# MAKING OPEN SOURCE MORE INCLUSIVE

Red Hat is committed to replacing problematic language in our code, documentation, and web properties. We are beginning with these four terms: master, slave, blacklist, and whitelist. Because of the enormity of this endeavor, these changes will be implemented gradually over several upcoming releases. For more details, see our CTO Chris Wright's message.

# PROVIDING FEEDBACK ON RED HAT DOCUMENTATION

We appreciate your feedback on our documentation. Let us know how we can improve it.

#### Submitting feedback through Jira (account required)

- 1. Log in to the Jira website.
- 2. Click **Create** in the top navigation bar.
- 3. Enter a descriptive title in the **Summary** field.
- 4. Enter your suggestion for improvement in the **Description** field. Include links to the relevant parts of the documentation.
- 5. Click **Create** at the bottom of the dialogue.

## **CHAPTER 1. USING APPSTREAM**

In the following sections, learn the concepts related to the AppStream repository in Red Hat Enterprise Linux 8:

- Distribution of content in RHEL 8.
- Application Streams.
- Packaging methods in RHEL 8.
- Package management using YUM in RHEL 8.

#### 1.1. DISTRIBUTION OF CONTENT IN RHEL 8

Red Hat Enterprise Linux 8 content is distributed through the two main repositories: **BaseOS** and **AppStream**.

#### **BaseOS**

The BaseOS repository contains the core set of the underlying operating system functionality that provides the foundation for all installations. This content is available in the form of RPM packages and is subject to support terms similar to those in earlier releases of Red Hat Enterprise Linux.

#### **AppStream**

The AppStream repository contains additional user-space applications, runtime languages, and databases in support of the varied workloads and use cases. Content in AppStream is available in one of two formats - the RPM packages and an extension to the RPM format called *modules*.

#### **IMPORTANT**

Both BaseOS and AppStream content sets are required for a basic RHEL installation, and are available with all RHEL subscriptions. For installation instructions, see the Performing a standard RHEL 8 installation document.

#### 1.2. APPLICATION STREAMS

Red Hat Enterprise Linux 8 introduces the concept of Application Streams - versions of user-space components. Multiple versions of these components are now delivered and updated more frequently than the core operating system packages. This provides greater flexibility to customize Red Hat Enterprise Linux without impacting the underlying stability of the platform or specific deployments.

Components made available as Application Streams can be packaged as modules or RPM packages, and are delivered through the AppStream repository in Red Hat Enterprise Linux 8. Each Application Stream has a given life cycle, either the same as RHEL 8 or shorter, more suitable to the particular application. Application Streams with a shorter life cycle are listed in the Red Hat Enterprise Linux 8 Application Streams Life Cycle page.

#### **NOTE**

Not all modules are Application Streams. Dependencies of other modules are not considered Application Streams.

#### **Additional Resources**

- Red Hat Enterprise Linux Life Cycle
- Red Hat Enterprise Linux 8 Application Streams Life Cycle

#### 1.3. PACKAGING METHODS IN RHEL 8

Content in the AppStream repository is packaged in two ways:

#### • Individual RPM packages

Traditional RPM packages available for immediate installation.

#### Modules

Modules are collections of packages representing a logical unit: an application, a language stack, a database, or a set of tools. These packages are built, tested, and released together.

#### 1.4. PACKAGE MANAGEMENT USING YUM IN RHEL 8

The **YUM** package management tool is now based on the DNF technology and it adds support for the new modular features.

Usage of **YUM** has not been changed when handling individual RPM packages. For handling the modular content, the **yum module** command has been added. See Installing RHEL 8 content for additional details.

Where required, the modular functionality automatically selects the appropriate combination of modules and streams to enable installation of logical sets of packages for convenient usage.

## **CHAPTER 2. INTRODUCTION TO MODULES**

Besides individual RPM packages, the AppStream repository contains modules. A module is a set of RPM packages that represent a component and are usually installed together. A typical module contains packages with an application, packages with the application-specific dependency libraries, packages with documentation for the application, and packages with helper utilities.

