## MAKING OPEN SOURCE MORE INCLUSIVE

Red Hat is committed to replacing problematic language in our code, documentation, and web properties. We are beginning with these four terms: master, slave, blacklist, and whitelist. Because of the enormity of this endeavor, these changes will be implemented gradually over several upcoming releases. For more details, see [our CTO Chris Wright's message](#).

# CHAPTER 1. REPORTING IN RED HAT ANSIBLE INSIDE

To comply with your Red Hat Ansible Inside subscription requirements, you must send metrics files about your automation usage to Red Hat. This guide describes the data that is collected, how to implement its collection, and how the data is returned to Red Hat.

## 1.1. ABOUT REPORTING METRICS

Ansible Inside saves high-level usage data about your automation jobs. Red Hat uses this data to identify where to focus effort in product improvements and new features.

After an automation job is completed, metrics are gathered to save the following information about the job:

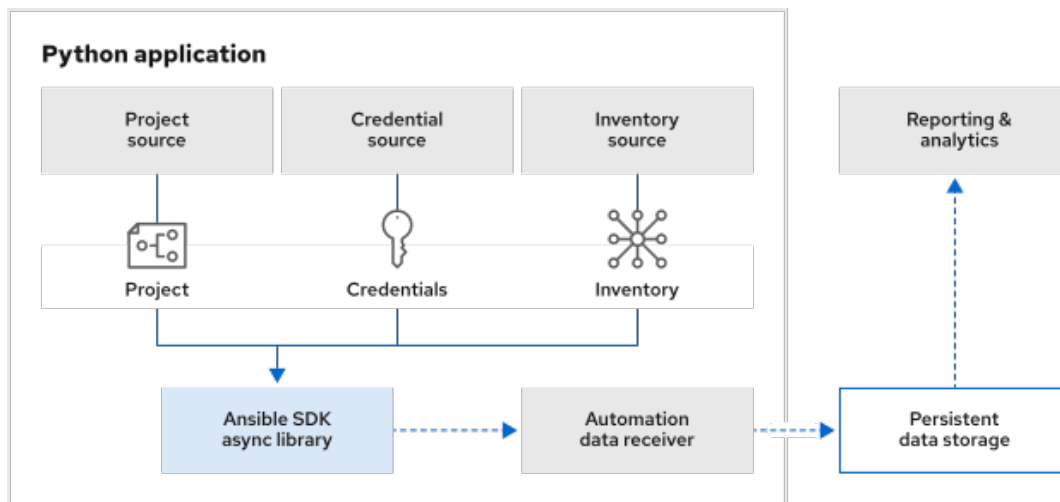

- The type, duration, and time of the automation job.
- The names of the collections and roles used in the job, and the number of times they are used.
- The number of nodes that were installed, updated, failed, and skipped.
- The events that occurred during the job.

### NOTE

Red Hat does not gather Personal Identifiable Information (PII), such as IP addresses, location, user details, or operating system specification.

The following architecture diagram illustrates how the data is saved to the persistent data storage outside the Python application so that it can be sent to Red Hat.

385\_0022

## 1.2. ABOUT THE METRICS FILES

The metrics data is bundled into a tarball file. A separate file is generated for each job. You can view the contents of the files: they are not encrypted.

Each tarball file contains the following unencrypted CSV files:

- **jobs.csv** records the duration and status of the automation job, the number of tasks executed, and the number of hosts that were affected by the job.
- **modules.csv** records the module name, the task count and the duration.
- **collections.csv**: records the collection name, the task count and the duration.
- **roles.csv** records the role name, the task count and the duration.
- **playbook\_on\_stats.csv** records the event ID and data.

## CHAPTER 2. METRICS FILE LOCATIONS

Reporting metrics to Red Hat is a requirement. Logging metrics for your automation jobs is automatically enabled when you install Ansible SDK. You cannot disable it.

Every time an automation job runs, a new tarball is created. You are responsible for scraping the data from the storage location and for monitoring the size of the directory.

You can customize the metrics storage location for each Python file that runs a playbook, or you can use the default location.

### 2.1. DEFAULT LOCATION FOR METRICS FILES

When you install Ansible SDK, the default metrics storage location is set to the `~/.ansible/metrics` directory.

After an automation job is complete, the metrics are written to a tarball in the directory. Ansible SDK creates the directory if it does not already exist.

### 2.2. CUSTOMIZING THE METRICS STORAGE LOCATION

You can specify the path to the directory to store your metrics files in the Python file that runs your playbook.

You can set a different directory path for every Python automation job file, or you can store the tarballs for multiple jobs in one directory. If you do not set the path in a Python file, the tarballs for the jobs that it runs will be saved in the default directory (`~/.ansible/metrics`).

#### Procedure

1. Decide on a location on your file system to store the metrics data. Ensure that the location is readable and writable. Ansible SDK creates the directory if it does not already exist.
2. In the `job_options` in the `main()` function of your Python file, set the `metrics_output_path` parameter to the directory where the tarballs are to be stored.

In the following example, the metrics files are stored in the `/tmp/metrics` directory after the `pb.yml` playbook has been executed:

```
async def main():
    executor = AnsibleSubprocessJobExecutor()
    executor_options = AnsibleSubprocessJobOptions()
    job_options = {
        'playbook': 'pb.yml',
        # Change the default job-related data path
        'metrics_output_path': '/tmp/metrics',
    }
```

### 2.3. VIEWING METRICS FILES

After an automation job has completed, navigate to the directory that you specified for storing the data and list the files.

The data for the newly-completed job is contained in a tarball file whose name begins with the date and time that the automation job was run. For example, the following file records data for an automation job executed on 8 March 2023 at 2.30AM.

```
$ ls
```

```
2023_03_08_02_30_24__aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaaa_job_data.tar.gz
```

To view the files in the tarball, run **tar xvf**.

```
$ tar xvf 2023_03_08_02_30_24__aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaaa_job_data.tar.gz
```

```
x jobs.csv
x modules.csv
x collections.csv
x roles.csv
x playbook_on_stats.csv
```

The following example shows the **jobs.csv** file.

```
$ cat jobs.csv
```

```
job_id,job_type,started,finished,job_state,hosts_ok,hosts_changed,hosts_skipped,hosts_failed,hosts_unreachable,task_count,task_duration
84896567-a586-4215-a914-7503010ef281,local,2023-03-08 02:30:22.440045,2023-03-08 02:30:24.316458,,5,0,0,0,2,0:00:01.876413
```

When a parameter value is not available, the corresponding entry in the CSV file is empty. In the **jobs.csv** file above, the **job\_state** value is not available.

## CHAPTER 3. REPORTING DATA TO RED HAT

Your subscription contract requires you to send your **.tar** files to Red Hat for accounting purposes. Your Red Hat partner representative will instruct you on how to send the files to Red Hat.
