		String

333.2.2. Query Parameters (17 parameters):

Name	Description	Default	Type
size (common)	The maximum capacity of the SEDA queue (i.e., the number of messages it can hold). Will by default use the defaultSize set on the SEDA component.	1000	int
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN/ERROR level and ignored.	false	boolean
concurrentConsumers (consumer)	Number of concurrent threads processing exchanges.	1	int

Name	Description	Default	Type
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option <code>bridgeErrorHandler</code> is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN/ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the default exchange pattern when creating an exchange.		ExchangePattern
limitConcurrentConsumers (consumer)	Whether to limit the number of <code>concurrentConsumers</code> to the maximum of 500. By default, an exception will be thrown if an endpoint is configured with a greater number. You can disable that check by turning this option off.	true	boolean
multipleConsumers (consumer)	Specifies whether multiple consumers are allowed. If enabled, you can use SEDA for Publish-Subscribe messaging. That is, you can send a message to the SEDA queue and have each consumer receive a copy of the message. When enabled, this option should be specified on every consumer endpoint.	false	boolean
pollTimeout (consumer)	The timeout used when polling. When a timeout occurs, the consumer can check whether it is allowed to continue running. Setting a lower value allows the consumer to react more quickly upon shutdown.	1000	int
purgeWhenStopping (consumer)	Whether to purge the task queue when stopping the consumer/route. This allows to stop faster, as any pending messages on the queue is discarded.	false	boolean
blockWhenFull (producer)	Whether a thread that sends messages to a full SEDA queue will block until the queue's capacity is no longer exhausted. By default, an exception will be thrown stating that the queue is full. By enabling this option, the calling thread will instead block and wait until the message can be accepted.	false	boolean
discardIfNoConsumers (producer)	Whether the producer should discard the message (do not add the message to the queue), when sending to a queue with no active consumers. Only one of the options <code>discardIfNoConsumers</code> and <code>failIfNoConsumers</code> can be enabled at the same time.	false	boolean

Name	Description	Default	Type
failIfNoConsumers (producer)	Whether the producer should fail by throwing an exception, when sending to a queue with no active consumers. Only one of the options <code>discardIfNoConsumers</code> and <code>failIfNoConsumers</code> can be enabled at the same time.	false	boolean
offerTimeout (producer)	<code>offerTimeout</code> (in milliseconds) can be added to the block case when queue is full. You can disable timeout by using 0 or a negative value.		long
timeout (producer)	Timeout (in milliseconds) before a SEDA producer will stop waiting for an asynchronous task to complete. You can disable timeout by using 0 or a negative value.	30000	long
waitForTaskToComplete (producer)	Option to specify whether the caller should wait for the async task to complete or not before continuing. The following three options are supported: <code>Always</code> , <code>Never</code> or <code>IfReplyExpected</code> . The first two values are self-explanatory. The last value, <code>IfReplyExpected</code> , will only wait if the message is Request Reply based. The default option is <code>IfReplyExpected</code> .	<code>IfReplyExpected</code>	<code>WaitForTaskToComplete</code>
queue (advanced)	Define the queue instance which will be used by the endpoint. This option is only for rare use-cases where you want to use a custom queue instance.		<code>BlockingQueue</code>
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

333.3. EXAMPLES

Here are a few samples of stubbing endpoint uris

```
stub:smtp://somehost.foo.com?user=whatnot&something=else
stub:http://somehost.bar.com/something
```

PART II. OPENAPI JAVA COMPONENT

Available as of Camel 3.1.0

The Rest DSL can be integrated with the **camel-openapi-java** module which is used for exposing the REST services and their APIs using [OpenApi](#).

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-openapi-java</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

The camel-openapi-java module can be used from the REST components (without the need for servlet)

CHAPTER 334. USING OPENAPI IN REST-DSL

You can enable the OpenApi api from the rest-dsl by configuring the **apiContextPath** dsl as shown below:

```
public class UserRouteBuilder extends RouteBuilder {
    @Override
    public void configure() throws Exception {
        // configure we want to use servlet as the component for the rest DSL
        // and we enable json binding mode
        restConfiguration().component("netty-http").bindingMode(RestBindingMode.json)
            // and output using pretty print
            .dataFormatProperty("prettyPrint", "true")
            // setup context path and port number that netty will use
            .contextPath("/") .port(8080)
            // add OpenApi api-doc out of the box
            .apiContextPath("/api-doc")
            .apiProperty("api.title", "User API").apiProperty("api.version", "1.2.3")
            // and enable CORS
            .apiProperty("cors", "true");

        // this user REST service is json only
        rest("/user").description("User rest service")
            .consumes("application/json").produces("application/json")
            .get("/{id}").description("Find user by id").outType(User.class)
            .param().name("id").type(path).description("The id of the user to
get").dataType("int").endParam()
            .to("bean:userService?method=getUser(${header.id})")
            .put().description("Updates or create a user").type(User.class)
            .param().name("body").type(body).description("The user to update or create").endParam()
            .to("bean:userService?method=updateUser")
            .get("/findAll").description("Find all users").outType(User[].class)
            .to("bean:userService?method=listUsers");
    }
}
```

CHAPTER 335. OPTIONS

The OpenApi module can be configured using the following options. To configure using a servlet you use the `init-param` as shown above. When configuring directly in the `rest-dsl`, you use the appropriate method, such as `enableCORS`, `host`, `contextPath`, `dsl`. The options with `api.xxx` is configured using `apiProperty` `dsl`.

Option	Type	Description
<code>cors</code>	Boolean	Whether to enable CORS. Notice this only enables CORS for the api browser, and not the actual access to the REST services. Is default false.
<code>openapi.version</code>	String	OpenApi spec version. Is default 3.0.
<code>host</code>	String	To setup the hostname. If not configured camel-openapi-java will calculate the name as localhost based.
<code>schemes</code>	String	The protocol schemes to use. Multiple values can be separated by comma such as "http,https". The default value is "http".
<code>base.path</code>	String	Required: To setup the base path where the REST services is available. The path is relative (eg do not start with http/https) and camel-openapi-java will calculate the absolute base path at runtime, which will be protocol://host:port/context-path/base.path
<code>api.path</code>	String	To setup the path where the API is available (eg /api-docs). The path is relative (eg do not start with http/https) and camel-openapi-java will calculate the absolute base path at runtime, which will be protocol://host:port/context-path/api.path So using relative paths is much easier. See above for an example.
<code>api.version</code>	String	The version of the api. Is default 0.0.0.
<code>api.title</code>	String	The title of the application.
<code>api.description</code>	String	A short description of the application.
<code>api.termsOfService</code>	String	A URL to the Terms of Service of the API.
<code>api.contact.name</code>	String	Name of person or organization to contact

Option	Type	Description
api.contact.email	String	An email to be used for API-related correspondence.
api.contact.url	String	A URL to a website for more contact information.
api.license.name	String	The license name used for the API.
api.license.url	String	A URL to the license used for the API.
apiContextListing	boolean	Whether to allow listing all the CamelContext names in the JVM that has REST services. When enabled then the root path of the api-doc will list all the contexts. When disabled then no context ids is listed and the root path of the api-doc lists the current CamelContext. Is default false.
apiContextPattern	String	A pattern that allows to filter which CamelContext names is shown in the context listing. The pattern is using regular expression and * as wildcard. Its the same pattern matching as used by Intercept

CHAPTER 336. ADDING SECURITY DEFINITIONS IN API DOC

Available as of Camel 3.1.0

The Rest DSL now supports declaring OpenApi **securityDefinitions** in the generated API document. For example as shown below:

```
rest("/user").tag("dude").description("User rest service")
  // setup security definitions
  .securityDefinitions()
    .oauth2("petstore_auth").authorizationUrl("http://petstore.swagger.io/oauth/dialog").end()
    .apiKey("api_key").withHeader("myHeader").end()
  .end()
  .consumes("application/json").produces("application/json")
```

Here we have setup two security definitions

- OAuth2 - with implicit authorization with the provided url
- Api Key - using an api key that comes from HTTP header named *myHeader*

Then you need to specify on the rest operations which security to use by referring to their key (petstore_auth or api_key).

```
.get("/{id}/{date}").description("Find user by id and date").outType(User.class)
  .security("api_key")

...

.put().description("Updates or create a user").type(User.class)
  .security("petstore_auth", "write:pets,read:pets")
```

Here the get operation is using the Api Key security and the put operation is using OAuth security with permitted scopes of read and write pets.

CHAPTER 337. CONTEXTIDLISTING ENABLED

When contextIdListing is enabled then its detecting all the running CamelContexts in the same JVM. These contexts are listed in the root path, eg **/api-docs** as a simple list of names in json format. To access the OpenApi documentation then the context-path must be appended with the Camel context id, such as **api-docs/myCamel**. The option apiContextIdPattern can be used to filter the names in this list.

CHAPTER 338. JSON OR YAML

*Available as of Camel 3.1.0

The camel-openapi-java module supports both JSON and YAML out of the box. You can specify in the request url what you want returned by using /openapi.json or /openapi.yaml for either one. If none is specified then the HTTP Accept header is used to detect if json or yaml can be accepted. If either both is accepted or none was set as accepted then json is returned as the default format.

CHAPTER 339. EXAMPLES

In the Apache Camel distribution we ship the **camel-example-openapi-cdi** and **camel-example-openapi-java** which demonstrates using this OpenApi component.

CHAPTER 340. SWAGGER JAVA COMPONENT

Available as of Camel 2.16

The Rest DSL can be integrated with the **camel-swagger-java** module which is used for exposing the REST services and their APIs using [Swagger](#).

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-swagger-java</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

The camel-swagger-java module can be used from the REST components (without the need for servlet)

340.1. USING SWAGGER IN REST-DSL

You can enable the swagger api from the rest-dsl by configuring the **apiContextPath** dsl as shown below:

```
public class UserRouteBuilder extends RouteBuilder {
  @Override
  public void configure() throws Exception {
    // configure we want to use servlet as the component for the rest DSL
    // and we enable json binding mode
    restConfiguration().component("netty4-http").bindingMode(RestBindingMode.json)
    // and output using pretty print
    .dataFormatProperty("prettyPrint", "true")
    // setup context path and port number that netty will use
    .contextPath("/").port(8080)
    // add swagger api-doc out of the box
    .apiContextPath("/api-doc")
    .apiProperty("api.title", "User API").apiProperty("api.version", "1.2.3")
    // and enable CORS
    .apiProperty("cors", "true");

    // this user REST service is json only
    rest("/user").description("User rest service")
    .consumes("application/json").produces("application/json")
    .get("/{id}").description("Find user by id").outType(User.class)
    .param().name("id").type(path).description("The id of the user to
get").dataType("int").endParam()
    .to("bean:userService?method=getUser({header.id})")
    .put().description("Updates or create a user").type(User.class)
    .param().name("body").type(body).description("The user to update or create").endParam()
    .to("bean:userService?method=updateUser")
    .get("/findAll").description("Find all users").outTypeList(User.class)
    .to("bean:userService?method=listUsers");
  }
}
```

340.2. OPTIONS

The swagger module can be configured using the following options. To configure using a servlet you use the `init-param` as shown above. When configuring directly in the `rest-dsl`, you use the appropriate method, such as `enableCORS`, `host`, `contextPath`, `dsl`. The options with `api.xxx` is configured using `apiProperty` `dsl`.

Option	Type	Description
<code>cors</code>	Boolean	Whether to enable CORS. Notice this only enables CORS for the api browser, and not the actual access to the REST services. Is default false.
<code>swagger.version</code>	String	Swagger spec version. The default 2.0.
<code>host</code>	String	To setup the hostname. If not configured camel-swagger-java will calculate the name as localhost based.
<code>schemas</code>	String	The protocol schemes to use. Multiple values can be separated by comma such as "http,https". The default value is "http". This option is deprecated from Camel 2.17 onwards due it should have been named schemes.
<code>schemes</code>	String	Camel 2.17: The protocol schemes to use. Multiple values can be separated by comma such as "http,https". The default value is "http".
<code>base.path</code>	String	Required: To setup the base path where the REST services is available. The path is relative (eg do not start with http/https) and camel-swagger-java will calculate the absolute base path at runtime, which will be protocol://host:port/context-path/base.path
<code>api.path</code>	String	To setup the path where the API is available (eg /api-docs). The path is relative (eg do not start with http/https) and camel-swagger-java will calculate the absolute base path at runtime, which will be protocol://host:port/context-path/api.path So using relative paths is much easier. See above for an example.
<code>api.version</code>	String	The version of the api. Is default 0.0.0.
<code>api.title</code>	String	The title of the application.
<code>api.description</code>	String	A short description of the application.
<code>api.termsOfService</code>	String	A URL to the Terms of Service of the API.

Option	Type	Description
api.con tact.na me	String	Name of person or organization to contact
api.con tact.em ail	String	An email to be used for API-related correspondence.
api.con tact.url	String	A URL to a website for more contact information.
api.lice nse.na me	String	The license name used for the API.
api.lice nse.url	String	A URL to the license used for the API.
apiCon textIdL isting	boolea n	Whether to allow listing all the CamelContext names in the JVM that has REST services. When enabled then the root path of the api-doc will list all the contexts. When disabled then no context ids is listed and the root path of the api-doc lists the current CamelContext. Is default false.
apiCon textIdP attern	String	A pattern that allows to filter which CamelContext names is shown in the context listing. The pattern is using regular expression and * as wildcard. Its the same pattern matching as used by Intercept

340.3. ADDING SECURITY DEFINITIONS IN API DOC

Available as of Camel 2.22.0

The Rest DSL now supports declaring Swagger **securityDefinitions** in the generated API document. For example as shown below:

```
rest("/user").tag("dude").description("User rest service")
  // setup security definitions
  .securityDefinitions()
    .oauth2("petstore_auth").authorizationUrl("http://petstore.swagger.io/oauth/dialog").end()
    .apiKey("api_key").withHeader("myHeader").end()
  .end()
  .consumes("application/json").produces("application/json")
```

Here we have setup two security definitions

- OAuth2 - with implicit authorization with the provided url
- Api Key - using an api key that comes from HTTP header named *myHeader*

Then you need to specify on the rest operations which security to use by referring to their key (petstore_auth or api_key).

```
.get("/{id}/{date}").description("Find user by id and date").outType(User.class)
    .security("api_key")

...

.put().description("Updates or create a user").type(User.class)
    .security("petstore_auth", "write:pets,read:pets")
```

Here the get operation is using the Api Key security and the put operation is using OAuth security with permitted scopes of read and write pets.

340.4. CONTEXTIDLISTING ENABLED

When contextIdListing is enabled then its detecting all the running CamelContexts in the same JVM. These contexts are listed in the root path, eg **/api-docs** as a simple list of names in json format. To access the swagger documentation then the context-path must be appended with the Camel context id, such as **api-docs/myCamel**. The option apiContextIdPattern can be used to filter the names in this list.

340.5. JSON OR YAML

Available as of Camel 2.17

The camel-swagger-java module supports both JSon and Yaml out of the box. You can specify in the request url what you want returned by using /swagger.json or /swagger.yaml for either one. If none is specified then the HTTP Accept header is used to detect if json or yaml can be accepted. If either both is accepted or none was set as accepted then json is returned as the default format.

340.6. EXAMPLES

In the Apache Camel distribution we ship the **camel-example-swagger-cdi** and **camel-example-swagger-java** which demonstrates using this Swagger component.

CHAPTER 341. SYSLOG DATAFORMAT

Available as of Camel version 2.6

The **syslog** dataformat is used for working with [RFC3164](#) and RFC5424 messages.

This component supports the following:

- UDP consumption of syslog messages
- Agnostic data format using either plain String objects or SyslogMessage model objects.
- Type Converter from/to SyslogMessage and String
- Integration with the [camel-mina](#) component.
- Integration with the [camel-netty](#) component.
- **Camel 2.14:** Encoder and decoder for the [camel-netty](#) component.
- **Camel 2.14:** Support for RFC5424 also.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-syslog</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

341.1. RFC3164 SYSLOG PROTOCOL

Syslog uses the user datagram protocol (UDP) [1](#) as its underlying transport layer mechanism. The UDP port that has been assigned to syslog is 514.

To expose a Syslog listener service we reuse the existing [camel-mina](#) component or [camel-netty](#) where we just use the **Rfc3164SyslogDataFormat** to marshal and unmarshal messages. Notice that from **Camel 2.14** onwards the syslog dataformat is renamed to **SyslogDataFormat**.

341.2. OPTIONS

The Syslog dataformat supports 1 options, which are listed below.

Name	Default	Java Type	Description
contentTypeHeader	false	Boolean	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSon etc.

341.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
<code>camel.dataformat.syslog.content-type-header</code>	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSon etc.	false	Boolean
<code>camel.dataformat.syslog.enabled</code>	Enable syslog dataformat	true	Boolean

ND

341.4. RFC5424 SYSLOG PROTOCOL

Available as of Camel 2.14

To expose a Syslog listener service we reuse the existing [camel-mina](#) component or [camel-netty](#) where we just use the **SyslogDataFormat** to marshal and unmarshal messages

341.4.1. Exposing a Syslog listener

In our Spring XML file, we configure an endpoint to listen for udp messages on port 10514, note that in netty we disable the defaultCodec, this will allow a fallback to a NettyTypeConverter and delivers the message as an InputStream:

```
<camelContext id="myCamel" xmlns="http://camel.apache.org/schema/spring">
  <dataFormats>
    <syslog id="mySyslog"/>
  </dataFormats>

  <route>
    <from uri="netty:udp://localhost:10514?sync=false&allowDefaultCodec=false"/>
    <unmarshal ref="mySyslog"/>
    <to uri="mock:stop1"/>
  </route>
</camelContext>
```

The same route using [camel-mina](#)

```
<camelContext id="myCamel" xmlns="http://camel.apache.org/schema/spring">
  <dataFormats>
    <syslog id="mySyslog"/>
  </dataFormats>
```

```
</dataFormats>

<route>
  <from uri="mina:udp://localhost:10514"/>
  <unmarshal ref="mySyslog"/>
  <to uri="mock:stop1"/>
</route>

</camelContext>
```

341.4.2. Sending syslog messages to a remote destination

```
<camelContext id="myCamel" xmlns="http://camel.apache.org/schema/spring">

  <dataFormats>
    <syslog id="mySyslog"/>
  </dataFormats>

  <route>
    <from uri="direct:syslogMessages"/>
    <marshal ref="mySyslog"/>
    <to uri="mina:udp://remotehost:10514"/>
  </route>

</camelContext>
```

341.5. SEE ALSO

- [Configuring Camel](#)
- [Component](#)
- [Endpoint](#)
- [Getting Started](#)

CHAPTER 342. TAR FILE DATAFORMAT

Available as of Camel version 2.16

The Tar File Data Format is a message compression and de-compression format. Messages can be marshalled (compressed) to Tar Files containing a single entry, and Tar Files containing a single entry can be unmarshalled (decompressed) to the original file contents.

There is also a aggregation strategy that can aggregate multiple messages into a single Tar File.

342.1. TARFILE OPTIONS

The Tar File dataformat supports 4 options, which are listed below.

Name	Default	Java Type	Description
<code>usingIterator</code>	false	Boolean	If the tar file has more then one entry, the setting this option to true, allows to work with the splitter EIP, to split the data using an iterator in a streaming mode.
<code>allowEmptyDirectory</code>	false	Boolean	If the tar file has more then one entry, setting this option to true, allows to get the iterator even if the directory is empty
<code>preservePathElements</code>	false	Boolean	If the file name contains path elements, setting this option to true, allows the path to be maintained in the tar file.
<code>contentTypeHeader</code>	false	Boolean	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example <code>application/xml</code> for data formats marshalling to XML, or <code>application/json</code> for data formats marshalling to JSon etc.

342.2. SPRING BOOT AUTO-CONFIGURATION

The component supports 5 options, which are listed below.

Name	Description	Default	Type
<code>camel.dataformat.tarfile.allow-empty-directory</code>	If the tar file has more then one entry, setting this option to true, allows to get the iterator even if the directory is empty	false	Boolean
<code>camel.dataformat.tarfile.content-type-header</code>	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example <code>application/xml</code> for data formats marshalling to XML, or <code>application/json</code> for data formats marshalling to JSon etc.	false	Boolean

Name	Description	Default	Type
<code>camel.dataformat.tarfile.enabled</code>	Enable tarfile dataformat	true	Boolean
<code>camel.dataformat.tarfile.preserve-path-elements</code>	If the file name contains path elements, setting this option to true, allows the path to be maintained in the tar file.	false	Boolean
<code>camel.dataformat.tarfile.using-iterator</code>	If the tar file has more than one entry, the setting this option to true, allows to work with the splitter EIP, to split the data using an iterator in a streaming mode.	false	Boolean

ND

342.3. MARSHAL

In this example we marshal a regular text/XML payload to a compressed payload using Tar File compression, and send it to an ActiveMQ queue called MY_QUEUE.

```
from("direct:start").marshal().tarFile().to("activemq:queue:MY_QUEUE");
```

The name of the Tar entry inside the created Tar File is based on the incoming **CamelFileName** message header, which is the standard message header used by the file component. Additionally, the outgoing **CamelFileName** message header is automatically set to the value of the incoming **CamelFileName** message header, with the ".tar" suffix. So for example, if the following route finds a file named "test.txt" in the input directory, the output will be a Tar File named "test.txt.tar" containing a single Tar entry named "test.txt":

```
from("file:input/directory?antInclude=/*.txt").marshal().tarFile().to("file:output/directory");
```

If there is no incoming **CamelFileName** message header (for example, if the file component is not the consumer), then the message ID is used by default, and since the message ID is normally a unique generated ID, you will end up with filenames like **ID-MACHINENAME-2443-1211718892437-1-0.tar**. If you want to override this behavior, then you can set the value of the **CamelFileName** header explicitly in your route:

```
from("direct:start").setHeader(Exchange.FILE_NAME,
    constant("report.txt")).marshal().tarFile().to("file:output/directory");
```

This route would result in a Tar File named "report.txt.tar" in the output directory, containing a single Tar entry named "report.txt".

342.4. UNMARSHAL

In this example we unmarshal a Tar File payload from an ActiveMQ queue called MY_QUEUE to its original format, and forward it for processing to the **UnTarpedMessageProcessor**.

```
from("activemq:queue:MY_QUEUE").unmarshal().tarFile().process(new
    UnTarpedMessageProcessor());
```

If the Tar File has more than one entry, the `usingIterator` option of `TarFileDataFormat` to be `true`, and you can use `splitter` to do the further work.

```
TarFileDataFormat tarFile = new TarFileDataFormat();
tarFile.setUsingIterator(true);
from("file:src/test/resources/org/apache/camel/dataformat/tarfile/?
consumer.delay=1000&noop=true")
    .unmarshal(tarFile)
    .split(body(Iterator.class))
    .streaming()
    .process(new UnTarpedMessageProcessor())
    .end();
```

Or you can use the `TarSplitter` as an expression for `splitter` directly like this

```
from("file:src/test/resources/org/apache/camel/dataformat/tarfile?
consumer.delay=1000&noop=true")
    .split(new TarSplitter())
    .streaming()
    .process(new UnTarpedMessageProcessor())
    .end();
```

342.5. AGGREGATE

INFO:Please note that this aggregation strategy requires eager completion check to work properly.

In this example we aggregate all text files found in the input directory into a single Tar File that is stored in the output directory.

```
from("file:input/directory?antInclude=*.txt")
    .aggregate(new TarAggregationStrategy())
    .constant(true)
    .completionFromBatchConsumer()
    .eagerCheckCompletion()
    .to("file:output/directory");
```

The outgoing **CamelFileName** message header is created using `java.io.File.createTempFile`, with the ".tar" suffix. If you want to override this behavior, then you can set the value of the **CamelFileName** header explicitly in your route:

```
from("file:input/directory?antInclude=*.txt")
    .aggregate(new TarAggregationStrategy())
    .constant(true)
    .completionFromBatchConsumer()
    .eagerCheckCompletion()
    .setHeader(Exchange.FILE_NAME, constant("reports.tar"))
    .to("file:output/directory");
```

342.6. DEPENDENCIES

To use Tar Files in your camel routes you need to add a dependency on **camel-tarfile** which implements this data format.

If you use Maven you can just add the following to your **pom.xml**, substituting the version number for the latest & greatest release (see the download page for the latest versions).

```
<dependency>  
  <groupId>org.apache.camel</groupId>  
  <artifactId>camel-tarfile</artifactId>  
  <version>x.x.x</version>  
  <!-- use the same version as your Camel core version -->  
</dependency>
```

CHAPTER 343. TELEGRAM COMPONENT

Available as of Camel version 2.18

The **Telegram** component provides access to the [Telegram Bot API](#). It allows a Camel-based application to send and receive messages by acting as a Bot, participating in direct conversations with normal users, private and public groups or channels.

A Telegram Bot must be created before using this component, following the instructions at the [Telegram Bot developers home](#). When a new Bot is created, the **BotFather** provides an **authorization token** corresponding to the Bot. The authorization token is a mandatory parameter for the camel-telegram endpoint.

NOTE

In order to allow the Bot to receive all messages exchanged within a group or channel (not just the ones starting with a '/' character), ask the BotFather to **disable the privacy mode**, using the `/setprivacy` command.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-telegram</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

343.1. URI FORMAT

```
telegram:type/authorizationToken[?options]
```

You can append query options to the URI in the following format, **?option=value&option=value&...**

343.2. OPTIONS

The Telegram component supports 2 options, which are listed below.

Name	Description	Default	Type
authorizationToken (security)	The default Telegram authorization token to be used when the information is not provided in the endpoints.		String
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Telegram endpoint is configured using URI syntax:

telegram:type/authorizationToken

with the following path and query parameters:

343.2.1. Path Parameters (2 parameters):

Name	Description	Default	Type
type	Required The endpoint type. Currently, only the 'bots' type is supported.		String
authorizationToken	Required The authorization token for using the bot (ask the BotFather), eg. 654321531:HGF_dTra456323dHuOedsE343211fqr3t-H.		String

343.2.2. Query Parameters (22 parameters):

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
limit (consumer)	Limit on the number of updates that can be received in a single polling request.	100	Integer
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean
timeout (consumer)	Timeout in seconds for long polling. Put 0 for short polling or a bigger number for long polling. Long polling produces shorter response time.	30	Integer
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler

Name	Description	Default	Type
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
pollStrategy (consumer)	A pluggable <code>org.apache.camel.PollingConsumerPollingStrategy</code> allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		PollingConsumerPollStrategy
chatId (producer)	The identifier of the chat that will receive the produced messages. Chat ids can be first obtained from incoming messages (eg. when a telegram user starts a conversation with a bot, its client sends automatically a '/start' message containing the chat id). It is an optional parameter, as the chat id can be set dynamically for each outgoing message (using body or headers).		String
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the <code>backoffMultiplier</code> should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the <code>backoffMultiplier</code> should kick-in.		int
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then <code>backoffIdleThreshold</code> and/or <code>backoffErrorThreshold</code> must also be configured.		int
delay (scheduler)	Milliseconds before the next poll. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	500	long
greedy (scheduler)	If greedy is enabled, then the <code>ScheduledPollConsumer</code> will run immediately again, if the previous run polled 1 or more messages.	false	boolean

Name	Description	Default	Type
initialDelay (scheduler)	Milliseconds before the first poll starts. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	1000	long
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that.	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz2 component	none	ScheduledPollConsumerScheduler
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz2, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for initialDelay and delay options.	MILLIS ECON DS	TimeUnit
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.	true	boolean

343.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 3 options, which are listed below.

Name	Description	Default	Type
camel.component.telegram.authorization-token	The default Telegram authorization token to be used when the information is not provided in the endpoints.		String
camel.component.telegram.enabled	Enable telegram component	true	Boolean

Name	Description	Default	Type
<code>camel.component.telegram.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

343.4. MESSAGE HEADERS

Name	Description
CamelTelegramChatId	This header is used by the producer endpoint in order to resolve the chat id that will receive the message. The recipient chat id can be placed (in order of priority) in message body, in the CamelTelegramChatId header or in the endpoint configuration (chatId option). This header is also present in all incoming messages.
CamelTelegramMediaType	This header is used to identify the media type when the outgoing message is composed of pure binary data. Possible values are strings or enum values belonging to the org.apache.camel.component.telegram.TelegramMediaType enumeration.
CamelTelegramMediaTitleCaption	This header is used to provide a caption or title for outgoing binary messages.
CamelTelegramParseMode	This header is used to format text messages using HTML or Markdown (see org.apache.camel.component.telegram.TelegramParseMode).

343.5. USAGE

The Telegram component supports both consumer and producer endpoints. It can also be used in reactive chat-bot mode (to consume, then produce messages).

343.6. PRODUCER EXAMPLE

The following is a basic example of how to send a message to a Telegram chat through the Telegram Bot API.

in Java DSL

```
from("direct:start").to("telegram:bots/123456789:insertYourAuthorizationTokenHere");
```

or in Spring XML

```
<route>
  <from uri="direct:start"/>
  <to uri="telegram:bots/123456789:insertYourAuthorizationTokenHere"/>
</route>
```

The code `123456789:insertYourAuthorizationTokenHere` is the **authorization token** corresponding to the Bot.

When using the producer endpoint without specifying the **chat id** option, the target chat will be identified using information contained in the body or headers of the message. The following message bodies are allowed for a producer endpoint (messages of type **OutgoingXXXMessage** belong to the package `org.apache.camel.component.telegram.model`)

Java Type	Description
OutgoingTextMessage	To send a text message to a chat
OutgoingPhotoMessage	To send a photo (JPG, PNG) to a chat
OutgoingAudioMessage	To send a mp3 audio to a chat
OutgoingVideoMessage	To send a mp4 video to a chat
OutgoingDocumentMessage	To send a file to a chat (any media type)
byte[]	To send any media type supported. It requires the CamelTelegramMediaType header to be set to the appropriate media type
String	To send a text message to a chat. It gets converted automatically into a OutgoingTextMessage

343.7. CONSUMER EXAMPLE

The following is a basic example of how to receive all messages that telegram users are sending to the configured Bot. In Java DSL

```
from("telegram:bots/123456789:insertYourAuthorizationTokenHere")
    .bean(ProcessorBean.class)
```

or in Spring XML

```
<route>
  <from uri="telegram:bots/123456789:insertYourAuthorizationTokenHere"/>
  <bean ref="myBean" />
</route>

<bean id="myBean" class="com.example.MyBean"/>
```

The **MyBean** is a simple bean that will receive the messages

```
public class MyBean {

  public void process(String message) {
    // or Exchange, or org.apache.camel.component.telegram.model.IncomingMessage (or both)
  }
}
```

```

    // do process
  }
}

```

Supported types for incoming messages are

Java Type	Description
IncomingMessage	The full object representation of an incoming message
String	The content of the message, for text messages only

343.8. REACTIVE CHAT-BOT EXAMPLE

The reactive chat-bot mode is a simple way of using the Camel component to build a simple chat bot that replies directly to chat messages received from the Telegram users.

The following is a basic configuration of the chat-bot in Java DSL

```

from("telegram:bots/123456789:insertYourAuthorizationTokenHere")
.bean(ChatBotLogic.class)
.to("telegram:bots/123456789:insertYourAuthorizationTokenHere");

```

or in Spring XML

```

<route>
  <from uri="telegram:bots/123456789:insertYourAuthorizationTokenHere"/>
  <bean ref="chatBotLogic" />
  <to uri="telegram:bots/123456789:insertYourAuthorizationTokenHere"/>
</route>

<bean id="chatBotLogic" class="com.example.ChatBotLogic"/>

```

The **ChatBotLogic** is a simple bean that implements a generic String-to-String method.

```

public class ChatBotLogic {

  public String chatBotProcess(String message) {
    if( "do-not-reply".equals(message) ) {
      return null; // no response in the chat
    }

    return "echo from the bot: " + message; // echoes the message
  }
}

```

Every non-null string returned by the **chatBotProcess** method is automatically routed to the chat that originated the request (as the **CamelTelegramChatId** header is used to route the message).

343.9. GETTING THE CHAT ID

If you want to push messages to a specific Telegram chat when an event occurs, you need to retrieve the corresponding chat ID. The chat ID is not currently shown in the telegram client, but you can obtain it using a simple route.

First, add the bot to the chat where you want to push messages, then run a route like the following one.

```
from("telegram:bots/123456789:insertYourAuthorizationTokenHere")
  .to("log:INFO?showHeaders=true");
```

Any message received by the bot will be dumped to your log together with information about the chat (**CamelTelegramChatId** header).

Once you get the chat ID, you can use the following sample route to push message to it.

```
from("timer:tick")
  .setBody().constant("Hello")
  to("telegram:bots/123456789:insertYourAuthorizationTokenHere?chatId=123456")
```

Note that the corresponding URI parameter is simply **chatId**.

343.10. CUSTOMIZING KEYBOARD

You can customize the user keyboard instead of asking him to write an option. **OutgoingTextMessage** has the property **ReplyKeyboardMarkup** which can be used for such thing.

```
from("telegram:bots/123456789:insertYourAuthorizationTokenHere")
  .process(exchange -> {

    OutgoingTextMessage msg = new OutgoingTextMessage();
    msg.setText("Choose one option!");

    InlineKeyboardButton buttonOptionOneI = InlineKeyboardButton.builder()
      .text("Option One - I").build();

    InlineKeyboardButton buttonOptionOneII = InlineKeyboardButton.builder()
      .text("Option One - II").build();

    InlineKeyboardButton buttonOptionTwoI = InlineKeyboardButton.builder()
      .text("Option Two - I").build();

    ReplyKeyboardMarkup replyMarkup = ReplyKeyboardMarkup.builder()
      .keyboard()
      .addRow(Arrays.asList(buttonOptionOneI, buttonOptionOneII))
      .addRow(Arrays.asList(buttonOptionTwoI))
      .close()
      .oneTimeKeyboard(true)
      .build();

    msg.setReplyKeyboardMarkup(replyMarkup);
```

```
exchange.getIn().setBody(msg);
})
.to("telegram:bots/123456789:insertYourAuthorizationTokenHere");
```

If you want to disable it the next message must have the property **removeKeyboard** set on **ReplyKeyboardMarkup** object.

```
from("telegram:bots/123456789:insertYourAuthorizationTokenHere")
.process(exchange -> {

    OutgoingTextMessage msg = new OutgoingTextMessage();
    msg.setText("Your answer was accepted!");

    ReplyKeyboardMarkup replyMarkup = ReplyKeyboardMarkup.builder()
        .removeKeyboard(true)
        .build();

    msg.setReplyKeyboardMarkup(replyMarkup);

    exchange.getIn().setBody(msg);
})
.to("telegram:bots/123456789:insertYourAuthorizationTokenHere");
```

CHAPTER 344. TEST COMPONENT

Available as of Camel version 1.3

Testing of distributed and asynchronous processing is notoriously difficult. The [Mock](#), [Test](#) and [DataSet](#) endpoints work great with the Camel Testing Framework to simplify your unit and integration testing using [Enterprise Integration Patterns](#) and Camel's large range of Components together with the powerful Bean Integration.

The **test** component extends the [Mock](#) component to support pulling messages from another endpoint on startup to set the expected message bodies on the underlying [Mock](#) endpoint. That is, you use the test endpoint in a route and messages arriving on it will be implicitly compared to some expected messages extracted from some other location.

So you can use, for example, an expected set of message bodies as files. This will then set up a properly configured [Mock](#) endpoint, which is only valid if the received messages match the number of expected messages and their message payloads are equal.

Maven users will need to add the following dependency to their **pom.xml** for this component when using **Camel 2.8** or older:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-spring</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

From Camel 2.9 onwards the [Test](#) component is provided directly in the camel-core.

344.1. URI FORMAT

```
test:expectedMessagesEndpointUri
```

Where **expectedMessagesEndpointUri** refers to some other Component URI that the expected message bodies are pulled from before starting the test.

344.2. URI OPTIONS

The Test component has no options.

The Test endpoint is configured using URI syntax:

```
test:name
```

with the following path and query parameters:

344.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
name	Required Name of endpoint to lookup in the registry to use for polling messages used for testing		String

344.2.2. Query Parameters (14 parameters):

Name	Description	Default	Type
anyOrder (producer)	Whether the expected messages should arrive in the same order or can be in any order.	false	boolean
assertPeriod (producer)	Sets a grace period after which the mock endpoint will re-assert to ensure the preliminary assertion is still valid. This is used for example to assert that exactly a number of messages arrives. For example if <code>expectedMessageCount(int)</code> was set to 5, then the assertion is satisfied when 5 or more message arrives. To ensure that exactly 5 messages arrives, then you would need to wait a little period to ensure no further message arrives. This is what you can use this <code>setAssertPeriod(long)</code> method for. By default this period is disabled.	0	long
delimiter (producer)	The split delimiter to use when split is enabled. By default the delimiter is new line based. The delimiter can be a regular expression.		String
expectedCount (producer)	Specifies the expected number of message exchanges that should be received by this endpoint. Beware: If you want to expect that 0 messages, then take extra care, as 0 matches when the tests starts, so you need to set a assert period time to let the test run for a while to make sure there are still no messages arrived; for that use <code>setAssertPeriod(long)</code> . An alternative is to use <code>NotifyBuilder</code> , and use the notifier to know when Camel is done routing some messages, before you call the <code>assertIsSatisfied()</code> method on the mocks. This allows you to not use a fixed assert period, to speedup testing times. If you want to assert that exactly n'th message arrives to this mock endpoint, then see also the <code>setAssertPeriod(long)</code> method for further details.	-1	int
reportGroup (producer)	A number that is used to turn on throughput logging based on groups of the size.		int

Name	Description	Default	Type
resultMinimumWaitTime (producer)	Sets the minimum expected amount of time (in millis) the <code>assertIsSatisfied()</code> will wait on a latch until it is satisfied	0	long
resultWaitTime (producer)	Sets the maximum amount of time (in millis) the <code>assertIsSatisfied()</code> will wait on a latch until it is satisfied	0	long
retainFirst (producer)	Specifies to only retain the first n'th number of received Exchanges. This is used when testing with big data, to reduce memory consumption by not storing copies of every Exchange this mock endpoint receives. Important: When using this limitation, then the <code>getReceivedCounter()</code> will still return the actual number of received Exchanges. For example if we have received 5000 Exchanges, and have configured to only retain the first 10 Exchanges, then the <code>getReceivedCounter()</code> will still return 5000 but there is only the first 10 Exchanges in the <code>getExchanges()</code> and <code>getReceivedExchanges()</code> methods. When using this method, then some of the other expectation methods is not supported, for example the <code>expectedBodiesReceived(Object...)</code> sets a expectation on the first number of bodies received. You can configure both <code>setRetainFirst(int)</code> and <code>setRetainLast(int)</code> methods, to limit both the first and last received.	-1	int
retainLast (producer)	Specifies to only retain the last n'th number of received Exchanges. This is used when testing with big data, to reduce memory consumption by not storing copies of every Exchange this mock endpoint receives. Important: When using this limitation, then the <code>getReceivedCounter()</code> will still return the actual number of received Exchanges. For example if we have received 5000 Exchanges, and have configured to only retain the last 20 Exchanges, then the <code>getReceivedCounter()</code> will still return 5000 but there is only the last 20 Exchanges in the <code>getExchanges()</code> and <code>getReceivedExchanges()</code> methods. When using this method, then some of the other expectation methods is not supported, for example the <code>expectedBodiesReceived(Object...)</code> sets a expectation on the first number of bodies received. You can configure both <code>setRetainFirst(int)</code> and <code>setRetainLast(int)</code> methods, to limit both the first and last received.	-1	int

Name	Description	Default	Type
sleepForEmptyTest (producer)	Allows a sleep to be specified to wait to check that this endpoint really is empty when <code>expectedMessageCount(int)</code> is called with zero	0	long
split (producer)	If enabled the messages loaded from the test endpoint will be split using new line delimiters so each line is an expected message. For example to use a file endpoint to load a file where each line is an expected message.	false	boolean
timeout (producer)	The timeout to use when polling for message bodies from the URI	2000	long
copyOnExchange (producer)	Sets whether to make a deep copy of the incoming Exchange when received at this mock endpoint. Is by default true.	true	boolean
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

344.3. EXAMPLE

For example, you could write a test case as follows:

```
from("seda:someEndpoint").
  to("test:file://data/expectedOutput?noop=true");
```

If your test then invokes the [MockEndpoint.assertIsSatisfied\(camelContext\)](#) method, your test case will perform the necessary assertions.

To see how you can set other expectations on the test endpoint, see the [Mock](#) component.

344.4. SEE ALSO

- [Spring Testing](#)

CHAPTER 345. THRIFT COMPONENT

Available as of Camel version 2.20

The Thrift component allows you to call or expose Remote Procedure Call (RPC) services using [Apache Thrift](#) binary communication protocol and serialization mechanism.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-thrift</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

345.1. URI FORMAT

```
thrift://service[?options]
```

345.2. ENDPOINT OPTIONS

The Thrift component supports 2 options, which are listed below.

Name	Description	Default	Type
useGlobalSslContext Parameters (security)	Determine if the thrift component is using global SSL context parameters	false	boolean
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Thrift endpoint is configured using URI syntax:

```
thrift:host:port/service
```

with the following path and query parameters:

345.2.1. Path Parameters (3 parameters):

Name	Description	Default	Type
------	-------------	---------	------

Name	Description	Default	Type
host	The Thrift server host name. This is localhost or 0.0.0.0 (if not defined) when being a consumer or remote server host name when using producer.		String
port	Required The Thrift server port		int
service	Required Fully qualified service name from the thrift descriptor file (package dot service definition name)		String

345.2.2. Query Parameters (12 parameters):

Name	Description	Default	Type
compressionType (common)	Protocol compression mechanism type	NONE	ThriftCompressionType
exchangeProtocol (common)	Exchange protocol serialization type	BINARY	ThriftExchangeProtocol
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
clientTimeout (consumer)	Client timeout for consumers		int
maxPoolSize (consumer)	The Thrift server consumer max thread pool size	10	int
poolSize (consumer)	The Thrift server consumer initial thread pool size	1	int
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler

Name	Description	Default	Type
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
method (producer)	The Thrift invoked method name		String
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
negotiationType (security)	Security negotiation type	PLAIN TEXT	ThriftNegotiationType
sslParameters (security)	Configuration parameters for SSL/TLS security negotiation		SSLContextParameters

345.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 7 options, which are listed below.

Name	Description	Default	Type
camel.component.thrift.enabled	Whether to enable auto configuration of the thrift component. This is enabled by default.		Boolean
camel.component.thrift.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
camel.component.thrift.use-global-ssl-context-parameters	Determine if the thrift component is using global SSL context parameters	false	Boolean
camel.dataformat.thrift.content-type-format	Defines a content type format in which thrift message will be serialized/deserialized from(to) the Java bean. The format can either be native or json for either native binary thrift, json or simple json fields representation. The default value is binary.	binary	String

Name	Description	Default	Type
<code>camel.dataformat.thrift.content-type-header</code>	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSon etc.	false	Boolean
<code>camel.dataformat.thrift.enabled</code>	Whether to enable auto configuration of the thrift data format. This is enabled by default.		Boolean
<code>camel.dataformat.thrift.instance-class</code>	Name of class to use when unarmshalling		String

345.4. THRIFT METHOD PARAMETERS MAPPING

Parameters in the called procedure must be passed as a list of objects inside the message body. The primitives are converted from the objects on the fly. In order to correctly find the corresponding method, all types must be transmitted regardless of the values. Please see an exmaple below, how to pass different parameters to the method with the Camel body

```
List requestBody = new ArrayList();

requestBody.add((boolean>true);
requestBody.add((byte)THRIFT_TEST_NUM1);
requestBody.add((short)THRIFT_TEST_NUM1);
requestBody.add((int)THRIFT_TEST_NUM1);
requestBody.add((long)THRIFT_TEST_NUM1);
requestBody.add((double)THRIFT_TEST_NUM1);
requestBody.add("empty"); // String parameter
requestBody.add(ByteBuffer.allocate(10)); // binary parameter
requestBody.add(new Work(THRIFT_TEST_NUM1, THRIFT_TEST_NUM2, Operation.MULTIPLY));
// Struct parameter
requestBody.add(new ArrayList<Integer>()); // list paramater
requestBody.add(new HashSet<String>()); // set parameter
requestBody.add(new HashMap<String, Long>()); // map parameter

Object responseBody = template.requestBody("direct:thrift-alltypes", requestBody);
```

Incoming parameters in the service consumer will also be passed to the message body as a list of objects.

345.5. THRIFT CONSUMER HEADERS (WILL BE INSTALLED AFTER THE CONSUMER INVOCATION)

Header name	Description	Possible values
CamelThriftMethodName	Method name handled by the consumer service	

345.6. EXAMPLES

Below is a simple synchronous method invoke with host and port parameters

```
from("direct:thrift-calculate")
.to("thrift://localhost:1101/org.apache.camel.component.thrift.generated.Calculator?
method=calculate&synchronous=true");
```

Below is a simple synchronous method invoke for the XML DSL configuration

```
<route>
  <from uri="direct:thrift-add" />
  <to uri="thrift://localhost:1101/org.apache.camel.component.thrift.generated.Calculator?
method=add&synchronous=true"/>
</route>
```

Thrift service consumer with asynchronous communication

```
from("thrift://localhost:1101/org.apache.camel.component.thrift.generated.Calculator")
.to("direct:thrift-service");
```

It's possible to automate Java code generation for .thrift files using **thrift-maven-plugin**, but before start the thrift compiler binary distribution for your operating system must be present on the running host.

CHAPTER 346. THRIFT DATAFORMAT

Available as of Camel version 2.20

Camel provides a Data Format to serialize between Java and the Apache Thrift . The project's site details why you may wish to <https://thrift.apache.org/>. Apache Thrift is language-neutral and platform-neutral, so messages produced by your Camel routes may be consumed by other language implementations.

[Apache Thrift Implementation](#)

346.1. THRIFT OPTIONS

The Thrift dataformat supports 3 options, which are listed below.

Name	Default	Java Type	Description
<code>instanceClass</code>		String	Name of class to use when unarmshalling
<code>contentTypeFormat</code>	binary	String	Defines a content type format in which thrift message will be serialized/deserialized from(to) the Java been. The format can either be native or json for either native binary thrift, json or simple json fields representation. The default value is binary.
<code>contentTypeHeader</code>	false	Boolean	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSon etc.