In the following sections, learn features for organization and handling of content within modules:

- Module streams organization of content by version.
- Module profiles organization of content by purpose.

#### 2.1. MODULE STREAMS

Module streams are filters that can be imagined as virtual repositories in the AppStream physical repository. Module streams represent versions of the AppStream components. Each of the streams receives updates independently.

Module streams can be active or inactive. Active streams give the system access to the RPM packages within the particular module stream, allowing installation of the respective component version. Streams are active either if marked as default or if they are explicitly enabled by a user action.

Only one stream of a particular module can be active at a given point in time. Therefore, only one version of a component can be installed on a system. Different versions can be used in separate containers.

Each module can have a default stream. Default streams make it easy to consume RHEL packages the usual way without the need to learn about modules. The default stream is active, unless the whole module has been disabled or another stream of that module enabled.

#### **IMPORTANT**

The default stream does not change throughout the RHEL major release. Always consider each stream's life cycle. Do not rely on the default stream for instances in which the default stream reaches the End of Life status prior to the end of the RHEL major release.

Certain module streams depend on other module streams. For example, the **perl-App-cpanminus**, **perl-DBD-MySQL**, **perl-DBD-Pg**, **perl-DBD-SQLite**, **perl-DBI**, **perl-YAML**, and **freeradius** module streams depend on certain **perl** module streams.

To select a particular stream for a runtime user application or a developer application, consider the following:

- Required functionality and which component versions support it
- Compatibility
- Life cycle length and your update plan

For a list of all available modules and streams, see the Package manifest. For per-component changes, see the Release Notes.

Example 2.1. postgresql module streams

The **postgresql** module provides the **PostgreSQL** database versions 9.6, 10, 12, and 13 in the respective streams **9.6**, **10**, **12**, **13**, and **15**. Stream **10** is the default one. This means that the system attempts to install the **postgresql-10.6** package if asked for **postgresql**.

Always decide which module stream you want to use, and install the version explicitly.

#### Additional resources

- Modular dependencies and stream changes
- Switching to a later stream
- Package manifest
- Release Notes

#### 2.2. MODULE PROFILES

A profile is a list of recommended packages that are installed together for a particular use case, such as a server, client, development, minimal install, or other. These package lists can contain packages outside the module stream, usually from the BaseOS repository or the dependencies of the stream.

Installing packages by using a profile is a one-time action provided for the user's convenience. It does not prevent installing or uninstalling any of the packages provided by the module. It is also possible to install packages by using multiple profiles of the same module stream without any further preparatory steps.

Each module stream can have any number of profiles, including none. For any given module stream, some of its profiles can be marked as *default* and are then used for profile installation actions when no profile is explicitly specified. However, existence of a default profile for a module stream is not required.

#### Example 2.2. httpd module profiles

The **httpd** module, which provides the **Apache** web server, offers the following profiles for installation:

- **common** a hardened production-ready deployment, the default profile.
- **devel** the packages necessary for making modifications to **httpd**.
- **minimal** the smallest set of packages that provide a running web server.

# **CHAPTER 3. FINDING RHEL 8 CONTENT**

In the following sections, learn how to locate and examine content in the AppStream and BaseOS repositories in Red Hat Enterprise Linux 8 by using **YUM**:

- Search for packages providing desired content.
- List available modules and find out details about them .
- Examine useful commands for inspecting RHEL 8 content.

#### 3.1. SEARCHING FOR A PACKAGE

To find a package providing a particular application or other content, complete the following steps.

#### **Procedure**

- 1. Search for a package with a text string, such as application name:
  - \$ yum search "text string"
- 2. View details about a package:
  - \$ yum info *package*

#### 3.2. LISTING AVAILABLE MODULES AND THEIR CONTENT

To find out which modules are available and what their details are, complete the following steps.

#### Procedure

- To list module streams available to your system, use:
  - \$ yum module list

The output of this command lists module streams with name, stream, profiles, and summary on a separate line.

- To display details about a module, including a description, a list of all profiles, and a list of all provided packages, use:
  - \$ yum module info *module-name*
- To list which of these packages are installed by each of module profiles, use:
  - \$ yum module info --profile module-name
- To display the current status of a module, including enabled streams and installed profiles, use:
  - \$ yum module list module-name

#### Additional resources

Introduction to modules

#### Example 3.1. Finding out details about a module

The following is an example of how to list available modules in the AppStream repository and how to obtain information about the **postgresql** module's contents.

#### **NOTE**

The outputs in this example have been edited for brevity. Actual outputs might contain more information than shown here.

1. List available modules:

```
$ yum module list
Name
           Stream Profiles Summary
(...)
postgresql 9.6
                   client,
                            PostgreSQL server and client module
             server [
             d]
postgresql 10 [d] client,
                            PostgreSQL server and client module
             server [
             d]
postgresql 12
                            PostgreSQL server and client module
                   client,
             server [
             d]
postgresql 13
                   client.
                            PostgreSQL server and client module
             server [
             d]
postgresql 15
                   client,
                            PostgreSQL server and client module
             server [
             d]
(...)
Hint: [d]efault, [e]nabled, [x]disabled, [i]nstalled
```

2. Examine details of the **postgresql** module:

\$ yum module info postgresql

• • •

Name : postgresql Stream : 10 [d][a]

Version : 8070020221124143148

Context : bd1311ed
Architecture : x86\_64
Profiles : client, server [d]

Default profiles : server
Repo : rhel-AppStream

Summary : PostgreSQL server and client module

...

Name : postgresql

Stream: 12

Version : 8060020221003080350

Context : ad008a3a
Architecture : x86\_64
Profiles : client, server [d]

Default profiles : server

Repo : rhel-AppStream

Summary : PostgreSQL server and client module

. . .

Name : postgresql

Stream: 13

Version : 8070020230227142544

Context : bd1311ed
Architecture : x86\_64
Profiles : client, server [d]

Default profiles : server

Repo : rhel-AppStream

Summary : PostgreSQL server and client module

• • •

Name : postgresql

Stream: 15

Version : 8080020230212204728

Context : fd72936b
Architecture : x86\_64
Profiles : elient serve

Profiles : client, server [d]

Default profiles : server

Repo : rhel-AppStream

Summary : PostgreSQL server and client module

...

Name : postgresql

Stream: 9.6

Version : 8040020210602182503

Context : 522a0ee4
Architecture : x86\_64
Profiles : client, server [d]

Default profiles : server

Repo: rhel-AppStream

Summary : PostgreSQL server and client module

. . .

Hint: [d]efault, [e]nabled, [x]disabled, [i]nstalled, [a]ctive

If you do not specify any stream, **yum** lists all available streams.

3. Examine profiles available in stream 10 of the **postgresql** module:

\$ yum module info --profile postgresql:10

(...)

Name : postgresql:10:8070020221124143148:bd1311ed:x86\_64

client: postgresql

server : postgresql-server

Note that each of the profiles installs a different set of packages, including their dependencies.

4. Install the **postgresql** module by using the default stream **10** and the default profile **server**:

# yum module install postgresql

- -

Dependencies resolved.

\_\_\_\_\_\_

Package Architecture Version Repository Size

\_\_\_\_\_

Installing group/module packages:

postgresql-server x86 64 10.23-1.module+el8.7.0+17280+3a452e1f rhel-

AppStream 5.1 M Installing dependencies:

libpq x86\_64 13.5-1.el8 rhel-AppStream 198 k

postgresql x86\_64 10.23-1.module+el8.7.0+17280+3a452e1f rhel-

AppStream 1.5 M Installing module profiles: postgresql/server

Enabling module streams: postgresql 10

**Transaction Summary** 

\_\_\_\_\_\_

Install 3 Packages

Total download size: 6.7 M

Installed size: 26 M Is this ok [y/N]: y

...

Installed:

libpq-13.5-1.el8.x86 64

postgresql-10.23-1.module+el8.7.0+17280+3a452e1f.x86\_64

postgresql-server-10.23-1.module+el8.7.0+17280+3a452e1f.x86\_64

Complete!