346.2. SPRING BOOT AUTO-CONFIGURATION

The component supports 7 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.thrift.enabled</code>	Whether to enable auto configuration of the thrift component. This is enabled by default.		Boolean
<code>camel.component.thrift.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.component.thrift.use-global-ssl-context-parameters</code>	Determine if the thrift component is using global SSL context parameters	false	Boolean

Name	Description	Default	Type
<code>camel.dataformat.thrift.content-type-format</code>	Defines a content type format in which thrift message will be serialized/deserialized from(to) the Java bean. The format can either be native or json for either native binary thrift, json or simple json fields representation. The default value is binary.	binary	String
<code>camel.dataformat.thrift.content-type-header</code>	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSon etc.	false	Boolean
<code>camel.dataformat.thrift.enabled</code>	Whether to enable auto configuration of the thrift data format. This is enabled by default.		Boolean
<code>camel.dataformat.thrift.instance-class</code>	Name of class to use when unarmshalling		String

ND

346.3. CONTENT TYPE FORMAT

It's possible to parse JSON message to convert it to the Thrift format and unparse it back using native util converter. To use this option, set `contentTypeFormat` value to 'json' or call `thrift` with second parameter. If default instance is not specified, always use native binary Thrift format. The simple JSON format is write-only (marshal) and produces a simple output format suitable for parsing by scripting languages. The sample code shows below:

```
from("direct:marshal")
  .unmarshal()
  .thrift("org.apache.camel.dataformat.thrift.generated.Work", "json")
  .to("mock:reverse");
```

346.4. THRIFT OVERVIEW

This quick overview of how to use Thrift. For more detail see the [complete tutorial](#)

346.5. DEFINING THE THRIFT FORMAT

The first step is to define the format for the body of your exchange. This is defined in a `.thrift` file as so:

`tutorial.thrift`

```
namespace java org.apache.camel.dataformat.thrift.generated

enum Operation {
```

```

    ADD = 1,
    SUBTRACT = 2,
    MULTIPLY = 3,
    DIVIDE = 4
}

struct Work {
    1: i32 num1 = 0,
    2: i32 num2,
    3: Operation op,
    4: optional string comment,
}

```

346.6. GENERATING JAVA CLASSES

The Apache Thrift provides a compiler which will generate the Java classes for the format we defined in our .thrift file.

You can also run the compiler for any additional supported languages you require manually.

```
thrift -r --gen java -out ../java/ ./tutorial-dataformat.thrift
```

This will generate separate Java class for each type defined in .thrift file, i.e. struct or enum. The generated classes implement org.apache.thrift.TBase which is required by the serialization mechanism. For this reason it important that only these classes are used in the body of your exchanges. Camel will throw an exception on route creation if you attempt to tell the Data Format to use a class that does not implement org.apache.thrift.TBase.

346.7. JAVA DSL

You can use create the ThriftDataFormat instance and pass it to Camel DataFormat marshal and unmarshal API like this.

```

ThriftDataFormat format = new ThriftDataFormat(new Work());

from("direct:in").marshal(format);
from("direct:back").unmarshal(format).to("mock:reverse");

```

Or use the DSL thrift() passing the unmarshal default instance or default instance class name like this.

```

// You don't need to specify the default instance for the thrift marshaling
from("direct:marshal").marshal().thrift();
from("direct:unmarshalA").unmarshal()
    .thrift("org.apache.camel.dataformat.thrift.generated.Work")
    .to("mock:reverse");

from("direct:unmarshalB").unmarshal().thrift(new Work()).to("mock:reverse");

```

346.8. SPRING DSL

The following example shows how to use Thrift to unmarshal using Spring configuring the thrift data type

```
<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="direct:start"/>
    <unmarshal>
      <thrift instanceClass="org.apache.camel.dataformat.thrift.generated.Work" />
    </unmarshal>
    <to uri="mock:result"/>
  </route>
</camelContext>
```

346.9. DEPENDENCIES

To use Thrift in your camel routes you need to add the a dependency on **camel-thrift** which implements this data format.

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-thrift</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

CHAPTER 347. TIDYMARKUP DATAFORMAT

Available as of Camel version 2.0

TidyMarkup is a Data Format that uses the [TagSoup](#) to tidy up HTML. It can be used to parse ugly HTML and return it as pretty wellformed HTML.

Camel eats our own -dog food- soap

We had some issues in our pdf Manual where we had some strange symbols. So [Jonathan](#) used this data format to tidy up the wiki html pages that are used as base for rendering the pdf manuals. And then the mysterious symbols vanished.

TidyMarkup only supports the **unmarshal** operation as we really don't want to turn well formed HTML into ugly HTML.

347.1. TIDYMARKUP OPTIONS

The TidyMarkup dataformat supports 3 options, which are listed below.

Name	Default	Java Type	Description
<code>dataObjectType</code>	org.w3c.dom.Node	String	What data type to unmarshal as, can either be <code>org.w3c.dom.Node</code> or <code>java.lang.String</code> . Is by default <code>org.w3c.dom.Node</code>
<code>omitXmlDeclaration</code>	false	Boolean	When returning a String, do we omit the XML declaration in the top.
<code>contentTypeHeader</code>	false	Boolean	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example <code>application/xml</code> for data formats marshalling to XML, or <code>application/json</code> for data formats marshalling to JSon etc.

347.2. SPRING BOOT AUTO-CONFIGURATION

The component supports 4 options, which are listed below.

Name	Description	Default	Type
<code>camel.dataformat.tidymarkup.content-type-header</code>	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example <code>application/xml</code> for data formats marshalling to XML, or <code>application/json</code> for data formats marshalling to JSon etc.	false	Boolean

Name	Description	Default	Type
<code>camel.dataformat.tidymarkup.data-object-type</code>	What data type to unmarshal as, can either be <code>org.w3c.dom.Node</code> or <code>java.lang.String</code> . Is by default <code>org.w3c.dom.Node</code>	<code>org.w3c.dom.Node</code>	String
<code>camel.dataformat.tidymarkup.enabled</code>	Enable tidymarkup dataformat	<code>true</code>	Boolean
<code>camel.dataformat.tidymarkup.omit-xml-declaration</code>	When returning a String, do we omit the XML declaration in the top.	<code>false</code>	Boolean

347.3. JAVA DSL EXAMPLE

An example where the consumer provides some HTML

```
from("file://site/inbox").unmarshal().tidyMarkup().to("file://site/blogs");
```

347.4. SPRING XML EXAMPLE

The following example shows how to use TidyMarkup to unmarshal using Spring

```
<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="file://site/inbox"/>
      <unmarshal>
        <tidyMarkup/>
      </unmarshal>
      <to uri="file://site/blogs"/>
    </route>
  </camelContext>
```

347.5. DEPENDENCIES

To use TidyMarkup in your camel routes you need to add the a dependency on **camel-tagsoup** which implements this data format.

If you use maven you could just add the following to your pom.xml, substituting the version number for the latest & greatest release (see the download page for the latest versions).

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-tagsoup</artifactId>
  <version>x.x.x</version>
</dependency>
```

CHAPTER 348. TIKA COMPONENT

Available as of Camel version 2.19

The **Tika**: components provides the ability to detect and parse documents with Apache Tika. This component uses [Apache Tika](#) as underlying library to work with documents.

In order to use the Tika component, Maven users will need to add the following dependency to their **pom.xml**:

pom.xml

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-tika</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

The TIKA component only supports producer endpoints.

348.1. OPTIONS

The Tika component has no options.

The Tika endpoint is configured using URI syntax:

```
tika:operation
```

with the following path and query parameters:

348.1.1. Path Parameters (1 parameters):

Name	Description	Default	Type
operation	Required Tika Operation. parse or detect		TikaOperation

348.1.2. Query Parameters (5 parameters):

Name	Description	Default	Type
tikaConfig (producer)	Tika Config		TikaConfig
tikaConfigUri (producer)	Tika Config Uri: The URL of tika-config.xml		String

Name	Description	Default	Type
tikaParseOutputEncoding (producer)	Tika Parse Output Encoding - Used to specify the character encoding of the parsed output. Defaults to <code>Charset.defaultCharset()</code> .		String
tikaParseOutputFormat (producer)	Tika Output Format. Supported output formats. <code>xml</code> : Returns Parsed Content as XML. <code>html</code> : Returns Parsed Content as HTML. <code>text</code> : Returns Parsed Content as Text. <code>textMain</code> : Uses the boilerpipe library to automatically extract the main content from a web page.	xml	TikaParseOutputFormat
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

348.2. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.component.tika.enabled	Enable tika component	true	Boolean
camel.component.tika.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

348.3. TO DETECT A FILE'S MIME TYPE

The file should be placed in the Body.

```
from("direct:start")
  .to("tika:detect");
```

348.4. TO PARSE A FILE

The file should be placed in the Body.

```
from("direct:start")
  .to("tika:parse");
```

CHAPTER 349. TIMER COMPONENT

Available as of Camel version 1.0

The **timer:** component is used to generate message exchanges when a timer fires. You can only consume events from this endpoint.

349.1. URI FORMAT

```
timer:name[?options]
```

Where **name** is the name of the **Timer** object, which is created and shared across endpoints. So if you use the same name for all your timer endpoints, only one **Timer** object and thread will be used.

You can append query options to the URI in the following format, **?option=value&option=value&...**

Note: The IN body of the generated exchange is **null**. So **exchange.getIn().getBody()** returns **null**.

TIP:**Advanced Scheduler** See also the [Quartz](#) component that supports much more advanced scheduling.

TIP:**Specify time in human friendly format** In **Camel 2.3** onwards you can specify the time in [human friendly syntax](#).

349.2. OPTIONS

The Timer component has no options.

The Timer endpoint is configured using URI syntax:

```
timer:timerName
```

with the following path and query parameters:

349.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
timerName	Required The name of the timer	t	String

349.2.2. Query Parameters (12 parameters):

Name	Description	Default	Type
------	-------------	---------	------

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN/ERROR level and ignored.	false	boolean
delay (consumer)	The number of milliseconds to wait before the first event is generated. Should not be used in conjunction with the time option. The default value is 1000. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	1000	long
fixedRate (consumer)	Events take place at approximately regular intervals, separated by the specified period.	false	boolean
period (consumer)	If greater than 0, generate periodic events every period milliseconds. The default value is 1000. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	1000	long
repeatCount (consumer)	Specifies a maximum limit of number of fires. So if you set it to 1, the timer will only fire once. If you set it to 5, it will only fire five times. A value of zero or negative means fire forever.	0	long
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option <code>bridgeErrorHandler</code> is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN/ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the default exchange pattern when creating an exchange.		ExchangePattern
daemon (advanced)	Specifies whether or not the thread associated with the timer endpoint runs as a daemon. The default value is true.	true	boolean
pattern (advanced)	Allows you to specify a custom Date pattern to use for setting the time option using URI syntax.		String

Name	Description	Default	Type
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
time (advanced)	A java.util.Date the first event should be generated. If using the URI, the pattern expected is: yyyy-MM-dd HH:mm:ss or yyyy-MM-dd'T'HH:mm:ss.		Date
timer (advanced)	To use a custom Timer		Timer

349.3. EXCHANGE PROPERTIES

When the timer is fired, it adds the following information as properties to the **Exchange**:

Name	Type	Description
Exchange.TIMER_NAME	String	The value of the name option.
Exchange.TIMER_TIME	Date	The value of the time option.
Exchange.TIMER_PERIOD	long	The value of the period option.
Exchange.TIMER_FIRED_TIME	Date	The time when the consumer fired.
Exchange.TIMER_COUNTER	Long	Camel 2.8: The current fire counter. Starts from 1.

349.4. SAMPLE

To set up a route that generates an event every 60 seconds:

```
from("timer://foo?fixedRate=true&period=60000").to("bean:myBean?method=someMethodName");
```

TIP

Instead of 60000 you can use `period=60s` which is more friendly to read.

The above route will generate an event and then invoke the **someMethodName** method on the bean called **myBean** in the Registry such as JNDI or Spring.

And the route in Spring DSL:

```
<route>
  <from uri="timer://foo?fixedRate=true&period=60000"/>
  <to uri="bean:myBean?method=someMethodName"/>
</route>
```

349.5. FIRING AS SOON AS POSSIBLE

Available as of Camel 2.17

You may want to fire messages in a Camel route as soon as possible you can use a negative delay:

```
<route>
  <from uri="timer://foo?delay=-1"/>
  <to uri="bean:myBean?method=someMethodName"/>
</route>
```

In this way the timer will fire messages immediately.

You can also specify a `repeatCount` parameter in conjunction with a negative delay to stop firing messages after a fixed number has been reached.

If you don't specify a `repeatCount` then the timer will continue firing messages until the route will be stopped.

349.6. FIRING ONLY ONCE

Available as of Camel 2.8

You may want to fire a message in a Camel route only once, such as when starting the route. To do that you use the `repeatCount` option as shown:

```
<route>
  <from uri="timer://foo?repeatCount=1"/>
  <to uri="bean:myBean?method=someMethodName"/>
</route>
```

349.7. SEE ALSO

- [Scheduler](#)

- [Quartz](#)

CHAPTER 350. TWILIO COMPONENT

Available as of Camel version 2.20

The Twilio component provides access to Version 2010-04-01 of Twilio REST APIs accessible using [Twilio Java SDK](#).

Maven users will need to add the following dependency to their pom.xml for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-twilio</artifactId>
  <version>${camel-version}</version>
</dependency>
```

350.1. TWILIO OPTIONS

The Twilio component supports 6 options, which are listed below.

Name	Description	Default	Type
configuration (advanced)	To use the shared configuration		TwilioConfiguration
restClient (advanced)	To use the shared REST client		TwilioRestClient
username (security)	The account to use.		String
password (security)	Auth token for the account.		String
accountSid (security)	The account SID to use.		String
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Twilio endpoint is configured using URI syntax:

```
twilio:apiName/methodName
```

with the following path and query parameters:

350.1.1. Path Parameters (2 parameters):

Name	Description	Default	Type
apiName	Required What kind of operation to perform		TwilioApiName
methodName	Required What sub operation to use for the selected operation		String

350.1.2. Query Parameters (5 parameters):

Name	Description	Default	Type
inBody (common)	Sets the name of a parameter to be passed in the exchange In Body		String
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

350.2. SPRING BOOT AUTO-CONFIGURATION

The component supports 8 options, which are listed below.

Name	Description	Default	Type
camel.component.twilio.account-sid	The account SID to use.		String

Name	Description	Default	Type
<code>camel.component.twilio.configuration.api-name</code>	What kind of operation to perform		TwilioApiName
<code>camel.component.twilio.configuration.method-name</code>	What sub operation to use for the selected operation		String
<code>camel.component.twilio.enabled</code>	Enable twilio component	true	Boolean
<code>camel.component.twilio.password</code>	Auth token for the account.		String
<code>camel.component.twilio.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.component.twilio.rest-client</code>	To use the shared REST client. The option is a <code>com.twilio.http.TwilioRestClient</code> type.		String
<code>camel.component.twilio.username</code>	The account to use.		String

350.3. URI FORMAT

`twilio://endpoint-prefix/endpoint?[options]`

Endpoint prefix can be one of:

- account
- address
- address-dependent-phone-number
- application
- available-phone-number-country
- available-phone-number-country-local
- available-phone-number-country-mobile
- available-phone-number-country-toll-free
- call

- call-feedback
- call-feedback-summary
- call-notification
- call-recording
- conference
- conference-participant
- connect-app
- incoming-phone-number
- incoming-phone-number-local
- incoming-phone-number-mobile
- incoming-phone-number-toll-free
- key
- message
- message-feedback
- message-media
- new-key
- new-signing-key
- notification
- outgoing-caller-id
- queue
- queue-member

- usage-record-monthly
- usage-record-this-month
- usage-record-today
- usage-record-yearly
- usage-record-yesterday
- usage-trigger
- validation-request

350.4. PRODUCER ENDPOINTS:

Producer endpoints can use endpoint prefixes followed by endpoint names and associated options described next. A shorthand alias can be used for all of the endpoints. The endpoint URI MUST contain a prefix.

Any of the endpoint options can be provided in either the endpoint URI, or dynamically in a message header. The message header name must be of the format **CamelTwilio.<option>**. Note that the **inBody** option overrides message header, i.e. the endpoint option **inBody=option** would override a **CamelTwilio.option** header.

Endpoint can be one of:

Endpoint	Shorthand Alias	Description
creator	create	Make the request to the Twilio API to perform the create
deleter	delete	Make the request to the Twilio API to perform the delete

Endpoint	Shorthand Alias	Description
fetcher	fetch	Make the request to the Twilio API to perform the fetch
reader	read	Make the request to the Twilio API to perform the read
updater	update	Make the request to the Twilio API to perform the update

Available endpoints differ depending on the endpoint prefixes.

For more information on the endpoints and options see API documentation at:
<https://www.twilio.com/docs/libraries/reference/twilio-java/index.html>

350.5. CONSUMER ENDPOINTS:

Any of the producer endpoints can be used as a consumer endpoint. Consumer endpoints can use [Scheduled Poll Consumer Options](#) with a **consumer.** prefix to schedule endpoint invocation. Consumer endpoints that return an array or collection will generate one exchange per element, and their routes will be executed once for each exchange.

If you want to receive calls or messages from Twilio and respond to them using a Camel consumer endpoint, you can use other HTTP-based components such as **camel-servlet**, **camel-undertow**, **camel-jetty**, and **camel-netty-http** to respond with [TwiML](#).

350.6. MESSAGE HEADER

Any of the options can be provided in a message header for producer endpoints with **CamelTwilio.** prefix.

350.7. MESSAGE BODY

All result message bodies utilize objects provided by the Twilio Java SDK. Producer endpoints can specify the option name for incoming message body in the **inBody** endpoint parameter.

CHAPTER 351. TWITTER COMPONENTS

Available as of Camel version 2.10

The camel-twitter consists of 4 components:

- [Twitter Direct Message](#)
- [Twitter Search](#)
- [Twitter Streaming](#)
- [Twitter Timeline](#)

The Twitter components enable the most useful features of the Twitter API by encapsulating [Twitter4J](#). It allows direct, polling, or event-driven consumption of timelines, users, trends, and direct messages. Also, it supports producing messages as status updates or direct messages.

Twitter now requires the use of OAuth for all client application authentication. In order to use camel-twitter with your account, you'll need to create a new application within Twitter at <https://dev.twitter.com/apps/new> and grant the application access to your account. Finally, generate your access token and secret.

Maven users will need to add the following dependency to their pom.xml for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-twitter</artifactId>
  <version>${camel-version}</version>
</dependency>
```

351.1. CONSUMER ENDPOINTS

Rather than the endpoints returning a List through one single route exchange, camel-twitter creates one route exchange per returned object. As an example, if "timeline/home" results in five statuses, the route will be executed five times (one for each Status).

Endpoint	Context	Body Type	Notice
twitter-directmessage	direct, polling	twitter4j.DirectMessage	
twitter-search	direct, polling	twitter4j.Status	
twitter-streaming	event, polling	twitter4j.Status	

Endpoint	Context	Body Type	Notice
twitter-timeline	direct, polling	twitter4j.Status	

351.2. PRODUCER ENDPOINTS

Endpoint	Body Type	Notice
twitter-directmessage	String	
twitter-search	List<twitter4j.Status>	
twitter-timeline	String	Only 'user' timelineType is supported for producer

351.3. MESSAGE HEADERS

Name	Description
CamelTwitterKeywords	This header is used by the search producer to change the search key words dynamically.
CamelTwitterSearchLanguage	Camel 2.11.0: This header can override the option of lang which set the search language for the search endpoint dynamically
CamelTwitterCount	Camel 2.11.0 This header can override the option of count which sets the max twitters that will be returned.
CamelTwitterNumberOfPages	Camel 2.11.0 This header can override the option of numberOfPages which sets how many pages we want to twitter returns.

351.4. MESSAGE BODY

All message bodies utilize objects provided by the Twitter4J API.

351.5. USE CASES

**NOTE**

API Rate Limits: Twitter REST APIs encapsulated by [Twitter4J](#) are subjected to [API Rate Limiting](#). You can find the per method limits in the [API Rate Limits](#) documentation. Note that endpoints/resources not listed in that page are default to 15 requests per allotted user per window.

351.5.1. To create a status update within your Twitter profile, send this producer a String body:

```
from("direct:foo")
  .to("twitter-timeline://user?consumerKey=[s]&consumerSecret=[s]&accessToken=[s]&accessTokenSecret=[s]");
```

351.5.2. To poll, every 60 sec., all statuses on your home timeline:

```
from("twitter-timeline://home?type=polling&delay=60&consumerKey=[s]&consumerSecret=[s]&accessToken=[s]&accessTokenSecret=[s]")
  .to("bean:blah");
```

351.5.3. To search for all statuses with the keyword 'camel' only once:

```
from("twitter-search://foo?type=polling&keywords=camel&consumerKey=[s]&consumerSecret=[s]&accessToken=[s]&accessTokenSecret=[s]")
  .to("bean:blah");
```

351.5.4. Searching using a producer with static keywords:

```
from("direct:foo")
  .to("twitter-search://foo?keywords=camel&consumerKey=[s]&consumerSecret=[s]&accessToken=[s]&accessTokenSecret=[s]");
```

351.5.5. Searching using a producer with dynamic keywords from header:

In the **bar** header we have the keywords we want to search, so we can assign this value to the **CamelTwitterKeywords** header:

```
from("direct:foo")
  .setHeader("CamelTwitterKeywords", header("bar"))
  .to("twitter-search://foo?consumerKey=[s]&consumerSecret=[s]&accessToken=[s]&accessTokenSecret=[s]");
```

351.6. EXAMPLE

See also the [Twitter Websocket Example](#).

- [Endpoint](#)
- [Getting Started](#)
- [Twitter Websocket Example](#)

CHAPTER 352. TWITTER DIRECT MESSAGE COMPONENT

Available as of Camel version 2.10

The Twitter Direct Message Component consumes/produces a user's direct messages.

352.1. COMPONENT OPTIONS

The Twitter Direct Message component supports 9 options, which are listed below.

Name	Description	Default	Type
accessToken (security)	The access token		String
accessTokenSecret (security)	The access token secret		String
consumerKey (security)	The consumer key		String
consumerSecret (security)	The consumer secret		String
httpProxyHost (proxy)	The http proxy host which can be used for the camel-twitter.		String
httpProxyUser (proxy)	The http proxy user which can be used for the camel-twitter.		String
httpProxyPassword (proxy)	The http proxy password which can be used for the camel-twitter.		String
httpProxyPort (proxy)	The http proxy port which can be used for the camel-twitter.		int
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

352.2. ENDPOINT OPTIONS

The Twitter Direct Message endpoint is configured using URI syntax:

```
twitter-directmessage:user
```

with the following path and query parameters:

352.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
user	Required The user name to send a direct message. This will be ignored for consumer.		String

352.2.2. Query Parameters (42 parameters):

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean
type (consumer)	Endpoint type to use. Only streaming supports event type.	polling	EndpointType
distanceMetric (consumer)	Used by the non-stream geography search, to search by radius using the configured metrics. The unit can either be mi for miles, or km for kilometers. You need to configure all the following options: longitude, latitude, radius, and distanceMetric.	km	String
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
extendedMode (consumer)	Used for enabling full text from twitter (eg receive tweets that contains more than 140 characters).	true	boolean

Name	Description	Default	Type
latitude (consumer)	Used by the non-stream geography search to search by latitude. You need to configure all the following options: longitude, latitude, radius, and distanceMetric.		Double
locations (consumer)	Bounding boxes, created by pairs of lat/lons. Can be used for streaming/filter. A pair is defined as lat,lon. And multiple paris can be separated by semi colon.		String
longitude (consumer)	Used by the non-stream geography search to search by longitude. You need to configure all the following options: longitude, latitude, radius, and distanceMetric.		Double
pollStrategy (consumer)	A pluggable org.apache.camel.PollingConsumerPollingStrategy allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		PollingConsumerPoll Strategy
radius (consumer)	Used by the non-stream geography search to search by radius. You need to configure all the following options: longitude, latitude, radius, and distanceMetric.		Double
twitterStream (consumer)	To use a custom instance of TwitterStream		TwitterStream
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
count (filter)	Limiting number of results per page.	5	Integer
filterOld (filter)	Filter out old tweets, that has previously been polled. This state is stored in memory only, and based on last tweet id.	true	boolean
lang (filter)	The lang string ISO_639-1 which will be used for searching		String
numberOfPages (filter)	The number of pages result which you want camel-twitter to consume.	1	Integer

Name	Description	Default	Type
sinceId (filter)	The last tweet id which will be used for pulling the tweets. It is useful when the camel route is restarted after a long running.	1	long
userIds (filter)	To filter by user ids for streaming/filter. Multiple values can be separated by comma.		String
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.		int
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.		int
delay (scheduler)	Milliseconds before the next poll.	30000	long
greedy (scheduler)	If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	1000	long
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that.	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz2 component	none	ScheduledPollConsumer Scheduler
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz2, Spring based scheduler.		Map

Name	Description	Default	Type
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for initialDelay and delay options.	MILLIS ECON DS	TimeUnit
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.	true	boolean
sortById (sort)	Sorts by id, so the oldest are first, and newest last.	true	boolean
httpProxyHost (proxy)	The http proxy host which can be used for the camel-twitter. Can also be configured on the TwitterComponent level instead.		String
httpProxyPasswo rd (proxy)	The http proxy password which can be used for the camel-twitter. Can also be configured on the TwitterComponent level instead.		String
httpProxyPort (proxy)	The http proxy port which can be used for the camel-twitter. Can also be configured on the TwitterComponent level instead.		Integer
httpProxyUser (proxy)	The http proxy user which can be used for the camel-twitter. Can also be configured on the TwitterComponent level instead.		String
accessToken (security)	The access token. Can also be configured on the TwitterComponent level instead.		String
accessTokenSecr et (security)	The access secret. Can also be configured on the TwitterComponent level instead.		String
consumerKey (security)	The consumer key. Can also be configured on the TwitterComponent level instead.		String
consumerSecret (security)	The consumer secret. Can also be configured on the TwitterComponent level instead.		String

352.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 10 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.twitter-directmessage.access-token</code>	The access token		String
<code>camel.component.twitter-directmessage.access-token-secret</code>	The access token secret		String
<code>camel.component.twitter-directmessage.consumer-key</code>	The consumer key		String
<code>camel.component.twitter-directmessage.consumer-secret</code>	The consumer secret		String
<code>camel.component.twitter-directmessage.enabled</code>	Whether to enable auto configuration of the twitter-directmessage component. This is enabled by default.		Boolean
<code>camel.component.twitter-directmessage.http-proxy-host</code>	The http proxy host which can be used for the camel-twitter.		String
<code>camel.component.twitter-directmessage.http-proxy-password</code>	The http proxy password which can be used for the camel-twitter.		String
<code>camel.component.twitter-directmessage.http-proxy-port</code>	The http proxy port which can be used for the camel-twitter.		Integer
<code>camel.component.twitter-directmessage.http-proxy-user</code>	The http proxy user which can be used for the camel-twitter.		String

Name	Description	Default	Type
camel.component.twitter-directmessage.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

CHAPTER 353. TWITTER SEARCH COMPONENT

Available as of Camel version 2.10

The Twitter Search component consumes search results.

353.1. COMPONENT OPTIONS

The Twitter Search component supports 9 options, which are listed below.

Name	Description	Default	Type
accessToken (security)	The access token		String
accessTokenSecret (security)	The access token secret		String
consumerKey (security)	The consumer key		String
consumerSecret (security)	The consumer secret		String
httpProxyHost (proxy)	The http proxy host which can be used for the camel-twitter.		String
httpProxyUser (proxy)	The http proxy user which can be used for the camel-twitter.		String
httpProxyPassword (proxy)	The http proxy password which can be used for the camel-twitter.		String
httpProxyPort (proxy)	The http proxy port which can be used for the camel-twitter.		int
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

353.2. ENDPOINT OPTIONS

The Twitter Search endpoint is configured using URI syntax:

```
twitter-search:keywords
```

with the following path and query parameters:

353.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
keywords	Required The search keywords. Multiple values can be separated with comma.		String

353.2.2. Query Parameters (42 parameters):

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean
type (consumer)	Endpoint type to use. Only streaming supports event type.	polling	EndpointType
distanceMetric (consumer)	Used by the non-stream geography search, to search by radius using the configured metrics. The unit can either be mi for miles, or km for kilometers. You need to configure all the following options: longitude, latitude, radius, and distanceMetric.	km	String
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
extendedMode (consumer)	Used for enabling full text from twitter (eg receive tweets that contains more than 140 characters).	true	boolean

Name	Description	Default	Type
latitude (consumer)	Used by the non-stream geography search to search by latitude. You need to configure all the following options: longitude, latitude, radius, and distanceMetric.		Double
locations (consumer)	Bounding boxes, created by pairs of lat/lons. Can be used for streaming/filter. A pair is defined as lat,lon. And multiple paris can be separated by semi colon.		String
longitude (consumer)	Used by the non-stream geography search to search by longitude. You need to configure all the following options: longitude, latitude, radius, and distanceMetric.		Double
pollStrategy (consumer)	A pluggable <code>org.apache.camel.PollingConsumerPollingStrategy</code> allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		PollingConsumerPoll Strategy
radius (consumer)	Used by the non-stream geography search to search by radius. You need to configure all the following options: longitude, latitude, radius, and distanceMetric.		Double
twitterStream (consumer)	To use a custom instance of <code>TwitterStream</code>		TwitterStream
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
count (filter)	Limiting number of results per page.	5	Integer
filterOld (filter)	Filter out old tweets, that has previously been polled. This state is stored in memory only, and based on last tweet id.	true	boolean
lang (filter)	The lang string ISO_639-1 which will be used for searching		String
numberOfPages (filter)	The number of pages result which you want camel-twitter to consume.	1	Integer

Name	Description	Default	Type
sinceId (filter)	The last tweet id which will be used for pulling the tweets. It is useful when the camel route is restarted after a long running.	1	long
userIds (filter)	To filter by user ids for streaming/filter. Multiple values can be separated by comma.		String
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.		int
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.		int
delay (scheduler)	Milliseconds before the next poll.	30000	long
greedy (scheduler)	If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	1000	long
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that.	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz2 component	none	ScheduledPollConsumer Scheduler
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz2, Spring based scheduler.		Map

Name	Description	Default	Type
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for initialDelay and delay options.	MILLIS ECON DS	TimeUnit
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.	true	boolean
sortById (sort)	Sorts by id, so the oldest are first, and newest last.	true	boolean
httpProxyHost (proxy)	The http proxy host which can be used for the camel-twitter. Can also be configured on the TwitterComponent level instead.		String
httpProxyPasswo rd (proxy)	The http proxy password which can be used for the camel-twitter. Can also be configured on the TwitterComponent level instead.		String
httpProxyPort (proxy)	The http proxy port which can be used for the camel-twitter. Can also be configured on the TwitterComponent level instead.		Integer
httpProxyUser (proxy)	The http proxy user which can be used for the camel-twitter. Can also be configured on the TwitterComponent level instead.		String
accessToken (security)	The access token. Can also be configured on the TwitterComponent level instead.		String
accessTokenSecr et (security)	The access secret. Can also be configured on the TwitterComponent level instead.		String
consumerKey (security)	The consumer key. Can also be configured on the TwitterComponent level instead.		String
consumerSecret (security)	The consumer secret. Can also be configured on the TwitterComponent level instead.		String

353.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 10 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.twitter-search.access-token</code>	The access token		String
<code>camel.component.twitter-search.access-token-secret</code>	The access token secret		String
<code>camel.component.twitter-search.consumer-key</code>	The consumer key		String
<code>camel.component.twitter-search.consumer-secret</code>	The consumer secret		String
<code>camel.component.twitter-search.enabled</code>	Whether to enable auto configuration of the twitter-search component. This is enabled by default.		Boolean
<code>camel.component.twitter-search.http-proxy-host</code>	The http proxy host which can be used for the camel-twitter.		String
<code>camel.component.twitter-search.http-proxy-password</code>	The http proxy password which can be used for the camel-twitter.		String
<code>camel.component.twitter-search.http-proxy-port</code>	The http proxy port which can be used for the camel-twitter.		Integer
<code>camel.component.twitter-search.http-proxy-user</code>	The http proxy user which can be used for the camel-twitter.		String

Name	Description	Default	Type
<code>camel.component.twitter-search.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

CHAPTER 354. TWITTER STREAMING COMPONENT

Available as of Camel version 2.10

The Twitter Streaming component consumes twitter statuses using Streaming API.

354.1. COMPONENT OPTIONS

The Twitter Streaming component supports 9 options, which are listed below.

Name	Description	Default	Type
accessToken (security)	The access token		String
accessTokenSecret (security)	The access token secret		String
consumerKey (security)	The consumer key		String
consumerSecret (security)	The consumer secret		String
httpProxyHost (proxy)	The http proxy host which can be used for the camel-twitter.		String
httpProxyUser (proxy)	The http proxy user which can be used for the camel-twitter.		String
httpProxyPassword (proxy)	The http proxy password which can be used for the camel-twitter.		String
httpProxyPort (proxy)	The http proxy port which can be used for the camel-twitter.		int
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

354.2. ENDPOINT OPTIONS

The Twitter Streaming endpoint is configured using URI syntax:

```
twitter-streaming:streamingType
```

with the following path and query parameters:

354.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
streamingType	Required The streaming type to consume.		StreamingType

354.2.2. Query Parameters (43 parameters):

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean
type (consumer)	Endpoint type to use. Only streaming supports event type.	polling	EndpointType
distanceMetric (consumer)	Used by the non-stream geography search, to search by radius using the configured metrics. The unit can either be mi for miles, or km for kilometers. You need to configure all the following options: longitude, latitude, radius, and distanceMetric.	km	String
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
extendedMode (consumer)	Used for enabling full text from twitter (eg receive tweets that contains more than 140 characters).	true	boolean

Name	Description	Default	Type
latitude (consumer)	Used by the non-stream geography search to search by latitude. You need to configure all the following options: longitude, latitude, radius, and distanceMetric.		Double
locations (consumer)	Bounding boxes, created by pairs of lat/lons. Can be used for streaming/filter. A pair is defined as lat,lon. And multiple paris can be separated by semi colon.		String
longitude (consumer)	Used by the non-stream geography search to search by longitude. You need to configure all the following options: longitude, latitude, radius, and distanceMetric.		Double
pollStrategy (consumer)	A pluggable org.apache.camel.PollingConsumerPollingStrategy allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		PollingConsumerPoll Strategy
radius (consumer)	Used by the non-stream geography search to search by radius. You need to configure all the following options: longitude, latitude, radius, and distanceMetric.		Double
twitterStream (consumer)	To use a custom instance of TwitterStream		TwitterStream
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
count (filter)	Limiting number of results per page.	5	Integer
filterOld (filter)	Filter out old tweets, that has previously been polled. This state is stored in memory only, and based on last tweet id.	true	boolean
keywords (filter)	Can be used for a streaming filter. Multiple values can be separated with comma.		String
lang (filter)	The lang string ISO_639-1 which will be used for searching		String
numberOfPages (filter)	The number of pages result which you want camel-twitter to consume.	1	Integer

Name	Description	Default	Type
sinceId (filter)	The last tweet id which will be used for pulling the tweets. It is useful when the camel route is restarted after a long running.	1	long
userIds (filter)	To filter by user ids for streaming/filter. Multiple values can be separated by comma.		String
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.		int
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.		int
delay (scheduler)	Milliseconds before the next poll.	30000	long
greedy (scheduler)	If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	1000	long
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that.	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz2 component	none	ScheduledPollConsumer Scheduler
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz2, Spring based scheduler.		Map

Name	Description	Default	Type
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for initialDelay and delay options.	MILLIS ECON DS	TimeUnit
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.	true	boolean
sortById (sort)	Sorts by id, so the oldest are first, and newest last.	true	boolean
httpProxyHost (proxy)	The http proxy host which can be used for the camel-twitter. Can also be configured on the TwitterComponent level instead.		String
httpProxyPasswo rd (proxy)	The http proxy password which can be used for the camel-twitter. Can also be configured on the TwitterComponent level instead.		String
httpProxyPort (proxy)	The http proxy port which can be used for the camel-twitter. Can also be configured on the TwitterComponent level instead.		Integer
httpProxyUser (proxy)	The http proxy user which can be used for the camel-twitter. Can also be configured on the TwitterComponent level instead.		String
accessToken (security)	The access token. Can also be configured on the TwitterComponent level instead.		String
accessTokenSecr et (security)	The access secret. Can also be configured on the TwitterComponent level instead.		String
consumerKey (security)	The consumer key. Can also be configured on the TwitterComponent level instead.		String
consumerSecret (security)	The consumer secret. Can also be configured on the TwitterComponent level instead.		String

354.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 10 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.twitter-streaming.access-token</code>	The access token		String
<code>camel.component.twitter-streaming.access-token-secret</code>	The access token secret		String
<code>camel.component.twitter-streaming.consumer-key</code>	The consumer key		String
<code>camel.component.twitter-streaming.consumer-secret</code>	The consumer secret		String
<code>camel.component.twitter-streaming.enabled</code>	Whether to enable auto configuration of the twitter-streaming component. This is enabled by default.		Boolean
<code>camel.component.twitter-streaming.http-proxy-host</code>	The http proxy host which can be used for the camel-twitter.		String
<code>camel.component.twitter-streaming.http-proxy-password</code>	The http proxy password which can be used for the camel-twitter.		String
<code>camel.component.twitter-streaming.http-proxy-port</code>	The http proxy port which can be used for the camel-twitter.		Integer
<code>camel.component.twitter-streaming.http-proxy-user</code>	The http proxy user which can be used for the camel-twitter.		String

Name	Description	Default	Type
<code>camel.component.twitter-streaming.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

CHAPTER 355. TWITTER TIMELINE COMPONENT

Available as of Camel version 2.10

The Twitter Timeline component consumes twitter timeline or update the status of specific user.

355.1. COMPONENT OPTIONS

The Twitter Timeline component supports 9 options, which are listed below.

Name	Description	Default	Type
accessToken (security)	The access token		String
accessTokenSecret (security)	The access token secret		String
consumerKey (security)	The consumer key		String
consumerSecret (security)	The consumer secret		String
httpProxyHost (proxy)	The http proxy host which can be used for the camel-twitter.		String
httpProxyUser (proxy)	The http proxy user which can be used for the camel-twitter.		String
httpProxyPassword (proxy)	The http proxy password which can be used for the camel-twitter.		String
httpProxyPort (proxy)	The http proxy port which can be used for the camel-twitter.		int
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

355.2. ENDPOINT OPTIONS

The Twitter Timeline endpoint is configured using URI syntax:

```
twitter-timeline:timelineType
```

with the following path and query parameters:

355.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
timelineType	Required The timeline type to produce/consume.		TimelineType

355.2.2. Query Parameters (43 parameters):

Name	Description	Default	Type
user (common)	The username when using timelineType=user		String
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean
type (consumer)	Endpoint type to use. Only streaming supports event type.	polling	EndpointType
distanceMetric (consumer)	Used by the non-stream geography search, to search by radius using the configured metrics. The unit can either be mi for miles, or km for kilometers. You need to configure all the following options: longitude, latitude, radius, and distanceMetric.	km	String
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
extendedMode (consumer)	Used for enabling full text from twitter (eg receive tweets that contains more than 140 characters).	true	boolean

Name	Description	Default	Type
latitude (consumer)	Used by the non-stream geography search to search by latitude. You need to configure all the following options: longitude, latitude, radius, and distanceMetric.		Double
locations (consumer)	Bounding boxes, created by pairs of lat/lons. Can be used for streaming/filter. A pair is defined as lat,lon. And multiple paris can be separated by semi colon.		String
longitude (consumer)	Used by the non-stream geography search to search by longitude. You need to configure all the following options: longitude, latitude, radius, and distanceMetric.		Double
pollStrategy (consumer)	A pluggable <code>org.apache.camel.PollingConsumerPollingStrategy</code> allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		PollingConsumerPollStrategy
radius (consumer)	Used by the non-stream geography search to search by radius. You need to configure all the following options: longitude, latitude, radius, and distanceMetric.		Double
twitterStream (consumer)	To use a custom instance of <code>TwitterStream</code>		TwitterStream
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
count (filter)	Limiting number of results per page.	5	Integer
filterOld (filter)	Filter out old tweets, that has previously been polled. This state is stored in memory only, and based on last tweet id.	true	boolean
lang (filter)	The lang string ISO_639-1 which will be used for searching		String
numberOfPages (filter)	The number of pages result which you want camel-twitter to consume.	1	Integer

Name	Description	Default	Type
sinceId (filter)	The last tweet id which will be used for pulling the tweets. It is useful when the camel route is restarted after a long running.	1	long
userIds (filter)	To filter by user ids for streaming/filter. Multiple values can be separated by comma.		String
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.		int
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.		int
delay (scheduler)	Milliseconds before the next poll.	30000	long
greedy (scheduler)	If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	1000	long
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that.	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz2 component	none	ScheduledPollConsumer Scheduler

Name	Description	Default	Type
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz2, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for initialDelay and delay options.	MILLIS ECON DS	TimeUnit
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.	true	boolean
sortById (sort)	Sorts by id, so the oldest are first, and newest last.	true	boolean
httpProxyHost (proxy)	The http proxy host which can be used for the camel-twitter. Can also be configured on the TwitterComponent level instead.		String
httpProxyPassword (proxy)	The http proxy password which can be used for the camel-twitter. Can also be configured on the TwitterComponent level instead.		String
httpProxyPort (proxy)	The http proxy port which can be used for the camel-twitter. Can also be configured on the TwitterComponent level instead.		Integer
httpProxyUser (proxy)	The http proxy user which can be used for the camel-twitter. Can also be configured on the TwitterComponent level instead.		String
accessToken (security)	The access token. Can also be configured on the TwitterComponent level instead.		String
accessTokenSecret (security)	The access secret. Can also be configured on the TwitterComponent level instead.		String
consumerKey (security)	The consumer key. Can also be configured on the TwitterComponent level instead.		String
consumerSecret (security)	The consumer secret. Can also be configured on the TwitterComponent level instead.		String

355.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 10 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.twitter-timeline.access-token</code>	The access token		String
<code>camel.component.twitter-timeline.access-token-secret</code>	The access token secret		String
<code>camel.component.twitter-timeline.consumer-key</code>	The consumer key		String
<code>camel.component.twitter-timeline.consumer-secret</code>	The consumer secret		String
<code>camel.component.twitter-timeline.enabled</code>	Whether to enable auto configuration of the twitter-timeline component. This is enabled by default.		Boolean
<code>camel.component.twitter-timeline.http-proxy-host</code>	The http proxy host which can be used for the camel-twitter.		String
<code>camel.component.twitter-timeline.http-proxy-password</code>	The http proxy password which can be used for the camel-twitter.		String
<code>camel.component.twitter-timeline.http-proxy-port</code>	The http proxy port which can be used for the camel-twitter.		Integer
<code>camel.component.twitter-timeline.http-proxy-user</code>	The http proxy user which can be used for the camel-twitter.		String

Name	Description	Default	Type
<code>camel.component.twitter-timeline.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

CHAPTER 356. TWITTER COMPONENT (DEPRECATED)

Available as of Camel version 2.10

IMPORTANT

The composite twitter component has been deprecated. Use individual component for directmessage, search, streaming and timeline.

- [Twitter Components](#)
 - [Twitter Direct Message](#)
 - [Twitter Search](#)
 - [Twitter Streaming](#)
 - [Twitter Timeline](#)

The Twitter component enables the most useful features of the Twitter API by encapsulating [Twitter4J](#). It allows direct, polling, or event-driven consumption of timelines, users, trends, and direct messages. Also, it supports producing messages as status updates or direct messages.

Twitter now requires the use of OAuth for all client application authentication. In order to use camel-twitter with your account, you'll need to create a new application within Twitter at <https://dev.twitter.com/apps/new> and grant the application access to your account. Finally, generate your access token and secret.

Maven users will need to add the following dependency to their pom.xml for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-twitter</artifactId>
  <version>${camel-version}</version>
</dependency>
```

356.1. URI FORMAT

```
twitter://endpoint[?options]
```

356.2. TWITTER COMPONENT

The twitter component can be configured with the Twitter account settings which is mandatory to configure before using.

The Twitter component supports 9 options, which are listed below.

Name	Description	Default	Type
<code>accessToken</code> (security)	The access token	t	String

Name	Description	Default	Type
accessTokenSecret (security)	The access token secret		String
consumerKey (security)	The consumer key		String
consumerSecret (security)	The consumer secret		String
httpProxyHost (proxy)	The http proxy host which can be used for the camel-twitter.		String
httpProxyUser (proxy)	The http proxy user which can be used for the camel-twitter.		String
httpProxyPassword (proxy)	The http proxy password which can be used for the camel-twitter.		String
httpProxyPort (proxy)	The http proxy port which can be used for the camel-twitter.		int
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

You can also configure these options directly in the endpoint.

356.3. CONSUMER ENDPOINTS

Rather than the endpoints returning a List through one single route exchange, camel-twitter creates one route exchange per returned object. As an example, if "timeline/home" results in five statuses, the route will be executed five times (one for each Status).

Endpoint	Context	Body Type	Notice
directmessage	direct, polling	twitter 4j.DirectMessage	
search	direct, polling	twitter 4j.Status	

Endpoint	Context	Body Type	Notice
streaming/filter	event, polling	twitter 4j.Stat us	
streaming/sample	event, polling	twitter 4j.Stat us	
streaming/user	event, polling	twitter 4j.Stat us	Camel 2.16: To receive tweets from protected users and accounts.
timeline/home	direct, polling	twitter 4j.Stat us	
timeline/mentions	direct, polling	twitter 4j.Stat us	
timeline/public	direct, polling	twitter 4j.Stat us	@deprecated. Use timeline/home or direct/home instead. Removed from *Camel 2.11 onwards.*
timeline/retweets_of_me	direct, polling	twitter 4j.Stat us	
timeline/user	direct, polling	twitter 4j.Stat us	
trends/daily	*Camel 2.10.1: direct, polling*	twitter 4j.Stat us	@deprecated. Removed from Camel 2.11 onwards.
trends/weekly	*Camel 2.10.1: direct, polling*	twitter 4j.Stat us	@deprecated. Removed from Camel 2.11 onwards.