5. Inspect the current status of the **postgresql** module:

\$ yum module list postgresql

rhel-AppStream				
Name	Stream	Profiles	Summary	
postgresql module	9.6	client, server [d]	PostgreSQL server and client	
postgresql module	10 [d][e]	client, server [d] [i]	PostgreSQL server and client	
postgresql module	12	client, server [d]	PostgreSQL server and client	
postgresql module	13	client, server [d]	PostgreSQL server and client	
postgresql	15	client, server [d]	PostgreSQL server and client	

module

Hint: [d]efault, [e]nabled, [x]disabled, [i]nstalled

The output shows that the default stream 10 is enabled and its profile **server** is installed.

# 3.3. COMMANDS FOR LISTING CONTENT

The following are the commonly used commands for finding content and its details in Red Hat Enterprise Linux 8.

Command	Description
yum list available	List available packages.
yum repoquery package	Search available <b>YUM</b> repositories for a selected package.
yum search "text string"	Search for a package by using arbitrary text string.
yum info <i>package</i>	Display details for a package.
yum module provides package	Display which modules provide a package.  If the package is available outside any modules, the output of this command is empty.
yum module list	List available modules.
yum module info module-name	Display details of a module.
yum module infoprofile module-name	List packages installed by profiles of a module by using the default stream.
yum module infoprofile module- name:stream	Display packages installed by profiles of a module by using a specified stream.
yum module list module-name	Display the current status of a module.

## **CHAPTER 4. INSTALLING RHEL 8 CONTENT**

In the following sections, learn how to install content in Red Hat Enterprise Linux 8:

- Install a package.
- Select a stream for package installation.
- Install sets of packages provided by modules, streams, and profiles .
- Run RHFL 8 installed content.
- Examine useful commands for installing RHEL 8 content .

#### 4.1. INSTALLING A PACKAGE

To install a package, complete the following steps.

#### **Procedure**

- Install a package:
  - # yum install *package*

Replace package with the name of the package.

- If the package is not provided by any module stream, this procedure is identical to the procedure used on earlier versions of Red Hat Enterprise Linux.
- If the package is provided by an module stream that is enabled, the package is installed without any further manipulation.
- If the package is provided by a module stream marked as default, **yum** automatically enables that module stream before installing this package.

#### **IMPORTANT**

It is recommended to always select a specific module stream for installation instead of relying on the default stream. Certain default module streams reach the End of Life status prior to the end of the RHEL major release. Always consider each stream's lifecycle.

• If the package is provided by a module stream that is not active (neither of the above cases), it is not recognized until you manually enable the respective module stream.

#### Additional resources

- Installing modular content
- Package management using YUM in RHEL 8
- Red Hat Enterprise Linux Application Streams Life Cycle

#### 4.2. SELECTING A STREAM BEFORE INSTALLATION OF PACKAGES

It is recommended to always select a specific module stream for installation. Always consider each stream's life cycle.

#### **IMPORTANT**

Certain default module streams reach the End of Life status prior to the end of the RHEL major release.

To install packages from a non-default stream, enable the stream first.

#### **Prerequisites**

• You understand the concept of an active module stream.

#### Procedure

Enable the module stream:

# yum module enable module-name:stream

Replace *module-name* and *stream* with names of the module and stream.

yum asks for confirmation and the stream is enabled and active.

#### **NOTE**

If another stream of the module was previously active because it was default, it is no longer active.

#### Additional resources

• Red Hat Enterprise Linux Application Streams Life Cycle

#### 4.3. INSTALLING MODULAR CONTENT

To install modular content provided by a module stream or a profile, complete the following steps.

#### **Prerequisites**

- You understand the concept of an active module stream.
- You do not have any packages installed from another stream of the same module.

#### **Procedure**

To install a selected module stream, use:

# yum module install module-name:stream

By running this command, you automatically enable selected stream. Note that if a default profile is defined for the stream, this profile is automatically installed.

#### **IMPORTANT**

Always consider the module stream's life cycle.

To install a selected profile of the module stream, use:

# yum module install module-name:stream/profile

By running this command, you enable the stream and install the recommended set of packages for a given stream (version) and profile (purpose) of the module.

#### Additional resources

- Introduction to modules
- Commands for installing RHEL 8 content
- Red Hat Enterprise Linux Application Streams Life Cycle

#### Example 4.1. Installing a non-default stream of an application

The following is an example of how to install an application from a non-default stream (version), namely, the **PostgreSQL** server (the **postgresql-server** package) in version **13**. The default stream provides version **10**.

#### **Procedure**

 List modules that provide the **postgresql-server** package to see which streams are available:

```
$ yum module list postgresql
Name Stream Profiles Summary
postgresql 9.6 client, server [d] PostgreSQL server and client module
postgresql 10 [d] client, server [d] PostgreSQL server and client module
postgresql 12 client, server [d] PostgreSQL server and client module
postgresql 13 client, server [d] PostgreSQL server and client module
postgresql 15 client, server [d] PostgreSQL server and client module
```

Hint: [d]efault, [e]nabled, [x]disabled, [i]nstalled

The output shows that the **postgresql** module is available with streams **9.6**, **10**, **12**, **13**, and **15**. The default stream is **10**.

2. Install the packages provided by the **postgresql** module in stream 13:

```
AppStream
               5.6 M
Installing dependencies:
libicu
                                                                            8.8 M
                x86_64
                            60.3-2.el8_1
                                                             rhel
libpq
                x86 64
                             13.5-1.el8
                                                            rhel-AppStream
                                                                                198 k
postgresql
                   x86 64
                               13.10-1.module+el8.7.0+18279+1ca8cf12
                                                                             rhel-
AppStream
               1.5 M
Installing module profiles:
postgresql/server
Enabling module streams:
postgresql
                            13
Transaction Summary
Install 4 Packages
Total download size: 16 M
Installed size: 61 M
Is this ok [y/N]: y
Installed:
 libicu-60.3-2.el8 1.x86 64
 libpq-13.5-1.el8.x86_64
 postgresql-13.10-1.module+el8.7.0+18279+1ca8cf12.x86_64
 postgresql-server-13.10-1.module+el8.7.0+18279+1ca8cf12.x86_64
Complete!
```

Because the installation profile was not specified, the default profile **server** was used.

3. Verify the installed version of **PostgreSQL**:

```
$ postgres --version postgres (PostgreSQL) 13.10
```

#### 4.4. RUNNING INSTALLED CONTENT

New commands are usually enabled after you install content from RHEL 8 repositories. If the commands originated from RPM packages that were enabled by a module, the experience of using these command should be no different.

#### Procedure

• To run the new commands, enter them directly:

\$ command

Replace command with the name of the command you want to run.

#### **NOTE**

In RHEL 8, GCC Toolset is packaged as a Software Collection. To run a command from a component packaged as a Software Collection, use:

\$ scl enable collection 'command'

Replace collection with the name of the Software Collection.

For more information, see Using GCC Toolset.

## 4.5. COMMANDS FOR INSTALLING RHEL 8 CONTENT

The following are the commonly used commands for installing Red Hat Enterprise Linux 8 content.

Command	Description
yum install package	Install a package.
	If the package is provided by a module stream, <b>yum</b> resolves the required module stream and enables it automatically while installing this package. This also happens recursively for all package dependencies. If more module streams satisfy the requirement, the default ones are used.
yum module enable <i>module-name</i> : stream	Enable a module by using a specific stream.
	Always consider the module stream's life cycle.
yum module install <i>module-name</i> : stream yum install @module-name: stream	Install a module by using a specific stream and default profiles
yum module install <i>module-</i> name: stream/profile	Install a module by using a specific stream and profile.
yum install @module-name:stream/profile	

# 4.6. ADDITIONAL RESOURCES

- Installing software packages with yum
- yum(8) man page

# **CHAPTER 5. REMOVING RHEL 8 CONTENT**

In the following sections, learn how to remove content in Red Hat Enterprise Linux 8:

- Remove a package.
- Remove content installed from a module stream or a profile .
- Examine commands for removing RHEL 8 content.