356.4. PRODUCER ENDPOINTS

Endpoint	Body Type
directmessage	String
search	List<twitter4j.Status>
timeline/user	String

356.5. URI OPTIONS

The Twitter endpoint is configured using URI syntax:

```
twitter:kind
```

with the following path and query parameters:

356.5.1. Path Parameters (1 parameters):

Name	Description	Default	Type
kind	Required The kind of endpoint	t	String

356.5.2. Query Parameters (44 parameters):

Name	Description	Default	Type
user (common)	Username, used for user timeline consumption, direct message production, etc.		String
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean
type (consumer)	Endpoint type to use. Only streaming supports event type.	polling	EndpointType

Name	Description	Default	Type
distanceMetric (consumer)	Used by the non-stream geography search, to search by radius using the configured metrics. The unit can either be mi for miles, or km for kilometers. You need to configure all the following options: longitude, latitude, radius, and distanceMetric.	km	String
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
extendedMode (consumer)	Used for enabling full text from twitter (eg receive tweets that contains more than 140 characters).	true	boolean
latitude (consumer)	Used by the non-stream geography search to search by latitude. You need to configure all the following options: longitude, latitude, radius, and distanceMetric.		Double
locations (consumer)	Bounding boxes, created by pairs of lat/lons. Can be used for streaming/filter. A pair is defined as lat,lon. And multiple paris can be separated by semi colon.		String
longitude (consumer)	Used by the non-stream geography search to search by longitude. You need to configure all the following options: longitude, latitude, radius, and distanceMetric.		Double
pollStrategy (consumer)	A pluggable org.apache.camel.PollingConsumerPollingStrategy allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		PollingConsumerPollStrategy
radius (consumer)	Used by the non-stream geography search to search by radius. You need to configure all the following options: longitude, latitude, radius, and distanceMetric.		Double
twitterStream (consumer)	To use a custom instance of TwitterStream		TwitterStream

Name	Description	Default	Type
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
count (filter)	Limiting number of results per page.	5	Integer
filterOld (filter)	Filter out old tweets, that has previously been polled. This state is stored in memory only, and based on last tweet id.	true	boolean
keywords (filter)	Can be used for search and streaming/filter. Multiple values can be separated with comma.		String
lang (filter)	The lang string ISO_639-1 which will be used for searching		String
numberOfPages (filter)	The number of pages result which you want camel-twitter to consume.	1	Integer
sinceId (filter)	The last tweet id which will be used for pulling the tweets. It is useful when the camel route is restarted after a long running.	1	long
userIds (filter)	To filter by user ids for streaming/filter. Multiple values can be separated by comma.		String
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.		int
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.		int
delay (scheduler)	Milliseconds before the next poll.	30000	long
greedy (scheduler)	If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.	false	boolean

Name	Description	Default	Type
initialDelay (scheduler)	Milliseconds before the first poll starts. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	1000	long
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that.	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz2 component	none	ScheduledPollConsumerScheduler
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz2, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for initialDelay and delay options.	MILLIS ECON DS	TimeUnit
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.	true	boolean
sortById (sort)	Sorts by id, so the oldest are first, and newest last.	true	boolean
httpProxyHost (proxy)	The http proxy host which can be used for the camel-twitter. Can also be configured on the TwitterComponent level instead.		String
httpProxyPassword (proxy)	The http proxy password which can be used for the camel-twitter. Can also be configured on the TwitterComponent level instead.		String
httpProxyPort (proxy)	The http proxy port which can be used for the camel-twitter. Can also be configured on the TwitterComponent level instead.		Integer

Name	Description	Default	Type
httpProxyUser (proxy)	The http proxy user which can be used for the camel-twitter. Can also be configured on the TwitterComponent level instead.		String
accessToken (security)	The access token. Can also be configured on the TwitterComponent level instead.		String
accessTokenSecret (security)	The access secret. Can also be configured on the TwitterComponent level instead.		String
consumerKey (security)	The consumer key. Can also be configured on the TwitterComponent level instead.		String
consumerSecret (security)	The consumer secret. Can also be configured on the TwitterComponent level instead.		String

356.6. SPRING BOOT AUTO-CONFIGURATION

The component supports 10 options, which are listed below.

Name	Description	Default	Type
camel.component.twitter.access-token	The access token		String
camel.component.twitter.access-token-secret	The access token secret		String
camel.component.twitter.consumer-key	The consumer key		String
camel.component.twitter.consumer-secret	The consumer secret		String
camel.component.twitter.enabled	Enable twitter component	true	Boolean
camel.component.twitter.http-proxy-host	The http proxy host which can be used for the camel-twitter.		String

Name	Description	Default	Type
<code>camel.component.twitter.http-proxy-password</code>	The http proxy password which can be used for the camel-twitter.		String
<code>camel.component.twitter.http-proxy-port</code>	The http proxy port which can be used for the camel-twitter.		Integer
<code>camel.component.twitter.http-proxy-user</code>	The http proxy user which can be used for the camel-twitter.		String
<code>camel.component.twitter.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

356.7. MESSAGE HEADERS

Name	Description
CamelTwitterKeywords	This header is used by the search producer to change the search key words dynamically.
CamelTwitterSearchLanguage	Camel 2.11.0: This header can override the option of lang which set the search language for the search endpoint dynamically
CamelTwitterCount	Camel 2.11.0 This header can override the option of count which sets the max twitters that will be returned.
CamelTwitterNumberOfPages	Camel 2.11.0 This header can override the option of numberOfPages which sets how many pages we want to twitter returns.

356.8. MESSAGE BODY

All message bodies utilize objects provided by the Twitter4J API.

356.9. USE CASES

NOTE

API Rate Limits: Twitter REST APIs encapsulated by [Twitter4J](#) are subjected to [API Rate Limiting](#). You can find the per method limits in the [API Rate Limits](#) documentation. Note that endpoints/resources not listed in that page are default to 15 requests per allotted user per window.

356.9.1. To create a status update within your Twitter profile, send this producer a String body:

```
from("direct:foo")
  .to("twitter://timeline/user?consumerKey=[s]&consumerSecret=[s]&accessToken=[s]&accessTokenSecret=[s]);
```

356.9.2. To poll, every 60 sec., all statuses on your home timeline:

```
from("twitter://timeline/home?type=polling&delay=60&consumerKey=[s]&consumerSecret=[s]&accessToken=[s]&accessTokenSecret=[s]")
  .to("bean:blah");
```

356.9.3. To search for all statuses with the keyword 'camel' only once:

```
from("twitter://search?type=polling&keywords=camel&consumerKey=[s]&consumerSecret=[s]&accessToken=[s]&accessTokenSecret=[s]")
  .to("bean:blah");
```

356.9.4. Searching using a producer with static keywords:

```
from("direct:foo")
  .to("twitter://search?keywords=camel&consumerKey=[s]&consumerSecret=[s]&accessToken=[s]&accessTokenSecret=[s]");
```

356.9.5. Searching using a producer with dynamic keywords from header:

In the **bar** header we have the keywords we want to search, so we can assign this value to the **CamelTwitterKeywords** header:

```
from("direct:foo")
  .setHeader("CamelTwitterKeywords", header("bar"))
  .to("twitter://search?consumerKey=[s]&consumerSecret=[s]&accessToken=[s]&accessTokenSecret=[s]");
```

356.10. EXAMPLE

CHAPTER 357. UNDERTOW COMPONENT

Available as of Camel version 2.16

The **undertow** component provides HTTP and WebSocket based endpoints for consuming and producing HTTP/WebSocket requests.

That is, the Undertow component behaves as a simple Web server. Undertow can also be used as a http client which mean you can also use it with Camel as a producer.

TIP

Since Camel version 2.21, the **undertow** component also supports WebSocket connections and can thus serve as a drop-in replacement for Camel websocket component or atmosphere-websocket component.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-undertow</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

357.1. URI FORMAT

```
undertow:http://hostname[:port]/resourceUri[?options]
undertow:https://hostname[:port]/resourceUri[?options]
undertow:ws://hostname[:port]/resourceUri[?options]
undertow:wss://hostname[:port]/resourceUri[?options]
```

You can append query options to the URI in the following format, **?option=value&option=value&...**

357.2. OPTIONS

The Undertow component supports 5 options which are listed below.

Name	Description	Default	Type
undertowHttpBinding (advanced)	To use a custom HttpBinding to control the mapping between Camel message and HttpClient.		UndertowHttpBinding
sslContextParameters (security)	To configure security using SSLContextParameters		SSLContextParameters
useGlobalSslContextParameters (security)	Enable usage of global SSL context parameters.	false	boolean

Name	Description	Default	Type
hostOptions (advanced)	To configure common options, such as thread pools		UndertowHostOptions
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Undertow endpoint is configured using URI syntax:

```
undertow:httpURI
```

with the following path and query parameters:

357.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
httpURI	Required The url of the HTTP endpoint to use.		URI

357.2.2. Query Parameters (21 parameters):

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
httpMethodRestrict (consumer)	Used to only allow consuming if the HttpMethod matches, such as GET/POST/PUT etc. Multiple methods can be specified separated by comma.		String
matchOnUriPrefix (consumer)	Whether or not the consumer should try to find a target consumer by matching the URI prefix if no exact match is found.	false	Boolean

Name	Description	Default	Type
optionsEnabled (consumer)	Specifies whether to enable HTTP OPTIONS for this Servlet consumer. By default OPTIONS is turned off.	false	boolean
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
cookieHandler (producer)	Configure a cookie handler to maintain a HTTP session		CookieHandler
keepAlive (producer)	Setting to ensure socket is not closed due to inactivity	true	Boolean
options (producer)	Sets additional channel options. The options that can be used are defined in org.xnio.Options. To configure from endpoint uri, then prefix each option with option., such as option.close-abort=true&option.send-buffer=8192		Map
reuseAddresses (producer)	Setting to facilitate socket multiplexing	true	Boolean
tcpNoDelay (producer)	Setting to improve TCP protocol performance	true	Boolean
throwExceptionOnFailure (producer)	Option to disable throwing the HttpOperationFailedException in case of failed responses from the remote server. This allows you to get all responses regardless of the HTTP status code.	true	Boolean
transferException (producer)	If enabled and an Exchange failed processing on the consumer side and if the caused Exception was send back serialized in the response as a application/x-java-serialized-object content type. On the producer side the exception will be deserialized and thrown as is instead of the HttpOperationFailedException. The caused exception is required to be serialized. This is by default turned off. If you enable this then be aware that Java will deserialize the incoming data from the request to Java and that can be a potential security risk.	false	Boolean

Name	Description	Default	Type
headerFilterStrategy (advanced)	To use a custom HeaderFilterStrategy to filter header to and from Camel message.		HeaderFilterStrategy
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
undertowHttpBinding (advanced)	To use a custom UndertowHttpBinding to control the mapping between Camel message and undertow.		UndertowHttpBinding
fireWebSocketChannelEvents (websocket)	if true, the consumer will post notifications to the route when a new WebSocket peer connects, disconnects, etc. See UndertowConstants.EVENT_TYPE and EventType.	false	boolean
sendTimeout (websocket)	Timeout in milliseconds when sending to a websocket channel. The default timeout is 30000 (30 seconds).	30000	Integer
sendToAll (websocket)	To send to all websocket subscribers. Can be used to configure on endpoint level, instead of having to use the UndertowConstants.SEND_TO_ALL header on the message.		Boolean
useStreaming (websocket)	if true, text and binary messages coming through a WebSocket will be wrapped as java.io.Reader and java.io.InputStream respectively before they are passed to an Exchange; otherwise they will be passed as String and byte respectively.	false	boolean
sslContextParameters (security)	To configure security using SSLContextParameters		SSLContextParameters

357.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 10 options, which are listed below.

Name	Description	Default	Type
camel.component.undertow.enabled	Enable undertow component	true	Boolean

Name	Description	Default	Type
<code>camel.component.undertow.host-options.buffer-size</code>	The buffer size of the Undertow host.		Integer
<code>camel.component.undertow.host-options.direct-buffers</code>	Set if the Undertow host should use direct buffers.		Boolean
<code>camel.component.undertow.host-options.http2-enabled</code>	Set if the Undertow host should use http2 protocol.		Boolean
<code>camel.component.undertow.host-options.io-threads</code>	The number of io threads to use in a Undertow host.		Integer
<code>camel.component.undertow.host-options.worker-threads</code>	The number of worker threads to use in a Undertow host.		Integer
<code>camel.component.undertow.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.component.undertow.ssl-context-parameters</code>	To configure security using <code>SSLContextParameters</code> . The option is a <code>org.apache.camel.util.jsse.SSLContextParameters</code> type.		String
<code>camel.component.undertow.undertow-http-binding</code>	To use a custom <code>HttpBinding</code> to control the mapping between Camel message and <code>HttpClient</code> . The option is a <code>org.apache.camel.component.undertow.UndertowHttpBinding</code> type.		String
<code>camel.component.undertow.use-global-ssl-context-parameters</code>	Enable usage of global SSL context parameters.	false	Boolean

357.4. MESSAGE HEADERS

Camel uses the same message headers as the [HTTP](#) component. From Camel 2.2, it also uses **Exchange.HTTP_CHUNKED**, **CamelHttpChunked** header to turn on or turn off the chunked encoding on the camel-undertow consumer.

Camel also populates **all** request.parameter and request.headers. For example, given a client request with the URL, <http://myserver/myserver?orderid=123>, the exchange will contain a header named **orderid** with the value 123.

357.5. HTTP PRODUCER EXAMPLE

The following is a basic example of how to send an HTTP request to an existing HTTP endpoint.

in Java DSL

```
from("direct:start")
  .to("undertow:http://www.google.com");
```

or in XML

```
<route>
  <from uri="direct:start"/>
  <to uri="undertow:http://www.google.com"/>
</route>
```

357.6. HTTP CONSUMER EXAMPLE

In this sample we define a route that exposes a HTTP service at <http://localhost:8080/myapp/myservice>:

```
<route>
  <from uri="undertow:http://localhost:8080/myapp/myservice"/>
  <to uri="bean:myBean"/>
</route>
```

357.7. WEBSOCKET EXAMPLE

In this sample we define a route that exposes a WebSocket service at <http://localhost:8080/myapp/mysocket> and returns back a response to the same channel:

```
<route>
  <from uri="undertow:ws://localhost:8080/myapp/mysocket"/>
  <transform><simple>Echo ${body}</simple></transform>
  <to uri="undertow:ws://localhost:8080/myapp/mysocket"/>
</route>
```

357.8. HTTP/2 EXAMPLE

In this sample, we configure the camel-undertow component to support the HTTP/2 protocol and expose a HTTP service at <http://localhost:7766/foo/bar>.

The directory structure of this sample is as follows:

-

The following files are important for configuring the camel-undertow component to support the HTTP/2 protocol:

1 pom.xml: Includes the following properties and dependencies:

```

<properties>
  <camel.version>2.23.1</camel.version>
</properties>

<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-core</artifactId>
  <version>${camel.version}</version>
</dependency>
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-spring</artifactId>
  <version>${camel.version}</version>
</dependency>
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-undertow</artifactId>
  <version>${camel.version}</version>
</dependency>
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-http-common</artifactId>
  <version>${camel.version}</version>
</dependency>

<plugin>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-maven-plugin</artifactId>
  <version>${camel.version}</version>
  <configuration>
    <fileApplicationContextUri>src/main/resources/META-INF/spring/camel-
context.xml</fileApplicationContextUri>
  </configuration>
</plugin>
  
```

2 camel-context.xml: Configures the camel-undertow component as follows:

```

<beans xmlns="http://www.springframework.org/schema/beans"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance" xsi:schemaLocation="
  http://www.springframework.org/schema/beans
  http://www.springframework.org/schema/beans/spring-beans.xsd
  
```

```

http://camel.apache.org/schema/spring http://camel.apache.org/schema/spring/camel-
spring.xsd">
  <camelContext id="cbr-example-context" xmlns="http://camel.apache.org/schema/spring">
    <route id="cbr-route" trace="true">
      <from id="_from1" uri="undertow:http://localhost:7766/foo/bar"/>
        <setBody id="_setBody1">
          <constant>Sending Response</constant>
        </setBody>
        <log id="_log5" message="Headers ${in.headers}"/>
        <log id="_log5" message="Done processing ${body}"/>
      </route>
    </camelContext>
    <bean class="org.apache.camel.component.undertow.UndertowComponent" id="undertow">
      <property name="hostOptions" ref="undertowHostOptions"/>
    </bean>
    <bean class="org.apache.camel.component.undertow.UndertowHostOptions"
id="undertowHostOptions">
      <property name="http2Enabled" value="true"/>
    </bean>
  </beans>

```

NOTE

The **http2Enabled** property which is set to **false** by default, is set to **true** for **UndertowHostOptions** class. This class is then referred to **UndertowComponent** which is used in camel route.

In this example, by using the **camel-maven-plugin** in the **pom.xml** file, we can expose a HTTP service at <http://localhost:7766/foo/bar> when we execute the Maven command **mvn camel:run**.

We can test this example using the curl command as follows:

```

$ curl -v --http2 http://localhost:7766/foo/bar
* Trying ::1...
* TCP_NODELAY set
* connect to ::1 port 7766 failed: Connection refused
* Trying 127.0.0.1...
* TCP_NODELAY set
* Connected to localhost (127.0.0.1) port 7766 (#0)
> GET /foo/bar HTTP/1.1
> Host: localhost:7766
> User-Agent: curl/7.53.1
> Accept: */*
> Connection: Upgrade, HTTP2-Settings
> Upgrade: h2c
> HTTP2-Settings: AAMAAABkAARAAAAAIAAAAA
>
< HTTP/1.1 101 Switching Protocols
< Connection: Upgrade
< Upgrade: h2c
< Date: Sun, 10 Dec 2017 08:43:58 GMT
* Received 101
* Using HTTP2, server supports multi-use
* Connection state changed (HTTP/2 confirmed)

```

```

* Copying HTTP/2 data in stream buffer to connection buffer after upgrade: len=0
* Connection state changed (MAX_CONCURRENT_STREAMS updated)!
< HTTP/2 200
< accept: */*
< http2-settings: AAMAAABkAARAAAAAIAAAAA
< breadcrumb: ID-dhcppc1-1512886066149-0-25
< content-length: 16
< user-agent: curl/7.53.1
< date: Sun, 10 Dec 2017 08:43:58 GMT
<
* Connection #0 to host localhost left intact
Sending Response

```

357.9. USING LOCALHOST AS HOST

When you specify **localhost** in a URL, Camel exposes the endpoint only on the local TCP/IP network interface, so it cannot be accessed from outside the machine it operates on.

If you need to expose a Jetty endpoint on a specific network interface, the numerical IP address of this interface should be used as the host. If you need to expose a Jetty endpoint on all network interfaces, the **0.0.0.0** address should be used.

To listen across an entire URI prefix, see [How do I let Jetty match wildcards](#) .

If you actually want to expose routes by HTTP and already have a Servlet, you should instead refer to the [Servlet Transport](#).

357.10. UNDERTOW CONSUMERS ON WILDFLY

The configuration of camel-undertow consumers on WildFly is different to that of standalone Camel. Producer endpoints work as per normal.

On WildFly, camel-undertow consumers leverage the default Undertow HTTP server provided by the container. The server is defined within the undertow subsystem configuration. Here's an excerpt of the default configuration from standalone.xml:

```

<subsystem xmlns="urn:jboss:domain:undertow:4.0">
  <buffer-cache name="default" />
  <server name="default-server">
    <http-listener name="default" socket-binding="http" redirect-socket="https" enable-http2="true" />
    <https-listener name="https" socket-binding="https" security-realm="ApplicationRealm" enable-
http2="true" />
    <host name="default-host" alias="localhost">
      <location name="/" handler="welcome-content" />
      <filter-ref name="server-header" />
      <filter-ref name="x-powered-by-header" />
      <http-invoker security-realm="ApplicationRealm" />
    </host>
  </server>
</subsystem>

```

In this instance, Undertow is configured to listen on interfaces / ports specified by the http and https socket-binding. By default this is port 8080 for http and 8443 for https.

This has the following implications:

- camel-undertow consumers will only bind to localhost:8080 or localhost:8443
- Some endpoint consumer configuration options have no effect (see below), since these settings are managed by the WildFly container

For example, if you configure an endpoint consumer using different host or port combinations, a warning will appear within the server log file. For example the following host & port configurations would be ignored:

```
from("undertow:http://somehost:1234/path/to/resource")
```

```
[org.wildfly.extension.camel] (pool-2-thread-1) Ignoring configured host:  
http://somehost:1234/path/to/resource
```

However, the consumer is still available on the default host & port localhost:8080 or localhost:8443.

357.10.1. Configuring alternative ports

If alternative ports are to be accepted, then these must be configured via the WildFly subsystem configuration. This is explained in the server documentation:

https://access.redhat.com/documentation/en-us/red_hat_jboss_enterprise_application_platform/7.1/html/configuration_guide/configuring_the_web_ser

357.10.2. Ignored camel-undertow consumer configuration options on WildFly

hostOptions

Refer to the WildFly undertow configuration guide for how to configure server host options:

https://access.redhat.com/documentation/en-us/red_hat_jboss_enterprise_application_platform/7.1/html-single/how_to_configure_server_security/#configure_one_way_and_two_way_ssl_tls_for_application

sslContextParameters

To configure SSL, refer to the WildFly SSL configuration guide:

https://access.redhat.com/documentation/en-us/red_hat_jboss_enterprise_application_platform/7.1/html-single/how_to_configure_server_security/#configure_one_way_and_two_way_ssl_tls_for_application

CHAPTER 358. UNIVOCITY CSV DATAFORMAT

Available as of Camel version 2.15

This [Data Format](#) uses [uniVocity-parsers](#) for reading and writing 3 kinds of tabular data text files:

- CSV (Comma Separated Values), where the values are separated by a symbol (usually a comma)
- fixed-width, where the values have known sizes
- TSV (Tabular Separated Values), where the fields are separated by a tabulation

Thus there are 3 data formats based on uniVocity-parsers.

If you use Maven you can just add the following to your pom.xml, substituting the version number for the latest and greatest release (see [the download page for the latest versions](#)).

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-univocity-parsers</artifactId>
  <version>x.x.x</version>
</dependency>
```

358.1. OPTIONS

Most configuration options of the uniVocity-parsers are available in the data formats. If you want more information about a particular option, please refer to their [documentation page](#).

The 3 data formats share common options and have dedicated ones, this section presents them all.

358.2. OPTIONS

The uniVocity CSV dataformat supports 18 options, which are listed below.

Name	Default	Java Type	Description
quoteAllFields	false	Boolean	Whether or not all values must be quoted when writing them.
quote	"	String	The quote symbol.
quoteEscape	"	String	The quote escape symbol
delimiter	,	String	The delimiter of values
nullValue		String	The string representation of a null value. The default value is null
skipEmptyLines	true	Boolean	Whether or not the empty lines must be ignored. The default value is true

Name	Default	Java Type	Description
ignoreTrailingWhitespaces	true	Boolean	Whether or not the trailing white spaces must be ignored. The default value is true
ignoreLeadingWhitespaces	true	Boolean	Whether or not the leading white spaces must be ignored. The default value is true
headersDisabled	false	Boolean	Whether or not the headers are disabled. When defined, this option explicitly sets the headers as null which indicates that there is no header. The default value is false
headerExtractionEnabled	false	Boolean	Whether or not the header must be read in the first line of the test document The default value is false
numberOfRecordsToRead		Integer	The maximum number of records to read.
emptyValue		String	The String representation of an empty value
lineSeparator		String	The line separator of the files The default value is to use the JVM platform line separator
normalizedLineSeparator		String	The normalized line separator of the files The default value is a new line character.
comment	#	String	The comment symbol. The default value is #
lazyLoad	false	Boolean	Whether the unmarshalling should produce an iterator that reads the lines on the fly or if all the lines must be read at one. The default value is false
asMap	false	Boolean	Whether the unmarshalling should produce maps for the lines values instead of lists. It requires to have header (either defined or collected). The default value is false
contentTypeHeader	false	Boolean	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON etc.

358.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 19 options, which are listed below.

Name	Description	Default	Type
<code>camel.dataformat.univocity-csv.as-map</code>	Whether the unmarshalling should produce maps for the lines values instead of lists. It requires to have header (either defined or collected). The default value is false	false	Boolean
<code>camel.dataformat.univocity-csv.comment</code>	The comment symbol. The default value is #	#	String
<code>camel.dataformat.univocity-csv.content-type-header</code>	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON etc.	false	Boolean
<code>camel.dataformat.univocity-csv.delimiter</code>	The delimiter of values	,	String
<code>camel.dataformat.univocity-csv.empty-value</code>	The String representation of an empty value		String
<code>camel.dataformat.univocity-csv.enabled</code>	Enable univocity-csv dataformat	true	Boolean
<code>camel.dataformat.univocity-csv.header-extraction-enabled</code>	Whether or not the header must be read in the first line of the test document The default value is false	false	Boolean
<code>camel.dataformat.univocity-csv.headers-disabled</code>	Whether or not the headers are disabled. When defined, this option explicitly sets the headers as null which indicates that there is no header. The default value is false	false	Boolean
<code>camel.dataformat.univocity-csv.ignore-leading-whitespaces</code>	Whether or not the leading white spaces must be ignored. The default value is true	true	Boolean

Name	Description	Default	Type
<code>camel.dataformat.univocity-csv.ignore-trailing-whitespaces</code>	Whether or not the trailing white spaces must ignored. The default value is true	true	Boolean
<code>camel.dataformat.univocity-csv.lazy-load</code>	Whether the unmarshalling should produce an iterator that reads the lines on the fly or if all the lines must be read at one. The default value is false	false	Boolean
<code>camel.dataformat.univocity-csv.line-separator</code>	The line separator of the files The default value is to use the JVM platform line separator		String
<code>camel.dataformat.univocity-csv.normalized-line-separator</code>	The normalized line separator of the files The default value is a new line character.		String
<code>camel.dataformat.univocity-csv.null-value</code>	The string representation of a null value. The default value is null		String
<code>camel.dataformat.univocity-csv.number-of-records-to-read</code>	The maximum number of record to read.		Integer
<code>camel.dataformat.univocity-csv.quote</code>	The quote symbol.	"	String
<code>camel.dataformat.univocity-csv.quote-all-fields</code>	Whether or not all values must be quoted when writing them.	false	Boolean
<code>camel.dataformat.univocity-csv.quote-escape</code>	The quote escape symbol	"	String
<code>camel.dataformat.univocity-csv.skip-empty-lines</code>	Whether or not the empty lines must be ignored. The default value is true	true	Boolean

358.4. MARSHALLING USAGES

The marshalling accepts either:

- A list of maps (`List<Map<String, ?>>`), one for each line
- A single map (`Map<String, ?>`), for a single line

Any other body will throws an exception.

358.4.1. Usage example: marshalling a Map into CSV format

```
<route>
  <from uri="direct:input"/>
  <marshal>
    <univocity-csv/>
  </marshal>
  <to uri="mock:result"/>
</route>
```

358.4.2. Usage example: marshalling a Map into fixed-width format

```
<route>
  <from uri="direct:input"/>
  <marshal>
    <univocity-fixed padding="_">
      <univocity-header length="5"/>
      <univocity-header length="5"/>
      <univocity-header length="5"/>
    </univocity-fixed>
  </marshal>
  <to uri="mock:result"/>
</route>
```

358.4.3. Usage example: marshalling a Map into TSV format

```
<route>
  <from uri="direct:input"/>
  <marshal>
    <univocity-tsv/>
  </marshal>
  <to uri="mock:result"/>
</route>
```

358.5. UNMARSHALLING USAGES

The unmarshalling uses an `InputStream` in order to read the data.

Each row produces either:

- a list with all the values in it (`asMap` option with `false`);
- A map with all the values indexed by the headers (`asMap` option with `true`).

All the rows can either:

- be collected at once into a list (**lazyLoad** option with **false**);
- be read on the fly using an iterator (**lazyLoad** option with **true**).

358.5.1. Usage example: unmarshalling a CSV format into maps with automatic headers

```
<route>
  <from uri="direct:input"/>
  <unmarshal>
    <univocity-csv headerExtractionEnabled="true" asMap="true"/>
  </unmarshal>
  <to uri="mock:result"/>
</route>
```

358.5.2. Usage example: unmarshalling a fixed-width format into lists

```
<route>
  <from uri="direct:input"/>
  <unmarshal>
    <univocity-fixed>
      <univocity-header length="5"/>
      <univocity-header length="5"/>
      <univocity-header length="5"/>
    </univocity-fixed>
  </unmarshal>
  <to uri="mock:result"/>
</route>
```

CHAPTER 359. UNIVOCITY FIXED LENGTH DATAFORMAT

Available as of Camel version 2.15

This [Data Format](#) uses [uniVocity-parsers](#) for reading and writing 3 kinds of tabular data text files:

- CSV (Comma Separated Values), where the values are separated by a symbol (usually a comma)
- fixed-width, where the values have known sizes
- TSV (Tabular Separated Values), where the fields are separated by a tabulation

Thus there are 3 data formats based on uniVocity-parsers.

If you use Maven you can just add the following to your pom.xml, substituting the version number for the latest and greatest release (see [the download page for the latest versions](#)).

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-univocity-parsers</artifactId>
  <version>x.x.x</version>
</dependency>
```

359.1. OPTIONS

Most configuration options of the uniVocity-parsers are available in the data formats. If you want more information about a particular option, please refer to their [documentation page](#).

The 3 data formats share common options and have dedicated ones, this section presents them all.

359.2. OPTIONS

The uniVocity Fixed Length dataformat supports 17 options, which are listed below.

Name	Default	Java Type	Description
skipTrailingChars UntilNewline	false	Boolean	Whether or not the trailing characters until new line must be ignored. The default value is false
recordEndsOnNewline	false	Boolean	Whether or not the record ends on new line. The default value is false
padding		String	The padding character. The default value is a space
nullValue		String	The string representation of a null value. The default value is null
skipEmptyLines	true	Boolean	Whether or not the empty lines must be ignored. The default value is true

Name	Default	Java Type	Description
ignoreTrailingWhitespaces	true	Boolean	Whether or not the trailing white spaces must be ignored. The default value is true
ignoreLeadingWhitespaces	true	Boolean	Whether or not the leading white spaces must be ignored. The default value is true
headersDisabled	false	Boolean	Whether or not the headers are disabled. When defined, this option explicitly sets the headers as null which indicates that there is no header. The default value is false
headerExtractionEnabled	false	Boolean	Whether or not the header must be read in the first line of the test document The default value is false
numberOfRecordsToRead		Integer	The maximum number of records to read.
emptyValue		String	The String representation of an empty value
lineSeparator		String	The line separator of the files The default value is to use the JVM platform line separator
normalizedLineSeparator		String	The normalized line separator of the files The default value is a new line character.
comment	#	String	The comment symbol. The default value is #
lazyLoad	false	Boolean	Whether the unmarshalling should produce an iterator that reads the lines on the fly or if all the lines must be read at one. The default value is false
asMap	false	Boolean	Whether the unmarshalling should produce maps for the lines values instead of lists. It requires to have header (either defined or collected). The default value is false
contentTypeHeader	false	Boolean	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON etc.

359.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 18 options, which are listed below.

Name	Description	Default	Type
<code>camel.dataformat.univocity-fixed.as-map</code>	Whether the unmarshalling should produce maps for the lines values instead of lists. It requires to have header (either defined or collected). The default value is false	false	Boolean
<code>camel.dataformat.univocity-fixed.comment</code>	The comment symbol. The default value is #	#	String
<code>camel.dataformat.univocity-fixed.content-type-header</code>	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON etc.	false	Boolean
<code>camel.dataformat.univocity-fixed.empty-value</code>	The String representation of an empty value		String
<code>camel.dataformat.univocity-fixed.enabled</code>	Enable univocity-fixed dataformat	true	Boolean
<code>camel.dataformat.univocity-fixed.header-extraction-enabled</code>	Whether or not the header must be read in the first line of the test document The default value is false	false	Boolean
<code>camel.dataformat.univocity-fixed.headers-disabled</code>	Whether or not the headers are disabled. When defined, this option explicitly sets the headers as null which indicates that there is no header. The default value is false	false	Boolean
<code>camel.dataformat.univocity-fixed.ignore-leading-whitespaces</code>	Whether or not the leading white spaces must be ignored. The default value is true	true	Boolean
<code>camel.dataformat.univocity-fixed.ignore-trailing-whitespaces</code>	Whether or not the trailing white spaces must be ignored. The default value is true	true	Boolean

Name	Description	Default	Type
<code>camel.dataformat.univocity-fixed.lazy-load</code>	Whether the unmarshalling should produce an iterator that reads the lines on the fly or if all the lines must be read at one. The default value is false	false	Boolean
<code>camel.dataformat.univocity-fixed.line-separator</code>	The line separator of the files The default value is to use the JVM platform line separator		String
<code>camel.dataformat.univocity-fixed.normalized-line-separator</code>	The normalized line separator of the files The default value is a new line character.		String
<code>camel.dataformat.univocity-fixed.null-value</code>	The string representation of a null value. The default value is null		String
<code>camel.dataformat.univocity-fixed.number-of-records-to-read</code>	The maximum number of record to read.		Integer
<code>camel.dataformat.univocity-fixed.padding</code>	The padding character. The default value is a space		String
<code>camel.dataformat.univocity-fixed.record-ends-on-newline</code>	Whether or not the record ends on new line. The default value is false	false	Boolean
<code>camel.dataformat.univocity-fixed.skip-empty-lines</code>	Whether or not the empty lines must be ignored. The default value is true	true	Boolean
<code>camel.dataformat.univocity-fixed.skip-trailing-chars-until-newline</code>	Whether or not the trailing characters until new line must be ignored. The default value is false	false	Boolean

359.4. MARSHALLING USAGES

The marshalling accepts either:

- A list of maps (L`ist<Map<String, ?>>`), one for each line
- A single map (**Map<String, ?>**), for a single line

Any other body will throws an exception.

359.4.1. Usage example: marshalling a Map into CSV format

```
<route>
  <from uri="direct:input"/>
  <marshal>
    <univocity-csv/>
  </marshal>
  <to uri="mock:result"/>
</route>
```

359.4.2. Usage example: marshalling a Map into fixed-width format

```
<route>
  <from uri="direct:input"/>
  <marshal>
    <univocity-fixed padding="_">
      <univocity-header length="5"/>
      <univocity-header length="5"/>
      <univocity-header length="5"/>
    </univocity-fixed>
  </marshal>
  <to uri="mock:result"/>
</route>
```

359.4.3. Usage example: marshalling a Map into TSV format

```
<route>
  <from uri="direct:input"/>
  <marshal>
    <univocity-tsv/>
  </marshal>
  <to uri="mock:result"/>
</route>
```

359.5. UNMARSHALLING USAGES

The unmarshalling uses an **InputStream** in order to read the data.

Each row produces either:

- a list with all the values in it (**asMap** option with **false**);
- A map with all the values indexed by the headers (**asMap** option with **true**).

All the rows can either:

- be collected at once into a list (**lazyLoad** option with **false**);

- be read on the fly using an iterator (**lazyLoad** option with **true**).

359.5.1. Usage example: unmarshalling a CSV format into maps with automatic headers

```
<route>
  <from uri="direct:input"/>
  <unmarshal>
    <univocity-csv headerExtractionEnabled="true" asMap="true"/>
  </unmarshal>
  <to uri="mock:result"/>
</route>
```

359.5.2. Usage example: unmarshalling a fixed-width format into lists

```
<route>
  <from uri="direct:input"/>
  <unmarshal>
    <univocity-fixed>
      <univocity-header length="5"/>
      <univocity-header length="5"/>
      <univocity-header length="5"/>
    </univocity-fixed>
  </unmarshal>
  <to uri="mock:result"/>
</route>
```

CHAPTER 360. UNIVOCITY TSV DATAFORMAT

Available as of Camel version 2.15

This [Data Format](#) uses [uniVocity-parsers](#) for reading and writing 3 kinds of tabular data text files:

- CSV (Comma Separated Values), where the values are separated by a symbol (usually a comma)
- fixed-width, where the values have known sizes
- TSV (Tabular Separated Values), where the fields are separated by a tabulation

Thus there are 3 data formats based on uniVocity-parsers.

If you use Maven you can just add the following to your pom.xml, substituting the version number for the latest and greatest release (see [the download page for the latest versions](#)).

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-univocity-parsers</artifactId>
  <version>x.x.x</version>
</dependency>
```

360.1. OPTIONS

Most configuration options of the uniVocity-parsers are available in the data formats. If you want more information about a particular option, please refer to their [documentation page](#).

The 3 data formats share common options and have dedicated ones, this section presents them all.

360.2. OPTIONS

The uniVocity TSV dataformat supports 15 options, which are listed below.

Name	Default	Java Type	Description
escapeChar	\	String	The escape character.
nullValue		String	The string representation of a null value. The default value is null
skipEmptyLines	true	Boolean	Whether or not the empty lines must be ignored. The default value is true
ignoreTrailingWhitespaces	true	Boolean	Whether or not the trailing white spaces must be ignored. The default value is true
ignoreLeadingWhitespaces	true	Boolean	Whether or not the leading white spaces must be ignored. The default value is true

Name	Default	Java Type	Description
headersDisabled	false	Boolean	Whether or not the headers are disabled. When defined, this option explicitly sets the headers as null which indicates that there is no header. The default value is false
headerExtractionEnabled	false	Boolean	Whether or not the header must be read in the first line of the test document The default value is false
numberOfRecordsToRead		Integer	The maximum number of record to read.
emptyValue		String	The String representation of an empty value
lineSeparator		String	The line separator of the files The default value is to use the JVM platform line separator
normalizedLineSeparator		String	The normalized line separator of the files The default value is a new line character.
comment	#	String	The comment symbol. The default value is #
lazyLoad	false	Boolean	Whether the unmarshalling should produce an iterator that reads the lines on the fly or if all the lines must be read at one. The default value is false
asMap	false	Boolean	Whether the unmarshalling should produce maps for the lines values instead of lists. It requires to have header (either defined or collected). The default value is false
contentTypeHeader	false	Boolean	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSON etc.

360.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 16 options, which are listed below.

Name	Description	Default	Type
<code>camel.dataformat.univocity-tsv.as-map</code>	Whether the unmarshalling should produce maps for the lines values instead of lists. It requires to have header (either defined or collected). The default value is false	false	Boolean
<code>camel.dataformat.univocity-tsv.comment</code>	The comment symbol. The default value is #	#	String
<code>camel.dataformat.univocity-tsv.content-type-header</code>	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSon etc.	false	Boolean
<code>camel.dataformat.univocity-tsv.empty-value</code>	The String representation of an empty value		String
<code>camel.dataformat.univocity-tsv.enabled</code>	Enable univocity-tsv dataformat	true	Boolean
<code>camel.dataformat.univocity-tsv.escape-char</code>	The escape character.	\	String
<code>camel.dataformat.univocity-tsv.header-extraction-enabled</code>	Whether or not the header must be read in the first line of the test document The default value is false	false	Boolean
<code>camel.dataformat.univocity-tsv.headers-disabled</code>	Whether or not the headers are disabled. When defined, this option explicitly sets the headers as null which indicates that there is no header. The default value is false	false	Boolean
<code>camel.dataformat.univocity-tsv.ignore-leading-whitespaces</code>	Whether or not the leading white spaces must be ignored. The default value is true	true	Boolean

Name	Description	Default	Type
<code>camel.dataformat.univocity-tsv.ignore-trailing-whitespaces</code>	Whether or not the trailing white spaces must be ignored. The default value is true	true	Boolean
<code>camel.dataformat.univocity-tsv.lazy-load</code>	Whether the unmarshalling should produce an iterator that reads the lines on the fly or if all the lines must be read at once. The default value is false	false	Boolean
<code>camel.dataformat.univocity-tsv.line-separator</code>	The line separator of the files The default value is to use the JVM platform line separator		String
<code>camel.dataformat.univocity-tsv.normalized-line-separator</code>	The normalized line separator of the files The default value is a new line character.		String
<code>camel.dataformat.univocity-tsv.null-value</code>	The string representation of a null value. The default value is null		String
<code>camel.dataformat.univocity-tsv.number-of-records-to-read</code>	The maximum number of record to read.		Integer
<code>camel.dataformat.univocity-tsv.skip-empty-lines</code>	Whether or not the empty lines must be ignored. The default value is true	true	Boolean

360.4. MARSHALLING USAGES

The marshalling accepts either:

- A list of maps (`List<Map<String, ?>>`), one for each line
- A single map (`Map<String, ?>`), for a single line

Any other body will throw an exception.

360.4.1. Usage example: marshalling a Map into CSV format

```
<route>
  <from uri="direct:input"/>
```

```

<marshal>
  <univocity-csv/>
</marshal>
<to uri="mock:result"/>
</route>

```

360.4.2. Usage example: marshalling a Map into fixed-width format

```

<route>
  <from uri="direct:input"/>
  <marshal>
    <univocity-fixed padding="_ ">
      <univocity-header length="5"/>
      <univocity-header length="5"/>
      <univocity-header length="5"/>
    </univocity-fixed>
  </marshal>
  <to uri="mock:result"/>
</route>

```

360.4.3. Usage example: marshalling a Map into TSV format

```

<route>
  <from uri="direct:input"/>
  <marshal>
    <univocity-tsv/>
  </marshal>
  <to uri="mock:result"/>
</route>

```

360.5. UNMARSHALLING USAGES

The unmarshalling uses an **InputStream** in order to read the data.

Each row produces either:

- a list with all the values in it (**asMap** option with **false**);
- A map with all the values indexed by the headers (**asMap** option with **true**).

All the rows can either:

- be collected at once into a list (**lazyLoad** option with **false**);
- be read on the fly using an iterator (**lazyLoad** option with **true**).

360.5.1. Usage example: unmarshalling a CSV format into maps with automatic headers

```

<route>
  <from uri="direct:input"/>
  <unmarshal>
    <univocity-csv headerExtractionEnabled="true" asMap="true"/>

```

```
</unmarshal>  
<to uri="mock:result"/>  
</route>
```

360.5.2. Usage example: unmarshalling a fixed-width format into lists

```
<route>  
  <from uri="direct:input"/>  
  <unmarshal>  
    <univocity-fixed>  
      <univocity-header length="5"/>  
      <univocity-header length="5"/>  
      <univocity-header length="5"/>  
    </univocity-fixed>  
  </unmarshal>  
  <to uri="mock:result"/>  
</route>
```

CHAPTER 361. VALIDATOR COMPONENT

Available as of Camel version 1.1

The Validation component performs XML validation of the message body using the JAXP Validation API and based on any of the supported XML schema languages, which defaults to [XML Schema](#)

Note that the [Jing](#) component also supports the following useful schema languages:

- [RelaxNG Compact Syntax](#)
- [RelaxNG XML Syntax](#)

The [MSV](#) component also supports [RelaxNG XML Syntax](#).

361.1. URI FORMAT

```
validator:someLocalOrRemoteResource
```

Where **someLocalOrRemoteResource** is some URL to a local resource on the classpath or a full URL to a remote resource or resource on the file system which contains the XSD to validate against. For example:

- **msv:org/foo/bar.xsd**
- **msv:file:../foo/bar.xsd**
- **msv:http://acme.com/cheese.xsd**
- **validator:com/mypackage/myschema.xsd**

Maven users will need to add the following dependency to their **pom.xml** for this component when using **Camel 2.8** or older:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-spring</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

From Camel 2.9 onwards the Validation component is provided directly in the camel-core.

361.2. OPTIONS

The Validator component supports 2 options, which are listed below.

Name	Description	Default	Type
resourceResolverFactory (advanced)	To use a custom LSResourceResolver which depends on a dynamic endpoint resource URI		ValidatorResourceResolverFactory

Name	Description	Default	Type
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Validator endpoint is configured using URI syntax:

```
validator:resourceUri
```

with the following path and query parameters:

361.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
resourceUri	Required URL to a local resource on the classpath, or a reference to lookup a bean in the Registry, or a full URL to a remote resource or resource on the file system which contains the XSD to validate against.		String

361.2.2. Query Parameters (11 parameters):

Name	Description	Default	Type
failOnNullBody (producer)	Whether to fail if no body exists.	true	boolean
failOnNullHeader (producer)	Whether to fail if no header exists when validating against a header.	true	boolean
headerName (producer)	To validate against a header instead of the message body.		String
errorHandler (advanced)	To use a custom <code>org.apache.camel.processor.validation.ValidatorErrorHandler</code> . The default error handler captures the errors and throws an exception.		ValidatorErrorHandler
resourceResolver (advanced)	To use a custom <code>LSResourceResolver</code> . See also <code>setResourceResolverFactory(ValidatorResourceResolverFactory)</code>		LSResourceResolver

Name	Description	Default	Type
resourceResolverFactory (advanced)	For creating a resource resolver which depends on the endpoint resource URI. Must not be used in combination with method <code>setResourceResolver(LSResourceResolver)</code> . If not set then <code>DefaultValidatorResourceResolverFactory</code> is used		ValidatorResourceResolverFactory
schemaFactory (advanced)	To use a custom <code>javax.xml.validation.SchemaFactory</code>		SchemaFactory
schemaLanguage (advanced)	Configures the W3C XML Schema Namespace URI.	http://www.w3.org/2001/XMLSchema	String
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
useDom (advanced)	Whether <code>DOMSource/DOMResult</code> or <code>SaxSource/SaxResult</code> should be used by the validator.	false	boolean
useSharedSchema (advanced)	Whether the Schema instance should be shared or not. This option is introduced to work around a JDK 1.6.x bug. Xerces should not have this issue.	true	boolean

361.3. EXAMPLE

The following [example](#) shows how to configure a route from endpoint `direct:start` which then goes to one of two endpoints, either `mock:valid` or `mock:invalid` based on whether or not the XML matches the given schema (which is supplied on the classpath).

361.4. ADVANCED: JMX METHOD CLEARCACHEDSCHEMA

Since **Camel 2.17**, you can force that the cached schema in the validator endpoint is cleared and reread with the next process call with the JMX operation `clearCachedSchema`. **You can also use this method to programmatically clear the cache. This method is available on the `ValidatorEndpoint`class`.`**

CHAPTER 362. VELOCITY COMPONENT

Available as of Camel version 1.2

The **velocity**: component allows you to process a message using an [Apache Velocity](#) template. This can be ideal when using Templating to generate responses for requests.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-velocity</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

362.1. URI FORMAT

```
velocity:templateName[?options]
```

Where **templateName** is the classpath-local URI of the template to invoke; or the complete URL of the remote template (eg: [file://folder/myfile.vm](#)).

You can append query options to the URI in the following format, **?option=value&option=value&...**

362.2. OPTIONS

The Velocity component supports 4 options, which are listed below.

Name	Description	Default	Type
allowContextMapAll (producer)	Sets whether the context map should allow access to all details. By default only the message body and headers can be accessed. This option can be enabled for full access to the current Exchange and CamelContext. Doing so imposes a potential security risk as this opens access to the full power of CamelContext API.	false	boolean
allowTemplateFromHeader (producer)	Whether to allow to use resource template from header or not (default false). Enabling this option has security ramifications. For example, if the header contains untrusted or user derived content, this can ultimately impact on the confidentiality and integrity of your end application, so use this option with caution.	false	boolean

Name	Description	Default	Type
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean
velocityEngine (advanced)	To use the VelocityEngine otherwise a new engine is created		VelocityEngine

The Velocity endpoint is configured using URI syntax:

```
velocity:resourceUri
```

with the following path and query parameters:

362.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
resourceUri	Required Path to the resource. You can prefix with: classpath, file, http, ref, or bean. classpath, file and http loads the resource using these protocols (classpath is default). ref will lookup the resource in the registry. bean will call a method on a bean to be used as the resource. For bean you can specify the method name after dot, eg bean:myBean.myMethod.		String

362.2.2. Query Parameters (7 parameters):

Name	Description	Default	Type
allowContextMapAll (producer)	Sets whether the context map should allow access to all details. By default only the message body and headers can be accessed. This option can be enabled for full access to the current Exchange and CamelContext. Doing so imposes a potential security risk as this opens access to the full power of CamelContext API.	false	boolean

Name	Description	Default	Type
allowTemplateFromHeader (producer)	Whether to allow to use resource template from header or not (default false). Enabling this option has security ramifications. For example, if the header contains untrusted or user derived content, this can ultimately impact on the confidentiality and integrity of your end application, so use this option with caution.	false	boolean
contentCache (producer)	Sets whether to use resource content cache or not	false	boolean
encoding (producer)	Character encoding of the resource content.		String
loaderCache (producer)	Enables / disables the velocity resource loader cache which is enabled by default	true	boolean
propertiesFile (producer)	The URI of the properties file which is used for VelocityEngine initialization.		String
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

362.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 3 options, which are listed below.

Name	Description	Default	Type
camel.component.velocity.enabled	Enable velocity component	true	Boolean
camel.component.velocity.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
camel.component.velocity.velocity-engine	To use the VelocityEngine otherwise a new engine is created. The option is a org.apache.velocity.app.VelocityEngine type.		String

362.4. MESSAGE HEADERS

The velocity component sets a couple headers on the message (you can't set these yourself and from Camel 2.1 velocity component will not set these headers which will cause some side effect on the dynamic template support):

Header	Description
Camel VelocityResourceUri	The <code>templateName</code> as a String object.
Camel VelocitySupplementalContext	Camel 2.16: To add additional information to the used <code>VelocityContext</code> . The value of this header should be a Map with key/values that will added (override any existing key with the same name). This can be used to pre setup some common key/values you want to reuse in your velocity endpoints.

Headers set during the Velocity evaluation are returned to the message and added as headers. Then its kinda possible to return values from Velocity to the Message.

For example, to set the header value of **fruit** in the Velocity template `.tm`:

```
$in.setHeader("fruit", "Apple")
```

The **fruit** header is now accessible from the `message.out.headers`.

362.5. VELOCITY CONTEXT

Camel will provide exchange information in the Velocity context (just a **Map**). The **Exchange** is transferred as:

key	value
exchange	The Exchange itself.
exchange.properties	The Exchange properties.
headers	The headers of the In message.
camelContext	The Camel Context instance.

key	value
request	The In message.
in	The In message.
body	The In message body.
out	The Out message (only for InOut message exchange pattern).
response	The Out message (only for InOut message exchange pattern).

Since Camel-2.14, you can setup a custom Velocity Context yourself by setting the message header `*CamelVelocityContext` just like this

```
VelocityContext velocityContext = new VelocityContext(variableMap);
exchange.getIn().setHeader("CamelVelocityContext", velocityContext);
```

362.6. HOT RELOADING

The Velocity template resource is, by default, hot reloadable for both file and classpath resources (expanded jar). If you set **contentCache=true**, Camel will only load the resource once, and thus hot reloading is not possible. This scenario can be used in production, when the resource never changes.

362.7. DYNAMIC TEMPLATES

Available as of Camel 2.1

Camel provides two headers by which you can define a different resource location for a template or the template content itself. If any of these headers is set then Camel uses this over the endpoint configured resource. This allows you to provide a dynamic template at runtime.

Header	Type	Description
Camel VelocityResourceUri	String	Camel 2.1: A URI for the template resource to use instead of the endpoint configured.
Camel VelocityTemplate	String	Camel 2.1: The template to use instead of the endpoint configured.

362.8. SAMPLES

For example you could use something like

```
from("activemq:My.Queue").
to("velocity:com/acme/MyResponse.vm");
```

To use a Velocity template to formulate a response to a message for InOut message exchanges (where there is a **JMSReplyTo** header).

If you want to use InOnly and consume the message and send it to another destination, you could use the following route:

```
from("activemq:My.Queue").
to("velocity:com/acme/MyResponse.vm").
to("activemq:Another.Queue");
```

And to use the content cache, e.g. for use in production, where the **.vm** template never changes:

```
from("activemq:My.Queue").
to("velocity:com/acme/MyResponse.vm?contentCache=true").
to("activemq:Another.Queue");
```

And a file based resource:

```
from("activemq:My.Queue").
to("velocity:file://myfolder/MyResponse.vm?contentCache=true").
to("activemq:Another.Queue");
```

In **Camel 2.1** it's possible to specify what template the component should use dynamically via a header, so for example:

```
from("direct:in").
setHeader("CamelVelocityResourceUri").constant("path/to/my/template.vm").
to("velocity:dummy?allowTemplateFromHeader=true");
```

In **Camel 2.1** it's possible to specify a template directly as a header the component should use dynamically via a header, so for example:

```
from("direct:in").
setHeader("CamelVelocityTemplate").constant("Hi this is a velocity template that can do templating
${body}").
to("velocity:dummy?allowTemplateFromHeader=true");
```

WARNING

Enabling the **allowTemplateFromHeader** option has security ramifications. For example, if the header contains untrusted or user derived content, this can ultimately impact on the confidentiality and integrity of your end application, so use this option with caution.

362.9. THE EMAIL SAMPLE

In this sample we want to use Velocity templating for an order confirmation email. The email template is laid out in Velocity as:

```
Dear ${headers.lastName}, ${headers.firstName}
```

```
Thanks for the order of ${headers.item}.
```

```
Regards Camel Riders Bookstore  
${body}
```

And the java code:

- [Getting Started](#)

CHAPTER 363. VERT.X COMPONENT

Available as of Camel version 2.12

The **vertx** component is for working with the [VertxEventBus](#).

The vertx [EventBus](#) sends and receives JSON events.

INFO:From **Camel 2.16** onwards vertx 3 is in use which requires Java 1.8 at runtime.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-vertx</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

363.1. URI FORMAT

```
vertx:channelName[?options]
```

363.2. OPTIONS

The Vert.x component supports 7 options, which are listed below.

Name	Description	Default	Type
vertxFactory (advanced)	To use a custom VertxFactory implementation		VertxFactory
host (common)	Hostname for creating an embedded clustered EventBus		String
port (common)	Port for creating an embedded clustered EventBus		int
vertxOptions (common)	Options to use for creating vertx		VertxOptions
vertx (common)	To use the given vertx EventBus instead of creating a new embedded EventBus		Vertx
timeout (common)	Timeout in seconds to wait for clustered Vertx EventBus to be ready. The default value is 60.	60	int

Name	Description	Default	Type
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Vert.x endpoint is configured using URI syntax:

```
vertx:address
```

with the following path and query parameters:

363.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
address	Required Sets the event bus address used to communicate		String

363.2.2. Query Parameters (5 parameters):

Name	Description	Default	Type
pubSub (common)	Whether to use publish/subscribe instead of point to point when sending to a vertx endpoint.		Boolean
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer)	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern

Name	Description	Default	Type
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

363.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 8 options, which are listed below.

Name	Description	Default	Type
camel.component.vertx.enabled	Enable vertx component	true	Boolean
camel.component.vertx.host	Hostname for creating an embedded clustered EventBus		String
camel.component.vertx.port	Port for creating an embedded clustered EventBus		Integer
camel.component.vertx.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
camel.component.vertx.timeout	Timeout in seconds to wait for clustered Vertx EventBus to be ready. The default value is 60.	60	Integer
camel.component.vertx.vertx	To use the given vertx EventBus instead of creating a new embedded EventBus. The option is a <code>io.vertx.core.Vertx</code> type.		String
camel.component.vertx.vertx-factory	To use a custom VertxFactory implementation. The option is a <code>io.vertx.core.spi.VertxFactory</code> type.		String
camel.component.vertx.vertx-options	Options to use for creating vertx. The option is a <code>io.vertx.core.VertxOptions</code> type.		String

Camel 2.12.3: Whether to use publish/subscribe instead of point to point when sending to a vertx endpoint.

You can append query options to the URI in the following format, `?option=value&option=value&...`

363.4. CONNECTING TO THE EXISTING VERT.X INSTANCE

If you would like to connect to the Vert.x instance already existing in your JVM, you can set the instance on the component level:

```
Vertex vertex = ...;
VertexComponent vertexComponent = new VertexComponent();
vertexComponent.setVertex(vertex);
camelContext.addComponent("vertex", vertexComponent);
```

363.5. SEE ALSO

- [Configuring Camel](#)
- [Component](#)
- [Endpoint](#)
- [Getting Started](#)

CHAPTER 364. VM COMPONENT

Available as of Camel version 1.1

The **vm**: component provides asynchronous [SEDA](#) behavior, exchanging messages on a [BlockingQueue](#) and invoking consumers in a separate thread pool.

This component differs from the [Seda](#) component in that VM supports communication across CamelContext instances - so you can use this mechanism to communicate across web applications (provided that **camel-core.jar** is on the **system/boot** classpath).

VM is an extension to the [Seda](#) component.

364.1. URI FORMAT

```
vm:queueName[?options]
```

Where **queueName** can be any string to uniquely identify the endpoint within the JVM (or at least within the classloader that loaded camel-core.jar)

You can append query options to the URI in the following format: **?option=value&option=value&...**

An exactly identical **VM** endpoint URI **must** be used for both the producer and the consumer endpoint. Otherwise, Camel will create a second **VM** endpoint despite that the **queueName** portion of the URI is identical. For example:

```
from("direct:foo").to("vm:bar?concurrentConsumers=5");
from("vm:bar?concurrentConsumers=5").to("file://output");
```

Notice that we have to use the full URI, including options in both the producer and consumer.

In Camel 2.4 this has been fixed so that only the queue name must match. Using the queue name **bar**, we could rewrite the previous example as follows:

```
from("direct:foo").to("vm:bar");
from("vm:bar?concurrentConsumers=5").to("file://output");
```

364.2. OPTIONS

The VM component supports 6 options, which are listed below.

Name	Description	Default	Type
queueSize (advanced)	Sets the default maximum capacity of the SEDA queue (i.e., the number of messages it can hold).	1000	int
concurrentConsumers (consumer)	Sets the default number of concurrent threads processing exchanges.	1	int

Name	Description	Default	Type
defaultQueueFactory (advanced)	Sets the default queue factory.		BlockingQueueFactory
defaultBlockWhenFull (producer)	Whether a thread that sends messages to a full SEDA queue will block until the queue's capacity is no longer exhausted. By default, an exception will be thrown stating that the queue is full. By enabling this option, the calling thread will instead block and wait until the message can be accepted.	false	boolean
defaultOfferTimeout (producer)	Whether a thread that sends messages to a full SEDA queue will block until the queue's capacity is no longer exhausted. By default, an exception will be thrown stating that the queue is full. By enabling this option, where a configured timeout can be added to the block case. Utilizing the <code>.offer(timeout)</code> method of the underlining java queue		long
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The VM endpoint is configured using URI syntax:

```
vm:name
```

with the following path and query parameters:

364.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
name	Required Name of queue		String

364.2.2. Query Parameters (17 parameters):

Name	Description	Default	Type
size (common)	The maximum capacity of the SEDA queue (i.e., the number of messages it can hold). Will by default use the <code>defaultSize</code> set on the SEDA component.	1000	int

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN/ERROR level and ignored.	false	boolean
concurrentConsumers (consumer)	Number of concurrent threads processing exchanges.	1	int
exceptionHandler (consumer)	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this options is not in use. By default the consumer will deal with exceptions, that will be logged at WARN/ERROR level and ignored.		<code>ExceptionHandler</code>
exchangePattern (consumer)	Sets the default exchange pattern when creating an exchange.		<code>ExchangePattern</code>
limitConcurrentConsumers (consumer)	Whether to limit the number of <code>concurrentConsumers</code> to the maximum of 500. By default, an exception will be thrown if an endpoint is configured with a greater number. You can disable that check by turning this option off.	true	boolean
multipleConsumers (consumer)	Specifies whether multiple consumers are allowed. If enabled, you can use SEDA for Publish-Subscribe messaging. That is, you can send a message to the SEDA queue and have each consumer receive a copy of the message. When enabled, this option should be specified on every consumer endpoint.	false	boolean
pollTimeout (consumer)	The timeout used when polling. When a timeout occurs, the consumer can check whether it is allowed to continue running. Setting a lower value allows the consumer to react more quickly upon shutdown.	1000	int
purgeWhenStopping (consumer)	Whether to purge the task queue when stopping the consumer/route. This allows to stop faster, as any pending messages on the queue is discarded.	false	boolean

Name	Description	Default	Type
blockWhenFull (producer)	Whether a thread that sends messages to a full SEDA queue will block until the queue's capacity is no longer exhausted. By default, an exception will be thrown stating that the queue is full. By enabling this option, the calling thread will instead block and wait until the message can be accepted.	false	boolean
discardIfNoConsumers (producer)	Whether the producer should discard the message (do not add the message to the queue), when sending to a queue with no active consumers. Only one of the options <code>discardIfNoConsumers</code> and <code>failIfNoConsumers</code> can be enabled at the same time.	false	boolean
failIfNoConsumers (producer)	Whether the producer should fail by throwing an exception, when sending to a queue with no active consumers. Only one of the options <code>discardIfNoConsumers</code> and <code>failIfNoConsumers</code> can be enabled at the same time.	false	boolean
offerTimeout (producer)	<code>offerTimeout</code> (in milliseconds) can be added to the block case when queue is full. You can disable timeout by using 0 or a negative value.		long
timeout (producer)	Timeout (in milliseconds) before a SEDA producer will stop waiting for an asynchronous task to complete. You can disable timeout by using 0 or a negative value.	30000	long
waitForTaskToComplete (producer)	Option to specify whether the caller should wait for the async task to complete or not before continuing. The following three options are supported: <code>Always</code> , <code>Never</code> or <code>IfReplyExpected</code> . The first two values are self-explanatory. The last value, <code>IfReplyExpected</code> , will only wait if the message is Request Reply based. The default option is <code>IfReplyExpected</code> .	IfReplyExpected	WaitForTaskToComplete
queue (advanced)	Define the queue instance which will be used by the endpoint. This option is only for rare use-cases where you want to use a custom queue instance.		BlockingQueue
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

See the [Seda](#) component for options and other important usage details as the same rules apply to the [Vm](#) component.

364.3. SAMPLES

In the route below we send exchanges across CamelContext instances to a VM queue named **order.email**:

```
from("direct:in").bean(MyOrderBean.class).to("vm:order.email");
```

And then we receive exchanges in some other Camel context (such as deployed in another **.war** application):

```
from("vm:order.email").bean(MyOrderEmailSender.class);
```

364.4. SEE ALSO

- [Seda](#)

CHAPTER 365. WEATHER COMPONENT

Available as of Camel version 2.12

The **weather:** component is used for polling weather information from [Open Weather Map](#) - a site that provides free global weather and forecast information. The information is returned as a json String object.

Camel will poll for updates to the current weather and forecasts once per hour by default. It can also be used to query the weather api based on the parameters defined on the endpoint which is used as producer.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-weather</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

365.1. URI FORMAT

```
weather://<unused name>[?options]
```

365.2. REMARK

Since the 9th of October, an Api Key is required to access the openweather service. This key is passed as parameter to the URI definition of the weather endpoint using the appid param !

365.3. GEOLOCATION PROVIDER

Since July 2018 FreegeoIP is no longer available. The camel-weather component was using this API. We switch to [IPstack](#) so you'll need to specify an Access Key and the IP from where you're using the API now on.

365.4. OPTIONS

The Weather component supports 3 options, which are listed below.

Name	Description	Default	Type
geolocationAccessKey (common)	The geolocation service now needs an accessKey to be used		String
geolocationRequestHostIP (common)	The geolocation service now needs to specify the IP associated to the accessKey you're using		String

Name	Description	Default	Type
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Weather endpoint is configured using URI syntax:

```
weather:name
```

with the following path and query parameters:

365.4.1. Path Parameters (1 parameters):

Name	Description	Default	Type
name	Required The name value is not used.		String

365.4.2. Query Parameters (45 parameters):

Name	Description	Default	Type
appid (common)	Required APPID ID used to authenticate the user connected to the API Server		String
headerName (common)	To store the weather result in this header instead of the message body. This is useable if you want to keep current message body as-is.		String
language (common)	Language of the response.	en	WeatherLanguage
mode (common)	The output format of the weather data.	JSON	WeatherMode
period (common)	If null, the current weather will be returned, else use values of 5, 7, 14 days. Only the numeric value for the forecast period is actually parsed, so spelling, capitalisation of the time period is up to you (its ignored)		String
units (common)	The units for temperature measurement.		WeatherUnits

Name	Description	Default	Type
weatherApi (common)	The API to be use (current, forecast/3 hour, forecast daily, station)		WeatherApi
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean
exceptionHandler (consumer)	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
pollStrategy (consumer)	A pluggable <code>org.apache.camel.PollingConsumerPollingStrategy</code> allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		PollingConsumerPollStrategy
httpClientManager (advanced)	To use a custom <code>HttpClientManager</code> to manage connections		HttpClientManager
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the <code>backoffMultiplier</code> should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the <code>backoffMultiplier</code> should kick-in.		int

Name	Description	Default	Type
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then <code>backoffIdleThreshold</code> and/or <code>backoffErrorThreshold</code> must also be configured.		int
delay (scheduler)	Milliseconds before the next poll. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	500	long
greedy (scheduler)	If greedy is enabled, then the <code>ScheduledPollConsumer</code> will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	1000	long
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that.	TRACE	LogLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz2 component	none	ScheduledPollConsumer Scheduler
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz2, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for <code>initialDelay</code> and <code>delay</code> options.	MILLIS ECON DS	TimeUnit
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See <code>ScheduledExecutorService</code> in JDK for details.	true	boolean

Name	Description	Default	Type
cnt (filter)	Number of results to be found		Integer
ids (filter)	List of id's of city/stations. You can separate multiple ids by comma.		String
lat (filter)	Latitude of location. You can use lat and lon options instead of location. For boxed queries this is the bottom latitude.		String
location (filter)	If null Camel will try and determine your current location using the geolocation of your ip address, else specify the city,country. For well known city names, Open Weather Map will determine the best fit, but multiple results may be returned. Hence specifying and country as well will return more accurate data. If you specify current as the location then the component will try to get the current latitude and longitude and use that to get the weather details. You can use lat and lon options instead of location.		String
lon (filter)	Longitude of location. You can use lat and lon options instead of location. For boxed queries this is the left longitude.		String
rightLon (filter)	For boxed queries this is the right longitude. Needs to be used in combination with topLat and zoom.		String
topLat (filter)	For boxed queries this is the top latitude. Needs to be used in combination with rightLon and zoom.		String
zip (filter)	Zip-code, e.g. 94040,us		String
zoom (filter)	For boxed queries this is the zoom. Needs to be used in combination with rightLon and topLat.		Integer
proxyAuthDomain (proxy)	Domain for proxy NTLM authentication		String
proxyAuthHost (proxy)	Optional host for proxy NTLM authentication		String
proxyAuthMethod (proxy)	Authentication method for proxy, either as Basic, Digest or NTLM.		String
proxyAuthPassword (proxy)	Password for proxy authentication		String

Name	Description	Default	Type
<code>proxyAuthUsername</code> (proxy)	Username for proxy authentication		String
<code>proxyHost</code> (proxy)	The proxy host name		String
<code>proxyPort</code> (proxy)	The proxy port number		Integer
<code>geolocationAccessKey</code> (security)	Required The geolocation service now needs an <code>accessKey</code> to be used		String
<code>geolocationRequestHostIP</code> (security)	Required The geolocation service now needs to specify the IP associated to the <code>accessKey</code> you're using		String

365.5. SPRING BOOT AUTO-CONFIGURATION

The component supports 4 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.weather.enabled</code>	Enable weather component	true	Boolean
<code>camel.component.weather.geolocation-access-key</code>	The geolocation service now needs an <code>accessKey</code> to be used		String
<code>camel.component.weather.geolocation-request-host-ip</code>	The geolocation service now needs to specify the IP associated to the <code>accessKey</code> you're using		String
<code>camel.component.weather.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

You can append query options to the URI in the following format, **?option=value&option=value&...**

365.6. EXCHANGE DATA FORMAT

Camel will deliver the body as a json formatted `java.lang.String` (see the **mode** option above).

365.7. MESSAGE HEADERS

Header	Description
CamelWeatherQuery	The original query URL sent to the Open Weather Map site
CamelWeatherLocation	Used by the producer to override the endpoint location and use the location from this header instead.

365.8. SAMPLES

In this sample we find the 7 day weather forecast for Madrid, Spain:

```
from("weather:foo?location=Madrid,Spain&period=7
days&appid=APIKEY&geolocationAccessKey=IPSTACK_ACCESS_KEY&geolocationRequestHostIP=LOCAL_IP").to("jms:queue:weather");
```

To just find the current weather for your current location you can use this:

```
from("weather:foo?
appid=APIKEY&geolocationAccessKey=IPSTACK_ACCESS_KEY&geolocationRequestHostIP=LOCAL_IP").to("jms:queue:weather");
```

And to find the weather using the producer we do:

```
from("direct:start")
.to("weather:foo?
location=Madrid,Spain&appid=APIKEY&geolocationAccessKey=IPSTACK_ACCESS_KEY&geolocationRequestHostIP=LOCAL_IP");
```

And we can send in a message with a header to get the weather for any location as shown:

```
String json = template.requestBodyAndHeader("direct:start", "", "CamelWeatherLocation",
"Paris,France&appid=APIKEY", String.class);
```

And to get the weather at the current location, then:

```
String json = template.requestBodyAndHeader("direct:start", "", "CamelWeatherLocation",
"current&appid=APIKEY", String.class);
```

CHAPTER 366. WEB3J ETHEREUM BLOCKCHAIN COMPONENT

Available as of Camel version 2.22

The **Ethereum** blockchain component uses the [web3j](#) client API and allows you to interact with Ethereum compatible nodes such as [Geth](#), [Parity](#), [Quorum](#), [Infura](#), etc.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-web3j</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

366.1. URI FORMAT

```
web3j://<local/remote host:port or local IPC path>[?options]
```

366.2. WEB3J OPTIONS

The Web3j Ethereum Blockchain component supports 2 options, which are listed below.

Name	Description	Default	Type
configuration (common)	Default configuration		Web3jConfigurati on
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Web3j Ethereum Blockchain endpoint is configured using URI syntax:

```
web3j:nodeAddress
```

with the following path and query parameters:

366.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
------	-------------	---------	------

Name	Description	Default	Type
nodeAddress	Required Sets the node address used to communicate		String

366.2.2. Query Parameters (38 parameters):

Name	Description	Default	Type
addresses (common)	Contract address or a list of addresses.		List
fromAddress (common)	The address the transaction is send from		String
fromBlock (common)	The block number, or the string latest for the last mined block or pending, earliest for not yet mined transactions.	latest	DefaultBlockParameter
fullTransactionObjects (common)	If true it returns the full transaction objects, if false only the hashes of the transactions.	false	boolean
gasLimit (common)	The maximum gas allowed in this block.		BigInteger
privateFor (common)	A transaction privateFor nodes with public keys in a Quorum network		List
quorumAPI (common)	If true, this will support Quorum API.	false	boolean
toAddress (common)	The address the transaction is directed to.		String
toBlock (common)	The block number, or the string latest for the last mined block or pending, earliest for not yet mined transactions.	latest	DefaultBlockParameter
topics (common)	Topics are order-dependent. Each topic can also be a list of topics. Specify multiple topics separated by comma.		String
web3j (common)	The preconfigured Web3j object.		Web3j

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
address (producer)	Contract address.		String
atBlock (producer)	The block number, or the string latest for the last mined block or pending, earliest for not yet mined transactions.	latest	DefaultBlockParameter
blockHash (producer)	Hash of the block where this transaction was in.		String
clientId (producer)	A random hexadecimal(32 bytes) ID identifying the client.		String
data (producer)	The compiled code of a contract OR the hash of the invoked method signature and encoded parameters.		String
databaseName (producer)	The local database name.		String
filterId (producer)	The filter id to use.		BigInteger
gasPrice (producer)	Gas price used for each paid gas.		BigInteger
hashrate (producer)	A hexadecimal string representation (32 bytes) of the hash rate.		String

Name	Description	Default	Type
headerPowHash (producer)	The header's pow-hash (256 bits) used for submitting a proof-of-work solution.		String
index (producer)	The transactions/uncle index position in the block.		BigInteger
keyName (producer)	The key name in the database.		String
mixDigest (producer)	The mix digest (256 bits) used for submitting a proof-of-work solution.		String
nonce (producer)	The nonce found (64 bits) used for submitting a proof-of-work solution.		String
operation (producer)	Operation to use.	transaction	String
position (producer)	The transaction index position withing a block.		BigInteger
priority (producer)	The priority of a whisper message.		BigInteger
sha3HashOfData ToSign (producer)	Message to sign by calculating an Ethereum specific signature.		String
signedTransactionData (producer)	The signed transaction data for a new message call transaction or a contract creation for signed transactions.		String
sourceCode (producer)	The source code to compile.		String
transactionHash (producer)	The information about a transaction requested by transaction hash.		String
ttl (producer)	The time to live in seconds of a whisper message.		BigInteger
value (producer)	The value sent within a transaction.		BigInteger
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

366.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 33 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.web3j.configuration.address</code>	Contract address.		String
<code>camel.component.web3j.configuration.addresses</code>	Contract address or a list of addresses.		List
<code>camel.component.web3j.configuration.block-hash</code>	Hash of the block where this transaction was in.		String
<code>camel.component.web3j.configuration.client-id</code>	A random hexadecimal(32 bytes) ID identifying the client.		String
<code>camel.component.web3j.configuration.data</code>	The compiled code of a contract OR the hash of the invoked method signature and encoded parameters.		String
<code>camel.component.web3j.configuration.database-name</code>	The local database name.		String
<code>camel.component.web3j.configuration.filter-id</code>	The filter id to use.		BigInteger
<code>camel.component.web3j.configuration.from-address</code>	The address the transaction is send from		String
<code>camel.component.web3j.configuration.full-transaction-objects</code>	If true it returns the full transaction objects, if false only the hashes of the transactions.	false	Boolean
<code>camel.component.web3j.configuration.gas-limit</code>	The maximum gas allowed in this block.		BigInteger
<code>camel.component.web3j.configuration.gas-price</code>	Gas price used for each paid gas.		BigInteger

Name	Description	Default	Type
<code>camel.component.web3j.configuration.hashrate</code>	A hexadecimal string representation (32 bytes) of the hash rate.		String
<code>camel.component.web3j.configuration.header-pow-hash</code>	The header's pow-hash (256 bits) used for submitting a proof-of-work solution.		String
<code>camel.component.web3j.configuration.index</code>	The transactions/uncle index position in the block.		BigInteger
<code>camel.component.web3j.configuration.key-name</code>	The key name in the database.		String
<code>camel.component.web3j.configuration.mix-digest</code>	The mix digest (256 bits) used for submitting a proof-of-work solution.		String
<code>camel.component.web3j.configuration.nonce</code>	The nonce found (64 bits) used for submitting a proof-of-work solution.		String
<code>camel.component.web3j.configuration.operation</code>	Operation to use.	transaction	String
<code>camel.component.web3j.configuration.position</code>	The transaction index position withing a block.		BigInteger
<code>camel.component.web3j.configuration.priority</code>	The priority of a whisper message.		BigInteger
<code>camel.component.web3j.configuration.private-for</code>	A transaction privateFor nodes with public keys in a Quorum network		List
<code>camel.component.web3j.configuration.quorum-a-p-i</code>	If true, this will support Quorum API.	false	Boolean

Name	Description	Default	Type
<code>camel.component.web3j.configuration.sha3-hash-of-data-to-sign</code>	Message to sign by calculating an Ethereum specific signature.		String
<code>camel.component.web3j.configuration.signed-transaction-data</code>	The signed transaction data for a new message call transaction or a contract creation for signed transactions.		String
<code>camel.component.web3j.configuration.source-code</code>	The source code to compile.		String
<code>camel.component.web3j.configuration.to-address</code>	The address the transaction is directed to.		String
<code>camel.component.web3j.configuration.topics</code>	Topics are order-dependent. Each topic can also be a list of topics. Specify multiple topics separated by comma.		List
<code>camel.component.web3j.configuration.transaction-hash</code>	The information about a transaction requested by transaction hash.		String
<code>camel.component.web3j.configuration.ttl</code>	The time to live in seconds of a whisper message.		BigInteger
<code>camel.component.web3j.configuration.value</code>	The value sent within a transaction.		BigInteger
<code>camel.component.web3j.configuration.web3j</code>	The preconfigured Web3j object.		Web3j
<code>camel.component.web3j.enabled</code>	Enable web3j component	true	Boolean
<code>camel.component.web3j.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

You can append query options to the URI in the following format, `?options=value&option2=value&...`

366.4. MESSAGE HEADERS

Header	Description
All URI options	All URI options can also be set as exchange headers.

366.5. SAMPLES

Listen for new mined blocks and send the block hash to a jms queue:

```
from("web3j://http://127.0.0.1:7545?operation=ETH_BLOCK_HASH_OBSERVABLE")
.to("jms:queue:blocks");
```

Use the block hash code to retrieve the block and full transaction details:

```
from("jms:queue:blocks")
.setHeader(BLOCK_HASH, body())
.to("web3j://http://127.0.0.1:7545?
operation=ETH_GET_BLOCK_BY_HASH&fullTransactionObjects=true");
```

Read the balance of an address at a specific block number:

```
from("direct:start")
.to("web3j://http://127.0.0.1:7545?
operation=ETH_GET_BALANCE&address=0xc8CDceCE5d006dAB638029EBCf6Dd666efF5A952&atBlock=10");
```

CHAPTER 367. JETTY WEBSOCKET COMPONENT

Available as of Camel version 2.10

The **websocket** component provides websocket endpoints for communicating with clients using websocket. The component uses Eclipse Jetty Server which implements the [IETF](#) specification (drafts and RFC 6455). It supports the protocols `ws://` and `wss://`. To use `wss://` protocol, the `SSLContextParameters` must be defined.

Version currently supported

Camel 2.18 uses Jetty 9

367.1. URI FORMAT

```
websocket://hostname[:port][/resourceUri][?options]
```

You can append query options to the URI in the following format, **?option=value&option=value&...**

367.2. WEBSOCKET OPTIONS

The Jetty Websocket component supports 14 options, which are listed below.

Name	Description	Default	Type
staticResources (consumer)	Set a resource path for static resources (such as .html files etc). The resources can be loaded from classpath, if you prefix with <code>classpath:</code> , otherwise the resources is loaded from file system or from JAR files. For example to load from root classpath use <code>classpath:.</code> , or <code>classpath:WEB-INF/static</code> If not configured (eg null) then no static resource is in use.		String
host (common)	The hostname. The default value is 0.0.0.0	0.0.0.0	String
port (common)	The port number. The default value is 9292	9292	Integer
sslKeyPassword (security)	The password for the keystore when using SSL.		String
sslPassword (security)	The password when using SSL.		String
sslKeystore (security)	The path to the keystore.		String
enableJmx (advanced)	If this option is true, Jetty JMX support will be enabled for this endpoint. See Jetty JMX support for more details.	false	boolean

Name	Description	Default	Type
minThreads (advanced)	To set a value for minimum number of threads in server thread pool. MaxThreads/minThreads or threadPool fields are required due to switch to Jetty9. The default values for minThreads is 1.		Integer
maxThreads (advanced)	To set a value for maximum number of threads in server thread pool. MaxThreads/minThreads or threadPool fields are required due to switch to Jetty9. The default values for maxThreads is 12 noCores.		Integer
threadPool (advanced)	To use a custom thread pool for the server. MaxThreads/minThreads or threadPool fields are required due to switch to Jetty9.		ThreadPool
sslContextParameters (security)	To configure security using SSLContextParameters		SSLContextParameters
useGlobalSslContextParameters (security)	Enable usage of global SSL context parameters.	false	boolean
socketFactory (common)	To configure a map which contains custom WebSocketFactory for sub protocols. The key in the map is the sub protocol. The default key is reserved for the default implementation.		Map
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Jetty WebSocket endpoint is configured using URI syntax:

```
websocket:host:port/resourceUri
```

with the following path and query parameters:

367.2.1. Path Parameters (3 parameters):

Name	Description	Default	Type
host	The hostname. The default value is 0.0.0.0. Setting this option on the component will use the component configured value as default.	0.0.0.0	String

Name	Description	Default	Type
port	The port number. The default value is 9292. Setting this option on the component will use the component configured value as default.	9292	Integer
resourceUri	Required Name of the websocket channel to use		String

367.2.2. Query Parameters (18 parameters):

Name	Description	Default	Type
maxBinaryMessageSize (common)	Can be used to set the size in bytes that the websocket created by the websocketServlet may be accept before closing. (Default is -1 - or unlimited)	-1	Integer
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
sessionSupport (consumer)	Whether to enable session support which enables HttpSession for each http request.	false	boolean
staticResources (consumer)	Set a resource path for static resources (such as .html files etc). The resources can be loaded from classpath, if you prefix with classpath:, otherwise the resources is loaded from file system or from JAR files. For example to load from root classpath use classpath:., or classpath:WEB-INF/static If not configured (eg null) then no static resource is in use.		String
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
sendTimeout (producer)	Timeout in millis when sending to a websocket channel. The default timeout is 30000 (30 seconds).	30000	Integer

Name	Description	Default	Type
sendToAll (producer)	To send to all websocket subscribers. Can be used to configure on endpoint level, instead of having to use the <code>WebSocketConstants.SEND_TO_ALL</code> header on the message.		Boolean
bufferSize (advanced)	Set the buffer size of the <code>websocketServlet</code> , which is also the max frame byte size (default 8192)	8192	Integer
maxIdleTime (advanced)	Set the time in ms that the websocket created by the <code>websocketServlet</code> may be idle before closing. (default is 300000)	300000	Integer
maxTextMessageSize (advanced)	Can be used to set the size in characters that the websocket created by the <code>websocketServlet</code> may be accept before closing.		Integer
minVersion (advanced)	Can be used to set the minimum protocol version accepted for the <code>websocketServlet</code> . (Default 13 - the RFC6455 version)	13	Integer
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
allowedOrigins (cors)	The CORS allowed origins. Use to allow all.		String
crossOriginFilterOn (cors)	Whether to enable CORS	false	boolean
filterPath (cors)	Context path for filtering CORS		String
enableJmx (monitoring)	If this option is true, Jetty JMX support will be enabled for this endpoint. See Jetty JMX support for more details.	false	boolean
sslContextParameters (security)	To configure security using <code>SSLContextParameters</code>		<code>SSLContextParameters</code>

367.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 15 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.websocket.enable-jmx</code>	If this option is true, Jetty JMX support will be enabled for this endpoint. See Jetty JMX support for more details.	false	Boolean
<code>camel.component.websocket.enabled</code>	Enable websocket component	true	Boolean
<code>camel.component.websocket.host</code>	The hostname. The default value is 0.0.0.0	0.0.0.0	String
<code>camel.component.websocket.max-threads</code>	To set a value for maximum number of threads in server thread pool. MaxThreads/minThreads or threadPool fields are required due to switch to Jetty9. The default values for maxThreads is 12 noCores.		Integer
<code>camel.component.websocket.min-threads</code>	To set a value for minimum number of threads in server thread pool. MaxThreads/minThreads or threadPool fields are required due to switch to Jetty9. The default values for minThreads is 1.		Integer
<code>camel.component.websocket.port</code>	The port number. The default value is 9292	9292	Integer
<code>camel.component.websocket.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.component.websocket.socket-factory</code>	To configure a map which contains custom WebSocketFactory for sub protocols. The key in the map is the sub protocol. The default key is reserved for the default implementation.		Map
<code>camel.component.websocket.ssl-context-parameters</code>	To configure security using SSLContextParameters. The option is a <code>org.apache.camel.util.jsse.SSLContextParameters</code> type.		String
<code>camel.component.websocket.ssl-key-password</code>	The password for the keystore when using SSL.		String
<code>camel.component.websocket.ssl-keystore</code>	The path to the keystore.		String

Name	Description	Default	Type
<code>camel.component.websocket.ssl-password</code>	The password when using SSL.		String
<code>camel.component.websocket.static-resources</code>	Set a resource path for static resources (such as .html files etc). The resources can be loaded from classpath, if you prefix with classpath:, otherwise the resources is loaded from file system or from JAR files. For example to load from root classpath use classpath:., or classpath:WEB-INF/static If not configured (eg null) then no static resource is in use.		String
<code>camel.component.websocket.thread-pool</code>	To use a custom thread pool for the server. MaxThreads/minThreads or threadPool fields are required due to switch to Jetty9. The option is a org.eclipse.jetty.util.thread.ThreadPool type.		String
<code>camel.component.websocket.use-global-ssl-context-parameters</code>	Enable usage of global SSL context parameters.	false	Boolean

367.4. MESSAGE HEADERS

The websocket component uses 2 headers to indicate to either send messages back to a single/current client, or to all clients.

Websocket Constants.END_TO_ALL	Sends the message to all clients which are currently connected. You can use the <code>sendToAll</code> option on the endpoint instead of using this header.
Websocket Constants.CONNECTION_KEY	Sends the message to the client with the given connection key.

Webs ocket Const ants.S END_ TO_A LL	Sends the message to all clients which are currently connected. You can use the <code>sendToAll</code> option on the endpoint instead of using this header.
Webs ocket Const ants.R EMOT E_AD DRES S	Remote address of the websocket session.

367.5. USAGE

In this example we let Camel exposes a websocket server which clients can communicate with. The websocket server uses the default host and port, which would be **0.0.0.0:9292**.

The example will send back an echo of the input. To send back a message, we need to send the transformed message to the same endpoint "**websocket://echo**". This is needed because by default the messaging is InOnly.

This example is part of an unit test, which you can find [here](#). As a client we use the [AHC](#) library which offers support for web socket as well.

Here is another example where webapp resources location have been defined to allow the Jetty Application Server to not only register the WebSocket servlet but also to expose web resources for the browser. Resources should be defined under the webapp directory.

```
from("activemq:topic:newsTopic")
  .routeId("fromJMStoWebSocket")
  .to("websocket://localhost:8443/newsTopic?sendToAll=true&staticResources=classpath:webapp");
```

367.6. SETTING UP SSL FOR WEBSOCKET COMPONENT

367.6.1. Using the JSSE Configuration Utility

As of Camel 2.10, the WebSocket component supports SSL/TLS configuration through the [Camel JSSE Configuration Utility](#). This utility greatly decreases the amount of component specific code you need to write and is configurable at the endpoint and component levels. The following examples demonstrate how to use the utility with the Cometd component.

Programmatic configuration of the component

```
KeyStoreParameters ksp = new KeyStoreParameters();
ksp.setResource("/users/home/server/keystore.jks");
ksp.setPassword("keystorePassword");
```

```

KeyManagersParameters kmp = new KeyManagersParameters();
kmp.setKeyStore(ksp);
kmp.setKeyPassword("keyPassword");

TrustManagersParameters tmp = new TrustManagersParameters();
tmp.setKeyStore(ksp);

SSLContextParameters scp = new SSLContextParameters();
scp.setKeyManagers(kmp);
scp.setTrustManagers(tmp);

CometdComponent cometdComponent = getContext().getComponent("cometds",
CometdComponent.class);
cometdComponent.setSslContextParameters(scp);

```

Spring DSL based configuration of endpoint

```

...
<camel:sslContextParameters
  id="sslContextParameters">
  <camel:keyManagers
    keyPassword="keyPassword">
    <camel:keyStore
      resource="/users/home/server/keystore.jks"
      password="keystorePassword"/>
    </camel:keyManagers>
  <camel:trustManagers>
    <camel:keyStore
      resource="/users/home/server/keystore.jks"
      password="keystorePassword"/>
    </camel:trustManagers>
  </camel:sslContextParameters>...
...
<to uri="websocket://127.0.0.1:8443/test?sslContextParameters=#sslContextParameters"/>...

```

Java DSL based configuration of endpoint

```

...
protected RouteBuilder createRouteBuilder() throws Exception {
  return new RouteBuilder() {
    public void configure() {

      String uri = "websocket://127.0.0.1:8443/test?
sslContextParameters=#sslContextParameters";

      from(uri)
        .log(">>> Message received from WebSocket Client : ${body}")
        .to("mock:client")
        .loop(10)
          .setBody().constant(">>> Welcome on board!")
          .to(uri);
    }
  };
}
...

```

CHAPTER 368. WEKA COMPONENT

Since Camel 3.1

Only producer is supported

The Weka component provides access to the [\(Weka Data Mining\)](#) toolset.

Weka is tried and tested open source machine learning software that can be accessed through a graphical user interface, standard terminal applications, or a Java API. It is widely used for teaching, research, and industrial applications, contains a plethora of built-in tools for standard machine learning tasks, and additionally gives transparent access to well-known toolboxes such as scikit-learn, R, and Deeplearning4j.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-weka</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

368.1. URI FORMAT

```
weka://cmd
```

368.2. OPTIONS

The Weka component supports 2 options, which are listed below.

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
basicPropertyBinding (advanced)	Whether the component should use basic property binding (Camel 2.x) or the newer property binding with additional capabilities	false	boolean

The Weka endpoint is configured using URI syntax:

weka:command

with the following path and query parameters:

368.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
command	Required The command to use. The value can be one of: filter, model, read, write, push, pop, version	t	Command

368.2.2. Query Parameters (12 parameters):

Name	Description	Default	Type
lazyStartProducer (producer)	Whether the producer should be started lazy (on the first message). By starting lazy you can use this to allow CamelContext and routes to startup in situations where a producer may otherwise fail during starting and cause the route to fail being started. By deferring this startup to be lazy then the startup failure can be handled during routing messages via Camel's routing error handlers. Beware that when the first message is processed then creating and starting the producer may take a little time and prolong the total processing time of the processing.	false	boolean
basicPropertyBinding (advanced)	Whether the endpoint should use basic property binding (Camel 2.x) or the newer property binding with additional capabilities	false	boolean
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
apply (filter)	The filter spec (i.e. Name Options)		String
build (model)	The classifier spec (i.e. Name Options)		String
dsname (model)	The named dataset to train the classifier with		String
folds (model)	Number of folds to use for cross-validation	10	int
loadFrom (model)	Path to load the model from		String
saveTo (model)	Path to save the model to		String

Name	Description	Default	Type
seed (model)	An optional seed for the randomizer	1	int
xval (model)	Flag on whether to use cross-validation with the current dataset	false	boolean
path (write)	An in/out path for the read/write commands		String

368.3. KARAF SUPPORT

This component is not supported in Karaf

368.4. MESSAGE HEADERS

368.5. SAMPLES

368.5.1. Read + Filter + Write

This first example shows how to read a CSV file with the file component and then pass it on to Weka. In Weka we apply a few filters to the data set and then pass it on to the file component for writing.

```
@Override
public void configure() throws Exception {

    // Use the file component to read the CSV file
    from("file:src/test/resources/data?fileName=sfny.csv")

    // Convert the 'in_sf' attribute to nominal
    .to("weka:filter?apply=NumericToNominal -R first")

    // Move the 'in_sf' attribute to the end
    .to("weka:filter?apply=Reorder -R 2-last,1")

    // Rename the relation
    .to("weka:filter?apply=RenameRelation -modify sfny")

    // Use the file component to write the Arff file
    .to("file:target/data?fileName=sfny.arff")
}
```

Here we do the same as above without use of the file component.

```
@Override
public void configure() throws Exception {

    // Initiate the route from somewhere
    .from("...")
}
```

```

// Use Weka to read the CSV file
.to("weka:read?path=src/test/resources/data/sfny.csv")

// Convert the 'in_sf' attribute to nominal
.to("weka:filter?apply=NumericToNominal -R first")

// Move the 'in_sf' attribute to the end
.to("weka:filter?apply=Reorder -R 2-last,1")

// Rename the relation
.to("weka:filter?apply=RenameRelation -modify sfny")

// Use Weka to write the Arff file
.to("weka:write?path=target/data/sfny.arff");
}

```

In this example, the client would provide the input path or some other supported type. Have a look at the **WekaTypeConverters** for the set of supported input types.

```

@Override
public void configure() throws Exception {

    // Initiate the route from somewhere
    .from("...")

    // Convert the 'in_sf' attribute to nominal
    .to("weka:filter?apply=NumericToNominal -R first")

    // Move the 'in_sf' attribute to the end
    .to("weka:filter?apply=Reorder -R 2-last,1")

    // Rename the relation
    .to("weka:filter?apply=RenameRelation -modify sfny")

    // Use Weka to write the Arff file
    .to("weka:write?path=target/data/sfny.arff");
}

```

368.5.2. Building a Model

When building a model, we first choose the classification algorithm to use and then train it with some data. The result is the trained model that we can later use to classify unseen data.

Here we train J48 with 10 fold cross-validation.

```

try (CamelContext camelctx = new DefaultCamelContext()) {

    camelctx.addRoutes(new RouteBuilder() {

        @Override
        public void configure() throws Exception {

            // Use the file component to read the training data
            from("file:src/test/resources/data?fileName=sfny-train.arff")

```

```

        // Build a J48 classifier using cross-validation with 10 folds
        .to("weka:model?build=J48&xval=true&folds=10&seed=1")

        // Persist the J48 model
        .to("weka:model?saveTo=src/test/resources/data/sfny-j48.model")
    }
});
camelctx.start();
}

```

368.5.3. Predicting a Class

Here we use a **Processor** to access functionality that is not directly available from endpoint URIs.

In case you come here directly and this syntax looks a bit overwhelming, you might want to have a brief look at the section about [Nessus API Concepts](#).

```

try (CamelContext camelctx = new DefaultCamelContext()) {

    camelctx.addRoutes(new RouteBuilder() {

        @Override
        public void configure() throws Exception {

            // Use the file component to read the test data
            from("file:src/test/resources/data?fileName=sfny-test.arff")

            // Remove the class attribute
            .to("weka:filter?apply=Remove -R last")

            // Add the 'prediction' placeholder attribute
            .to("weka:filter?apply=Add -N predicted -T NOM -L 0,1")

            // Rename the relation
            .to("weka:filter?apply=RenameRelation -modify sfny-predicted")

            // Load an already existing model
            .to("weka:model?loadFrom=src/test/resources/data/sfny-j48.model")

            // Use a processor to do the prediction
            .process(new Processor() {
                public void process(Exchange exchange) throws Exception {
                    Dataset dataset = exchange.getMessage().getBody(Dataset.class);
                    dataset.applyToInstances(new NominalPredictor());
                }
            })

            // Write the data file
            .to("weka:write?path=src/test/resources/data/sfny-predicted.arff")
        }
    });
    camelctx.start();
}

```

368.6. RESOURCES

- [Practical Machine Learning Tools and Techniques](#)
- [Machine Learning Courses](#)

- [Nessus-Weka](#)

CHAPTER 369. WORDPRESS COMPONENT

Available as of Camel version 2.21

Camel component for [Wordpress API](#).

Currently only the **Posts** and **Users** operations are supported.

369.1. OPTIONS

The Wordpress component supports 2 options, which are listed below.

Name	Description	Default	Type
configuration (advanced)	Wordpress component configuration		WordpressComponent Configuration
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Wordpress endpoint is configured using URI syntax:

```
wordpress:operationDetail
```

with the following path and query parameters:

369.1.1. Path Parameters (2 parameters):

Name	Description	Default	Type
operation	Required The endpoint operation.		String
operationDetail	The second part of an endpoint operation. Needed only when endpoint semantic is not enough, like <code>wordpress:post:delete</code>		String

369.1.2. Query Parameters (11 parameters):

Name	Description	Default	Type
apiVersion (common)	The Wordpress REST API version	2	String

Name	Description	Default	Type
criteria (common)	The criteria to use with complex searches.		Map
force (common)	Whether to bypass trash and force deletion.	false	Boolean
id (common)	The entity id		Integer
password (common)	Password from authorized user		String
url (common)	Required The Wordpress API URL from your site, e.g. http://myblog.com/wp-json/		String
user (common)	Authorized user to perform writing operations		String
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

369.2. SPRING BOOT AUTO-CONFIGURATION

The component supports 10 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.wordpress.configuration.api-version</code>	The Wordpress REST API version	2	String
<code>camel.component.wordpress.configuration.criteria-properties</code>			Map
<code>camel.component.wordpress.configuration.force</code>	Whether to bypass trash and force deletion.	false	Boolean
<code>camel.component.wordpress.configuration.id</code>	The entity id		Integer
<code>camel.component.wordpress.configuration.password</code>	Password from authorized user		String
<code>camel.component.wordpress.configuration.search-criteria</code>			SearchCriteria
<code>camel.component.wordpress.configuration.url</code>	The Wordpress API URL from your site, e.g. http://myblog.com/wp-json/		String
<code>camel.component.wordpress.configuration.user</code>	Authorized user to perform writing operations		String
<code>camel.component.wordpress.enabled</code>	Whether to enable auto configuration of the wordpress component. This is enabled by default.		Boolean
<code>camel.component.wordpress.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

Most of parameters needed when performing a read operation mirrors from the official [API](#). When performing searches operations, the **criteria**. suffix is needed. Take the following **Consumer** as example:

■

```
wordpress:post?criteria.perPage=10&criteria.orderBy=author&criteria.categories=camel,dozer,json
```

369.2.1. Configuring Wordpress component

The **WordpressConfiguration** class can be used to set initial properties configuration to the component instead of passing it as query parameter. The following listing shows how to set the component to be used in your routes.