#### 5.1. REMOVING INSTALLED PACKAGES

To remove a package installed on your system, complete the following steps.

#### **Procedure**

• To remove a specific package, use:

Replace package-name with the name of the package you want to remove.

#### **NOTE**

The **yum** command removes a package together with any other dependent packages.

#### 5.2. REMOVING INSTALLED MODULAR CONTENT

When removing installed modular content, you can remove packages either from a selected profile or from the whole stream.

#### **IMPORTANT**

**YUM** removes all packages with a name corresponding to the packages installed with a profile or a stream, including their dependent packages. Always check the list of packages to be removed before you proceed, especially if you have enabled custom repositories on your system.

#### 5.2.1. Removing all packages from a module stream

When you remove packages installed with a module stream, **yum** removes all packages with a name corresponding to the packages installed by the stream. This includes packages' dependencies, with the exception of packages required by other modules.

#### **Prerequisites**

- The module stream has been enabled and at least some packages from the stream have been installed.
- You understand modular dependency resolution.

#### **Procedure**

1. Remove all packages from a selected stream:

# yum module remove --all module-name:stream

Replace module-name and stream with the module and stream you want to uninstall.

- 2. Check the list of packages under **Removing:** and **Removing unused dependencies:** before you proceed with the removal transaction.
- 3. Optionally, reset or disable the stream.

If you want to remove only packages from a selected profile, follow instructions in Removing packages from an installed profile.

#### Example 5.1. Removing packages from the whole stream

The following is an example of how to remove all packages from the **php:7.3** module stream.