```
public void configure() {
    final WordpressConfiguration configuration = new WordpressConfiguration();
    final WordpressComponentConfiguration component = new WordpressComponentConfiguration();
    configuration.setApiVersion("2");
    configuration.setUrl("http://yoursite.com/wp-json/");
    component.setConfiguration(configuration);
    getContext().addComponent("wordpress", component);

    from("wordpress:post?id=1")
        .to("mock:result");
}
```

369.2.2. Consumer Example

Consumer polls from the API from time to time domain objects from Wordpress. Following, an example using the **Post** operation:

- **wordpress:post** retrieves posts (defaults to 10 posts)
- **wordpress:post?id=1** search for a specific post

369.2.3. Producer Example

Producer performs write operations on Wordpress like adding a new user or update a post. To be able to write, you must have an authorized user credentials (see Authentication).

- **wordpress:post** creates a new post from the **org.apache.camel.component.wordpress.api.model.Post** class in the message body.
- **wordpress:post?id=1** updates a post based on data **org.apache.camel.component.wordpress.api.model.Post** from the message body.
- **wordpress:post:delete?id=1** deletes a specific post

369.3. AUTHENTICATION

Producers that perform write operations (e.g. create a new post) **must have an authenticated user** to do so. The standard authentication mechanism used by Wordpress is cookie. Unfortunately this method is not supported outside Wordpress environment because it's rely on **nonce** internal function.

There's some alternatives to use the Wordpress API without nonces, but requires specific plugin installations.

At this time, **camel-wordpress** only supports Basic Authentication (more to come). To configure it, you must install the **Basic-Auth Wordpress plugin** and pass the credentials to the endpoint:

```
from("direct:deletePost").to("wordpress:post:delete?  
id=9&user=ben&password=password123").to("mock:resultDelete");
```

It's not recommend to use Basic Authentication in production without TLS!!

CHAPTER 370. XCHANGE COMPONENT

Available as of Camel version 2.21

The **xchange**: component uses the [XChange](#) Java library to provide access to 60+ Bitcoin and Altcoin exchanges. It comes with a consistent interface for trading and accessing market data.

Camel can get crypto currency market data, query historical data, place market orders and much more.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-xchange</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

370.1. URI FORMAT

```
xchange://exchange?options
```

370.2. OPTIONS

The XChange component has no options.

The XChange endpoint is configured using URI syntax:

```
xchange:name
```

with the following path and query parameters:

370.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
name	Required The exchange to connect to		String

370.2.2. Query Parameters (5 parameters):

Name	Description	Default	Type
currency (producer)	The currency		Currency
currencyPair (producer)	The currency pair		CurrencyPair

Name	Description	Default	Type
method (producer)	Required The method to execute		XChangeMethod
service (producer)	Required The service to call		XChangeService
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

370.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
camel.component.xchange.enabled	Whether to enable auto configuration of the xchange component. This is enabled by default.		Boolean
camel.component.xchange.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

370.4. AUTHENTICATION

This component communicates with supported crypto currency exchanges via REST API. Some API requests use simple unauthenticated GET request. For most of the interesting stuff however, you'd need an account with the exchange and have API access keys enabled.

These API access keys need to be guarded tightly, especially so when they also allow for the withdraw functionality. In which case, anyone who can get hold of your API keys can easily transfer funds from your account to some other address i.e. steal your money.

Your API access keys can be stored in an exchange specific properties file in your SSH directory. For Binance for example this would be: **~/ssh/binance-secret.keys**

```
##
# This file MUST NEVER be committed to source control.
# It is therefore added to .gitignore.
#
apiKey = GuRW0*****
secretKey = nKLki*****
```

370.5. MESSAGE HEADERS

<TODO><title>Samples</title>

In this sample we find the current Bitcoin market price in USDT:

```
from("direct:ticker").to("xchange:binance?service=market&method=ticker&currencyPair=BTC/USDT")
```

</TODO>

CHAPTER 371. XML BEANS DATAFORMAT (DEPRECATED)

Available as of Camel version 1.2

XmlBeans is a Data Format which uses the [XmlBeans library](#) to unmarshal an XML payload into Java objects or to marshal Java objects into an XML payload.

```
from("activemq:My.Queue").
  unmarshal().xmlBeans().
  to("mqseries:Another.Queue");
```

371.1. OPTIONS

The XML Beans dataformat supports 2 options, which are listed below.

Name	Default	Java Type	Description
<code>prettyPrint</code>	false	Boolean	To enable pretty printing output nicely formatted. Is by default false.
<code>contentTypeHeader</code>	false	Boolean	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSon etc.

371.2. SPRING BOOT AUTO-CONFIGURATION

The component supports 3 options, which are listed below.

Name	Description	Default	Type
<code>camel.dataformat.xmlbeans.content-type-header</code>	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSon etc.	false	Boolean
<code>camel.dataformat.xmlbeans.enabled</code>	Enable xmlbeans dataformat	true	Boolean
<code>camel.dataformat.xmlbeans.pretty-print</code>	To enable pretty printing output nicely formatted. Is by default false.	false	Boolean

371.3. DEPENDENCIES

To use XmlBeans in your camel routes you need to add the dependency on **camel-xmlbeans** which implements this data format.

If you use maven you could just add the following to your pom.xml, substituting the version number for the latest & greatest release (see the download page for the latest versions).

```
<dependency>  
  <groupId>org.apache.camel</groupId>  
  <artifactId>camel-xmlbeans</artifactId>  
  <version>x.x.x</version>  
  <!-- use the same version as your Camel core version -->  
</dependency>
```

CHAPTER 372. XML JSON DATAFORMAT (DEPRECATED)

Available as of Camel version 2.10

Camel already supports a number of data formats to perform XML and JSON-related conversions, but all of them require a POJO either as an input (for marshalling) or produce a POJO as output (for unmarshalling). This data format provides the capability to convert from XML to JSON and vice-versa directly, without stepping through intermediate POJOs.

This data format leverages the [Json-lib](#) library to achieve direct conversion. In this context, XML is considered the high-level format, while JSON is the low-level format. Hence, the marshal/unmarshal semantics are assigned as follows:

- marshalling ⇒ converting from XML to JSON
- unmarshalling ⇒ converting from JSON to XML.

372.1. OPTIONS

The XML JSon dataformat supports 13 options, which are listed below.

Name	Default	Java Type	Description
<code>encoding</code>		String	Sets the encoding. Used for unmarshalling (JSON to XML conversion).
<code>elementName</code>		String	Specifies the name of the XML elements representing each array element. Used for unmarshalling (JSON to XML conversion).
<code>arrayName</code>		String	Specifies the name of the top-level XML element. Used for unmarshalling (JSON to XML conversion). For example, when converting 1, 2, 3, it will be output by default as 123. By setting this option or <code>rootName</code> , you can alter the name of element 'a'.
<code>forceTopLevelObject</code>	false	Boolean	Determines whether the resulting JSON will start off with a top-most element whose name matches the XML root element. Used for marshalling (XML to JSon conversion). If disabled, XML string 12 turns into 'x: '1', 'y: '2' . Otherwise, it turns into 'a: 'x: '1', 'y: '2' .
<code>namespaceLenient</code>	false	Boolean	Flag to be tolerant to incomplete namespace prefixes. Used for unmarshalling (JSON to XML conversion). In most cases, <code>json-lib</code> automatically changes this flag at runtime to match the processing.

Name	Default	Java Type	Description
rootName		String	Specifies the name of the top-level element. Used for unmarshalling (JSON to XML conversion). If not set, json-lib will use arrayName or objectName (default value: 'o', at the current time it is not configurable in this data format). If set to 'root', the JSON string 'x': 'value1', 'y': 'value2' would turn into value1value2, otherwise the 'root' element would be named 'o'.
skipWhitespace	false	Boolean	Determines whether white spaces between XML elements will be regarded as text values or disregarded. Used for marshalling (XML to JSon conversion).
trimSpaces	false	Boolean	Determines whether leading and trailing white spaces will be omitted from String values. Used for marshalling (XML to JSon conversion).
skipNamespaces	false	Boolean	Signals whether namespaces should be ignored. By default they will be added to the JSON output using xmlns elements. Used for marshalling (XML to JSon conversion).
removeNamespacePrefixes	false	Boolean	Removes the namespace prefixes from XML qualified elements, so that the resulting JSON string does not contain them. Used for marshalling (XML to JSon conversion).
expandableProperties		List	With expandable properties, JSON array elements are converted to XML as a sequence of repetitive XML elements with the local name equal to the JSON key, for example: number: 1,2,3 , normally converted to: 123 (where e can be modified by setting elementName), would instead translate to 123, if number is set as an expandable property Used for unmarshalling (JSON to XML conversion).
typeHints		String	Adds type hints to the resulting XML to aid conversion back to JSON. Used for unmarshalling (JSON to XML conversion).
contentTypeHeader	false	Boolean	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSon etc.

372.2. SPRING BOOT AUTO-CONFIGURATION

The component supports 14 options, which are listed below.

Name	Description	Default	Type
<code>camel.dataformat.xmljson.array-name</code>	Specifies the name of the top-level XML element. Used for unmarshalling (JSON to XML conversion). For example, when converting 1, 2, 3, it will be output by default as 123. By setting this option or <code>rootName</code> , you can alter the name of element 'a'.		String
<code>camel.dataformat.xmljson.content-type-header</code>	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example <code>application/xml</code> for data formats marshalling to XML, or <code>application/json</code> for data formats marshalling to JSon etc.	false	Boolean
<code>camel.dataformat.xmljson.element-name</code>	Specifies the name of the XML elements representing each array element. Used for unmarshalling (JSON to XML conversion).		String
<code>camel.dataformat.xmljson.enabled</code>	Enable xmljson dataformat	true	Boolean
<code>camel.dataformat.xmljson.encoding</code>	Sets the encoding. Used for unmarshalling (JSON to XML conversion).		String
<code>camel.dataformat.xmljson.expandable-properties</code>	With expandable properties, JSON array elements are converted to XML as a sequence of repetitive XML elements with the local name equal to the JSON key, for example: <code>number: 1,2,3</code> , normally converted to: 123 (where e can be modified by setting <code>elementName</code>), would instead translate to 123, if <code>number</code> is set as an expandable property Used for unmarshalling (JSON to XML conversion).		List
<code>camel.dataformat.xmljson.force-top-level-object</code>	Determines whether the resulting JSON will start off with a top-most element whose name matches the XML root element. Used for marshalling (XML to JSon conversion). If disabled, XML string 12 turns into <code>'x': '1', 'y': '2'</code> . Otherwise, it turns into <code>'a': 'x: '1', 'y': '2'</code> .	false	Boolean
<code>camel.dataformat.xmljson.namespace-lenient</code>	Flag to be tolerant to incomplete namespace prefixes. Used for unmarshalling (JSON to XML conversion). In most cases, <code>json-lib</code> automatically changes this flag at runtime to match the processing.	false	Boolean
<code>camel.dataformat.xmljson.remove-namespace-prefixes</code>	Removes the namespace prefixes from XML qualified elements, so that the resulting JSON string does not contain them. Used for marshalling (XML to JSon conversion).	false	Boolean

Name	Description	Default	Type
<code>camel.dataformat.xmljson.root-name</code>	Specifies the name of the top-level element. Used for unmarshalling (JSON to XML conversion). If not set, json-lib will use <code>arrayName</code> or <code>objectName</code> (default value: 'o', at the current time it is not configurable in this data format). If set to 'root', the JSON string 'x': 'value1', 'y': 'value2' would turn into <code>value1value2</code> , otherwise the 'root' element would be named 'o'.		String
<code>camel.dataformat.xmljson.skip-namespaces</code>	Signals whether namespaces should be ignored. By default they will be added to the JSON output using <code>xmlns</code> elements. Used for marshalling (XML to JSON conversion).	false	Boolean
<code>camel.dataformat.xmljson.skip-whitespace</code>	Determines whether white spaces between XML elements will be regarded as text values or disregarded. Used for marshalling (XML to JSON conversion).	false	Boolean
<code>camel.dataformat.xmljson.trim-spaces</code>	Determines whether leading and trailing white spaces will be omitted from String values. Used for marshalling (XML to JSON conversion).	false	Boolean
<code>camel.dataformat.xmljson.type-hints</code>	Adds type hints to the resulting XML to aid conversion back to JSON. Used for unmarshalling (JSON to XML conversion).		String

ND

372.3. BASIC USAGE WITH JAVA DSL

372.3.1. Explicitly instantiating the data format

Just instantiate the `XmlJsonDataFormat` from package `org.apache.camel.dataformat.xmljson`. Make sure you have installed the `camel-xmljson` feature (if running on OSGi) or that you've included `camel-xmljson-7.8.jar` and its transitive dependencies in your classpath. Example initialization with a default configuration:

```
XmlJsonDataFormat xmlJsonFormat = new XmlJsonDataFormat();
```

To tune the behaviour of the data format as per the options above, use the appropriate setters:

```
XmlJsonDataFormat xmlJsonFormat = new XmlJsonDataFormat();
xmlJsonFormat.setEncoding("UTF-8");
xmlJsonFormat.setForceTopLevelObject(true);
xmlJsonFormat.setTrimSpaces(true);
xmlJsonFormat.setRootName("newRoot");
```

```
xmlJsonFormat.setSkipNamespaces(true);
xmlJsonFormat.setRemoveNamespacePrefixes(true);
xmlJsonFormat.setExpandableProperties(Arrays.asList("d", "e"));
```

Once you've instantiated the data format, the next step is to actually use it from within the **marshal()** and **unmarshal()** DSL elements:

```
// from XML to JSON
from("direct:marshal").marshal(xmlJsonFormat).to("mock:json");
// from JSON to XML
from("direct:unmarshal").unmarshal(xmlJsonFormat).to("mock:xml");
```

372.3.2. Defining the data format in-line

Alternatively, you can define the data format inline by using the **xmljson()** DSL element:

```
// from XML to JSON - inline dataformat
from("direct:marshalInline").marshal().xmljson().to("mock:jsonInline");
// from JSON to XML - inline dataformat
from("direct:unmarshalInline").unmarshal().xmljson().to("mock:xmlInline");
```

If you wish, you can even pass in a **Map<String, String>** to the inline methods to provide custom options:

```
Map<String, String> xmlJsonOptions = new HashMap<String, String>();
xmlJsonOptions.put(org.apache.camel.model.dataformat.XmlJsonDataFormat.ENCODING, "UTF-8");
xmlJsonOptions.put(org.apache.camel.model.dataformat.XmlJsonDataFormat.ROOT_NAME,
    "newRoot");
xmlJsonOptions.put(org.apache.camel.model.dataformat.XmlJsonDataFormat.SKIP_NAMESPACES,
    "true");
xmlJsonOptions.put(org.apache.camel.model.dataformat.XmlJsonDataFormat.REMOVE_NAMESPACE
    _PREFIXES, "true");
xmlJsonOptions.put(org.apache.camel.model.dataformat.XmlJsonDataFormat.EXPANDABLE_PROPE
    RTIES, "d e");

// from XML to JSON - inline dataformat w/ options
from("direct:marshalInlineOptions").marshal().xmljson(xmlJsonOptions).to("mock:jsonInlineOptions");
// from JSON to XML - inline dataformat w/ options
from("direct:unmarshalInlineOptions").unmarshal().xmljson(xmlJsonOptions).to("mock:xmlInlineOption
s");
```

372.4. BASIC USAGE WITH SPRING OR BLUEPRINT DSL

Within the **<dataFormats>** block, simply configure an **xmljson** element with unique IDs:

```
<dataFormats>
  <xmljson id="xmljson"/>
  <xmljson id="xmljsonWithOptions" forceTopLevelObject="true" trimSpaces="true"
    rootName="newRoot" skipNamespaces="true"
    removeNamespacePrefixes="true" expandableProperties="d e"/>
</dataFormats>
```

Then you simply refer to the data format object within your **<marshal />** and **<unmarshal />** DSLs:

```

<route>
  <from uri="direct:marshal"/>
  <marshal ref="xmljson"/>
  <to uri="mock:json" />
</route>

<route>
  <from uri="direct:unmarshalWithOptions"/>
  <unmarshal ref="xmljsonWithOptions"/>
  <to uri="mock:xmlWithOptions"/>
</route>

```

Enabling XML DSL autocompletion for this component is easy: just refer to the appropriate [Schema locations](#), depending on whether you're using [Spring](#) or [Blueprint](#) DSL. Remember that this data format is available from Camel 2.10 onwards, so only schemas from that version onwards will include these new XML elements and attributes.

The syntax with Blueprint is identical to that of the Spring DSL. Just ensure the correct namespaces and `schemaLocations` are in use.

372.5. NAMESPACE MAPPINGS

XML has namespaces to fully qualify elements and attributes; JSON doesn't. You need to take this into account when performing XML-JSON conversions.

To bridge the gap, [Json-lib](#) has an option to bind namespace declarations in the form of prefixes and namespace URIs to XML output elements while unmarshalling (i.e. converting from JSON to XML). For example, provided the following JSON string:

```
{ "pref1:a": "value1", "pref2:b": "value2" }
```

you can ask `Json-lib` to output namespace declarations on elements **pref1:a** and **pref2:b** to bind the prefixes **pref1** and **pref2** to specific namespace URIs.

To use this feature, simply create `XmlJsonDataFormat.NamespacesPerElementMapping` objects and add them to the `namespaceMappings` option (which is a `List`).

The `XmlJsonDataFormat.NamespacesPerElementMapping` holds an element name and a Map of [prefix ⇒ namespace URI]. To facilitate mapping multiple prefixes and namespace URIs, the `NamespacesPerElementMapping(String element, String pipeSeparatedMappings)` constructor takes a String-based pipe-separated sequence of [prefix, namespaceURI] pairs in the following way: `|ns2|http://camel.apache.org/personalData|ns3|http://camel.apache.org/personalData2|`.

In order to define a default namespace, just leave the corresponding key field empty: `|ns1|http://camel.apache.org/test1||http://camel.apache.org/default|`.

Binding namespace declarations to an element name = empty string will attach those namespaces to the root element.

The full code would look like that:

```

XmlJsonDataFormat namespacesFormat = new XmlJsonDataFormat();
List<XmlJsonDataFormat.NamespacesPerElementMapping> namespaces = new
ArrayList<XmlJsonDataFormat.NamespacesPerElementMapping>();
namespaces.add(new XmlJsonDataFormat.

```

```

NamespacesPerElementMapping("",
"|ns1|http://camel.apache.org/test1||http://camel.apache.org/default|");
namespaces.add(new XmlJsonDataFormat.
NamespacesPerElementMapping("surname",
"|ns2|http://camel.apache.org/personalData|" +
"ns3|http://camel.apache.org/personalData2|"));
namespacesFormat.setNamespaceMappings(namespaces);
namespacesFormat.setRootElement("person");

```

And you can achieve the same in Spring DSL.

372.5.1. Example

Using the namespace bindings in the Java snippet above on the following JSON string:

```
{ "name": "Raul", "surname": "Kripalani", "f": true, "g": null}
```

Would yield the following XML:

```

<person xmlns="http://camel.apache.org/default" xmlns:ns1="http://camel.apache.org/test1">
  <f>true</f>
  <g null="true"/>
  <name>Raul</name>
  <surname xmlns:ns2="http://camel.apache.org/personalData"
xmlns:ns3="http://camel.apache.org/personalData2">Kripalani</surname>
</person>

```

Remember that the JSON spec defines a JSON object as follows:

An object is an unordered set of name/value pairs. [...].

That's why the elements are in a different order in the output XML.

372.6. DEPENDENCIES

To use the [XmlJson](#) dataformat in your camel routes you need to add the following dependency to your pom:

```

<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-xmljson</artifactId>
  <version>x.x.x</version>
  <!-- Use the same version as camel-core, but remember that this component is only available from
2.10 onwards -->
</dependency>

<!-- And also XOM must be included. XOM cannot be included by default due to an incompatible
license with ASF; so add this manually -->
<dependency>
  <groupId>xom</groupId>

```

```
<artifactId>xom</artifactId>  
<version>1.2.5</version>  
</dependency>
```

- [json-lib](#)

CHAPTER 373. XML SECURITY COMPONENT

Available as of Camel version 2.12

With this Apache Camel component, you can generate and validate XML signatures as described in the W3C standard [XML Signature Syntax and Processing](#) or as described in the successor [version 1.1](#). For XML Encryption support, please refer to the XML Security [Data Format](#).

You can find an introduction to XML signature [here](#). The implementation of the component is based on [JSR 105](#), the Java API corresponding to the W3C standard and supports the Apache Santuario and the JDK provider for JSR 105. The implementation will first try to use the Apache Santuario provider; if it does not find the Santuario provider, it will use the JDK provider. Further, the implementation is DOM based.

Since Camel 2.15.0 we also provide support for **XAdES-BES/EPES** for the signer endpoint; see subsection "XAdES-BES/EPES for the Signer Endpoint".

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-xmlsecurity</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

373.1. XML SIGNATURE WRAPPING MODES

XML Signature differs between enveloped, enveloping, and detached XML signature. In the [enveloped](#) XML signature case, the XML Signature is wrapped by the signed XML Document; which means that the XML signature element is a child element of a parent element, which belongs to the signed XML Document. In the [enveloping](#) XML signature case, the XML Signature contains the signed content. All other cases are called [detached](#) XML signatures. A certain form of detached XML signature is supported since **2.14.0**.

In the **enveloped XML signature** case, the supported generated XML signature has the following structure (Variables are surrounded by `[]`).

```
<[parent element]>
  ... <!-- Signature element is added as last child of the parent element-->
  <Signature Id="generated_unique_signature_id">
    <SignedInfo>
      <Reference URI="">
        <Transform Algorithm="http://www.w3.org/2000/09/xmldsig#enveloped-signature"/>
        (<Transform>)* <!-- By default "http://www.w3.org/2006/12/xml-c14n11" is added to the
transforms -->
        <DigestMethod>
        <DigestValue>
      </Reference>
      (<Reference URI="#[keyinfo_id]">
        <Transform Algorithm="http://www.w3.org/TR/2001/REC-xml-c14n-20010315"/>
        <DigestMethod>
        <DigestValue>
      </Reference>)?
    <!-- further references possible, see option 'properties' below -->
```

```

</SignedInfo>
<SignatureValue>
  (<KeyInfo Id="[keyinfo_id]">)?
  <!-- Object elements possible, see option 'properties' below -->
</Signature>
</[parent element]>

```

In the **enveloping XML signature** case, the supported generated XML signature has the structure:

```

<Signature Id="generated_unique_signature_id">
  <SignedInfo>
    <Reference URI="#generated_unique_object_id" type="[optional_type_value]">
      (<Transform>)* <!-- By default "http://www.w3.org/2006/12/xml-c14n11" is added to the
transforms -->
      <DigestMethod>
      <DigestValue>
    </Reference>
    (<Reference URI="#[keyinfo_id]">
      <Transform Algorithm="http://www.w3.org/TR/2001/REC-xml-c14n-20010315"/>
      <DigestMethod>
      <DigestValue>
    </Reference>)?
    <!-- further references possible, see option 'properties' below -->
  </SignedInfo>
  <SignatureValue>
  (<KeyInfo Id="[keyinfo_id]">)?
  <Object Id="generated_unique_object_id"/> <!-- The Object element contains the in-message body;
the object ID can either be generated or set by the option parameter "contentObjectId" -->
  <!-- Further Object elements possible, see option 'properties' below -->
</Signature>

```

As of 2.14.0 **detached XML signatures** with the following structure are supported (see also sub-chapter XML Signatures as Siblings of Signed Elements):

```

(<[signed element] Id="[id_value]">
  <!-- signed element must have an attribute of type ID -->
  ...
</[signed element]>
<other sibling/>*
<!-- between the signed element and the corresponding signature element, there can be other
siblings.
Signature element is added as last sibling. -->
<Signature Id="generated_unique_ID">
  <SignedInfo>
    <CanonicalizationMethod>
    <SignatureMethod>
    <Reference URI="#[id_value]" type="[optional_type_value]">
      <!-- reference URI contains the ID attribute value of the signed element -->
      (<Transform>)* <!-- By default "http://www.w3.org/2006/12/xml-c14n11" is added to the
transforms -->
      <DigestMethod>
      <DigestValue>
    </Reference>
    (<Reference URI="#[generated_keyinfo_id]">

```

```

    <Transform Algorithm="http://www.w3.org/TR/2001/REC-xml-c14n-20010315"/>
    <DigestMethod>
    <DigestValue>
    </Reference>)?
  </SignedInfo>
  <SignatureValue>
  (<KeyInfo Id="[generated_keyinfo_id]">)?
</Signature>)+

```

373.2. URI FORMAT

The camel component consists of two endpoints which have the following URI format:

```

xmlsecurity:sign:name[?options]
xmlsecurity:verify:name[?options]

```

- With the signer endpoint, you can generate a XML signature for the body of the in-message which can be either a XML document or a plain text. The enveloped, enveloping, or detached (as of 12.14) XML signature(s) will be set to the body of the out-message.
- With the verifier endpoint, you can validate an enveloped or enveloping XML signature or even several detached (as of 2.14.0) XML signatures contained in the body of the in-message; if the validation is successful, then the original content is extracted from the XML signature and set to the body of the out-message.
- The **name** part in the URI can be chosen by the user to distinguish between different signer/verifier endpoints within the camel context.

373.3. BASIC EXAMPLE

The following example shows the basic usage of the component.

```

from("direct:enveloping").to("xmlsecurity:sign://enveloping?keyAccessor=#accessor",
    "xmlsecurity:verify://enveloping?keySelector=#selector",
    "mock:result")

```

In Spring XML:

```

<from uri="direct:enveloping" />
  <to uri="xmlsecurity:sign://enveloping?keyAccessor=#accessor" />
  <to uri="xmlsecurity:verify://enveloping?keySelector=#selector" />
<to uri="mock:result" />

```

For the signing process, a private key is necessary. You specify a key accessor bean which provides this private key. For the validation, the corresponding public key is necessary; you specify a key selector bean which provides this public key.

The key accessor bean must implement the [KeyAccessor](#) interface. The package `org.apache.camel.component.xmlsecurity.api` contains the default implementation class [DefaultKeyAccessor](#) which reads the private key from a Java keystore.

The key selector bean must implement the [javax.xml.crypto.KeySelector](#) interface. The package `org.apache.camel.component.xmlsecurity.api` contains the default implementation class `DefaultKeySelector` which reads the public key from a keystore.

In the example, the default signature algorithm <http://www.w3.org/2000/09/xmlsig#rsa-sha1> is used. You can set the signature algorithm of your choice by the option `signatureAlgorithm` (see below). The signer endpoint creates an *enveloping* XML signature. If you want to create an *enveloped* XML signature then you must specify the parent element of the Signature element; see option `parentLocalName` for more details.

For creating *detached* XML signatures, see sub-chapter "Detached XML Signatures as Siblings of the Signed Elements".

373.4. COMPONENT OPTIONS

The XML Security component supports 3 options, which are listed below.

Name	Description	Default	Type
<code>signerConfiguration</code> (advanced)	To use a shared <code>XmlSignerConfiguration</code> configuration to use as base for configuring endpoints.		<code>XmlSignerConfiguration</code>
<code>verifierConfiguration</code> (advanced)	To use a shared <code>XmlVerifierConfiguration</code> configuration to use as base for configuring endpoints.		<code>XmlVerifierConfiguration</code>
<code>resolvePropertyPlaceholders</code> (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

373.5. ENDPOINT OPTIONS

The XML Security endpoint is configured using URI syntax:

```
xmlsecurity:command:name
```

with the following path and query parameters:

373.5.1. Path Parameters (2 parameters):

Name	Description	Default	Type
<code>command</code>	Required Whether to sign or verify.		<code>XmlCommand</code>

Name	Description	Default	Type
name	Required The name part in the URI can be chosen by the user to distinguish between different signer/verifier endpoints within the camel context.		String

373.5.2. Query Parameters (35 parameters):

Name	Description	Default	Type
baseUri (common)	You can set a base URI which is used in the URI dereferencing. Relative URIs are then concatenated with the base URI.		String
clearHeaders (common)	Determines if the XML signature specific headers be cleared after signing and verification. Defaults to true.	true	Boolean
cryptoContextProperties (common)	Sets the crypto context properties. See link XMLCryptoContext#setProperty(String, Object) . Possible properties are defined in XMLSignContext an XMLValidateContext (see Supported Properties). The following properties are set by default to the value <code>Boolean#TRUE</code> for the XML validation. If you want to switch these features off you must set the property value to <code>Boolean#FALSE</code> . org.jcp.xml.dsig.validateManifests javax.xml.crypto.dsig.cacheReference		Map
disallowDoctypeDecl (common)	Disallows that the incoming XML document contains DTD DOCTYPE declaration. The default value is <code>Boolean#TRUE</code> .	true	Boolean
omitXmlDeclaration (common)	Indicator whether the XML declaration in the outgoing message body should be omitted. Default value is false. Can be overwritten by the header <code>XmlSignatureConstants#HEADER_OMIT_XML_DECLARATION</code> .	false	Boolean
outputXmlEncoding (common)	The character encoding of the resulting signed XML document. If null then the encoding of the original XML document is used.		String

Name	Description	Default	Type
schemaResourceUri (common)	Classpath to the XML Schema. Must be specified in the detached XML Signature case for determining the ID attributes, might be set in the enveloped and enveloping case. If set, then the XML document is validated with the specified XML schema. The schema resource URI can be overwritten by the header <code>XmlSignatureConstants#HEADER_SCHEMA_RESOURCE_URI</code> .		String
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
uriDereferencer (advanced)	If you want to restrict the remote access via reference URIs, you can set an own dereferencer. Optional parameter. If not set the provider default dereferencer is used which can resolve URI fragments, HTTP, file and XPpointer URIs. Attention: The implementation is provider dependent!		URIDereferencer
addKeyInfoReference (sign)	In order to protect the KeyInfo element from tampering you can add a reference to the signed info element so that it is protected via the signature value. The default value is true. Only relevant when a KeyInfo is returned by KeyAccessor. and <code>KeyInfo#getId()</code> is not null.	true	Boolean
canonicalizationMethod (sign)	Canonicalization method used to canonicalize the SignedInfo element before the digest is calculated. You can use the helper methods <code>XmlSignatureHelper.getCanonicalizationMethod(String algorithm)</code> or <code>getCanonicalizationMethod(String algorithm, List inclusiveNamespacePrefixes)</code> to create a canonicalization method.	http://www.w3.org/TR/2001/REC-xml-c14n-20010315	AlgorithmMethod
contentObjectId (sign)	Sets the content object Id attribute value. By default a UUID is generated. If you set the null value, then a new UUID will be generated. Only used in the enveloping case.		String
contentReferenceType (sign)	Type of the content reference. The default value is null. This value can be overwritten by the header <code>XmlSignatureConstants#HEADER_CONTENT_REFERENCE_TYPE</code> .		String

Name	Description	Default	Type
contentReferenceUri (sign)	Reference URI for the content to be signed. Only used in the enveloped case. If the reference URI contains an ID attribute value, then the resource schema URI (<code>setSchemaResourceUri(String)</code>) must also be set because the schema validator will then find out which attributes are ID attributes. Will be ignored in the enveloping or detached case.		String
digestAlgorithm (sign)	Digest algorithm URI. Optional parameter. This digest algorithm is used for calculating the digest of the input message. If this digest algorithm is not specified then the digest algorithm is calculated from the signature algorithm. Example: http://www.w3.org/2001/04/xmlenc#sha256		String
keyAccessor (sign)	For the signing process, a private key is necessary. You specify a key accessor bean which provides this private key. The key accessor bean must implement the <code>KeyAccessor</code> interface. The package <code>org.apache.camel.component.xmlsecurity.api</code> contains the default implementation class <code>DefaultKeyAccessor</code> which reads the private key from a Java keystore.		KeyAccessor
parentLocalName (sign)	Local name of the parent element to which the XML signature element will be added. Only relevant for enveloped XML signature. Alternatively you can also use <code>setParentXPath(XPathFilterParameterSpec)</code> . Default value is null. The value must be null for enveloping and detached XML signature. This parameter or the parameter <code>setParentXPath(XPathFilterParameterSpec)</code> for enveloped signature and the parameter <code>setXpathsToldAttributes(List)</code> for detached signature must not be set in the same configuration. If the parameters <code>parentXPath</code> and <code>parentLocalName</code> are specified in the same configuration then an exception is thrown.		String
parentNamespace (sign)	Namespace of the parent element to which the XML signature element will be added.		String

Name	Description	Default	Type
parentXPath (sign)	Sets the XPath to find the parent node in the enveloped case. Either you specify the parent node via this method or the local name and namespace of the parent with the methods <code>setParentLocalName(String)</code> and <code>setParentNamespace(String)</code> . Default value is null. The value must be null for enveloping and detached XML signature. If the parameters <code>parentXPath</code> and <code>parentLocalName</code> are specified in the same configuration then an exception is thrown.		XPathFilterParameter Spec
plainText (sign)	Indicator whether the message body contains plain text. The default value is false, indicating that the message body contains XML. The value can be overwritten by the header <code>XmlSignatureConstants#HEADER_MESSAGE_IS_PLAIN_TEXT</code> .	false	Boolean
plainTextEncoding (sign)	Encoding of the plain text. Only relevant if the message body is plain text (see parameter <code>plainText</code>). Default value is UTF-8.	UTF-8	String
prefixForXmlSignature Namespace (sign)	Namespace prefix for the XML signature namespace http://www.w3.org/2000/09/xmldsig# . Default value is ds. If null or an empty value is set then no prefix is used for the XML signature namespace. See best practice http://www.w3.org/TR/xmldsig-bestpractices/#signing-xml-without-namespaces	ds	String
properties (sign)	For adding additional References and Objects to the XML signature which contain additional properties, you can provide a bean which implements the <code>XmlSignatureProperties</code> interface.		XmlSignatureProperties
signatureAlgorithm (sign)	Signature algorithm. Default value is http://www.w3.org/2000/09/xmldsig#rsa-sha1 .	http://www.w3.org/2000/09/xmldsig#rsa-sha1	String
signatureId (sign)	Sets the signature Id. If this parameter is not set (null value) then a unique ID is generated for the signature ID (default). If this parameter is set to (empty string) then no Id attribute is created in the signature element.		String

Name	Description	Default	Type
transformMethods (sign)	Transforms which are executed on the message body before the digest is calculated. By default, C14n is added and in the case of enveloped signature (see option <code>parentLocalName</code>) also http://www.w3.org/2000/09/xmldsig#enveloped-signature is added at position 0 of the list. Use methods in <code>XmlSignatureHelper</code> to create the transform methods.		List
xpathsToldAttributes (sign)	Define the elements which are signed in the detached case via XPATH expressions to ID attributes (attributes of type ID). For each element found via the XPATH expression a detached signature is created whose reference URI contains the corresponding attribute value (preceded by '#'). The signature becomes the last sibling of the signed element. Elements with deeper hierarchy level are signed first. You can also set the XPATH list dynamically via the header <code>XmlSignatureConstants#HEADER_XPATHS_TO_ID_ATTRIBUTES</code> . The parameter <code>setParentLocalName(String)</code> or <code>setParentXPath(XPathFilterParameterSpec)</code> for enveloped signature and this parameter for detached signature must not be set in the same configuration.		List
keySelector (verify)	Provides the key for validating the XML signature.		KeySelector
outputNodeSearch (verify)	Sets the output node search value for determining the node from the XML signature document which shall be set to the output message body. The class of the value depends on the type of the output node search. The output node search is forwarded to <code>XmlSignature2Message</code> .		String
outputNodeSearchType (verify)	Determines the search type for determining the output node which is serialized into the output message body. See <code>setOutputNodeSearch(Object)</code> . The supported default search types you can find in <code>DefaultXmlSignature2Message</code> .	Default	String

Name	Description	Default	Type
removeSignatureElements (verify)	Indicator whether the XML signature elements (elements with local name <code>Signature</code> and namespace http://www.w3.org/2000/09/xmldsig#) shall be removed from the document set to the output message. Normally, this is only necessary, if the XML signature is enveloped. The default value is <code>Boolean#FALSE</code> . This parameter is forwarded to <code>XmlSignature2Message</code> . This indicator has no effect if the output node search is of type <code>DefaultXmlSignature2Message#OUTPUT_NODE_SEARCH_TYPE_DEFAULT.F</code>	false	Boolean
secureValidation (verify)	Enables secure validation. If true then secure validation is enabled.	true	Boolean
validationFailedHandler (verify)	Handles the different validation failed situations. The default implementation throws specific exceptions for the different situations (All exceptions have the package name <code>org.apache.camel.component.xmlsecurity.api</code> and are a sub-class of <code>XmlSignatureInvalidException</code> . If the signature value validation fails, a <code>XmlSignatureInvalidValueException</code> is thrown. If a reference validation fails, a <code>XmlSignatureInvalidContentHashException</code> is thrown. For more detailed information, see the JavaDoc.		ValidationFailedHandler

Name	Description	Default	Type
xmlSignature2Message (verify)	Bean which maps the XML signature to the output-message after the validation. How this mapping should be done can be configured by the options <code>outputNodeSearchType</code> , <code>outputNodeSearch</code> , and <code>removeSignatureElements</code> . The default implementation offers three possibilities which are related to the three output node search types <code>Default</code> , <code>ElementName</code> , and <code>XPath</code> . The default implementation determines a node which is then serialized and set to the body of the output message. If the search type is <code>ElementName</code> then the output node (which must be in this case an element) is determined by the local name and namespace defined in the search value (see option <code>outputNodeSearch</code>). If the search type is <code>XPath</code> then the output node is determined by the <code>XPath</code> specified in the search value (in this case the output node can be of type <code>Element</code> , <code>TextNode</code> or <code>Document</code>). If the output node search type is <code>Default</code> then the following rules apply: In the enveloped XML signature case (there is a reference with <code>URI=</code> and <code>transform</code> http://www.w3.org/2000/09/xmldsig#enveloped-signature), the incoming XML document without the <code>Signature</code> element is set to the output message body. In the non-enveloped XML signature case, the message body is determined from a referenced Object; this is explained in more detail in chapter <code>Output Node Determination in Enveloping XML Signature Case</code> .		<code>XmlSignature2Message</code>
xmlSignatureChecker (verify)	This interface allows the application to check the XML signature before the validation is executed. This step is recommended in http://www.w3.org/TR/xmldsig-bestpractices/#check-what-is-signed		<code>XmlSignatureChecker</code>

373.6. SPRING BOOT AUTO-CONFIGURATION

The component supports 63 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.xmlsecurity.enabled</code>	Enable <code>xmlsecurity</code> component	<code>true</code>	<code>Boolean</code>

Name	Description	Default	Type
<code>camel.component.xmlsecurity.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.component.xmlsecurity.signer-configuration.add-key-info-reference</code>	In order to protect the KeyInfo element from tampering you can add a reference to the signed info element so that it is protected via the signature value. The default value is true. Only relevant when a KeyInfo is returned by KeyAccessor. and KeyInfo#getId() is not null.	true	Boolean
<code>camel.component.xmlsecurity.signer-configuration.base-uri</code>	You can set a base URI which is used in the URI dereferencing. Relative URIs are then concatenated with the base URI.		String
<code>camel.component.xmlsecurity.signer-configuration.canonicalization-method</code>	Canonicalization method used to canonicalize the SignedInfo element before the digest is calculated. You can use the helper methods XmlSignatureHelper.getCanonicalizationMethod(String algorithm) or getCanonicalizationMethod(String algorithm, List inclusiveNamespacePrefixes) to create a canonicalization method.		AlgorithmMethod
<code>camel.component.xmlsecurity.signer-configuration.canonicalization-method-name</code>			String
<code>camel.component.xmlsecurity.signer-configuration.clear-headers</code>	Determines if the XML signature specific headers be cleared after signing and verification. Defaults to true.	true	Boolean
<code>camel.component.xmlsecurity.signer-configuration.content-object-id</code>	Sets the content object Id attribute value. By default a UUID is generated. If you set the null value, then a new UUID will be generated. Only used in the enveloping case.		String

Name	Description	Default	Type
<code>camel.component.xmlsecurity.signer-configuration.content-reference-type</code>	Type of the content reference. The default value is null. This value can be overwritten by the header <code>XmlSignatureConstants#HEADER_CONTENT_REFERENCE_TYPE</code> .		String
<code>camel.component.xmlsecurity.signer-configuration.content-reference-uri</code>	Reference URI for the content to be signed. Only used in the enveloped case. If the reference URI contains an ID attribute value, then the resource schema URI (<code>setSchemaResourceUri(String)</code>) must also be set because the schema validator will then find out which attributes are ID attributes. Will be ignored in the enveloping or detached case.		String
<code>camel.component.xmlsecurity.signer-configuration.crypto-context-properties</code>	Sets the crypto context properties. See link <code>XMLCryptoContext#setProperty(String, Object)</code> . Possible properties are defined in <code>XMLSignContext</code> an <code>XMLValidateContext</code> (see Supported Properties). The following properties are set by default to the value <code>Boolean#TRUE</code> for the XML validation. If you want to switch these features off you must set the property value to <code>Boolean#FALSE</code> . <code>org.jcp.xml.dsig.validateManifests</code> <code>javax.xml.crypto.dsig.cacheReference</code>		Map
<code>camel.component.xmlsecurity.signer-configuration.digest-algorithm</code>	Digest algorithm URI. Optional parameter. This digest algorithm is used for calculating the digest of the input message. If this digest algorithm is not specified then the digest algorithm is calculated from the signature algorithm. Example: http://www.w3.org/2001/04/xmlenc#sha256		String
<code>camel.component.xmlsecurity.signer-configuration.disallow-doctype-decl</code>	Disallows that the incoming XML document contains DTD DOCTYPE declaration. The default value is <code>Boolean#TRUE</code> .	true	Boolean
<code>camel.component.xmlsecurity.signer-configuration.key-accessor</code>	For the signing process, a private key is necessary. You specify a key accessor bean which provides this private key. The key accessor bean must implement the <code>KeyAccessor</code> interface. The package <code>org.apache.camel.component.xmlsecurity.api</code> contains the default implementation class <code>DefaultKeyAccessor</code> which reads the private key from a Java keystore.		KeyAccessor

Name	Description	Default	Type
<code>camel.component.xmlsecurity.signer-configuration.key-accessor-name</code>			String
<code>camel.component.xmlsecurity.signer-configuration.omit-xml-declaration</code>	Indicator whether the XML declaration in the outgoing message body should be omitted. Default value is false. Can be overwritten by the header <code>XmlSignatureConstants#HEADER_OMIT_XML_DECLARATION</code> .	false	Boolean
<code>camel.component.xmlsecurity.signer-configuration.output-xml-encoding</code>	The character encoding of the resulting signed XML document. If null then the encoding of the original XML document is used.		String
<code>camel.component.xmlsecurity.signer-configuration.parent-local-name</code>	Local name of the parent element to which the XML signature element will be added. Only relevant for enveloped XML signature. Alternatively you can also use <code>setParentXPath(XPathFilterParameterSpec)</code> . Default value is null. The value must be null for enveloping and detached XML signature. This parameter or the parameter <code>setParentXPath(XPathFilterParameterSpec)</code> for enveloped signature and the parameter <code>setXpathsToldAttributes(List)</code> for detached signature must not be set in the same configuration. If the parameters <code>parentXPath</code> and <code>parentLocalName</code> are specified in the same configuration then an exception is thrown.		String
<code>camel.component.xmlsecurity.signer-configuration.parent-namespace</code>	Namespace of the parent element to which the XML signature element will be added.		String
<code>camel.component.xmlsecurity.signer-configuration.parent-xpath</code>	Sets the XPath to find the parent node in the enveloped case. Either you specify the parent node via this method or the local name and namespace of the parent with the methods <code>setParentLocalName(String)</code> and <code>setParentNamespace(String)</code> . Default value is null. The value must be null for enveloping and detached XML signature. If the parameters <code>parentXPath</code> and <code>parentLocalName</code> are specified in the same configuration then an exception is thrown.		XPathFilterParameterSpec

Name	Description	Default	Type
<code>camel.component.xmlsecurity.signer-configuration.plain-text</code>	Indicator whether the message body contains plain text. The default value is false, indicating that the message body contains XML. The value can be overwritten by the header <code>XmlSignatureConstants#HEADER_MESSAGE_IS_PLAIN_TEXT</code> .	false	Boolean
<code>camel.component.xmlsecurity.signer-configuration.plain-text-encoding</code>	Encoding of the plain text. Only relevant if the message body is plain text (see parameter <code>plainText</code>). Default value is UTF-8.	UTF-8	String
<code>camel.component.xmlsecurity.signer-configuration.prefix-for-xml-signature-namespace</code>	Namespace prefix for the XML signature namespace http://www.w3.org/2000/09/xmldsig# . Default value is ds. If null or an empty value is set then no prefix is used for the XML signature namespace. See best practice http://www.w3.org/TR/xmldsig-bestpractices/#signing-xml-without-namespaces	ds	String
<code>camel.component.xmlsecurity.signer-configuration.properties</code>	For adding additional References and Objects to the XML signature which contain additional properties, you can provide a bean which implements the <code>XmlSignatureProperties</code> interface.		<code>XmlSignatureProperties</code>
<code>camel.component.xmlsecurity.signer-configuration.properties-name</code>			String
<code>camel.component.xmlsecurity.signer-configuration.schema-resource-uri</code>	Classpath to the XML Schema. Must be specified in the detached XML Signature case for determining the ID attributes, might be set in the enveloped and enveloping case. If set, then the XML document is validated with the specified XML schema. The schema resource URI can be overwritten by the header <code>XmlSignatureConstants#HEADER_SCHEMA_RESOURCE_URI</code> .		String

Name	Description	Default	Type
<code>camel.component.xmlsecurity.signer-configuration.signature-algorithm</code>	Signature algorithm. Default value is http://www.w3.org/2000/09/xmldsig#rsa-sha1 .	http://www.w3.org/2000/09/xmldsig#rsa-sha1	String
<code>camel.component.xmlsecurity.signer-configuration.signature-id</code>	Sets the signature Id. If this parameter is not set (null value) then a unique ID is generated for the signature ID (default). If this parameter is set to (empty string) then no Id attribute is created in the signature element.		String
<code>camel.component.xmlsecurity.signer-configuration.transform-methods</code>	Transforms which are executed on the message body before the digest is calculated. By default, C14n is added and in the case of enveloped signature (see option <code>parentLocalName</code>) also http://www.w3.org/2000/09/xmldsig#enveloped-signature is added at position 0 of the list. Use methods in <code>XmlSignatureHelper</code> to create the transform methods.		List
<code>camel.component.xmlsecurity.signer-configuration.transform-methods-name</code>			String
<code>camel.component.xmlsecurity.signer-configuration.uri-dereferencer</code>	If you want to restrict the remote access via reference URIs, you can set an own dereferencer. Optional parameter. If not set the provider default dereferencer is used which can resolve URI fragments, HTTP, file and XPPpointer URIs. Attention: The implementation is provider dependent!		URIDereferencer

Name	Description	Default	Type
<code>camel.component.xmlsecurity.signer-configuration.xpathstosid-attributes</code>	Define the elements which are signed in the detached case via XPATH expressions to ID attributes (attributes of type ID). For each element found via the XPATH expression a detached signature is created whose reference URI contains the corresponding attribute value (preceded by '#'). The signature becomes the last sibling of the signed element. Elements with deeper hierarchy level are signed first. You can also set the XPATH list dynamically via the header <code>XmlSignatureConstants#HEADER_XPATHS_TO_ID_ATTRIBUTES</code> . The parameter <code>setParentLocalName(String)</code> or <code>setParentXPath(XPathFilterParameterSpec)</code> for enveloped signature and this parameter for detached signature must not be set in the same configuration.		List
<code>camel.component.xmlsecurity.verifier-configuration.base-uri</code>	You can set a base URI which is used in the URI dereferencing. Relative URIs are then concatenated with the base URI.		String
<code>camel.component.xmlsecurity.verifier-configuration.clear-headers</code>	Determines if the XML signature specific headers be cleared after signing and verification. Defaults to true.	true	Boolean
<code>camel.component.xmlsecurity.verifier-configuration.crypto-context-properties</code>	Sets the crypto context properties. See link <code>XMLCryptoContext#setProperty(String, Object)</code> . Possible properties are defined in <code>XMLSignContext</code> an <code>XMLValidateContext</code> (see Supported Properties). The following properties are set by default to the value <code>Boolean#TRUE</code> for the XML validation. If you want to switch these features off you must set the property value to <code>Boolean#FALSE</code> . <code>org.jcp.xml.dsig.validateManifests</code> <code>javax.xml.crypto.dsig.cacheReference</code>		Map
<code>camel.component.xmlsecurity.verifier-configuration.disallow-doctype-decl</code>	Disallows that the incoming XML document contains DTD DOCTYPE declaration. The default value is <code>Boolean#TRUE</code> .	true	Boolean

Name	Description	Default	Type
<code>camel.component.xmlsecurity.verifier-configuration.key-selector</code>	Provides the key for validating the XML signature.		KeySelector
<code>camel.component.xmlsecurity.verifier-configuration.omit-xml-declaration</code>	Indicator whether the XML declaration in the outgoing message body should be omitted. Default value is false. Can be overwritten by the header <code>XmlSignatureConstants#HEADER_OMIT_XML_DECLARATION</code> .	false	Boolean
<code>camel.component.xmlsecurity.verifier-configuration.output-node-search</code>	Sets the output node search value for determining the node from the XML signature document which shall be set to the output message body. The class of the value depends on the type of the output node search. The output node search is forwarded to <code>XmlSignature2Message</code> .		Object
<code>camel.component.xmlsecurity.verifier-configuration.output-node-search-type</code>	Determines the search type for determining the output node which is serialized into the output message body. See <code>setOutputNodeSearch(Object)</code> . The supported default search types you can find in <code>DefaultXmlSignature2Message</code> .	Default	String
<code>camel.component.xmlsecurity.verifier-configuration.output-xml-encoding</code>	The character encoding of the resulting signed XML document. If null then the encoding of the original XML document is used.		String
<code>camel.component.xmlsecurity.verifier-configuration.remove-signature-elements</code>	Indicator whether the XML signature elements (elements with local name <code>Signature</code> and namespace http://www.w3.org/2000/09/xmldsig#) shall be removed from the document set to the output message. Normally, this is only necessary, if the XML signature is enveloped. The default value is <code>Boolean#FALSE</code> . This parameter is forwarded to <code>XmlSignature2Message</code> . This indicator has no effect if the output node search is of type <code>DefaultXmlSignature2Message#OUTPUT_NODE_SEARCH_TYPE_DEFAULT.F</code>	false	Boolean

Name	Description	Default	Type
<code>camel.component.xmlsecurity.verifier-configuration.schema-resource-uri</code>	Classpath to the XML Schema. Must be specified in the detached XML Signature case for determining the ID attributes, might be set in the enveloped and enveloping case. If set, then the XML document is validated with the specified XML schema. The schema resource URI can be overwritten by the header XmlSignatureConstants#HEADER_SCHEMA_RESOURCE_URI.		String
<code>camel.component.xmlsecurity.verifier-configuration.secure-validation</code>	Enables secure validation. If true then secure validation is enabled.	true	Boolean
<code>camel.component.xmlsecurity.verifier-configuration.uri-dereferencer</code>	If you want to restrict the remote access via reference URIs, you can set an own dereferencer. Optional parameter. If not set the provider default dereferencer is used which can resolve URI fragments, HTTP, file and XPointer URIs. Attention: The implementation is provider dependent!		URIDereferencer
<code>camel.component.xmlsecurity.verifier-configuration.validation-failed-handler</code>	Handles the different validation failed situations. The default implementation throws specific exceptions for the different situations (All exceptions have the package name <code>org.apache.camel.component.xmlsecurity.api</code> and are a sub-class of <code>XmlSignatureInvalidException</code> . If the signature value validation fails, a <code>XmlSignatureInvalidValueException</code> is thrown. If a reference validation fails, a <code>XmlSignatureInvalidContentHashException</code> is thrown. For more detailed information, see the JavaDoc.		ValidationFailedHandler
<code>camel.component.xmlsecurity.verifier-configuration.validation-failed-handler-name</code>	Name of handler to @param <code>validationFailedHandlerName</code>		String

Name	Description	Default	Type
camel.component.xmlsecurity.verifier-configuration.xml-signature-checker	This interface allows the application to check the XML signature before the validation is executed. This step is recommended in http://www.w3.org/TR/xmlsig-bestpractices/#check-what-is-signed		XmlSignatureChecker
camel.component.xmlsecurity.verifier-configuration.xml-signature2-message	Bean which maps the XML signature to the output-message after the validation. How this mapping should be done can be configured by the options <code>outputNodeSearchType</code> , <code>outputNodeSearch</code> , and <code>removeSignatureElements</code> . The default implementation offers three possibilities which are related to the three output node search types <code>Default</code> , <code>ElementName</code> , and <code>XPath</code> . The default implementation determines a node which is then serialized and set to the body of the output message. If the search type is <code>ElementName</code> then the output node (which must be in this case an element) is determined by the local name and namespace defined in the search value (see option <code>outputNodeSearch</code>). If the search type is <code>XPath</code> then the output node is determined by the <code>XPath</code> specified in the search value (in this case the output node can be of type <code>Element</code> , <code>TextNode</code> or <code>Document</code>). If the output node search type is <code>Default</code> then the following rules apply: In the enveloped XML signature case (there is a reference with <code>URI=</code> and <code>transform</code> http://www.w3.org/2000/09/xmlsig#enveloped-signature), the incoming XML document without the <code>Signature</code> element is set to the output message body. In the non-enveloped XML signature case, the message body is determined from a referenced Object; this is explained in more detail in chapter <code>Output Node Determination in Enveloping XML Signature Case</code> .		XmlSignature2Message
camel.dataformat.securexml.add-key-value-for-encrypted-key	Whether to add the public key used to encrypt the session key as a <code>KeyValue</code> in the <code>EncryptedKey</code> structure or not.	true	Boolean
camel.dataformat.securexml.content-type-header	Whether the data format should set the <code>Content-Type</code> header with the type from the data format if the data format is capable of doing so. For example <code>application/xml</code> for data formats marshalling to XML, or <code>application/json</code> for data formats marshalling to JSON etc.	false	Boolean

Name	Description	Default	Type
<code>camel.dataformat.securexml.digest-algorithm</code>	The digest algorithm to use with the RSA OAEP algorithm. The available choices are: XMLCipher.SHA1 XMLCipher.SHA256 XMLCipher.SHA512 The default value is XMLCipher.SHA1	SHA1	String
<code>camel.dataformat.securexml.enabled</code>	Enable securexml dataformat	true	Boolean
<code>camel.dataformat.securexml.key-cipher-algorithm</code>	The cipher algorithm to be used for encryption/decryption of the asymmetric key. The available choices are: XMLCipher.RSA_v1dot5 XMLCipher.RSA_OAEP XMLCipher.RSA_OAEP_11 The default value is XMLCipher.RSA_OAEP	RSA_OAEP	String
<code>camel.dataformat.securexml.key-or-trust-store-parameters-id</code>	Refers to a KeyStore instance to lookup in the registry, which is used for configuration options for creating and loading a KeyStore instance that represents the sender's trustStore or recipient's keyStore.		String
<code>camel.dataformat.securexml.key-password</code>	The password to be used for retrieving the private key from the KeyStore. This key is used for asymmetric decryption.		String
<code>camel.dataformat.securexml.mgf-algorithm</code>	The MGF Algorithm to use with the RSA OAEP algorithm. The available choices are: EncryptionConstants.MGF1_SHA1 EncryptionConstants.MGF1_SHA256 EncryptionConstants.MGF1_SHA512 The default value is EncryptionConstants.MGF1_SHA1	MGF1_SHA1	String
<code>camel.dataformat.securexml.passphrase</code>	A String used as passPhrase to encrypt/decrypt content. The passPhrase has to be provided. If no passPhrase is specified, a default passPhrase is used. The passPhrase needs to be put together in conjunction with the appropriate encryption algorithm. For example using TRIPLEDES the passPhase can be a Only another 24 Byte key		String

Name	Description	Default	Type
<code>camel.dataformat.securexml.passphrase-byte</code>	A byte used as passPhrase to encrypt/decrypt content. The passPhrase has to be provided. If no passPhrase is specified, a default passPhrase is used. The passPhrase needs to be put together in conjunction with the appropriate encryption algorithm. For example using TRIPEDES the passPhrase can be a Only another 24 Byte key		Byte[]
<code>camel.dataformat.securexml.recipient-key-alias</code>	The key alias to be used when retrieving the recipient's public or private key from a KeyStore when performing asymmetric key encryption or decryption.		String
<code>camel.dataformat.securexml.secure-tag</code>	The XPath reference to the XML Element selected for encryption/decryption. If no tag is specified, the entire payload is encrypted/decrypted.		String
<code>camel.dataformat.securexml.secure-tag-contents</code>	A boolean value to specify whether the XML Element is to be encrypted or the contents of the XML Element false = Element Level true = Element Content Level	false	Boolean
<code>camel.dataformat.securexml.xml-cipher-algorithm</code>	The cipher algorithm to be used for encryption/decryption of the XML message content. The available choices are: XMLCipher.TRIPEDES XMLCipher.AES_128 XMLCipher.AES_128_GCM XMLCipher.AES_192 XMLCipher.AES_192_GCM XMLCipher.AES_256 XMLCipher.AES_256_GCM XMLCipher.SEED_128 XMLCipher.CAMELLIA_128 XMLCipher.CAMELLIA_192 XMLCipher.CAMELLIA_256 The default value is XMLCipher.TRIPEDES	TRIPLEDES	String

373.6.1. Output Node Determination in Enveloping XML Signature Case

After the validation the node is extracted from the XML signature document which is finally returned to the output-message body. In the enveloping XML signature case, the default implementation [DefaultXmlSignature2Message](#) of [XmlSignature2Message](#) does this for the node search type **Default** in the following way (see option **xmlSignature2Message**):

- First an object reference is determined:
 - Only same document references are taken into account (URI must start with #)
 - Also indirect same document references to an object via manifest are taken into account.
 - The resulting number of object references must be 1.
- Then, the object is dereferenced and the object must only contain one XML element. This element is returned as output node.

This does mean that the enveloping XML signature must have either the structure:

```
<Signature>
  <SignedInfo>
    <Reference URI="#object"/>
    <!-- further references possible but they must not point to an Object or Manifest containing an
object reference -->
    ...
  </SignedInfo>

  <Object Id="object">
    <!-- contains one XML element which is extracted to the message body -->
  </Object>
  <!-- further object elements possible which are not referenced-->
  ...
  (<KeyInfo>)?
</Signature>
```

or the structure:

```
<Signature>
  <SignedInfo>
    <Reference URI="#manifest"/>
    <!-- further references are possible but they must not point to an Object or other manifest
containing an object reference -->
    ...
  </SignedInfo>

  <Object >
    <Manifest Id="manifest">
      <Reference URI=#object/>
    </Manifest>
  </Object>
  <Object Id="object">
    <!-- contains the DOM node which is extracted to the message body -->
  </Object>
  <!-- further object elements possible which are not referenced -->
  ...
  (<KeyInfo>)?
</Signature>
```

373.7. DETACHED XML SIGNATURES AS SIBLINGS OF THE SIGNED ELEMENTS

Since 2.14.0

You can create detached signatures where the signature is a sibling of the signed element. The following example contains two detached signatures. The first signature is for the element **C** and the second signature is for element **A**. The signatures are *nested*; the second signature is for the element **A** which also contains the first signature.

Example Detached XML Signatures

```
<?xml version="1.0" encoding="UTF-8" ?>
```

```

<root>
  <A ID="IDforA">
    <B>
      <C ID="IDforC">
        <D>dvalue</D>
      </C>
      <ds:Signature xmlns:ds="http://www.w3.org/2000/09/xmldsig#"
        Id="_6bf13099-0568-4d76-8649-faf5dcb313c0">
        <ds:SignedInfo>
          <ds:CanonicalizationMethod
            Algorithm="http://www.w3.org/TR/2001/REC-xml-c14n-20010315" />
          <ds:SignatureMethod
            Algorithm="http://www.w3.org/2000/09/xmldsig#rsa-sha1" />
          <ds:Reference URI="#IDforC">
            ...
          </ds:Reference>
        </ds:SignedInfo>
        <ds:SignatureValue>aUDFmiG71</ds:SignatureValue>
      </ds:Signature>
    </B>
  </A>
  <ds:Signature xmlns:ds="http://www.w3.org/2000/09/xmldsig#"Id="_6b02fb8a-30df-42c6-ba25-
76eba02c8214">
    <ds:SignedInfo>
      <ds:CanonicalizationMethod
        Algorithm="http://www.w3.org/TR/2001/REC-xml-c14n-20010315" />
      <ds:SignatureMethod
        Algorithm="http://www.w3.org/2000/09/xmldsig#rsa-sha1" />
      <ds:Reference URI="#IDforA">
        ...
      </ds:Reference>
    </ds:SignedInfo>
    <ds:SignatureValue>q3tvRoGgc8cMUqUSzP6C21zb7tt04riPnDuk=</ds:SignatureValue>
  </ds:Signature>
</root>

```

The example shows that you can sign several elements and that for each element a signature is created as sibling. The elements to be signed must have an attribute of type ID. The ID type of the attribute must be defined in the XML schema (see option **schemaResourceUri**). You specify a list of XPATH expressions pointing to attributes of type ID (see option **xpathsToldAttributes**). These attributes determine the elements to be signed. The elements are signed by the same key given by the **keyAccessor** bean. Elements with higher (i.e. deeper) hierarchy level are signed first. In the example, the element **C** is signed before the element **A**.

Java DSL Example

```

from("direct:detached")
  .to("xmlsecurity:sign://detached?
keyAccessor=#keyAccessorBean&xpathsToldAttributes=#xpathsToldAttributesBean&schemaResource
Uri=Test.xsd")
  .to("xmlsecurity:verify://detached?
keySelector=#keySelectorBean&schemaResourceUri=org/apache/camel/component/xmlsecurity/Test.xs
d")
  .to("mock:result");

```

Spring Example

```

<bean id="xpathstoldAttributesBean" class="java.util.ArrayList">
  <constructor-arg type="java.util.Collection">
    <list>
      <bean
        class="org.apache.camel.component.xmlsecurity.api.XmlSignatureHelper"
        factory-method="getXpathFilter">
          <constructor-arg type="java.lang.String"
            value="/ns:root/a/@ID" />
          <constructor-arg>
            <map key-type="java.lang.String" value-type="java.lang.String">
              <entry key="ns" value="http://test" />
            </map>
          </constructor-arg>
        </bean>
      </list>
    </constructor-arg>
  </bean>
  ...
  <from uri="direct:detached" />
    <to
      uri="xmlsecurity:sign://detached?
keyAccessor=#keyAccessorBean&xpathstoldAttributes=#xpathstoldAttributesBean&schema
ResourceUri=Test.xsd" />
    <to
      uri="xmlsecurity:verify://detached?
keySelector=#keySelectorBean&schemaResourceUri=Test.xsd" />
    <to uri="mock:result" />

```

373.8. XAdES-BES/EPES FOR THE SIGNER ENDPOINT

Available as of Camel 2.15.0

[XML Advanced Electronic Signatures \(XAdES\)](#) defines extensions to XML Signature. This standard was defined by the [European Telecommunication Standards Institute](#) and allows you to create signatures which are compliant to the [European Union Directive \(1999/93/EC\) on a Community framework for electronic signatures](#). XAdES defines different sets of signature properties which are called signature forms. We support the signature forms **Basic Electronic Signature** (XAdES-BES) and **Explicit Policy Based Electronic Signature** (XAdES-EPES) for the Signer Endpoint. The forms **Electronic Signature with Validation Data** XAdES-T and XAdES-C are not supported.

We support the following properties of the XAdES-EPES form ("?" denotes zero or one occurrence):

Supported XAdES-EPES Properties

```

<QualifyingProperties Target>
  <SignedProperties>
    <SignedSignatureProperties>
      (SigningTime)?
      (SigningCertificate)?
      (SignaturePolicyIdentifier)
      (SignatureProductionPlace)?
      (SignerRole)?
    </SignedSignatureProperties>
    <SignedDataObjectProperties>

```

```

        (DataObjectFormat)?
        (CommitmentTypeIndication)?
    </SignedDataObjectProperties>
</SignedProperties>
</QualifyingProperties>

```

The properties of the XAdES-BES form are the same except that the **SignaturePolicyIdentifier** property is not part of XAdES-BES.

You can configure the XAdES-BES/EPES properties via the bean **org.apache.camel.component.xmlsecurity.api.XAdESSignatureProperties** or **org.apache.camel.component.xmlsecurity.api.DefaultXAdESSignatureProperties**. **XAdESSignatureProperties** does support all properties mentioned above except the **SigningCertificate** property. To get the **SigningCertificate** property, you must overwrite either the method **XAdESSignatureProperties.getSigningCertificate()** or **XAdESSignatureProperties.getSigningCertificateChain()**. The class **DefaultXAdESSignatureProperties** overwrites the method **getSigningCertificate()** and allows you to specify the signing certificate via a keystore and alias. The following example shows all parameters you can specify. If you do not need certain parameters you can just omit them.

XAdES-BES/EPES Example in Java DSL

```

Keystore keystore = ... // load a keystore
DefaultKeyAccessor accessor = new DefaultKeyAccessor();
accessor.setKeyStore(keystore);
accessor.setPassword("password");
accessor.setAlias("cert_alias"); // signer key alias

DefaultXAdESSignatureProperties props = new DefaultXAdESSignatureProperties();
props.setNamespace("http://uri.etsi.org/01903/v1.3.2#"); // sets the namespace for the XAdES
elements; the namespace is related to the XAdES version, default value is
"http://uri.etsi.org/01903/v1.3.2#", other possible values are "http://uri.etsi.org/01903/v1.1.1#" and
"http://uri.etsi.org/01903/v1.2.2#"
props.setPrefix("etsi"); // sets the prefix for the XAdES elements, default value is "etsi"

// signing certificate
props.setKeystore(keystore);
props.setAlias("cert_alias"); // specify the alias of the signing certificate in the keystore = signer key
alias
props.setDigestAlgorithmForSigningCertificate(DigestMethod.SHA256); // possible values for the
algorithm are "http://www.w3.org/2000/09/xmldsig#sha1",
"http://www.w3.org/2001/04/xmlenc#sha256", "http://www.w3.org/2001/04/xmldsig-more#sha384",
"http://www.w3.org/2001/04/xmlenc#sha512", default value is
"http://www.w3.org/2001/04/xmlenc#sha256"
props.setSigningCertificateURIs(Collections.singletonList("http://certuri"));

// signing time
props.setAddSigningTime(true);

// policy
props.setSignaturePolicy(XAdESSignatureProperties.SIG_POLICY_EXPLICIT_ID);
// also the values XAdESSignatureProperties.SIG_POLICY_NONE ("None"), and
XAdESSignatureProperties.SIG_POLICY IMPLIED ("Implied") are possible, default value is
XAdESSignatureProperties.SIG_POLICY_EXPLICIT_ID ("ExplicitId")
// For "None" and "Implied" you must not specify any further policy parameters
props.setSigPolicyId("urn:oid:1.2.840.113549.1.9.16.6.1");

```

```

props.setSigPolicyIdQualifier("OIDAsURN"); //allowed values are empty string, "OIDAsURI",
"OIDAsURN"; default value is empty string
props.setSigPolicyIdDescription("invoice version 3.1");
props.setSignaturePolicyDigestAlgorithm(DigestMethod.SHA256); // possible values for the algorithm
are "http://www.w3.org/2000/09/xmldsig#sha1", "http://www.w3.org/2001/04/xmlenc#sha256",
"http://www.w3.org/2001/04/xmldsig-more#sha384", "http://www.w3.org/2001/04/xmlenc#sha512",
default value is http://www.w3.org/2001/04/xmlenc#sha256"
props.setSignaturePolicyDigestValue("Ohixl6upD6av8N7pEvDABhEL6hM=");
// you can add qualifiers for the signature policy either by specifying text or an XML fragment with the
root element "SigPolicyQualifier"
props.setSigPolicyQualifiers(Arrays
    .asList(new String[] {
        "<SigPolicyQualifier xmlns=\"http://uri.etsi.org/01903/v1.3.2#\">
<SPURI>http://test.com/sig.policy.pdf</SPURI><SPUserNotice><ExplicitText>display
text</ExplicitText>
        + "</SPUserNotice></SigPolicyQualifier>", "category B" }));
props.setSigPolicyIdDocumentationReferences(Arrays.asList(new String[]
{"http://test.com/policy.doc.ref1.txt",
    "http://test.com/policy.doc.ref2.txt" }));

// production place
props.setSignatureProductionPlaceCity("Munich");
props.setSignatureProductionPlaceCountryName("Germany");
props.setSignatureProductionPlacePostalCode("80331");
props.setSignatureProductionPlaceStateOrProvince("Bavaria");

//role
// you can add claimed roles either by specifying text or an XML fragment with the root element
"ClaimedRole"
props.setSignerClaimedRoles(Arrays.asList(new String[] {"test",
    "<a:ClaimedRole xmlns:a=\"http://uri.etsi.org/01903/v1.3.2#\"><TestRole>TestRole</TestRole>
</a:ClaimedRole>" }));
props.setSignerCertifiedRoles(Collections.singletonList(new
XAdESEncapsulatedPKIData("Ahixl6upD6av8N7pEvDABhEL6hM=",
    "http://uri.etsi.org/01903/v1.2.2#DER", "IdCertifiedRole")));

// data object format
props.setDataObjectFormatDescription("invoice");
props.setDataObjectFormatMimeType("text/xml");
props.setDataObjectFormatIdentifier("urn:oid:1.2.840.113549.1.9.16.6.2");
props.setDataObjectFormatIdentifierQualifier("OIDAsURN"); //allowed values are empty string,
"OIDAsURI", "OIDAsURN"; default value is empty string
props.setDataObjectFormatIdentifierDescription("identifier desc");
props.setDataObjectFormatIdentifierDocumentationReferences(Arrays.asList(new String[] {
    "http://test.com/dataobject.format.doc.ref1.txt", "http://test.com/dataobject.format.doc.ref2.txt" }));

//commitment
props.setCommitmentTypeId("urn:oid:1.2.840.113549.1.9.16.6.4");
props.setCommitmentTypeIdQualifier("OIDAsURN"); //allowed values are empty string, "OIDAsURI",
"OIDAsURN"; default value is empty string
props.setCommitmentTypeIdDescription("description for commitment type ID");
props.setCommitmentTypeIdDocumentationReferences(Arrays.asList(new String[]
{"http://test.com/commitment.ref1.txt",
    "http://test.com/commitment.ref2.txt" }));
// you can specify a commitment type qualifier either by simple text or an XML fragment with root
element "CommitmentTypeQualifier"

```

```

props.setCommitmentTypeQualifiers(Arrays.asList(new String[] {"commitment qualifier",
    "<c:CommitmentTypeQualifier xmlns:c='http://uri.etsi.org/01903/v1.3.2#'><C>c</C>
</c:CommitmentTypeQualifier>" }));

beanRegistry.bind("xmlSignatureProperties",props);
beanRegistry.bind("keyAccessorDefault",keyAccessor);

// you must reference the properties bean in the "xmlsecurity" URI
from("direct:xades").to("xmlsecurity:sign://xades?
keyAccessor=#keyAccessorDefault&properties=#xmlSignatureProperties")
    .to("mock:result");

```

XAdES-BES/EPES Example in Spring XML

```

...
<from uri="direct:xades" />
  <to
    uri="xmlsecurity:sign://xades?keyAccessor=#accessorRsa&properties=#xadesProperties"
  />
  <to uri="mock:result" />
...
<bean id="xadesProperties"
  class="org.apache.camel.component.xmlsecurity.api.XAdESSignatureProperties">
  <!-- For more properties see the previous Java DSL example.
    If you want to have a signing certificate then use the bean class
    DefaultXAdESSignatureProperties (see the previous Java DSL example). -->
  <property name="signaturePolicy" value="ExplicitId" />
  <property name="sigPolicyId" value="http://www.test.com/policy.pdf" />
  <property name="sigPolicyIdDescription" value="factura" />
  <property name="signaturePolicyDigestAlgorithm"
value="http://www.w3.org/2000/09/xmldsig#sha1" />
  <property name="signaturePolicyDigestValue" value="Ohixl6upD6av8N7pEvDABhEL1hM=" />
  <property name="signerClaimedRoles" ref="signerClaimedRoles_XMLSigner" />
  <property name="dataObjectFormatDescription" value="Factura electrónica" />
  <property name="dataObjectFormatMimeType" value="text/xml" />
</bean>
<bean class="java.util.ArrayList" id="signerClaimedRoles_XMLSigner">
  <constructor-arg>
    <list>
      <value>Emisor</value>
      <value>&lt;ClaimedRole
        xmlns='http://uri.etsi.org/01903/v1.3.2#'&gt;&lt;test
        xmlns='http://test.com/'&gt;&lt;test&gt;&lt;/ClaimedRole&gt;</value>
    </list>
  </constructor-arg>
</bean>

```

373.8.1. Headers

Header	Type	Description
CamelXmlSignatureXAdESQualifyingPropertiesId	String	for the 'Id' attribute value of QualifyingProperties element
CamelXmlSignatureXAdESSignedDataObjectPropertiesId	String	for the 'Id' attribute value of SignedDataObjectProperties element
CamelXmlSignatureXAdESSignedSignaturePropertiesId	String	for the 'Id' attribute value of SignedSignatureProperties element
CamelXmlSignatureXAdESDataObjectFormatEncoding	String	for the value of the Encoding element of the DataObjectFormat element
CamelXmlSignatureXAdESNamespace	String	overwrites the XAdES namespace parameter value
CamelXmlSignatureXAdESPrefix	String	overwrites the XAdES prefix parameter value

373.8.2. Limitations with regard to XAdES version 1.4.2

- No support for signature form XAdES-T and XAdES-C
- Only signer part implemented. Verifier part currently not available.
- No support for the **QualifyingPropertiesReference** element (see section 6.3.2 of spec).
- No support for the **Transforms** element contained in the **SignaturePolicyId** element contained in the **SignaturePolicyIdentifier** element
- No support of the **CounterSignature** element → no support for the **UnsignedProperties** element
- At most one **DataObjectFormat** element. More than one **DataObjectFormat** element makes no sense because we have only one data object which is signed (this is the incoming message body to the XML signer endpoint).

- At most one **CommitmentTypeIndication** element. More than one **CommitmentTypeIndication** element makes no sense because we have only one data object which is signed (this is the incoming message body to the XML signer endpoint).
- A **CommitmentTypeIndication** element contains always the **AllSignedDataObjects** element. The **ObjectReference** element within **CommitmentTypeIndication** element is not supported.
- The **AllDataObjectsTimeStamp** element is not supported
- The **IndividualDataObjectsTimeStamp** element is not supported

373.9. SEE ALSO

- [Best Practices](#)

CHAPTER 374. XMPP COMPONENT

Available as of Camel version 1.0

The `xmpp`: component implements an XMPP (Jabber) transport.

Maven users will need to add the following dependency to their `pom.xml` for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-xmpp</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

374.1. URI FORMAT

```
xmpp://[login@]hostname[:port][/]participant[?Options]
```

The component supports both room based and private person-person conversations.

The component supports both producer and consumer (you can get messages from XMPP or send messages to XMPP). Consumer mode supports rooms starting.

You can append query options to the URI in the following format, `?option=value&option=value&...`

374.2. OPTIONS

The XMPP component has no options.

The XMPP endpoint is configured using URI syntax:

```
xmpp:host:port/participant
```

with the following path and query parameters:

374.2.1. Path Parameters (3 parameters):

Name	Description	Default	Type
<code>host</code>	Required Hostname for the chat server		String
<code>port</code>	Required Port number for the chat server		int
<code>participant</code>	JID (Jabber ID) of person to receive messages. room parameter has precedence over participant.		String

374.2.2. Query Parameters (18 parameters):

Name	Description	Default	Type
login (common)	Whether to login the user.	true	boolean
nickname (common)	Use nickname when joining room. If room is specified and nickname is not, user will be used for the nickname.		String
pubsub (common)	Accept pubsub packets on input, default is false	false	boolean
room (common)	If this option is specified, the component will connect to MUC (Multi User Chat). Usually, the domain name for MUC is different from the login domain. For example, if you are supermanjabber.org and want to join the krypton room, then the room URL is kryptonconference.jabber.org. Note the conference part. It is not a requirement to provide the full room JID. If the room parameter does not contain the symbol, the domain part will be discovered and added by Camel		String
serviceName (common)	The name of the service you are connecting to. For Google Talk, this would be gmail.com.		String
testConnectionOnStartup (common)	Specifies whether to test the connection on startup. This is used to ensure that the XMPP client has a valid connection to the XMPP server when the route starts. Camel throws an exception on startup if a connection cannot be established. When this option is set to false, Camel will attempt to establish a lazy connection when needed by a producer, and will poll for a consumer connection until the connection is established. Default is true.	true	boolean
createAccount (common)	If true, an attempt to create an account will be made. Default is false.	false	boolean
resource (common)	XMPP resource. The default is Camel.	Camel	String
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean

Name	Description	Default	Type
connectionPollDelay (consumer)	The amount of time in seconds between polls (in seconds) to verify the health of the XMPP connection, or between attempts to establish an initial consumer connection. Camel will try to re-establish a connection if it has become inactive. Default is 10 seconds.	10	int
doc (consumer)	Set a doc header on the IN message containing a Document form of the incoming packet; default is true if presence or pubsub are true, otherwise false	false	boolean
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
connectionConfig (advanced)	To use an existing connection configuration. Currently org.jivesoftware.smack.tcp.XMPPTCPConnectionConfiguration is only supported (XMPP over TCP).		ConnectionConfiguration
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
headerFilterStrategy (filter)	To use a custom HeaderFilterStrategy to filter header to and from Camel message.		HeaderFilterStrategy
password (security)	Password for login		String
user (security)	User name (without server name). If not specified, anonymous login will be attempted.		String

374.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 2 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.xmpp.enabled</code>	Enable xmpp component	true	Boolean
<code>camel.component.xmpp.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

374.4. HEADERS AND SETTING SUBJECT OR LANGUAGE

Camel sets the message IN headers as properties on the XMPP message. You can configure a **HeaderFilterStrategy** if you need custom filtering of headers. The **Subject** and **Language** of the XMPP message are also set if they are provided as IN headers.

374.5. EXAMPLES

User **superman** to join room **krypton** at **jabber** server with password, **secret**:

```
xmpp://superman@jabber.org/?room=krypton@conference.jabber.org&password=secret
```

User **superman** to send messages to **joker**:

```
xmpp://superman@jabber.org/joker@jabber.org?password=secret
```

Routing example in Java:

```
from("timer://kickoff?period=10000").
  setBody(constant("I will win!\n Your Superman.")).
  to("xmpp://superman@jabber.org/joker@jabber.org?password=secret");
```

Consumer configuration, which writes all messages from **joker** into the queue, **evil.talk**.

```
from("xmpp://superman@jabber.org/joker@jabber.org?password=secret").
  to("activemq:evil.talk");
```

Consumer configuration, which listens to room messages:

```
from("xmpp://superman@jabber.org/?password=secret&room=krypton@conference.jabber.org").
  to("activemq:krypton.talk");
```

Room in short notation (no domain part):

```
from("xmpp://superman@jabber.org/?password=secret&room=krypton").
  to("activemq:krypton.talk");
```

When connecting to the Google Chat service, you'll need to specify the **serviceName** as well as your credentials:

```
from("direct:start").  
  to("xmpp://talk.google.com:5222/touser@gmail.com?  
  serviceName=gmail.com&user=fromuser&password=secret").  
  to("mock:result");
```

374.6. SEE ALSO

- [Configuring Camel](#)
- [Component](#)
- [Endpoint](#)
- [Getting Started](#)

CHAPTER 375. XPATH LANGUAGE

Available as of Camel version 1.1

Camel supports [XPath](#) to allow an Expression or Predicate to be used in the DSL or [Xml Configuration](#). For example you could use XPath to create an Predicate in a [Message Filter](#) or as an Expression for a Recipient List.

Streams

If the message body is stream based, which means the input it receives is submitted to Camel as a stream. That means you will only be able to read the content of the stream **once**. So often when you use [XPath](#) as [Message Filter](#) or Content Based Router then you need to access the data multiple times, and you should use Stream Caching or convert the message body to a **String** prior which is safe to be re-read multiple times.

```
from("queue:foo").
  filter().xpath("//foo").
  to("queue:bar")
```

```
from("queue:foo").
  choice().xpath("//foo").to("queue:bar").
  otherwise().to("queue:others");
```

375.1. XPATH LANGUAGE OPTIONS

The XPath language supports 9 options, which are listed below.

Name	Default	Java Type	Description
documentType		String	Name of class for document type The default value is org.w3c.dom.Document
resultType	NODE SET	String	Sets the class name of the result type (type from output) The default result type is NodeSet
saxon	false	Boolean	Whether to use Saxon.
factoryRef		String	References to a custom XPathFactory to lookup in the registry
objectModel		String	The XPath object model to use
logNamespaces	false	Boolean	Whether to log namespaces which can assist during trouble shooting
headerName		String	Name of header to use as input, instead of the message body

Name	Default	Java Type	Description
threadSafety	false	Boolean	Whether to enable thread-safety for the returned result of the xpath expression. This applies to when using NODESET as the result type, and the returned set has multiple elements. In this situation there can be thread-safety issues if you process the NODESET concurrently such as from a Camel Splitter EIP in parallel processing mode. This option prevents concurrency issues by doing defensive copies of the nodes. It is recommended to turn this option on if you are using camel-saxon or Saxon in your application. Saxon has thread-safety issues which can be prevented by turning this option on.
trim	true	Boolean	Whether to trim the value to remove leading and trailing whitespaces and line breaks

375.2. NAMESPACES

You can easily use namespaces with XPath expressions using the Namespaces helper class.

375.3. VARIABLES

Variables in XPath is defined in different namespaces. The default namespace is <http://camel.apache.org/schema/spring>.

Namespace URI	Local part	Type	Description
http://camel.apache.org/xml/in/	in	Message	the exchange.in message
http://camel.apache.org/xml/out/	out	Message	the exchange.out message
http://camel.apache.org/xml/function/	functions	Object	Camel 2.5: Additional functions

Names pace URI	Local part	Type	Description
http://camel.apache.org/xml/variables/environment-variables	env	Object	OS environment variables
http://camel.apache.org/xml/variables/system-properties	system	Object	Java System properties
http://camel.apache.org/xml/variables/exchange-property		Object	the exchange property

Camel will resolve variables according to either:

- namespace given
- no namespace given

375.3.1. Namespace given

If the namespace is given then Camel is instructed exactly what to return. However when resolving either **in** or **out** Camel will try to resolve a header with the given local part first, and return it. If the local part has the value **body** then the body is returned instead.

375.3.2. No namespace given

If there is no namespace given then Camel resolves only based on the local part. Camel will try to resolve a variable in the following steps:

- from **variables** that has been set using the **variable(name, value)** fluent builder

- from message.in.header if there is a header with the given key
- from exchange.properties if there is a property with the given key

375.4. FUNCTIONS

Camel adds the following XPath functions that can be used to access the exchange:

Function	Argument	Type	Description
in:body	none	Object	Will return the in message body.
in:header	the header name	Object	Will return the in message header.
out:body	none	Object	Will return the out message body.
out:header	the header name	Object	Will return the out message header.
function:properties	key for property	String	Camel 2.5: To lookup a property using the Properties component (property placeholders).
function:simple	simple expression	Object	Camel 2.5: To evaluate a Simple expression.

CAUTION

function:properties and **function:simple** is not supported when the return type is a **NodeSet**, such as when using with a Splitter EIP.

Here's an example showing some of these functions in use.

And the new functions introduced in Camel 2.5:

375.5. USING XML CONFIGURATION

If you prefer to configure your routes in your Spring XML file then you can use XPath expressions as follows

```
<beans xmlns="http://www.springframework.org/schema/beans"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="
    http://www.springframework.org/schema/beans
    http://www.springframework.org/schema/beans/spring-beans.xsd
```

```

    http://camel.apache.org/schema/spring http://camel.apache.org/schema/spring/camel-
spring.xsd">

    <camelContext id="camel" xmlns="http://activemq.apache.org/camel/schema/spring"
xmlns:foo="http://example.com/person">
    <route>
    <from uri="activemq:MyQueue"/>
    <filter>
    <xpath>/foo:person[@name='James']</xpath>
    <to uri="mqseries:SomeOtherQueue"/>
    </filter>
    </route>
    </camelContext>
</beans>

```

Notice how we can reuse the namespace prefixes, **foo** in this case, in the XPath expression for easier namespace based XPath expressions!

See also this [discussion on the mailinglist](#) about using your own namespaces with xpath

375.6. SETTING RESULT TYPE

The XPath expression will return a result type using native XML objects such as **org.w3c.dom.NodeList**. But many times you want a result type to be a String. To do this you have to instruct the XPath which result type to use.

In Java DSL:

```

xpath("/foo:person/@id", String.class)

```

In Spring DSL you use the **resultType** attribute to provide a fully qualified classname:

```

<xpath resultType="java.lang.String"/>/foo:person/@id</xpath>

```

In @XPath:

Available as of Camel 2.1

```

@XPath(value = "concat('foo-',//order/name)", resultType = String.class) String name)

```

Where we use the xpath function concat to prefix the order name with **foo-**. In this case we have to specify that we want a String as result type so the concat function works.

375.7. USING XPATH ON HEADERS

Available as of Camel 2.11

Some users may have XML stored in a header. To apply an XPath to a header's value you can do this by defining the 'headerName' attribute.

And in Java DSL you specify the headerName as the 2nd parameter as shown:

```

xpath("/invoice/@orderType = 'premium'", "invoiceDetails")

```

375.8. EXAMPLES

Here is a simple [example](#) using an XPath expression as a predicate in a Message Filter

If you have a standard set of namespaces you wish to work with and wish to share them across many different XPath expressions you can use the NamespaceBuilder as shown [in this example](#)

In this sample we have a choice construct. The first choice evaluates if the message has a header key **type** that has the value **Camel**.

The 2nd choice evaluates if the message body has a name tag **<name>** which values is **Kong**.

If neither is true the message is routed in the otherwise block:

And the spring XML equivalent of the route:

375.9. XPATH INJECTION

You can use Bean Integration to invoke a method on a bean and use various languages such as XPath to extract a value from the message and bind it to a method parameter.

The default XPath annotation has SOAP and XML namespaces available. If you want to use your own namespace URIs in an XPath expression you can use your own copy of the [XPath annotation](#) to create whatever namespace prefixes you want to use.

i.e. cut and paste upper code to your own project in a different package and/or annotation name then add whatever namespace prefix/uris you want in scope when you use your annotation on a method parameter. Then when you use your annotation on a method parameter all the namespaces you want will be available for use in your XPath expression.

For example

```
public class Foo {
    @MessageDriven(uri = "activemq:my.queue")
    public void doSomething(@MyXPath("/ns1:foo/ns2:bar/text()") String correlationID, @Body String
body) {
        // process the inbound message here
    }
}
```

375.10. USING XPATHBUILDER WITHOUT AN EXCHANGE

Available as of Camel 2.3

You can now use the **org.apache.camel.builder.XPathBuilder** without the need for an Exchange. This comes handy if you want to use it as a helper to do custom xpath evaluations.

It requires that you pass in a CamelContext since a lot of the moving parts inside the XPathBuilder requires access to the Camel Type Converter and hence why CamelContext is needed.

For example you can do something like this:

```
boolean matches = XPathBuilder.xpath("/foo/bar/@xyz").matches(context, "<foo><bar xyz='cheese'/>
</foo>");
```

This will match the given predicate.

You can also evaluate for example as shown in the following three examples:

```
String name = XPathBuilder.xpath("foo/bar").evaluate(context, "<foo><bar>cheese</bar></foo>",
String.class);
Integer number = XPathBuilder.xpath("foo/bar").evaluate(context, "<foo><bar>123</bar></foo>",
Integer.class);
Boolean bool = XPathBuilder.xpath("foo/bar").evaluate(context, "<foo><bar>>true</bar></foo>",
Boolean.class);
```

Evaluating with a String result is a common requirement and thus you can do it a bit simpler:

```
String name = XPathBuilder.xpath("foo/bar").evaluate(context, "<foo><bar>cheese</bar></foo>");
```

375.11. USING SAXON WITH XPATHBUILDER

Available as of Camel 2.3

You need to add **camel-saxon** as dependency to your project.

Its now easier to use [Saxon](#) with the XPathBuilder which can be done in several ways as shown below. Where as the latter ones are the easiest ones.

- Using a factory
- Using ObjectModel

The easy one

375.12. SETTING A CUSTOM XPATHFACTORY USING SYSTEM PROPERTY

Available as of Camel 2.3

Camel now supports reading the [JVM system property](#) **javax.xml.xpath.XPathFactory** that can be used to set a custom XPathFactory to use.

This unit test shows how this can be done to use Saxon instead:

Camel will log at **INFO** level if it uses a non default XPathFactory such as:

```
XPathBuilder INFO Using system property
javax.xml.xpath.XPathFactory:http://saxon.sf.net/jaxp/xpath/om with value:
    net.sf.saxon.xpath.XPathFactoryImpl when creating XPathFactory
```

To use Apache Xerces you can configure the system property

```
-Djavax.xml.xpath.XPathFactory=org.apache.xpath.jaxp.XPathFactoryImpl
```

375.13. ENABLING SAXON FROM SPRING DSL

Available as of Camel 2.10

Similarly to Java DSL, to enable Saxon from Spring DSL you have three options:

Specifying the factory

```
<xpath factoryRef="saxonFactory" resultType="java.lang.String">current-dateTime()</xpath>
```

Specifying the object model

```
<xpath objectModel="http://saxon.sf.net/jaxp/xpath/om" resultType="java.lang.String">current-dateTime()</xpath>
```

Shortcut

```
<xpath saxon="true" resultType="java.lang.String">current-dateTime()</xpath>
```

375.14. NAMESPACE AUDITING TO AID DEBUGGING

Available as of Camel 2.10

A large number of XPath-related issues that users frequently face are linked to the usage of namespaces. You may have some misalignment between the namespaces present in your message and those that your XPath expression is aware of or referencing. XPath predicates or expressions that are unable to locate the XML elements and attributes due to namespaces issues may simply look like "they are not working", when in reality all there is to it is a lack of namespace definition.

Namespaces in XML are completely necessary, and while we would love to simplify their usage by implementing some magic or voodoo to wire namespaces automatically, truth is that any action down this path would disagree with the standards and would greatly hinder interoperability.

Therefore, the utmost we can do is assist you in debugging such issues by adding two new features to the XPath Expression Language and are thus accesible from both predicates and expressions.

#=== Logging the Namespace Context of your XPath expression/predicate

Every time a new XPath expression is created in the internal pool, Camel will log the namespace context of the expression under the **org.apache.camel.builder.xml.XPathBuilder** logger. Since Camel represents Namespace Contexts in a hierarchical fashion (parent-child relationships), the entire tree is output in a recursive manner with the following format:

```
[me: {prefix -> namespace}, {prefix -> namespace}], [parent: [me: {prefix -> namespace}, {prefix -> namespace}], [parent: [me: {prefix -> namespace}]]]
```

Any of these options can be used to activate this logging:

1. Enable TRACE logging on the **org.apache.camel.builder.xml.XPathBuilder** logger, or some parent logger such as **org.apache.camel** or the root logger
2. Enable the **logNamespaces** option as indicated in [Auditing Namespaces](#), in which case the logging will occur on the INFO level

375.15. AUDITING NAMESPACES

Camel is able to discover and dump all namespaces present on every incoming message before evaluating an XPath expression, providing all the richness of information you need to help you analyse and pinpoint possible namespace issues.

To achieve this, it in turn internally uses another specially tailored XPath expression to extract all namespace mappings that appear in the message, displaying the prefix and the full namespace URI(s) for each individual mapping.

Some points to take into account:

- The implicit XML namespace (`xmlns:xml="http://www.w3.org/XML/1998/namespace"`) is suppressed from the output because it adds no value
- Default namespaces are listed under the `DEFAULT` keyword in the output
- Keep in mind that namespaces can be remapped under different scopes. Think of a top-level 'a' prefix which in inner elements can be assigned a different namespace, or the default namespace changing in inner scopes. For each discovered prefix, all associated URIs are listed.

You can enable this option in Java DSL and Spring DSL.

Java DSL:

```
XPathBuilder.xpath("/foo:person/@id", String.class).logNamespaces()
```

Spring DSL:

```
<xpath logNamespaces="true" resultType="String">/foo:person/@id</xpath>
```

The result of the auditing will be appear at the INFO level under the **org.apache.camel.builder.xml.XPathBuilder** logger and will look like the following:

```
2012-01-16 13:23:45,878 [stSaxonWithFlag] INFO XPathBuilder - Namespaces discovered in
message:
{xmlns:a=[http://apache.org/camel], DEFAULT=[http://apache.org/default],
xmlns:b=[http://apache.org/camelA, http://apache.org/camelB]}
```

375.16. LOADING SCRIPT FROM EXTERNAL RESOURCE

Available as of Camel 2.11

You can externalize the script and have Camel load it from a resource such as **"classpath:"**, **"file:"**, or **"http:"**.

This is done using the following syntax: **"resource:scheme:location"**, eg to refer to a file on the classpath you can do:

```
.setHeader("myHeader").xpath("resource:classpath:myxpath.txt", String.class)
```

375.17. DEPENDENCIES

The XPath language is part of camel-core.

CHAPTER 376. XQUERY COMPONENT

Available as of Camel version 1.0

Camel supports [XQuery](#) to allow an Expression or Predicate to be used in the DSL or [Xml Configuration](#). For example you could use XQuery to create an Predicate in a [Message Filter](#) or as an Expression for a Recipient List.

376.1. OPTIONS

The XQuery component supports 4 options, which are listed below.

Name	Description	Default	Type
moduleURIResolver (advanced)	To use the custom ModuleURIResolver		ModuleURIResolver
configuration (advanced)	To use a custom Saxon configuration		Configuration
configurationProperties (advanced)	To set custom Saxon configuration properties		Map
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The XQuery endpoint is configured using URI syntax:

```
xquery:resourceUri
```

with the following path and query parameters:

376.1.1. Path Parameters (1 parameters):

Name	Description	Default	Type
resourceUri	Required The name of the template to load from classpath or file system		String

376.1.2. Query Parameters (31 parameters):

Name	Description	Default	Type
allowStAX (common)	Whether to allow using StAX mode	false	boolean
headerName (common)	To use a Camel Message header as the input source instead of Message body.		String
namespacePrefixes (common)	Allows to control which namespace prefixes to use for a set of namespace mappings		Map
resultsFormat (common)	What output result to use	DOM	ResultFormat
resultType (common)	What output result to use defined as a class		Class
stripsAllWhiteSpace (common)	Whether to strip all whitespaces	true	boolean
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
pollStrategy (consumer)	A pluggable <code>org.apache.camel.PollingConsumerPollingStrategy</code> allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an Exchange have been created and being routed in Camel.		PollingConsumerPollStrategy

Name	Description	Default	Type
configuration (advanced)	To use a custom Saxon configuration		Configuration
configurationProperties (advanced)	To set custom Saxon configuration properties		Map
moduleURIResolver (advanced)	To use the custom ModuleURIResolver		ModuleURIResolver
parameters (advanced)	Additional parameters		Map
properties (advanced)	Properties to configure the serialization parameters		Properties
staticQueryContext (advanced)	To use a custom Saxon StaticQueryContext		StaticQueryContext
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the backoffMultiplier should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the backoffMultiplier should kick-in.		int
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then backoffIdleThreshold and/or backoffErrorThreshold must also be configured.		int
delay (scheduler)	Milliseconds before the next poll. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	500	long
greedy (scheduler)	If greedy is enabled, then the ScheduledPollConsumer will run immediately again, if the previous run polled 1 or more messages.	false	boolean

Name	Description	Default	Type
initialDelay (scheduler)	Milliseconds before the first poll starts. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	1000	long
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that.	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz2 component	none	ScheduledPollConsumerScheduler
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz2, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for initialDelay and delay options.	MILLISECONDS	TimeUnit
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See ScheduledExecutorService in JDK for details.	true	boolean

376.2. SPRING BOOT AUTO-CONFIGURATION

The component supports 8 options, which are listed below.

Name	Description	Default	Type
camel.component.xquery.configuration	To use a custom Saxon configuration. The option is a net.sf.saxon.Configuration type.		String
camel.component.xquery.configuration-properties	To set custom Saxon configuration properties		Map

Name	Description	Default	Type
<code>camel.component.xquery.enabled</code>	Enable xquery component	true	Boolean
<code>camel.component.xquery.module-uri-resolver</code>	To use the custom ModuleURIResolver. The option is a <code>net.sf.saxon.lib.ModuleURIResolver</code> type.		String
<code>camel.component.xquery.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.language.xquery.enabled</code>	Enable xquery language	true	Boolean
<code>camel.language.xquery.trim</code>	Whether to trim the value to remove leading and trailing whitespaces and line breaks	true	Boolean
<code>camel.language.xquery.type</code>	Sets the class name of the result type (type from output) The default result type is <code>NodeSet</code>		String

376.3. EXAMPLES

```
from("queue:foo").filter().
  xquery("//foo").
  to("queue:bar")
```

You can also use functions inside your query, in which case you need an explicit type conversion (or you will get a `org.w3c.dom.DOMException: HIERARCHY_REQUEST_ERR`) by passing the Class as a second argument to the `xquery()` method.