#### **Procedure**

1. Install the **php:7.3** module stream, including all available profiles:

```
# yum module install php:7.3/*
Updating Subscription Management repositories.
Last metadata expiration check: 0:20:19 ago on Tue Mar 3 11:32:05 2020.
Dependencies resolved.

Name : php Stream : 7.3 [e] [a]

Version : 8020020200715124551

Context : ceb1cf90 Architecture : x86\_64

Profiles : common [d], devel, minimal

Default profiles: common

. . .

Hint: [d]efault, [e]nabled, [x]disabled, [i]nstalled, [a]ctive

The **7.3** stream of the **php** module is currently enabled but no packages from this streams are installed.

#### 5.2.2. Removing packages from an installed profile

When you remove packages installed with a profile, **yum** removes all packages with a name corresponding to the packages installed by the profile. This includes package dependencies, with the exception of packages required by a different profile.

#### **Prerequisites**

- The selected profile has been installed by using the yum module install modulename: stream/profile command or as a default profile by using the yum install modulename: stream command.
- You understand modular dependency resolution.

#### **Procedure**

1. Uninstall packages belonging to the selected profile:

# yum module remove module-name:stream/profile

Replace *module-name*, *stream*, and *profile* with the module, stream, and profile you want to uninstall.

Alternatively, uninstall packages from all installed profiles within a stream:

# yum module remove module-name:stream

These operations will not remove packages from the stream that do not belong to any of the profiles.

2. Check the list of packages under **Removing:** and **Removing unused dependencies:** before you proceed with the removal transaction.

To remove all packages from a selected stream, follow instructions in Removing all packages from a module stream.

#### Example 5.2. Removing packages from a selected profile

The following is an example of how to remove packages and their dependencies that belong to the **devel** profile of the **php:7.3** module stream.

#### NOTE

The outputs in this example have been edited for brevity. Actual outputs might contain more information than shown here.

#### **Procedure**

1. Install the **php:7.3** module stream, including all available profiles:

# yum module install php:7.3/\*
Updating Subscription Management repositories.

Last metadata expiration check: 0:08:41 ago on Tue Mar 3 11:32:05 2020.

Dependencies resolved.

# **5.3. COMMANDS FOR REMOVING CONTENT**

The following are the commonly used commands for removing content in Red Hat Enterprise Linux 8.

Command	Description
yum remove <i>package</i>	Remove a package.
yum module remove <i>module-</i> name:stream/profile	Remove packages from an installed profile.
yum module removeall <i>module-</i> name:stream	Remove all packages from an active stream.
yum module reset module-name	Reset a module to the initial state.
yum module disable <i>module-name</i>	Disable a module and all its streams.

# CHAPTER 6. MANAGING VERSIONS OF APPLICATION STREAM CONTENT

Content in the AppStream repository can be available in multiple versions, corresponding to module streams.

In the following sections, learn operations you must perform when changing existing enabled module streams:

- Modular dependencies and stream changes.
- Interaction of modular and non-modular dependencies.
- Resetting modules to their initial state .
- Completely disable a module and all its streams .
- Switch to a later stream of a module.
- Override module default streams.

#### 6.1. MODULAR DEPENDENCIES AND STREAM CHANGES

Traditionally, packages providing content depend on further packages, and usually specify the desired dependency versions. For packages contained in modules, this mechanism applies as well, but the grouping of packages and their particular versions into modules and streams provides further constraints. Additionally, module streams can declare dependencies on streams of other modules, independent of the packages contained and provided by them.

After any operations with packages or modules, the whole dependency tree of all underlying installed packages must satisfy all the conditions the packages declare. Additionally, all module stream dependencies must be satisfied.

#### As a result:

- Enabling a module stream can require enabling streams of further modules.
- Installing a module stream profile or installing packages from a stream can require enabling streams of further modules and installing further packages.
- Disabling a stream of a module can require disabling other module streams. No packages will be removed automatically.
- Removing a package can require removing further packages. If these packages were provided by
  modules, the module streams remain enabled in preparation for further installation, even if there
  are no packages installed from these streams anymore. This mirrors the behavior of an unused
  YUM repository.

#### **IMPORTANT**

You cannot enable a stream of a module when another stream of the same module is already enabled. To switch streams, follow the procedure in Switching to a later stream. Alternatively, reset the module, and then enable the new stream.

Removing all packages installed from a stream before switching to a different stream prevents the system from reaching states where packages could be installed with no repository or stream that provides them.

Technically, resetting module does not automatically change any installed packages. Removing the packages provided by the previous stream and any packages that depend on them is an explicit manual operation.

# 6.2. INTERACTION OF MODULAR AND NON-MODULAR DEPENDENCIES

Modular dependencies are an additional layer on top of regular RPM dependencies. Modular dependencies behave similarly to hypothetical dependencies between repositories. This means that installing different packages requires not only resolution of the RPM dependencies, but also the modular dependencies must be resolved beforehand.

The system always retains the module and stream choices, unless explicitly instructed to change them. A modular package receives updates contained in the currently enabled stream of the module that provides this package, but does not upgrade to a version contained in a different stream.

#### 6.3. RESETTING MODULE STREAMS

Resetting a module is an action that returns all of its streams to their initial state - neither enabled nor disabled. If the module has a default stream, this stream becomes active as a result of resetting the module.

#### Procedure

• Reset the module state:

# yum module reset *module-name* 

Replace module-name with the name of the module that you want to reset.

The module is returned to the initial state. Information about an enabled stream and installed profiles is erased but no installed content is removed.

#### 6.4. DISABLING ALL STREAMS OF A MODULE

Modules that have a default stream always have one stream active. In situations where the content from all the module streams must not be accessible, it is possible to disable the whole module.

#### **Prerequisites**

You understand the concept of an active module stream.

#### **Procedure**

Disable the module:

# yum module disable module-name

Replace module-name with the name of the module that you want to disable.

The **yum** command asks for confirmation and then disables the module with all its streams. All of the module streams become inactive. No installed content is removed.

#### 6.5. SWITCHING TO A LATER STREAM

When you switch to a later module stream, all packages from the module are replaced with their later versions.

#### **IMPORTANT**

This procedure is feasible only under the conditions described in the Prerequisites section.

#### **Prerequisites**

- The system is fully updated.
- No packages installed on the system are newer than the packages available in the repository.

#### **Procedure**

1. Determine if your system is prepared for switching to a later stream:

# yum distro-sync

This command must finish with the message *Nothing to do. Complete!* If it instead proposes changes and asks for confirmation, carefully review these changes and consider whether you want to proceed. Run the **yum distro-sync** command repeatedly if necessary. Alternatively, you can refuse the suggested changes and manually modify your system to a state where the command returns *Nothing to do. Complete!* 

#### **NOTE**

By checking the **yum distro-sync** result before switching the streams, you prevent making changes to the system that are unrelated to the stream switching because the same command is required as the last step of this procedure.

2. Change the active stream to the later one:

# yum module reset *module-name*# yum module enable *module-name:new-stream* 

3. Synchronize installed packages to perform the change between streams:

# yum distro-sync

If this action suggests changes to content outside the streams, review them carefully.

#### NOTE

- If certain installed packages depend on the earlier stream, and there is no compatible version in the later stream, yum reports a dependency conflict. In this case, use the --allowerasing option to remove such packages because they cannot be installed together with the later stream due to missing dependencies.
- When switching Perl modules, you must always use the --allowerasing option because certain packages in the base RHEL 8 installation depend on Perl 5.26.
- Binary extensions (typically written in C or C++) for interpreted languages need to be reinstalled after the new stream is enabled; for example, certain packages installed by the gem command from the ruby module, the npm command from the nodejs module, the cpan command from the perl module, or the pecl command from the php module. For more information, see How to switch Ruby streams in RHEL 8.

Alternatively, remove all the module's content installed from the current stream, reset the module, and install the new stream.

#### 6.6. OVERRIDING MODULE DEFAULT STREAMS

By default, the **YUM** utility uses the module default streams defined in the repository that contains the modules. You can override the default stream in the /etc/dnf/modules.defaults.d/ directory.

#### **IMPORTANT**

Always consider the module stream's life cycle.

#### **Prerequisites**

• You understand the concept of an active module stream.

#### Procedure

1. Create a YAML configuration file in the /etc/dnf/modules.defaults.d/ drop-in directory.