```
from("direct:start").
  recipientList().xquery("concat('mock:foo.', /person/@city)", String.class);
```

376.4. VARIABLES

The IN message body will be set as the **contextItem**. Besides this these Variables is also added as parameters:

Variable	Type	Description
<code>exchange</code>	Exchange	The current Exchange

Variable	Type	Description
in.body	Object	The In message's body
out.body	Object	The OUT message's body (if any)
in.headers.*	Object	You can access the value of exchange.in.headers with key foo by using the variable which name is in.headers.foo
out.headers.*	Object	You can access the value of exchange.out.headers with key foo by using the variable which name is out.headers.foo variable
key name	Object	Any exchange.properties and exchange.in.headers and any additional parameters set using setParameters(Map) . These parameters is added with they own key name, for instance if there is an IN header with the key name foo then its added as foo .

376.5. USING XML CONFIGURATION

If you prefer to configure your routes in your Spring XML file then you can use XPath expressions as follows

```
<beans xmlns="http://www.springframework.org/schema/beans"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xmlns:foo="http://example.com/person"
  xsi:schemaLocation="
    http://www.springframework.org/schema/beans
    http://www.springframework.org/schema/beans/spring-beans.xsd
    http://camel.apache.org/schema/spring http://camel.apache.org/schema/spring/camel-
    spring.xsd">

  <camelContext id="camel" xmlns="http://activemq.apache.org/camel/schema/spring">
    <route>
      <from uri="activemq:MyQueue"/>
      <filter>
        <xquery>/foo:person[@name='James']</xquery>
        <to uri="mqseries:SomeOtherQueue"/>
      </filter>
    </route>
  </camelContext>
</beans>
```

Notice how we can reuse the namespace prefixes, **foo** in this case, in the XPath expression for easier namespace based XQuery expressions!

When you use functions in your XQuery expression you need an explicit type conversion which is done in the xml configuration via the **@type** attribute:

```
<xquery type="java.lang.String">concat('mock:foo.', /person/@city)</xquery>
```

376.6. USING XQUERY AS TRANSFORMATION

We can do a message translation using transform or setBody in the route, as shown below:

```
from("direct:start").
  transform().xquery("/people/person");
```

Notice that xquery will use DOMResult by default, so if we want to grab the value of the person node, using text() we need to tell xquery to use String as result type, as shown:

```
from("direct:start").
  transform().xquery("/people/person/text()", String.class);
```

376.7. USING XQUERY AS AN ENDPOINT

Sometimes an XQuery expression can be quite large; it can essentially be used for Templating. So you may want to use an XQuery Endpoint so you can route using XQuery templates.

The following example shows how to take a message of an ActiveMQ queue (MyQueue) and transform it using XQuery and send it to MQSeries.

```
<camelContext id="camel" xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="activemq:MyQueue"/>
    <to uri="xquery:com/acme/someTransform.xquery"/>
    <to uri="mqseries:SomeOtherQueue"/>
  </route>
</camelContext>
```

Currently custom functions in XQuery might result in a NullPointerException (Camel 2.18, 2.19 and 2.20). This is expected to be fixed in Camel 2.21

376.8. EXAMPLES

Here is a simple [example](#) using an XQuery expression as a predicate in a Message Filter

This [example](#) uses XQuery with namespaces as a predicate in a Message Filter

376.9. LEARNING XQUERY

XQuery is a very powerful language for querying, searching, sorting and returning XML. For help learning XQuery try these tutorials

- Mike Kay's [XQuery Primer](#)
- the W3Schools [XQuery Tutorial](#)

You might also find the [XQuery function reference](#) useful

376.10. LOADING SCRIPT FROM EXTERNAL RESOURCE

Available as of Camel 2.11

You can externalize the script and have Camel load it from a resource such as **"classpath:"**, **"file:"**, or **"http:"**.

This is done using the following syntax: **"resource:scheme:location"**, eg to refer to a file on the classpath you can do:

```
.setHeader("myHeader").xquery("resource:classpath:myxquery.txt", String.class)
```

376.11. DEPENDENCIES

To use XQuery in your camel routes you need to add the a dependency on **camel-saxon** which implements the XQuery language.

If you use maven you could just add the following to your pom.xml, substituting the version number for the latest & greatest release (see the download page for the latest versions).

```
<dependency>  
  <groupId>org.apache.camel</groupId>  
  <artifactId>camel-saxon</artifactId>  
  <version>x.x.x</version>  
</dependency>
```

CHAPTER 377. XSLT COMPONENT

Available as of Camel version 1.3

The `xslt:` component allows you to process a message using an [XSLT](#) template. This can be ideal when using Templating to generate responses for requests.

377.1. URI FORMAT

```
xslt:templateName[?options]
```

The URI format contains `templateName`, which can be one of the following:

- the classpath-local URI of the template to invoke
- the complete URL of the remote template.

You can append query options to the URI in the following format:

```
?option=value&option=value&...
```

Refer to the [Spring Documentation](#) for more detail of the URI syntax.

Table 377.1. Example URIs

URI	Description
<code>xslt:com/acme/mytransform.xml</code>	Refers to the file <code>com/acme/mytransform.xml</code> on the classpath
<code>xslt:file:///foo/bar.xml</code>	Refers to the file <code>/foo/bar.xml</code>
<code>xslt:http://acme.com/cheese/foo.xml</code>	Refers to the remote http resource

For **Camel 2.8** or older, Maven users will need to add the following dependency to their `pom.xml` for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-spring</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

From **Camel 2.9** onwards the [XSLT](#) component is provided directly in the camel-core.

377.2. OPTIONS

The XSLT component supports 9 options, which are listed below.

Name	Description	Default	Type
xmlConverter (advanced)	To use a custom implementation of <code>org.apache.camel.converter.jaxp.XmlConverter</code>		XmlConverter
uriResolverFactory (advanced)	To use a custom <code>UriResolver</code> which depends on a dynamic endpoint resource URI. Should not be used together with the option 'uriResolver'.		XsltUriResolverFactory
uriResolver (advanced)	To use a custom <code>UriResolver</code> . Should not be used together with the option 'uriResolverFactory'.		UriResolver
contentCache (producer)	Cache for the resource content (the stylesheet file) when it is loaded. If set to false Camel will reload the stylesheet file on each message processing. This is good for development. A cached stylesheet can be forced to reload at runtime via JMX using the <code>clearCachedStylesheet</code> operation.	true	boolean
saxon (producer)	Whether to use Saxon as the <code>transformerFactoryClass</code> . If enabled then the class <code>net.sf.saxon.TransformerFactoryImpl</code> . You would need to add Saxon to the classpath.	false	boolean
saxonExtensionFunctions (advanced)	Allows you to use a custom <code>net.sf.saxon.lib.ExtensionFunctionDefinition</code> . You would need to add <code>camel-saxon</code> to the classpath. The function is looked up in the registry, where you can comma to separate multiple values to lookup.		String
saxonConfiguration (advanced)	To use a custom Saxon configuration		Object
saxonConfigurationProperties (advanced)	To set custom Saxon configuration properties		Map
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The XSLT endpoint is configured using URI syntax:

```
xslt:resourceUri
```

with the following path and query parameters:

377.2.1. Path Parameters (1 parameters):

Name	Description	Default	Type
resourceUri	Required Path to the template. The following is supported by the default URIResolver. You can prefix with: classpath, file, http, ref, or bean. classpath, file and http loads the resource using these protocols (classpath is default). ref will lookup the resource in the registry. bean will call a method on a bean to be used as the resource. For bean you can specify the method name after dot, eg bean:myBean.myMethod		String

377.2.2. Query Parameters (17 parameters):

Name	Description	Default	Type
allowStAX (producer)	Whether to allow using StAX as the javax.xml.transform.Source.	true	boolean
contentCache (producer)	Cache for the resource content (the stylesheet file) when it is loaded. If set to false Camel will reload the stylesheet file on each message processing. This is good for development. A cached stylesheet can be forced to reload at runtime via JMX using the clearCachedStylesheet operation.	true	boolean
deleteOutputFile (producer)	If you have output=file then this option dictates whether or not the output file should be deleted when the Exchange is done processing. For example suppose the output file is a temporary file, then it can be a good idea to delete it after use.	false	boolean
failOnNullBody (producer)	Whether or not to throw an exception if the input body is null.	true	boolean
output (producer)	Option to specify which output type to use. Possible values are: string, bytes, DOM, file. The first three options are all in memory based, where as file is streamed directly to a java.io.File. For file you must specify the filename in the IN header with the key Exchange.XSLT_FILE_NAME which is also CamelXsltFileName. Also any paths leading to the filename must be created beforehand, otherwise an exception is thrown at runtime.	string	XsltOutput
saxon (producer)	Whether to use Saxon as the transformerFactoryClass. If enabled then the class net.sf.saxon.TransformerFactoryImpl. You would need to add Saxon to the classpath.	false	boolean

Name	Description	Default	Type
transformerCacheSize (producer)	The number of javax.xml.transform.Transformer object that are cached for reuse to avoid calls to Template.newTransformer().	0	int
converter (advanced)	To use a custom implementation of org.apache.camel.converter.jaxp.XmlConverter		XmlConverter
entityResolver (advanced)	To use a custom org.xml.sax.EntityResolver with javax.xml.transform.sax.SAXSource.		EntityResolver
errorListener (advanced)	Allows to configure to use a custom javax.xml.transform.ErrorListener. Beware when doing this then the default error listener which captures any errors or fatal errors and store information on the Exchange as properties is not in use. So only use this option for special use-cases.		ErrorListener
resultHandlerFactory (advanced)	Allows you to use a custom org.apache.camel.builder.xml.ResultHandlerFactory which is capable of using custom org.apache.camel.builder.xml.ResultHandler types.		ResultHandlerFactory
saxonConfiguration (advanced)	To use a custom Saxon configuration		Object
saxonExtensionFunctions (advanced)	Allows you to use a custom net.sf.saxon.lib.ExtensionFunctionDefinition. You would need to add camel-saxon to the classpath. The function is looked up in the registry, where you can comma to separate multiple values to lookup.		String
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
transformerFactory (advanced)	To use a custom XSLT transformer factory		TransformerFactory
transformerFactoryClass (advanced)	To use a custom XSLT transformer factory, specified as a FQN class name		String
uriResolver (advanced)	To use a custom javax.xml.transform.URIResolver		URIResolver

377.3. USING XSLT ENDPOINTS

The following format is an example of using an XSLT template to formulate a response for a message for InOut message exchanges (where there is a **JMSReplyTo** header)

```
from("activemq:My.Queue").
  to("xslt:com/acme/mytransform.xsl");
```

If you want to use InOnly and consume the message and send it to another destination you could use the following route:

```
from("activemq:My.Queue").
  to("xslt:com/acme/mytransform.xsl").
  to("activemq:Another.Queue");
```

377.4. GETTING USEABLE PARAMETERS INTO THE XSLT

By default, all headers are added as parameters which are then available in the XSLT. To make the parameters useable, you will need to declare them.

```
<setHeader headerName="myParam"><constant>42</constant></setHeader>
<to uri="xslt:MyTransform.xsl"/>
```

The parameter also needs to be declared in the top level of the XSLT for it to be available:

```
<xsl: ..... >
  <xsl:param name="myParam"/>
  <xsl:template ...>
```

377.5. SPRING XML VERSIONS

To use the above examples in Spring XML you would use something like the following code:

```
<camelContext xmlns="http://activemq.apache.org/camel/schema/spring">
  <route>
    <from uri="activemq:My.Queue"/>
    <to uri="xslt:org/apache/camel/spring/processor/example.xsl"/>
    <to uri="activemq:Another.Queue"/>
  </route>
</camelContext>
```

To see an example, look at the [test case](#) along with its [Spring XML](#).

377.6. USING XSL:INCLUDE

Camel 2.2 or older

If you use **xsl:include** in your XSL files in **Camel 2.2 or older**, the default **javax.xml.transform.URIResolver** is used. Files will be resolved relative to the JVM starting folder.

For example the following include statement will look up the **staff_template.xsl** file starting from the folder where the application was started.

```
<xsl:include href="staff_template.xml"/>
```

Camel 2.3 or newer

For Camel 2.3 or newer, Camel provides its own implementation of **URIResolver**. This allows Camel to load included files from the classpath.

For example the include file in the following code will be located relative to the starting endpoint.

```
<xsl:include href="staff_template.xml"/>
```

This means that Camel will locate the file in the **classpath** as **org/apache/camel/component/xslt/staff_template.xml**

You can use **classpath:** or **file:** to instruct Camel to look either in the classpath or file system. If you omit the prefix then Camel uses the prefix from the endpoint configuration. If no prefix is specified in the endpoint configuration, the default is **classpath:**.

You can also refer backwards in the include paths. In the following example, the xml file will be resolved under **org/apache/camel/component**.

```
<xsl:include href="../staff_other_template.xml"/>
```

377.7. USING XSL:INCLUDE AND DEFAULT PREFIX

In **Camel 2.10.3 and older**, **classpath:** is used as the default prefix.

If you configure the starting resource to load using **file:** then all subsequent includes will have to be prefixed with **file:**.

From **Camel 2.10.4**, Camel will use the prefix from the endpoint configuration as the default prefix.

You can explicitly specify **file:** or **classpath:** loading. The two loading types can be mixed in a XSLT script, if necessary.

377.8. USING SAXON EXTENSION FUNCTIONS

Since Saxon 9.2, writing extension functions has been supplemented by a new mechanism, referred to as **integrated extension functions** you can now easily use camel as shown in the below example:

```
SimpleRegistry registry = new SimpleRegistry();
registry.put("function1", new MyExtensionFunction1());
registry.put("function2", new MyExtensionFunction2());

CamelContext context = new DefaultCamelContext(registry);
context.addRoutes(new RouteBuilder() {
    @Override
    public void configure() throws Exception {
        from("direct:start")
            .to("xslt:org/apache/camel/component/xslt/extensions/extensions.xml?
saxonExtensionFunctions=#function1,#function2");
    }
});
```

With Spring XML:

```

<bean id="function1" class="org.apache.camel.component.xslt.extensions.MyExtensionFunction1"/>
<bean id="function2" class="org.apache.camel.component.xslt.extensions.MyExtensionFunction2"/>

<camelContext xmlns="http://camel.apache.org/schema/spring">
  <route>
    <from uri="direct:extensions"/>
    <to uri="xslt:org/apache/camel/component/xslt/extensions/extensions.xslt?
saxonExtensionFunctions=#function1,#function2"/>
  </route>
</camelContext>

```

377.9. DYNAMIC STYLESHEETS

To provide a dynamic stylesheet at runtime you can define a dynamic URI. See [How to use a dynamic URI in to\(\)](#) for more information.

Available as of Camel 2.9 (removed in 2.11.4, 2.12.3 and 2.13.0)

Camel provides the **CamelXsltResourceUri** header which you can use to define an alternative stylesheet to that configured on the endpoint URI. This allows you to provide a dynamic stylesheet at runtime.

377.10. ACCESSING WARNINGS, ERRORS AND FATAL ERRORS FROM XSLT ERRORLISTENER

Available as of Camel 2.14

From **Camel 2.14**, any warning/error or fatalError is stored on the current Exchange as a property with the keys **Exchange.XSLT_ERROR**, **Exchange.XSLT_FATAL_ERROR**, or **Exchange.XSLT_WARNING** which allows end users to get hold of any errors happening during transformation.

For example in the stylesheet below, we want to terminate if a staff has an empty dob field. And to include a custom error message using `xsl:message`.

```

<xsl:template match="/">
  <html>
    <body>
      <xsl:for-each select="staff/programmer">
        <p>Name: <xsl:value-of select="name"/><br />
          <xsl:if test="dob="">
            <xsl:message terminate="yes">Error: DOB is an empty string!</xsl:message>
          </xsl:if>
        </p>
      </xsl:for-each>
    </body>
  </html>
</xsl:template>

```

The exception is stored on the Exchange as a warning with the key **Exchange.XSLT_WARNING**.

377.11. NOTES ON USING XSLT AND JAVA VERSIONS

Here are some observations from Sameer, a Camel user, which he kindly shared with us:

In case anybody faces issues with the XSLT endpoint please review these points.

I was trying to use an xslt endpoint for a simple transformation from one xml to another using a simple xsl. The output xml kept appearing (after the xslt processor in the route) with outermost xml tag with no content within.

No explanations show up in the DEBUG logs. On the TRACE logs however I did find some error/warning indicating that the XMLConverter bean could no be initialized.

After a few hours of cranking my mind, I had to do the following to get it to work (thanks to some posts on the users forum that gave some clue):

1. Use the transformerFactory option in the route ("**xslt:my-transformer.xsl? transformerFactory=tFactory**") with the **tFactory** bean having been defined in the spring context for **class="org.apache.xalan.xsltc.trax.TransformerFactoryImpl"**.
2. Added the Xalan jar into my maven pom.

My guess is that the default xml parsing mechanism supplied within the JDK (I am using 1.6.0_03) does not work right in this context and does not throw up any error either. When I switched to Xalan this way it works. This is not a Camel issue, but might need a mention on the xslt component page.

Another note, jdk 1.6.0_03 ships with JAXB 2.0 while Camel needs 2.1. One workaround is to add the 2.1 jar to the **jre/lib/endorsed** directory for the jvm or as specified by the container.

Hope this post saves newbie Camel riders some time.

- [Configuring Camel](#)
- [Component](#)
- [Endpoint](#)
- [Getting Started](#)

CHAPTER 378. XSTREAM DATAFORMAT

Available as of Camel version 1.3

XStream is a Data Format which uses the [XStream library](#) to marshal and unmarshal Java objects to and from XML.

To use XStream in your camel routes you need to add the a dependency on **camel-xstream** which implements this data format.

Maven users will need to add the following dependency to their **pom.xml** for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-xstream</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

378.1. OPTIONS

The XStream dataformat supports 10 options, which are listed below.

Name	Default	Java Type	Description
permissions		String	Adds permissions that controls which Java packages and classes XStream is allowed to use during unmarshal from xml/json to Java beans. A permission must be configured either here or globally using a JVM system property. The permission can be specified in a syntax where a plus sign is allow, and minus sign is deny. Wildcards is supported by using . as prefix. For example to allow com.foo and all subpackages then specify com.foo.. Multiple permissions can be configured separated by comma, such as com.foo.,-com.foo.bar.MySecretBean. The following default permission is always included: - java.lang.,java.util. unless its overridden by specifying a JVM system property with they key org.apache.camel.xstream.permissions.
encoding		String	Sets the encoding to use
driver		String	To use a custom XStream driver. The instance must be of type com.thoughtworks.xstream.io.HierarchicalStreamDriver
driverRef		String	To refer to a custom XStream driver to lookup in the registry. The instance must be of type com.thoughtworks.xstream.io.HierarchicalStreamDriver

Name	Default	Java Type	Description
<code>mode</code>		String	Mode for dealing with duplicate references The possible values are: NO_REFERENCES ID_REFERENCES XPATH_RELATIVE_REFERENCES XPATH_ABSOLUTE_REFERENCES SINGLE_NODE_XPATH_RELATIVE_REFERENCES SINGLE_NODE_XPATH_ABSOLUTE_REFERENCES
<code>converters</code>		List	List of class names for using custom XStream converters. The classes must be of type <code>com.thoughtworks.xstream.converters.Converter</code>
<code>aliases</code>		Map	Alias a Class to a shorter name to be used in XML elements.
<code>omitFields</code>		Map	Prevents a field from being serialized. To omit a field you must always provide the declaring type and not necessarily the type that is converted.
<code>implicitCollections</code>		Map	Adds a default implicit collection which is used for any unmapped XML tag.
<code>contentTypeHeader</code>	false	Boolean	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example <code>application/xml</code> for data formats marshalling to XML, or <code>application/json</code> for data formats marshalling to JSON etc.

378.2. SPRING BOOT AUTO-CONFIGURATION

The component supports 31 options, which are listed below.

Name	Description	Default	Type
<code>camel.dataformat.json-xstream.allow-jms-type</code>	Used for JMS users to allow the JMSType header from the JMS spec to specify a FQN classname to use to unmarshal to.	false	Boolean
<code>camel.dataformat.json-xstream.allow-unmarshall-type</code>	If enabled then Jackson is allowed to attempt to use the CamelJacksonUnmarshalType header during the unmarshalling. This should only be enabled when desired to be used.	false	Boolean

Name	Description	Default	Type
<code>camel.dataformat.json-xstream.collection-type-name</code>	Refers to a custom collection type to lookup in the registry to use. This option should rarely be used, but allows to use different collection types than <code>java.util.Collection</code> based as default.		String
<code>camel.dataformat.json-xstream.content-type-header</code>	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example <code>application/xml</code> for data formats marshalling to XML, or <code>application/json</code> for data formats marshalling to JSON etc.	false	Boolean
<code>camel.dataformat.json-xstream.disable-features</code>	Set of features to disable on the Jackson <code>com.fasterxml.jackson.databind.ObjectMapper</code> . The features should be a name that matches a enum from <code>com.fasterxml.jackson.databind.SerializationFeature</code> , <code>com.fasterxml.jackson.databind.DeserializationFeature</code> , or <code>com.fasterxml.jackson.databind.MapperFeature</code> . Multiple features can be separated by comma		String
<code>camel.dataformat.json-xstream.enable-features</code>	Set of features to enable on the Jackson <code>com.fasterxml.jackson.databind.ObjectMapper</code> . The features should be a name that matches a enum from <code>com.fasterxml.jackson.databind.SerializationFeature</code> , <code>com.fasterxml.jackson.databind.DeserializationFeature</code> , or <code>com.fasterxml.jackson.databind.MapperFeature</code> . Multiple features can be separated by comma		String
<code>camel.dataformat.json-xstream.enable-jaxb-annotation-module</code>	Whether to enable the JAXB annotations module when using jackson. When enabled then JAXB annotations can be used by Jackson.	false	Boolean
<code>camel.dataformat.json-xstream.enabled</code>	Enable json-xstream dataformat	true	Boolean
<code>camel.dataformat.json-xstream.include</code>	If you want to marshal a pojo to JSON, and the pojo has some fields with null values. And you want to skip these null values, you can set this option to <code>NON_NULL</code>		String
<code>camel.dataformat.json-xstream.json-view</code>	When marshalling a POJO to JSON you might want to exclude certain fields from the JSON output. With Jackson you can use JSON views to accomplish this. This option is to refer to the class which has <code>JsonView</code> annotations		Class

Name	Description	Default	Type
<code>camel.dataformat.json-xstream.library</code>	Which json library to use.		JsonLibrary
<code>camel.dataformat.json-xstream.module-class-names</code>	To use custom Jackson modules <code>com.fasterxml.jackson.databind.Module</code> specified as a String with FQN class names. Multiple classes can be separated by comma.		String
<code>camel.dataformat.json-xstream.module-refs</code>	To use custom Jackson modules referred from the Camel registry. Multiple modules can be separated by comma.		String
<code>camel.dataformat.json-xstream.object-mapper</code>	Lookup and use the existing ObjectMapper with the given id when using Jackson.		String
<code>camel.dataformat.json-xstream.permissions</code>	Adds permissions that controls which Java packages and classes XStream is allowed to use during unmarshal from xml/json to Java beans. A permission must be configured either here or globally using a JVM system property. The permission can be specified in a syntax where a plus sign is allow, and minus sign is deny. Wildcards is supported by using <code>.</code> as prefix. For example to allow <code>com.foo</code> and all subpackages then specify <code>com.foo.</code> . Multiple permissions can be configured separated by comma, such as <code>com.foo.,-com.foo.bar.MySecretBean</code> . The following default permission is always included: <code>java.lang,java.util</code> . unless its overridden by specifying a JVM system property with they key <code>org.apache.camel.xstream.permissions</code> .		String
<code>camel.dataformat.json-xstream.pretty-print</code>	To enable pretty printing output nicely formatted. Is by default false.	false	Boolean
<code>camel.dataformat.json-xstream.timezone</code>	If set then Jackson will use the Timezone when marshalling/unmarshalling. This option will have no effect on the others Json DataFormat, like gson, fastjson and xstream.		String
<code>camel.dataformat.json-xstream.unmarshal-type-name</code>	Class name of the java type to use when unarmshalling		String

Name	Description	Default	Type
<code>camel.dataformat.json-xstream.use-default-object-mapper</code>	Whether to lookup and use default Jackson ObjectMapper from the registry.	true	Boolean
<code>camel.dataformat.json-xstream.use-list</code>	To unarmshal to a List of Map or a List of Pojo.	false	Boolean
<code>camel.dataformat.xstream.aliases</code>	Alias a Class to a shorter name to be used in XML elements.		Map
<code>camel.dataformat.xstream.content-type-header</code>	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSon etc.	false	Boolean
<code>camel.dataformat.xstream.converters</code>	List of class names for using custom XStream converters. The classes must be of type <code>com.thoughtworks.xstream.converters.Converter</code>		List
<code>camel.dataformat.xstream.driver</code>	To use a custom XStream driver. The instance must be of type <code>com.thoughtworks.xstream.io.HierarchicalStreamDriver</code>		String
<code>camel.dataformat.xstream.driver-ref</code>	To refer to a custom XStream driver to lookup in the registry. The instance must be of type <code>com.thoughtworks.xstream.io.HierarchicalStreamDriver</code>		String
<code>camel.dataformat.xstream.enabled</code>	Enable xstream dataformat	true	Boolean
<code>camel.dataformat.xstream.encoding</code>	Sets the encoding to use		String
<code>camel.dataformat.xstream.implicit-collections</code>	Adds a default implicit collection which is used for any unmapped XML tag.		Map

Name	Description	Default	Type
<code>camel.dataformat.xstream.mode</code>	Mode for dealing with duplicate references The possible values are: NO_REFERENCES ID_REFERENCES XPATH_RELATIVE_REFERENCES XPATH_ABSOLUTE_REFERENCES SINGLE_NODE_XPATH_RELATIVE_REFERENCES SINGLE_NODE_XPATH_ABSOLUTE_REFERENCES		String
<code>camel.dataformat.xstream.omit-fields</code>	Prevents a field from being serialized. To omit a field you must always provide the declaring type and not necessarily the type that is converted.		Map
<code>camel.dataformat.xstream.permissions</code>	Adds permissions that controls which Java packages and classes XStream is allowed to use during unmarshal from xml/json to Java beans. A permission must be configured either here or globally using a JVM system property. The permission can be specified in a syntax where a plus sign is allow, and minus sign is deny. Wildcards is supported by using . as prefix. For example to allow com.foo and all subpackages then specify com.foo.. Multiple permissions can be configured separated by comma, such as com.foo.,-com.foo.bar.MySecretBean. The following default permission is always included: - ,java.lang.,java.util. unless its overridden by specifying a JVM system property with they key org.apache.camel.xstream.permissions.		String

ND

378.3. USING THE JAVA DSL

```
// lets turn Object messages into XML then send to MQSeries
from("activemq:My.Queue").
  marshal().xstream().
  to("mqseries:Another.Queue");
```

If you would like to configure the **XStream** instance used by the Camel for the message transformation, you can simply pass a reference to that instance on the DSL level.

```
XStream xStream = new XStream();
xStream.aliasField("money", PurchaseOrder.class, "cash");
// new Added setModel option since Camel 2.14
xStream.setModel("NO_REFERENCES");
...

from("direct:marshal").
  marshal(new XStreamDataFormat(xStream)).
  to("mock:marshaled");
```

378.4. XMLINPUTFACTORY AND XMLOUTPUTFACTORY

The [XStream library](#) uses the `javax.xml.stream.XMLInputFactory` and `javax.xml.stream.XMLOutputFactory`, you can control which implementation of this factory should be used.

The Factory is discovered using this algorithm: 1. Use the `javax.xml.stream.XMLInputFactory`, `javax.xml.stream.XMLOutputFactory` system property. 2. Use the `lib/xml.stream.properties` file in the `JRE_HOME` directory. 3. Use the Services API, if available, to determine the classname by looking in the `META-INF/services/javax.xml.stream.XMLInputFactory`, `META-INF/services/javax.xml.stream.XMLOutputFactory` files in jars available to the JRE. 4. Use the platform default `XMLInputFactory`, `XMLOutputFactory` instance.

378.5. HOW TO SET THE XML ENCODING IN XSTREAM DATAFORMAT?

From Camel 2.2.0, you can set the encoding of XML in Xstream DataFormat by setting the Exchange's property with the key `Exchange.CHARSET_NAME`, or setting the encoding property on Xstream from DSL or Spring config.

```
from("activemq:My.Queue").
  marshal().xstream("UTF-8").
  to("mqseries:Another.Queue");
```

378.6. SETTING THE TYPE PERMISSIONS OF XSTREAM DATAFORMAT

In Camel, one can always use its own processing step in the route to filter and block certain XML documents to be routed to the XStream's unmarshall step. From Camel 2.16.1, 2.15.5, you can set [XStream's type permissions](#) to automatically allow or deny the instantiation of certain types.

The default type permissions setting used by Camel denies all types except for those from `java.lang` and `java.util` packages. This setting can be changed by setting System property `org.apache.camel.xstream.permissions`. Its value is a string of comma-separated permission terms, each representing a type being allowed or denied, depending on whether the term is prefixed with " (note " may be omitted) or with '-', respectively.

Each term may contain a wildcard character ". For example, value `"-java.lang.,java.util."` indicates denying all types except for `java.lang.*` and `java.util.*` classes. Setting this value to an empty string "" reverts to the default XStream's type permissions handling which denies certain blacklisted classes and allow others.

The type permissions setting can be extended at an individual XStream DataFormat instance by setting its type permissions property.

```
<dataFormats>
  <xstream id="xstream-default"
    permissions="org.apache.camel.samples.xstream.*"/>
  ...
```

CHAPTER 379. YAML SNAKEYAML DATAFORMAT

Available as of Camel version 2.17

YAML is a Data Format to marshal and unmarshal Java objects to and from [YAML](#).

For YAML to object marshalling, Camel provides integration with three popular YAML libraries:

- The [SnakeYAML](#) library

Every library requires adding the special camel component (see "Dependency..." paragraphs further down). By default Camel uses the SnakeYAML library.

379.1. YAML OPTIONS

The YAML SnakeYAML dataformat supports 11 options, which are listed below.

Name	Default	Java Type	Description
library	SnakeYAML	YAML Library	Which yaml library to use. By default it is SnakeYAML
unmarshalTypeName		String	Class name of the java type to use when unmarshalling
constructor		String	BaseConstructor to construct incoming documents.
representer		String	Representer to emit outgoing objects.
dumperOptions		String	DumperOptions to configure outgoing objects.
resolver		String	Resolver to detect implicit type
useApplicationContextClassLoader	true	Boolean	Use ApplicationContextClassLoader as custom ClassLoader
prettyFlow	false	Boolean	Force the emitter to produce a pretty YAML document when using the flow style.
allowAnyType	false	Boolean	Allow any class to be un-marshaled
typeFilter		List	Set the types SnakeYAML is allowed to un-marshall

Name	Default	Java Type	Description
<code>contentTypeHeader</code>	false	Boolean	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example <code>application/xml</code> for data formats marshalling to XML, or <code>application/json</code> for data formats marshalling to JSON etc.

379.2. SPRING BOOT AUTO-CONFIGURATION

The component supports 12 options, which are listed below.

Name	Description	Default	Type
<code>camel.dataformat.yaml-snakeyaml.allow-any-type</code>	Allow any class to be un-marshaled	false	Boolean
<code>camel.dataformat.yaml-snakeyaml.constructor</code>	BaseConstructor to construct incoming documents.		String
<code>camel.dataformat.yaml-snakeyaml.content-type-header</code>	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example <code>application/xml</code> for data formats marshalling to XML, or <code>application/json</code> for data formats marshalling to JSON etc.	false	Boolean
<code>camel.dataformat.yaml-snakeyaml.dumper-options</code>	DumperOptions to configure outgoing objects.		String
<code>camel.dataformat.yaml-snakeyaml.enabled</code>	Enable yaml-snakeyaml dataformat	true	Boolean
<code>camel.dataformat.yaml-snakeyaml.library</code>	Which yaml library to use. By default it is SnakeYAML		YAMLLibrary

Name	Description	Default	Type
<code>camel.dataformat.yaml-snakeyaml.pretty-flow</code>	Force the emitter to produce a pretty YAML document when using the flow style.	false	Boolean
<code>camel.dataformat.yaml-snakeyaml.representer</code>	Representer to emit outgoing objects.		String
<code>camel.dataformat.yaml-snakeyaml.resolver</code>	Resolver to detect implicit type		String
<code>camel.dataformat.yaml-snakeyaml.type-filter</code>	Set the types SnakeYAML is allowed to un-marshall		List
<code>camel.dataformat.yaml-snakeyaml.unmarshal-type-name</code>	Class name of the java type to use when unmarshalling		String
<code>camel.dataformat.yaml-snakeyaml.use-application-context-class-loader</code>	Use ApplicationContextClassLoader as custom ClassLoader	true	Boolean

WARNING

SnakeYAML can load any class from YAML definition which may lead to security breach so by default, SnakeYAML DataFormat restrict the object it can load to standard Java objects like List or Long. If you want to load custom POJOs you need to add theirs type to SnakeYAML DataFormat type filter list. If your source is trusted, you can set the property `allowAnyType` to true so SnakeYAML DataFormat won't perform any filter on the types.

379.3. USING YAML DATA FORMAT WITH THE SNAKEYAML LIBRARY

- Turn Object messages into yaml then send to MQSeries

```
from("activemq:My.Queue")
  .marshal().yaml()
  .to("mqseries:Another.Queue");
```

```
from("activemq:My.Queue")
  .marshal().yaml(YAMLLibrary.SnakeYAML)
  .to("mqseries:Another.Queue");
```

- Restrict classes to be loaded from YAML

```
// Create a SnakeYAMLDataFormat instance
SnakeYAMLDataFormat yaml = new SnakeYAMLDataFormat();

// Restrict classes to be loaded from YAML
yaml.addTypeFilters(TypeFilters.types(MyPojo.class, MyOtherPojo.class));

from("activemq:My.Queue")
  .unmarshal(yaml)
  .to("mqseries:Another.Queue");
```

379.4. USING YAML IN SPRING DSL

When using Data Format in Spring DSL you need to declare the data formats first. This is done in the **DataFormats** XML tag.

```
<dataFormats>
  <!--
    here we define a YAML data format with the id snake and that it should use
    the TestPojo as the class type when doing unmarshal. The unmarshalTypeName
    is optional
  -->
  <yaml
    id="snake"
    library="SnakeYAML"
    unmarshalTypeName="org.apache.camel.component.yaml.model.TestPojo"/>

  <!--
    here we define a YAML data format with the id snake-safe which restricts the
    classes to be loaded from YAML to TestPojo and those belonging to package
    com.mycompany
  -->
  <yaml id="snake-safe">
    <typeFilter value="org.apache.camel.component.yaml.model.TestPojo"/>
    <typeFilter value="com.mycompany\..*" type="regexp"/>
  </yaml>
</dataFormats>
```

And then you can refer to those ids in the route:

```
<route>
  <from uri="direct:unmarshal"/>
  <unmarshal>
    <custom ref="snake"/>
  </unmarshal>
</route>
```

```
</unmarshal>
<to uri="mock:unmarshal"/>
</route>
<route>
  <from uri="direct:unmarshal-safe"/>
  <unmarshal>
    <custom ref="snake-safe"/>
  </unmarshal>
  <to uri="mock:unmarshal-safe"/>
</route>
```

379.5. DEPENDENCIES FOR SNAKEYAML

To use YAML in your camel routes you need to add the a dependency on **camel-snakeyaml** which implements this data format.

If you use maven you could just add the following to your pom.xml, substituting the version number for the latest & greatest release (see the download page for the latest versions).

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-snakeyaml</artifactId>
  <version>${camel-version}</version>
</dependency>
```

CHAPTER 380. YAMMER COMPONENT

Available as of Camel version 2.12

The Yammer component allows you to interact with the [Yammer](#) enterprise social network. Consuming messages, users, and user relationships is supported as well as creating new messages.

Yammer uses OAuth 2 for all client application authentication. In order to use camel-yammer with your account, you'll need to create a new application within Yammer and grant the application access to your account. Finally, generate your access token. More details are at <https://developer.yammer.com/authentication/>.

Maven users will need to add the following dependency to their pom.xml for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-yammer</artifactId>
  <version>${camel-version}</version>
</dependency>
```

380.1. URI FORMAT

```
yammer:[function]?[options]
```

380.2. COMPONENT OPTIONS

The Yammer component can be configured with the Yammer account settings which are mandatory to configure before using.

The Yammer component supports 5 options, which are listed below.

Name	Description	Default	Type
consumerKey (security)	The consumer key		String
consumerSecret (security)	The consumer secret		String
accessToken (security)	The access token		String
config (advanced)	To use a shared yammer configuration		YammerConfiguration
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

You can also configure these options directly in the endpoint.

380.3. ENDPOINT OPTIONS

The Yammer endpoint is configured using URI syntax:

```
yammer:function
```

with the following path and query parameters:

380.3.1. Path Parameters (1 parameters):

Name	Description	Default	Type
function	Required The function to use		YammerFunctionType

380.3.2. Query Parameters (28 parameters):

Name	Description	Default	Type
useJson (common)	Set to true if you want to use raw JSON rather than converting to POJOs.	false	boolean
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
delay (consumer)	Delay between polling in millis	5000	long
limit (consumer)	Return only the specified number of messages. Works for <code>threaded=true</code> and <code>threaded=extended</code> .	-1	int
newerThan (consumer)	Returns messages newer than the message ID specified as a numeric string. This should be used when polling for new messages. If you're looking at messages, and the most recent message returned is 3516, you can make a request with the parameter <code>newerThan=3516</code> to ensure that you do not get duplicate copies of messages already on your page.	-1	int

Name	Description	Default	Type
olderThan (consumer)	Returns messages older than the message ID specified as a numeric string. This is useful for paginating messages. For example, if you're currently viewing 20 messages and the oldest is number 2912, you could append <code>olderThan=2912</code> to your request to get the 20 messages prior to those you're seeing.	-1	int
sendEmptyMessageWhenIdle (consumer)	If the polling consumer did not poll any files, you can enable this option to send an empty message (no body) instead.	false	boolean
threaded (consumer)	<code>threaded=true</code> will only return the first message in each thread. This parameter is intended for apps which display message threads collapsed. <code>threaded=extended</code> will return the thread starter messages in order of most recently active as well as the two most recent messages, as they are viewed in the default view on the Yammer web interface.		String
userId (consumer)	The user id		String
exceptionHandler (consumer)	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at <code>WARN</code> or <code>ERROR</code> level and ignored.		<code>ExceptionHandler</code>
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		<code>ExchangePattern</code>
pollStrategy (consumer)	A pluggable <code>org.apache.camel.PollingConsumerPollingStrategy</code> allowing you to provide your custom implementation to control error handling usually occurred during the poll operation before an <code>Exchange</code> have been created and being routed in Camel.		<code>PollingConsumerPollStrategy</code>
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
backoffErrorThreshold (scheduler)	The number of subsequent error polls (failed due some error) that should happen before the <code>backoffMultiplier</code> should kick-in.		int
backoffIdleThreshold (scheduler)	The number of subsequent idle polls that should happen before the <code>backoffMultiplier</code> should kick-in.		int

Name	Description	Default	Type
backoffMultiplier (scheduler)	To let the scheduled polling consumer backoff if there has been a number of subsequent idles/errors in a row. The multiplier is then the number of polls that will be skipped before the next actual attempt is happening again. When this option is in use then <code>backoffIdleThreshold</code> and/or <code>backoffErrorThreshold</code> must also be configured.		int
greedy (scheduler)	If <code>greedy</code> is enabled, then the <code>ScheduledPollConsumer</code> will run immediately again, if the previous run polled 1 or more messages.	false	boolean
initialDelay (scheduler)	Milliseconds before the first poll starts. You can also specify time values using units, such as 60s (60 seconds), 5m30s (5 minutes and 30 seconds), and 1h (1 hour).	1000	long
runLoggingLevel (scheduler)	The consumer logs a start/complete log line when it polls. This option allows you to configure the logging level for that.	TRACE	LoggingLevel
scheduledExecutorService (scheduler)	Allows for configuring a custom/shared thread pool to use for the consumer. By default each consumer has its own single threaded thread pool.		ScheduledExecutorService
scheduler (scheduler)	To use a cron scheduler from either camel-spring or camel-quartz2 component	none	ScheduledPollConsumerScheduler
schedulerProperties (scheduler)	To configure additional properties when using a custom scheduler or any of the Quartz2, Spring based scheduler.		Map
startScheduler (scheduler)	Whether the scheduler should be auto started.	true	boolean
timeUnit (scheduler)	Time unit for <code>initialDelay</code> and <code>delay</code> options.	MILLIS ECON DS	TimeUnit
useFixedDelay (scheduler)	Controls if fixed delay or fixed rate is used. See <code>ScheduledExecutorService</code> in JDK for details.	true	boolean
accessToken (security)	Required The access token		String
consumerKey (security)	Required The consumer key		String

Name	Description	Default	Type
<code>consumerSecret</code> (security)	Required The consumer secret		String

380.4. SPRING BOOT AUTO-CONFIGURATION

The component supports 18 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.yammer.access-token</code>	The access token		String
<code>camel.component.yammer.config.access-token</code>	The access token		String
<code>camel.component.yammer.config.consumer-key</code>	The consumer key		String
<code>camel.component.yammer.config.consumer-secret</code>	The consumer secret		String
<code>camel.component.yammer.config.delay</code>	Delay between polling in millis	5000	Long
<code>camel.component.yammer.config.function</code>	The function to use		String
<code>camel.component.yammer.config.function-type</code>	The function to use		YammerFunctionType
<code>camel.component.yammer.config.limit</code>	Return only the specified number of messages. Works for <code>threaded=true</code> and <code>threaded=extended</code> .	-1	Integer

Name	Description	Default	Type
<code>camel.component.yammer.config.newer-than</code>	Returns messages newer than the message ID specified as a numeric string. This should be used when polling for new messages. If you're looking at messages, and the most recent message returned is 3516, you can make a request with the parameter <code>newerThan=3516</code> to ensure that you do not get duplicate copies of messages already on your page.	-1	Integer
<code>camel.component.yammer.config.older-than</code>	Returns messages older than the message ID specified as a numeric string. This is useful for paginating messages. For example, if you're currently viewing 20 messages and the oldest is number 2912, you could append <code>olderThan=2912</code> to your request to get the 20 messages prior to those you're seeing.	-1	Integer
<code>camel.component.yammer.config.requestor</code>			ApiRequestor
<code>camel.component.yammer.config.threaded</code>	<code>threaded=true</code> will only return the first message in each thread. This parameter is intended for apps which display message threads collapsed. <code>threaded=extended</code> will return the thread starter messages in order of most recently active as well as the two most recent messages, as they are viewed in the default view on the Yammer web interface.		String
<code>camel.component.yammer.config.use-json</code>	Set to true if you want to use raw JSON rather than converting to POJOs.	false	Boolean
<code>camel.component.yammer.config.user-id</code>	The user id		String
<code>camel.component.yammer.consumer-key</code>	The consumer key		String
<code>camel.component.yammer.consumer-secret</code>	The consumer secret		String
<code>camel.component.yammer.enabled</code>	Enable yammer component	true	Boolean

Name	Description	Default	Type
<code>camel.component.yammer.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

380.5. CONSUMING MESSAGES

The Yammer component provides several endpoints for consuming messages:

URI	Description
<code>yammer:messages?[options]</code>	All public messages in the user's (whose access token is being used to make the API call) Yammer network. Corresponds to "All" conversations in the Yammer web interface.
<code>yammer:my_feed?[options]</code>	The user's feed, based on the selection they have made between "Following" and "Top" conversations.
<code>yammer:algo?[options]</code>	The algorithmic feed for the user that corresponds to "Top" conversations, which is what the vast majority of users will see in the Yammer web interface.
<code>yammer:following?[options]</code>	The "Following" feed which is conversations involving people, groups and topics that the user is following.
<code>yammer:sent?[options]</code>	All messages sent by the user.
<code>yammer:private?[options]</code>	Private messages received by the user.
<code>yammer:received?[options]</code>	Camel 2.12.1: All messages received by the user

380.5.1. Message format

All messages by default are converted to a POJO model provided in the **org.apache.camel.component.yammer.model** package. The original message coming from yammer is in JSON. For all message consuming and producing endpoints, a **Messages** object is returned. Take for example a route like:

```
from("yammer:messages?
consumerKey=aConsumerKey&consumerSecret=aConsumerSecretKey&accessToken=aAccessToken"
)
```

```
.to("mock:result");
```

and lets say the yammer server returns:

```
{
  "messages":[
    {
      "replied_to_id":null,
      "network_id":7654,
      "url":"https://www.yammer.com/api/v1/messages/305298242",
      "thread_id":305298242,
      "id":305298242,
      "message_type":"update",
      "chat_client_sequence":null,
      "body":{
        "parsed":"Testing yammer API...",
        "plain":"Testing yammer API...",
        "rich":"Testing yammer API..."
      },
      "client_url":"https://www.yammer.com/",
      "content_excerpt":"Testing yammer API...",
      "created_at":"2013/06/25 18:14:45 +0000",
      "client_type":"Web",
      "privacy":"public",
      "sender_type":"user",
      "liked_by":{
        "count":1,
        "names":[
          {
            "permalink":"janstey",
            "full_name":"Jonathan Anstey",
            "user_id":1499642294
          }
        ]
      }
    },
    {
      "sender_id":1499642294,
      "language":null,
      "system_message":false,
      "attachments":[]
    },
    {
      "direct_message":false,
      "web_url":"https://www.yammer.com/redhat.com/messages/305298242"
    },
    {
      "replied_to_id":null,
      "network_id":7654,
      "url":"https://www.yammer.com/api/v1/messages/294326302",
      "thread_id":294326302,
      "id":294326302,
      "message_type":"system",
      "chat_client_sequence":null,
      "body":{
        "parsed":"(Principal Software Engineer) has [[tag:14658]] the redhat.com network. Take a
```

```

moment to welcome Jonathan.",
    "plain":"(Principal Software Engineer) has #joined the redhat.com network. Take a moment
to welcome Jonathan.",
    "rich":"(Principal Software Engineer) has #joined the redhat.com network. Take a moment
to welcome Jonathan."
},
"client_url":"https://www.yammer.com/",
"content_excerpt":"(Principal Software Engineer) has #joined the redhat.com network. Take a
moment to welcome Jonathan.",
"created_at":"2013/05/10 19:08:29 +0000",
"client_type":"Web",
"sender_type":"user",
"privacy":"public",
"liked_by":{
    "count":0,
    "names":[

    ]
}
}
]
}

```

Camel will marshal that into a **Messages** object containing 2 **Message** objects. As shown below there is a rich object model that makes it easy to get any information you need:

```

Exchange exchange = mock.getExchanges().get(0);
Messages messages = exchange.getIn().getBody(Messages.class);

assertEquals(2, messages.getMessages().size());
assertEquals("Testing yammer API...", messages.getMessages().get(0).getBody().getPlain());
assertEquals("(Principal Software Engineer) has #joined the redhat.com network. Take a moment to
welcome Jonathan.", messages.getMessages().get(1).getBody().getPlain());

```

That said, marshaling this data into POJOs is not free so if you need you can switch back to using pure JSON by adding the **useJson=false** option to your URI.

380.6. CREATING MESSAGES

To create a new message in the account of the current user, you can use the following URI:

```
yammer:messages?[options]
```

The current Camel message body is what will be used to set the text of the Yammer message. The response body will include the new message formatted the same way as when you consume messages (i.e. as a **Messages** object by default).

Take this route for instance:

```

from("direct:start")
    .to("yammer:messages?
consumerKey=aConsumerKey&consumerSecret=aConsumerSecretKey&accessToken=aAccessToken")

```

```
)
    .to("mock:result");
```

By sending to the **direct:start** endpoint a **"Hi from Camel!"** message body:

```
template.sendBody("direct:start", "Hi from Camel!");
```

a new message will be created in the current user's account on the server and also this new message will be returned to Camel and converted into a **Messages** object. Like when consuming messages you can interrogate the **Messages** object:

```
Exchange exchange = mock.getExchanges().get(0);
Messages messages = exchange.getIn().getBody(Messages.class);

assertEquals(1, messages.getMessages().size());
assertEquals("Hi from Camel!", messages.getMessages().get(0).getBody().getPlain());
```

380.7. RETRIEVING USER RELATIONSHIPS

The Yammer component can retrieve user relationships:

```
yammer:relationships?[options]
```

380.8. RETRIEVING USERS

The Yammer component provides several endpoints for retrieving users:

URI	Description
yammer:users?[options]	Retrieve users in the current user's Yammer network.
yammer:current?[options]	View data about the current user.

380.9. USING AN ENRICHER

It is helpful sometimes (or maybe always in the case of users or relationship consumers) to use an enricher pattern rather than a route initiated with one of the polling consumers in camel-yammer. This is because the consumers will fire repeatedly, however often you set the delay for. If you just want to look up a user's data, or grab a message at a point in time, it is better to call that consumer once and then get one with your route.

Lets say you have a route that at some point needs to go out and fetch user data for the current user. Rather than polling for this user over and over again, use the **pollEnrich** DSL method:

```
from("direct:start")
    .pollEnrich("yammer:current?
consumerKey=aConsumerKey&consumerSecret=aConsumerSecretKey&accessToken=aAccessToken")
```

```
    )  
    .to("mock:result");
```

This will go out and fetch the current user's **User** object and set it as the Camel message body.

380.10. SEE ALSO

- [Configuring Camel](#)
- [Component](#)
- [Endpoint](#)
- [Getting Started](#)

CHAPTER 381. ZENDESK COMPONENT

Available as of Camel version 2.19

The Zendesk component provides access to all of the zendesk.com APIs accessible using [zendesk-java-client](#). It allows producing messages to manage Zendesk ticket, user, organization, etc.

Maven users will need to add the following dependency to their pom.xml for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-zendesk</artifactId>
  <version>${camel-version}</version>
</dependency>
```

381.1. ZENDESK OPTIONS

The Zendesk component supports 3 options, which are listed below.

Name	Description	Default	Type
configuration (common)	To use the shared configuration		ZendeskConfigura tion
zendesk (advanced)	To use a shared Zendesk instance.		Zendesk
resolveProperty Placeholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The Zendesk endpoint is configured using URI syntax:

```
zendesk:methodName
```

with the following path and query parameters:

381.1.1. Path Parameters (1 parameters):

Name	Description	Default	Type
methodName	Required What operation to use		String

381.1.2. Query Parameters (10 parameters):

Name	Description	Default	Type
inBody (common)	Sets the name of a parameter to be passed in the exchange In Body		String
serverUrl (common)	The server URL to connect.		String
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
exceptionHandler (consumer)	To let the consumer use a custom <code>ExceptionHandler</code> . Notice if the option <code>bridgeErrorHandler</code> is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean
oauthToken (security)	The OAuth token.		String
password (security)	The password.		String
token (security)	The security token.		String
username (security)	The user name.		String

381.2. SPRING BOOT AUTO-CONFIGURATION

The component supports 9 options, which are listed below.

Name	Description	Default	Type
<code>camel.component.zendesk.configuration.method-name</code>	What operation to use		String
<code>camel.component.zendesk.configuration.oauth-token</code>	The OAuth token.		String
<code>camel.component.zendesk.configuration.password</code>	The password.		String
<code>camel.component.zendesk.configuration.server-url</code>	The server URL to connect.		String
<code>camel.component.zendesk.configuration.token</code>	The security token.		String
<code>camel.component.zendesk.configuration.username</code>	The user name.		String
<code>camel.component.zendesk.enabled</code>	Enable zendesk component	true	Boolean
<code>camel.component.zendesk.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.component.zendesk.zendesk</code>	To use a shared Zendesk instance. The option is a <code>org.zendesk.client.v2.Zendesk</code> type.		String

381.3. URI FORMAT

`zendesk://endpoint?[options]`

381.4. PRODUCER ENDPOINTS:

Producer endpoints can use endpoint names and associated options described next.

381.5. CONSUMER ENDPOINTS:

Any of the producer endpoints can be used as a consumer endpoint. Consumer endpoints can use [Scheduled Poll Consumer Options](#) with a **consumer.** prefix to schedule endpoint invocation. Consumer endpoints that return an array or collection will generate one exchange per element, and their routes will be executed once for each exchange.

381.6. MESSAGE HEADER

Any of the options can be provided in a message header for producer endpoints with **CamelZendesk.** prefix. In principal, parameter names are same as the arugument name of each API methods on the original **org.zendesk.client.v2.Zendesk** class. However some of them are renamed to the other name to avoid confliction in the camel API component framework. To see actual parameter name, please check **org.apache.camel.component.zendesk.internal.ZendeskApiMethod**.

381.7. MESSAGE BODY

All result message bodies utilize objects provided by the Zendesk Java Client. Producer endpoints can specify the option name for incoming message body in the **inBody** endpoint parameter.

CHAPTER 382. ZIP DEFLATE COMPRESSION DATAFORMAT

Available as of Camel version 2.12

The Zip Data Format is a message compression and de-compression format. Messages marshalled using Zip compression can be unmarshalled using Zip decompression just prior to being consumed at the endpoint. The compression capability is quite useful when you deal with large XML and Text based payloads. It facilitates more optimal use of network bandwidth while incurring a small cost in order to compress and decompress payloads at the endpoint.

INFO:*About using with Files** The Zip data format, does not (yet) have special support for files. Which means that when using big files, the entire file content is loaded into memory. This is subject to change in the future, to allow a streaming based solution to have a low memory footprint.

382.1. OPTIONS

The Zip Deflate Compression dataformat supports 2 options, which are listed below.

Name	Default	Java Type	Description
<code>compressionLevel</code>	<code>-1</code>	<code>Integer</code>	To specify a specific compression between 0-9. -1 is default compression, 0 is no compression, and 9 is best compression.
<code>contentTypeHeader</code>	<code>false</code>	<code>Boolean</code>	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example application/xml for data formats marshalling to XML, or application/json for data formats marshalling to JSon etc.

382.2. MARSHAL

In this example we marshal a regular text/XML payload to a compressed payload employing zip compression **Deflater.BEST_COMPRESSION** and send it an ActiveMQ queue called MY_QUEUE.

```
from("direct:start").marshal().zip(Deflater.BEST_COMPRESSION).to("activemq:queue:MY_QUEUE");
```

Alternatively if you would like to use the default setting you could send it as

```
from("direct:start").marshal().zip().to("activemq:queue:MY_QUEUE");
```

382.3. UNMARSHAL

In this example we unmarshal a zipped payload from an ActiveMQ queue called MY_QUEUE to its original format, and forward it for processing to the UnZippedMessageProcessor. Note that the compression Level employed during the marshalling should be identical to the one employed during unmarshalling to avoid errors.

```
from("activemq:queue:MY_QUEUE").unmarshal().zip().process(new UnZippedMessageProcessor());
```

382.4. DEPENDENCIES

This data format is provided in **camel-core** so no additional dependencies are needed.

CHAPTER 383. ZIP FILE DATAFORMAT

Available as of Camel version 2.11

The Zip File Data Format is a message compression and de-compression format. Messages can be marshalled (compressed) to Zip files containing a single entry, and Zip files containing a single entry can be unmarshalled (decompressed) to the original file contents. This data format supports ZIP64, as long as Java 7 or later is being used].

383.1. ZIPFILE OPTIONS

The Zip File dataformat supports 4 options, which are listed below.

Name	Default	Java Type	Description
<code>usingIterator</code>	false	Boolean	If the zip file has more than one entry, the setting this option to true, allows to work with the splitter EIP, to split the data using an iterator in a streaming mode.
<code>allowEmptyDirectory</code>	false	Boolean	If the zip file has more than one entry, setting this option to true, allows to get the iterator even if the directory is empty
<code>preservePathElements</code>	false	Boolean	If the file name contains path elements, setting this option to true, allows the path to be maintained in the zip file.
<code>contentTypeHeader</code>	false	Boolean	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example <code>application/xml</code> for data formats marshalling to XML, or <code>application/json</code> for data formats marshalling to JSON etc.

383.2. SPRING BOOT AUTO-CONFIGURATION

The component supports 5 options, which are listed below.

Name	Description	Default	Type
<code>camel.dataformat.zipfile.allow-empty-directory</code>	If the zip file has more than one entry, setting this option to true, allows to get the iterator even if the directory is empty	false	Boolean
<code>camel.dataformat.zipfile.content-type-header</code>	Whether the data format should set the Content-Type header with the type from the data format if the data format is capable of doing so. For example <code>application/xml</code> for data formats marshalling to XML, or <code>application/json</code> for data formats marshalling to JSON etc.	false	Boolean

Name	Description	Default	Type
<code>camel.dataformat.zipfile.enabled</code>	Enable zipfile dataformat	true	Boolean
<code>camel.dataformat.zipfile.preserve-path-elements</code>	If the file name contains path elements, setting this option to true, allows the path to be maintained in the zip file.	false	Boolean
<code>camel.dataformat.zipfile.using-iterator</code>	If the zip file has more then one entry, the setting this option to true, allows to work with the splitter EIP, to split the data using an iterator in a streaming mode.	false	Boolean

ND

383.3. MARSHAL

In this example we marshal a regular text/XML payload to a compressed payload using Zip file compression, and send it to an ActiveMQ queue called MY_QUEUE.

```
from("direct:start")
  .marshal().zipFile()
  .to("activemq:queue:MY_QUEUE");
```

The name of the Zip entry inside the created Zip file is based on the incoming **CamelFileName** message header, which is the standard message header used by the file component. Additionally, the outgoing **CamelFileName** message header is automatically set to the value of the incoming **CamelFileName** message header, with the ".zip" suffix. So for example, if the following route finds a file named "test.txt" in the input directory, the output will be a Zip file named "test.txt.zip" containing a single Zip entry named "test.txt":

```
from("file:input/directory?antInclude=/*.txt")
  .marshal().zipFile()
  .to("file:output/directory");
```

If there is no incoming **CamelFileName** message header (for example, if the file component is not the consumer), then the message ID is used by default, and since the message ID is normally a unique generated ID, you will end up with filenames like **ID-MACHINENAME-2443-1211718892437-1-0.zip**. If you want to override this behavior, then you can set the value of the **CamelFileName** header explicitly in your route:

```
from("direct:start")
  .setHeader(Exchange.FILE_NAME, constant("report.txt"))
  .marshal().zipFile()
  .to("file:output/directory");
```

This route would result in a Zip file named "report.txt.zip" in the output directory, containing a single Zip entry named "report.txt".

383.4. UNMARSHAL

In this example we unmarshal a Zip file payload from an ActiveMQ queue called MY_QUEUE to its original format, and forward it for processing to the **UnZippedMessageProcessor**.

```
from("activemq:queue:MY_QUEUE")
  .unmarshal().zipFile()
  .process(new UnZippedMessageProcessor());
```

If the zip file has more than one entry, the usingIterator option of ZipFileDataFormat to be true, and you can use splitter to do the further work.

```
ZipFileDataFormat zipFile = new ZipFileDataFormat();
zipFile.setUsingIterator(true);

from("file:src/test/resources/org/apache/camel/dataformat/zipfile/?consumer.delay=1000&noop=true")
  .unmarshal(zipFile)
  .split(body(Iterator.class)).streaming()
  .process(new UnZippedMessageProcessor())
  .end();
```

Or you can use the ZipSplitter as an expression for splitter directly like this

```
from("file:src/test/resources/org/apache/camel/dataformat/zipfile?consumer.delay=1000&noop=true")
  .split(new ZipSplitter()).streaming()
  .process(new UnZippedMessageProcessor())
  .end();
```

383.5. AGGREGATE

NOTE

Please note that this aggregation strategy requires eager completion check to work properly.

In this example we aggregate all text files found in the input directory into a single Zip file that is stored in the output directory.

```
from("file:input/directory?antInclude=/*.txt")
  .aggregate(constant(true), new ZipAggregationStrategy())
  .completionFromBatchConsumer().eagerCheckCompletion()
  .to("file:output/directory");
```

The outgoing **CamelFileName** message header is created using java.io.File.createTempFile, with the ".zip" suffix. If you want to override this behavior, then you can set the value of the **CamelFileName** header explicitly in your route:

```
from("file:input/directory?antInclude=/*.txt")
  .aggregate(constant(true), new ZipAggregationStrategy())
  .completionFromBatchConsumer().eagerCheckCompletion()
  .setHeader(Exchange.FILE_NAME, constant("reports.zip"))
  .to("file:output/directory");
```

383.6. DEPENDENCIES

To use Zip files in your camel routes you need to add a dependency on **camel-zipfile** which implements this data format.

If you use Maven you can just add the following to your **pom.xml**, substituting the version number for the latest & greatest release (see the download page for the latest versions).

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-zipfile</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

383.7. ZIPKIN COMPONENT

Available as of Camel 2.18

The camel-zipkin component is used for tracing and timing incoming and outgoing Camel messages using [zipkin](#).

Events (span) are captured for incoming and outgoing messages being sent to/from Camel.

NOTE

camel-zipkin is planned to be refactored in Camel 2.22.0 to not use zipkin-scribe but use the default http transport. This work may cause backwards incompatibility.

This means you need to configure which Camel endpoints map to zipkin service names.

The mapping can be configured using:

- route id - A Camel route id
- endpoint url - A Camel endpoint url

For both kinds you can match using wildcards and regular expressions, using the rules from Intercept.

To match all Camel messages you can use `*` in the pattern and configure that to the same service name.

If no mapping has been configured, Camel will fallback and use endpoint uri's as service names. However, it's recommended to configure service mappings so you can use human-readable names instead of Camel endpoint uris in the names.

Camel will auto-configure a span reporter one hasn't been explicitly configured, and if the hostname and port to a zipkin collector has been configured as environment variables

- ZIPKIN_COLLECTOR_HTTP_SERVICE_HOST - The http hostname
- ZIPKIN_COLLECTOR_HTTP_SERVICE_PORT - The port number

or

- ZIPKIN_COLLECTOR_THRIFT_SERVICE_HOST - The Scribe (Thrift RPC) hostname

- ZIPKIN_COLLECTOR_THRIFT_SERVICE_PORT - The port number

This makes it easy to use camel-zipkin in container platforms where the platform can run your application in a linux container where service configurations are provided as environment variables.

383.8. OPTIONS

Option	Default	Description
rate	1.0f	Configures a rate that decides how many events should be traced by zipkin. The rate is expressed as a percentage (1.0f = 100%, 0.5f is 50%, 0.1f is 10%).
spanReporter		Mandatory: The reporter to use for sending zipkin span events to the zipkin server.
serviceName		To use a global service name that matches all Camel events
clientServiceMappings		Sets the client service mappings that matches Camel events to the given zipkin service name. The content is a Map<String, String> where the key is a pattern and the value is the service name. The pattern uses the rules from Intercept.
serverServiceMappings		Sets the server service mappings that matches Camel events to the given zipkin service name. The content is a Map<String, String> where the key is a pattern and the value is the service name. The pattern uses the rules from Intercept.
excludePatterns		Sets exclude pattern(s) that will disable tracing with zipkin for Camel messages that matches the pattern. The content is a Set<String> where the key is a pattern. The pattern uses the rules from Intercept.
includeMessageBody	false	Whether to include the Camel message body in the zipkin traces. This is not recommended for production usage, or when having big payloads. You can limit the size by configuring the max debug log size .
includeMessageBodies	false	Whether to include message bodies that are stream based in the zipkin traces. This requires enabling streamcaching on the routes or globally on the CamelContext. This is not recommended for production usage, or when having big payloads. You can limit the size by configuring the max debug log size .

383.9. SPRING BOOT AUTO-CONFIGURATION

The component supports 10 options, which are listed below.

Name	Description	Default	Type
<code>camel.zipkin.client-service-mappings</code>	Sets client service mapping(s) that matches Camel events to the given zipkin service name. The key is the pattern, the value is the service name.		Map
<code>camel.zipkin.endpoint</code>	Sets the POST URL for zipkin's <code>v2 api</code> , usually <code>"http://zipkinhost:9411/api/v2/spans"</code>		String
<code>camel.zipkin.exclude-patterns</code>	Sets exclude pattern(s) that will disable tracing with zipkin for Camel messages that matches the pattern.		Set
<code>camel.zipkin.hostname</code>	Sets the hostname if sending spans to a remote zipkin scribe (thrift RPC) collector.		String
<code>camel.zipkin.include-message-body</code>	Whether to include the Camel message body in the zipkin traces. This is not recommended for production usage, or when having big payloads. You can limit the size by configuring <code>camel.springboot.log-debug-max-chars</code> option.	false	Boolean
<code>camel.zipkin.include-message-body-streams</code>	Whether to include message bodies that are stream based in the zipkin traces. This is not recommended for production usage, or when having big payloads. You can limit the size by configuring <code>camel.springboot.log-debug-max-chars</code> option.	false	Boolean
<code>camel.zipkin.port</code>	Sets the port if sending spans to a remote zipkin scribe (thrift RPC) collector.	0	Integer
<code>camel.zipkin.rate</code>	Configures a rate that decides how many events should be traced by zipkin. The rate is expressed as a percentage (1.0f = 100%, 0.5f is 50%, 0.1f is 10%).	1	Float
<code>camel.zipkin.server-service-mappings</code>	Sets server service mapping(s) that matches Camel events to the given zipkin service name. The key is the pattern, the value is the service name.		Map
<code>camel.zipkin.service-name</code>	To use a global service name that matches all Camel events		String

383.10. EXAMPLE

To enable camel-zipkin you need to configure first

```
ZipkinTracer zipkin = new ZipkinTracer();
// Configure a reporter, which controls how often spans are sent
```

```
// (the dependency is io.zipkin.reporter2:zipkin-sender-okhttp3)
sender = OkHttpSender.create("http://127.0.0.1:9411/api/v2/spans");
zipkin.setSpanReporter(AsyncReporter.create(sender));
// and then add zipkin to the CamelContext
zipkin.init(camelContext);
```

The configuration above will trace all incoming and outgoing messages in Camel routes.

To use ZipkinTracer in XML, all you need to do is to define scribe and zipkin tracer beans. Camel will automatically discover and use them.

```
<!-- configure how to reporter spans to a Zipkin collector
      (the dependency is io.zipkin.reporter2:zipkin-reporter-spring-beans) -->
<bean id="http" class="zipkin2.reporter.beans.AsyncReporterFactoryBean">
  <property name="sender">
    <bean id="sender" class="zipkin2.reporter.beans.OkHttpSenderFactoryBean">
      <property name="endpoint" value="http://localhost:9411/api/v2/spans"/>
    </bean>
  </property>
  <!-- wait up to half a second for any in-flight spans on close -->
  <property name="closeTimeout" value="500"/>
</bean>

<!-- setup zipkin tracer -->
<bean id="zipkinTracer" class="org.apache.camel.zipkin.ZipkinTracer">
  <property name="serviceName" value="dude"/>
  <property name="spanReporter" ref="http"/>
</bean>
```

383.10.1. ServiceName

However, if you want to map Camel endpoints to human friendly logical names, you can add mappings

- ServiceName *

You can configure a global service name that all events will fallback and use, such as:

```
zipkin.setServiceName("invoices");
```

This will use the same service name for all incoming and outgoing zipkin traces. If your application uses different services, you should map them to more finely grained client / server service mappings

383.10.2. Client and Server Service Mappings

- ClientServiceMappings
- ServerServiceMappings

If your application hosts a service that others can call, you can map the Camel route endpoint to a server service mapping. For example, suppose your Camel application has the following route:

```
from("activemq:queue:inbox")
.to("http:someserver/somepath");
```

And you want to make that as a server service, you can add the following mapping:

```
zipkin.addServerServiceMapping("activemq:queue:inbox", "orders");
```

Then when a message is consumed from that inbox queue, it becomes a zipkin server event with the service name 'orders'.

Now suppose that the call to `http:someserver/somepath` is also a service, which you want to map to a client service name, which can be done as:

```
zipkin.addClientServiceMapping("http:someserver/somepath", "audit");
```

Then in the same Camel application you have mapped incoming and outgoing endpoints to different zipkin service names.

You can use wildcards in the service mapping. To match all outgoing calls to the same HTTP server you can do:

```
zipkin.addClientServiceMapping("http:someserver*", "audit");
```

383.11. MAPPING RULES

The service name mapping for server occurs using the following rules

1. Is there an exclude pattern that matches the endpoint uri of the from endpoint? If yes then skip.
2. Is there a match in the `serviceServiceMapping` that matches the endpoint uri of the from endpoint? If yes, then use the found service name
3. Is there a match in the `serviceServiceMapping` that matches the route id of the current route? If yes, then use the found service name
4. Is there a match in the `serviceServiceMapping` that matches the original route id where the exchange started? If yes, then use the found service name
5. No service name was found, the exchange is not traced by zipkin

The service name mapping for client occurs using the following rules

1. Is there an exclude pattern that matches the endpoint uri of the from endpoint? If yes then skip.
2. Is there a match in the `clientServiceMapping` that matches the endpoint uri of endpoint where the message is being sent to? If yes, then use the found service name
3. Is there a match in the `clientServiceMapping` that matches the route id of the current route? If yes, then use the found service name
4. Is there a match in the `clientServiceMapping` that matches the original route id where the exchange started? If yes, then use the found service name
5. No service name was found, the exchange is not traced by zipkin

383.11.1. No client or server mappings

If there has been no configuration of client or server service mappings, CamelZipkin runs in a fallback mode, and uses endpoint uris as the service name.

In the example above, this would mean the service names would be defined as if you add the following code yourself:

```
zipkin.addServerServiceMapping("activemq:queue:inbox", "activemq:queue:inbox");  
zipkin.addClientServiceMapping("http:someserver/somepath", "http:someserver/somepath");
```

This is not a recommended approach, but gets you up and running quickly without doing any service name mappings. However, when you have multiple systems across your infrastructure, then you should consider using human-readable service names, that you map to instead of using the camel endpoint uris.

383.12. CAMEL-ZIPIN-STARTER

If you are using Spring Boot then you can add the **camel-zipkin-starter** dependency, and turn on zipkin by annotating the main class with **@CamelZipkin**. You can then configure camel-zipkin in the **application.properties** file where you can configure the hostname and port number for the Zipkin Server, and all the other options as listed in the options table above.

You can find an example of this in the [camel-example-zipkin](#)

CHAPTER 384. ZOOKEEPER COMPONENT

Available as of Camel version 2.9

The ZooKeeper component allows interaction with a [ZooKeeper](#) cluster and exposes the following features to Camel:

1. Creation of nodes in any of the ZooKeeper create modes.
2. Get and Set the data contents of arbitrary cluster nodes (data being set must be convertible to `byte[]`).
3. Create and retrieve the list the child nodes attached to a particular node.
4. A Distributed **RoutePolicy** that leverages a Leader election coordinated by ZooKeeper to determine if exchanges should get processed.

Maven users will need to add the following dependency to their `pom.xml` for this component:

```
<dependency>
  <groupId>org.apache.camel</groupId>
  <artifactId>camel-zookeeper</artifactId>
  <version>x.x.x</version>
  <!-- use the same version as your Camel core version -->
</dependency>
```

384.1. URI FORMAT

```
zookeeper://zookeeper-server[:port][/path][?options]
```

The path from the URI specifies the node in the ZooKeeper server (a.k.a. *znode*) that will be the target of the endpoint:

384.2. OPTIONS

The ZooKeeper component supports 2 options, which are listed below.

Name	Description	Default	Type
configuration (advanced)	To use a shared ZooKeeperConfiguration		ZooKeeperConfiguration
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The ZooKeeper endpoint is configured using URI syntax:

```
zookeeper:serverUrls/path
```

with the following path and query parameters:

384.2.1. Path Parameters (2 parameters):

Name	Description	Default	Type
serverUrls	Required The zookeeper server hosts (multiple servers can be separated by comma)		String
path	Required The node in the ZooKeeper server (aka znode)		String

384.2.2. Query Parameters (12 parameters):

Name	Description	Default	Type
awaitExistence (common)	Deprecated Not in use	true	boolean
listChildren (common)	Whether the children of the node should be listed	false	boolean
timeout (common)	The time interval to wait on connection before timing out.	5000	int
backoff (consumer)	The time interval to backoff for after an error before retrying.	5000	long
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the <code>org.apache.camel.spi.ExceptionHandler</code> to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean
repeat (consumer)	Should changes to the znode be 'watched' and repeatedly processed.	false	boolean
sendEmptyMessageOnDelete (consumer)	Upon the delete of a znode, should an empty message be send to the consumer	true	boolean

Name	Description	Default	Type
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
create (producer)	Should the endpoint create the node if it does not currently exist.	false	boolean
createMode (producer)	The create mode that should be used for the newly created node	EPHEMERAL	String
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

384.3. SPRING BOOT AUTO-CONFIGURATION

The component supports 57 options, which are listed below.

Name	Description	Default	Type
camel.component.zookeeper.cluster.service.attributes	Custom service attributes.		Map
camel.component.zookeeper.cluster.service.auth-info-list			List
camel.component.zookeeper.cluster.service.base-path			String
camel.component.zookeeper.cluster.service.connection-timeout			Long

Name	Description	Default	Type
camel.component.zookeeper.cluster.service.connection-timeout-unit			TimeUnit
camel.component.zookeeper.cluster.service.curator-framework			CuratorFramework
camel.component.zookeeper.cluster.service.enabled	Sets if the zookeeper cluster service should be enabled or not, default is false.	false	Boolean
camel.component.zookeeper.cluster.service.id	Cluster Service ID		String
camel.component.zookeeper.cluster.service.max-close-wait			Long
camel.component.zookeeper.cluster.service.max-close-wait-unit			TimeUnit
camel.component.zookeeper.cluster.service.namespace			String
camel.component.zookeeper.cluster.service.nodes			List
camel.component.zookeeper.cluster.service.order	Service lookup order/priority.		Integer
camel.component.zookeeper.cluster.service.reconnect-base-sleep-time			Long

Name	Description	Default	Type
camel.component.zookeeper.cluster.service.reconnect-base-sleep-time-unit			TimeUnit
camel.component.zookeeper.cluster.service.reconnect-max-retries			Integer
camel.component.zookeeper.cluster.service.reconnect-max-sleep-time			Long
camel.component.zookeeper.cluster.service.reconnect-max-sleep-time-unit			TimeUnit
camel.component.zookeeper.cluster.service.retry-policy			RetryPolicy
camel.component.zookeeper.cluster.service.session-timeout			Long
camel.component.zookeeper.cluster.service.session-timeout-unit			TimeUnit
camel.component.zookeeper.configuration.backoff	The time interval to backoff for after an error before retrying.	5000	Long
camel.component.zookeeper.configuration.create	Should the endpoint create the node if it does not currently exist.	false	Boolean

Name	Description	Default	Type
<code>camel.component.zookeeper.configuration.create-mode</code>	The create mode that should be used for the newly created node	EPHEMERAL	String
<code>camel.component.zookeeper.configuration.list-children</code>	Whether the children of the node should be listed	false	Boolean
<code>camel.component.zookeeper.configuration.path</code>	The node in the ZooKeeper server (aka znode)		String
<code>camel.component.zookeeper.configuration.repeat</code>	Should changes to the znode be 'watched' and repeatedly processed.	false	Boolean
<code>camel.component.zookeeper.configuration.send-empty-message-on-delete</code>	Upon the delete of a znode, should an empty message be send to the consumer	true	Boolean
<code>camel.component.zookeeper.configuration.servers</code>	The zookeeper server hosts		List
<code>camel.component.zookeeper.configuration.timeout</code>	The time interval to wait on connection before timing out.	5000	Integer
<code>camel.component.zookeeper.enabled</code>	Enable zookeeper component	true	Boolean
<code>camel.component.zookeeper.resolve-property-placeholders</code>	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean
<code>camel.component.zookeeper.service-registry.attributes</code>	Custom service attributes.		Map

Name	Description	Default	Type
camel.component.zookeeper.service-registry.auth-info-list			List
camel.component.zookeeper.service-registry.base-path			String
camel.component.zookeeper.service-registry.connection-timeout			Long
camel.component.zookeeper.service-registry.connection-timeout-unit			TimeUnit
camel.component.zookeeper.service-registry.curator-framework			CuratorFramework
camel.component.zookeeper.service-registry.deregister-services-on-stop			Boolean
camel.component.zookeeper.service-registry.enabled	Sets if the zookeeper service registry should be enabled or not, default is false.	false	Boolean
camel.component.zookeeper.service-registry.id	Service Registry ID		String
camel.component.zookeeper.service-registry.max-close-wait			Long

Name	Description	Default	Type
camel.component.zookeeper.service-registry.max-close-wait-unit			TimeUnit
camel.component.zookeeper.service-registry.namespace			String
camel.component.zookeeper.service-registry.nodes			List
camel.component.zookeeper.service-registry.order	Service lookup order/priority.		Integer
camel.component.zookeeper.service-registry.override-service-host			Boolean
camel.component.zookeeper.service-registry.reconnect-base-sleep-time			Long
camel.component.zookeeper.service-registry.reconnect-base-sleep-time-unit			TimeUnit
camel.component.zookeeper.service-registry.reconnect-max-retries			Integer

Name	Description	Default	Type
camel.component.zookeeper.service-registry.reconnect-max-sleep-time			Long
camel.component.zookeeper.service-registry.reconnect-max-sleep-time-unit			TimeUnit
camel.component.zookeeper.service-registry.retry-policy			RetryPolicy
camel.component.zookeeper.service-registry.service-host			String
camel.component.zookeeper.service-registry.session-timeout			Long
camel.component.zookeeper.service-registry.session-timeout-unit			TimeUnit
camel.component.zookeeper.configuration.await-existence	Not in use	true	Boolean

384.4. USE CASES

384.4.1. Reading from a *znode*

The following snippet will read the data from the *znode/somepath/somenode/* provided that it already exists. The data retrieved will be placed into an exchange and passed onto the rest of the route:

```
from("zookeeper://localhost:39913/somepath/somenode").to("mock:result");
```

If the node does not yet exist then a flag can be supplied to have the endpoint await its creation:

```
from("zookeeper://localhost:39913/somepath/somenode?awaitCreation=true").to("mock:result");
```

384.4.2. Reading from a *znode* (additional Camel 2.10 onwards)

When data is read due to a **WatchedEvent** received from the ZooKeeper ensemble, the **CamelZookeeperEventType** header holds ZooKeeper's **EventType** value from that **WatchedEvent**. If the data is read initially (not triggered by a **WatchedEvent**) the **CamelZookeeperEventType** header will not be set.

384.4.3. Writing to a *znode*

The following snippet will write the payload of the exchange into the *znode* at */somepath/somenode/* provided that it already exists:

```
from("direct:write-to-znode")
    .to("zookeeper://localhost:39913/somepath/somenode");
```

For flexibility, the endpoint allows the target *znode* to be specified dynamically as a message header. If a header keyed by the string **CamelZooKeeperNode** is present then the value of the header will be used as the path to the *znode* on the server. For instance using the same route definition above, the following code snippet will write the data not to */somepath/somenode* but to the path from the header */somepath/someothernode*.

WARNING

the **testPayload** must be convertible to **byte[]** as the data stored in ZooKeeper is byte based.

```
Object testPayload = ...
template.sendBodyAndHeader("direct:write-to-znode", testPayload, "CamelZooKeeperNode",
    "/somepath/someothernode");
```

To also create the node if it does not exist the **create** option should be used.

```
from("direct:create-and-write-to-znode")
    .to("zookeeper://localhost:39913/somepath/somenode?create=true");
```

Starting **version 2.11** it is also possible to **delete** a node using the header **CamelZookeeperOperation** by setting it to **DELETE**:

```
from("direct:delete-znode")
  .setHeader(ZooKeeperMessage.ZOOKEEPER_OPERATION, constant("DELETE"))
  .to("zookeeper://localhost:39913/somepath/somenode");
```

or equivalently:

```
<route>
  <from uri="direct:delete-znode" />
  <setHeader headerName="CamelZookeeperOperation">
    <constant>DELETE</constant>
  </setHeader>
  <to uri="zookeeper://localhost:39913/somepath/somenode" />
</route>
```

ZooKeeper nodes can have different types; they can be 'Ephemeral' or 'Persistent' and 'Sequenced' or 'Unsequenced'. For further information of each type you can check [here](#). By default endpoints will create unsequenced, ephemeral nodes, but the type can be easily manipulated via a uri config parameter or via a special message header. The values expected for the create mode are simply the names from the **CreateMode** enumeration:

- **PERSISTENT**
- **PERSISTENT_SEQUENTIAL**
- **EPHEMERAL**
- **EPHEMERAL_SEQUENTIAL**

For example to create a persistent *znode* via the URI config:

```
from("direct:create-and-write-to-persistent-znode")
  .to("zookeeper://localhost:39913/somepath/somenode?create=true&createMode=PERSISTENT");
```

or using the header **CamelZookeeperCreateMode**.

WARNING

the **testPayload** must be convertible to **byte[]** as the data stored in ZooKeeper is byte based.

```
Object testPayload = ...
template.sendBodyAndHeader("direct:create-and-write-to-persistent-znode", testPayload,
  "CamelZookeeperCreateMode", "PERSISTENT");
```

384.5. ZOOKEEPER ENABLED ROUTE POLICIES

ZooKeeper allows for very simple and effective leader election out of the box. This component exploits this election capability in a **RoutePolicy** to control when and how routes are enabled. This policy would typically be used in fail-over scenarios, to control identical instances of a route across a cluster of Camel

based servers. A very common scenario is a simple 'Master-Slave' setup where there are multiple instances of a route distributed across a cluster but only one of them, that of the master, should be running at a time. If the master fails, a new master should be elected from the available slaves and the route in this new master should be started.

The policy uses a common *znode* path across all instances of the **RoutePolicy** that will be involved in the election. Each policy writes its id into this node and Zookeeper will order the writes in the order it received them. The policy then reads the listing of the node to see what position of its id; this position is used to determine if the route should be started or not. The policy is configured at startup with the number of route instances that should be started across the cluster and if its position in the list is less than this value then its route will be started. For a Master-slave scenario, the route is configured with 1 route instance and only the first entry in the listing will start its route. All policies watch for updates to the listing and if the listing changes they recalculate if their route should be started. For more info on Zookeeper's leader election capability see [this page](#).

The following example uses the node **/someapplication/somepolicy** for the election and is set up to start only the top '1' entries in the node listing i.e. elect a master:

```
ZooKeeperRoutePolicy policy = new
ZooKeeperRoutePolicy("zookeeper:localhost:39913/someapp/somepolicy", 1);
from("direct:policy-controlled")
    .routePolicy(policy)
    .to("mock:controlled");
```

There are currently 3 policies defined in the component, with different SLAs:

- **ZooKeeperRoutePolicy**
- **CuratorLeaderRoutePolicy** (since 2.19)
- **MultiMasterCuratorLeaderRoutePolicy** (since 2.19)

ZooKeeperRoutePolicy supports multiple active nodes, but it's activation kicks in only after a Camel component and its correspondent Consumer have already been started, this introduces, depending on your routes definition, the risk that you component can already start consuming events and producing `Exchange`s, before the policy could establish that the node should not be activated.

CuratorLeaderRoutePolicy supports only a single active node, but it's bound to a different **CamelContext** lifecycle method; this Policy kicks in before any route or consumer is started thus you can be sure that no even is processed before the Policy takes its decision.

MultiMasterCuratorLeaderRoutePolicy support multiple active nodes, and it's bound to the same lifecycle method as **CuratorLeaderRoutePolicy**; this Policy kicks in before any route or consumer is started thus you can be sure that no even is processed before the Policy takes its decision.

CHAPTER 385. ZOOKEEPER MASTER COMPONENT

Available as of Camel version 2.19

The **zookeeper-master**: endpoint provides a way to ensure only a single consumer in a cluster consumes from a given endpoint; with automatic failover if that JVM dies.

This can be very useful if you need to consume from some legacy back end which either doesn't support concurrent consumption or due to commercial or stability reasons you can only have a single connection at any point in time.

385.1. USING THE MASTER ENDPOINT

Just prefix any camel endpoint with **zookeeper-master:someName**: where *someName* is a logical name and is used to acquire the master lock. e.g.

```
from("zookeeper-master:cheese:jms:foo").to("activemq:wine");
```

The above simulates the [Exclusive Consumers](<http://activemq.apache.org/exclusive-consumer.html>) type feature in ActiveMQ; but on any third party JMS provider which maybe doesn't support exclusive consumers.

385.2. URI FORMAT

```
zookeeper-master:name:endpoint[?options]
```

Where endpoint is any Camel endpoint you want to run in master/slave mode.

385.3. OPTIONS

The ZooKeeper Master component supports 7 options, which are listed below.

Name	Description	Default	Type
containerIdFactory (consumer)	To use a custom ContainerIdFactory for creating container ids.		ContainerIdFactory
zkRoot (consumer)	The root path to use in zookeeper where information is stored which nodes are master/slave etc. Will by default use: /camel/zookeepermaster/clusters/master	/camel/zookeepermaster/clusters/master	String
curator (advanced)	To use a custom configured CuratorFramework as connection to zookeeper ensemble.		CuratorFramework

Name	Description	Default	Type
maximumConnectionTimeout (consumer)	Timeout in millis to use when connecting to the zookeeper ensemble	10000	int
zooKeeperUrl (consumer)	The url for the zookeeper ensemble	localhost:2181	String
zooKeeperPassword (security)	The password to use when connecting to the zookeeper ensemble		String
resolvePropertyPlaceholders (advanced)	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	boolean

The ZooKeeper Master endpoint is configured using URI syntax:

```
zookeeper-master:groupName:consumerEndpointUri
```

with the following path and query parameters:

385.3.1. Path Parameters (2 parameters):

Name	Description	Default	Type
groupName	Required The name of the cluster group to use		String
consumerEndpointUri	Required The consumer endpoint to use in master/slave mode		String

385.3.2. Query Parameters (4 parameters):

Name	Description	Default	Type
bridgeErrorHandler (consumer)	Allows for bridging the consumer to the Camel routing Error Handler, which mean any exceptions occurred while the consumer is trying to pickup incoming messages, or the likes, will now be processed as a message and handled by the routing Error Handler. By default the consumer will use the org.apache.camel.spi.ExceptionHandler to deal with exceptions, that will be logged at WARN or ERROR level and ignored.	false	boolean

Name	Description	Default	Type
exceptionHandler (consumer)	To let the consumer use a custom ExceptionHandler. Notice if the option bridgeErrorHandler is enabled then this option is not in use. By default the consumer will deal with exceptions, that will be logged at WARN or ERROR level and ignored.		ExceptionHandler
exchangePattern (consumer)	Sets the exchange pattern when the consumer creates an exchange.		ExchangePattern
synchronous (advanced)	Sets whether synchronous processing should be strictly used, or Camel is allowed to use asynchronous processing (if supported).	false	boolean

385.4. SPRING BOOT AUTO-CONFIGURATION

The component supports 8 options, which are listed below.

Name	Description	Default	Type
camel.component.zookeeper-master.container-id-factory	To use a custom ContainerIdFactory for creating container ids. The option is a <code>org.apache.camel.component.zookeepermaster.ContainerIdFactory</code> type.		String
camel.component.zookeeper-master.curator	To use a custom configured CuratorFramework as connection to zookeeper ensemble. The option is a <code>org.apache.curator.framework.CuratorFramework</code> type.		String
camel.component.zookeeper-master.enabled	Enable zookeeper-master component	true	Boolean
camel.component.zookeeper-master.maximum-connection-timeout	Timeout in millis to use when connecting to the zookeeper ensemble	10000	Integer
camel.component.zookeeper-master.resolve-property-placeholders	Whether the component should resolve property placeholders on itself when starting. Only properties which are of String type can use property placeholders.	true	Boolean

Name	Description	Default	Type
<code>camel.component.zookeeper-master.zk-root</code>	The root path to use in zookeeper where information is stored which nodes are master/slave etc. Will by default use: <code>/camel/zookeepermaster/clusters/master</code>	<code>/camel/zookeepermaster/clusters/master</code>	String
<code>camel.component.zookeeper-master.zookeeper-password</code>	The password to use when connecting to the zookeeper ensemble		String
<code>camel.component.zookeeper-master.zookeeper-url</code>	The url for the zookeeper ensemble	<code>localhost:2181</code>	String

385.5. EXAMPLE

You can protect a clustered Camel application to only consume files from one active node.

```
// the file endpoint we want to consume from
String url = "file:target/inbox?delete=true";

// use the zookeeper master component in the clustered group named myGroup
// to run a master/slave mode in the following Camel url
from("zookeeper-master:myGroup:" + url)
    .log(name + " - Received file: ${file:name}")
    .delay(delay)
    .log(name + " - Done file:  ${file:name}")
    .to("file:target/outbox");
```

ZooKeeper will by default connect to **localhost:2181**, but you can configure this on the component level.

```
MasterComponent master = new MasterComponent();
master.setZooKeeperUrl("myzookeeper:2181");
```

However you can also configure the url of the ZooKeeper ensemble using environment variables.

```
export ZOOKEEPER_URL = "myzookeeper:2181"
```

CHAPTER 386. MASTER ROUTEPOLICY

You can also use a **RoutePolicy** to control routes in master/slave mode.

When doing so you must configure the route policy with

- url to zookeeper ensemble
- name of cluster group
- **important** and set the route to not auto startup

A little example

```
MasterRoutePolicy master = new MasterRoutePolicy();
master.setZooKeeperUrl("localhost:2181");
master.setGroupName("myGroup");

// its import to set the route to not auto startup
// as we let the route policy start/stop the routes when it becomes a master/slave etc
from("file:target/inbox?delete=true").noAutoStartup()
    // use the zookeeper master route policy in the clustered group
    // to run this route in master/slave mode
    .routePolicy(master)
    .log(name + " - Received file: ${file:name}")
    .delay(delay)
    .log(name + " - Done file:  ${file:name}")
    .to("file:target/outbox");
```