```
document: modulemd-defaults
version: 1
data:
  module: postgresql
  stream: "10"
  profiles:
    10: [server]
    12: [server]
    13: [server]
    9.6: [server]
```

The preceding output represents the default definition present for the **postgresql** module at the time of this writing.

#### Example 6.1. Example postgresql module with original defaults

The following is an example of how to configure the stream **13** of the **postgresql** module as the default stream.

1. Examine the **postgresql** module:

```
# yum module list postgresql
(...)
Red Hat Enterprise Linux 8 for x86_64 - AppStream (RPMs)
                         Profiles
                                          Summary
Name
             Stream
                        client, server [d]
                                           PostgreSQL server and client module
              9.6
postgresql
postgresql
              10 [d]
                        client, server [d]
                                            PostgreSQL server and client module
                        client, server [d]
postgresql
              12
                                           PostgreSQL server and client module
              13
                        client, server [d]
                                           PostgreSQL server and client module
postgresql
              15
                        client, server [d]
                                           PostgreSQL server and client module
postgresql
Hint: [d]efault, [e]nabled, [x]disabled, [i]nstalled
```

2. To set the default stream to **13**, implement the following YAML file configuration in the /etc/dnf/modules.defaults.d/postgresql.yaml file.

```
document: modulemd-defaults
version: 1
data:
module: postgresql
stream: "13"
profiles:
10: [server]
12: [server]
13: [server]
15: [server]
9.6: [server]
```

3. Examine the **postgresql** module again:

#### # yum module list postgresql Red Hat Enterprise Linux 8 for x86\_64 - AppStream (RPMs) Name Stream **Profiles** Summary postgresql 9.6 client, server [d] PostgreSQL server and client module 10 client, server [d] PostgreSQL server and client module postgresql postgresql 12 client, server [d] PostgreSQL server and client module 13 [d] client, server [d] PostgreSQL server and client module postgresql postgresql 15 client, server [d] PostgreSQL server and client module Hint: [d]efault, [e]nabled, [x]disabled, [i]nstalled
