# CHAPTER 1. INTRODUCTION TO SERVICE TELEMETRY FRAMEWORK 1.3

Service Telemetry Framework (STF) collects monitoring data from Red Hat OpenStack Platform (RHOSP) or third-party nodes. You can use STF to perform the following tasks:

- Store or archive the monitoring data for historical information.
- View the monitoring data graphically on the dashboard.
- Use the monitoring data to trigger alerts or warnings.

The monitoring data can be either metric or event:

## Metric

A numeric measurement of an application or system.

## Event

Irregular and discrete occurrences that happen in a system.

The components of STF use a message bus for data transport. Other modular components that receive and store data are deployed as containers on Red Hat OpenShift Container Platform.

## IMPORTANT

Service Telemetry Framework (STF) is compatible with Red Hat OpenShift Container Platform versions 4.6 through 4.8.

## Additional resources

- For more information about how to deploy Red Hat OpenShift Container Platform, see the [Red Hat OpenShift Container Platform product documentation](#).
- You can install Red Hat OpenShift Container Platform on cloud platforms or on bare metal. For more information about STF performance and scaling, see <https://access.redhat.com/articles/4907241>.
- You can install Red Hat OpenShift Container Platform on bare metal or other supported cloud platforms. For more information about installing Red Hat OpenShift Container Platform, see [OpenShift Container Platform 4.8 Documentation](#).

## 1.1. SUPPORT FOR SERVICE TELEMETRY FRAMEWORK

Red Hat supports the two most recent versions of Service Telemetry Framework (STF). Earlier versions are not supported. For more information, see the [Service Telemetry Framework Supported Version Matrix](#).

## 1.2. SERVICE TELEMETRY FRAMEWORK ARCHITECTURE

Service Telemetry Framework (STF) uses a client-server architecture, in which Red Hat OpenStack Platform (RHOSP) is the client and Red Hat OpenShift Container Platform is the server.

STF consists of the following components:

- Data collection
  - collectd: Collects infrastructure metrics and events.
  - Ceilometer: Collects RHOSP metrics and events.
- Transport
  - AMQ Interconnect: An AMQP 1.x compatible messaging bus that provides fast and reliable data transport to transfer the metrics to STF for storage.
  - Smart Gateway: A Golang application that takes metrics and events from the AMQP 1.x bus to deliver to ElasticSearch or Prometheus.
- Data storage
  - Prometheus: Time-series data storage that stores STF metrics received from the Smart Gateway.
  - ElasticSearch: Events data storage that stores STF events received from the Smart Gateway.
- Observation
  - Alertmanager: An alerting tool that uses Prometheus alert rules to manage alerts.
  - Grafana: A visualization and analytics application that you can use to query, visualize, and explore data.

The following table describes the application of the client and server components:

**Table 1.1. Client and server components of STF**

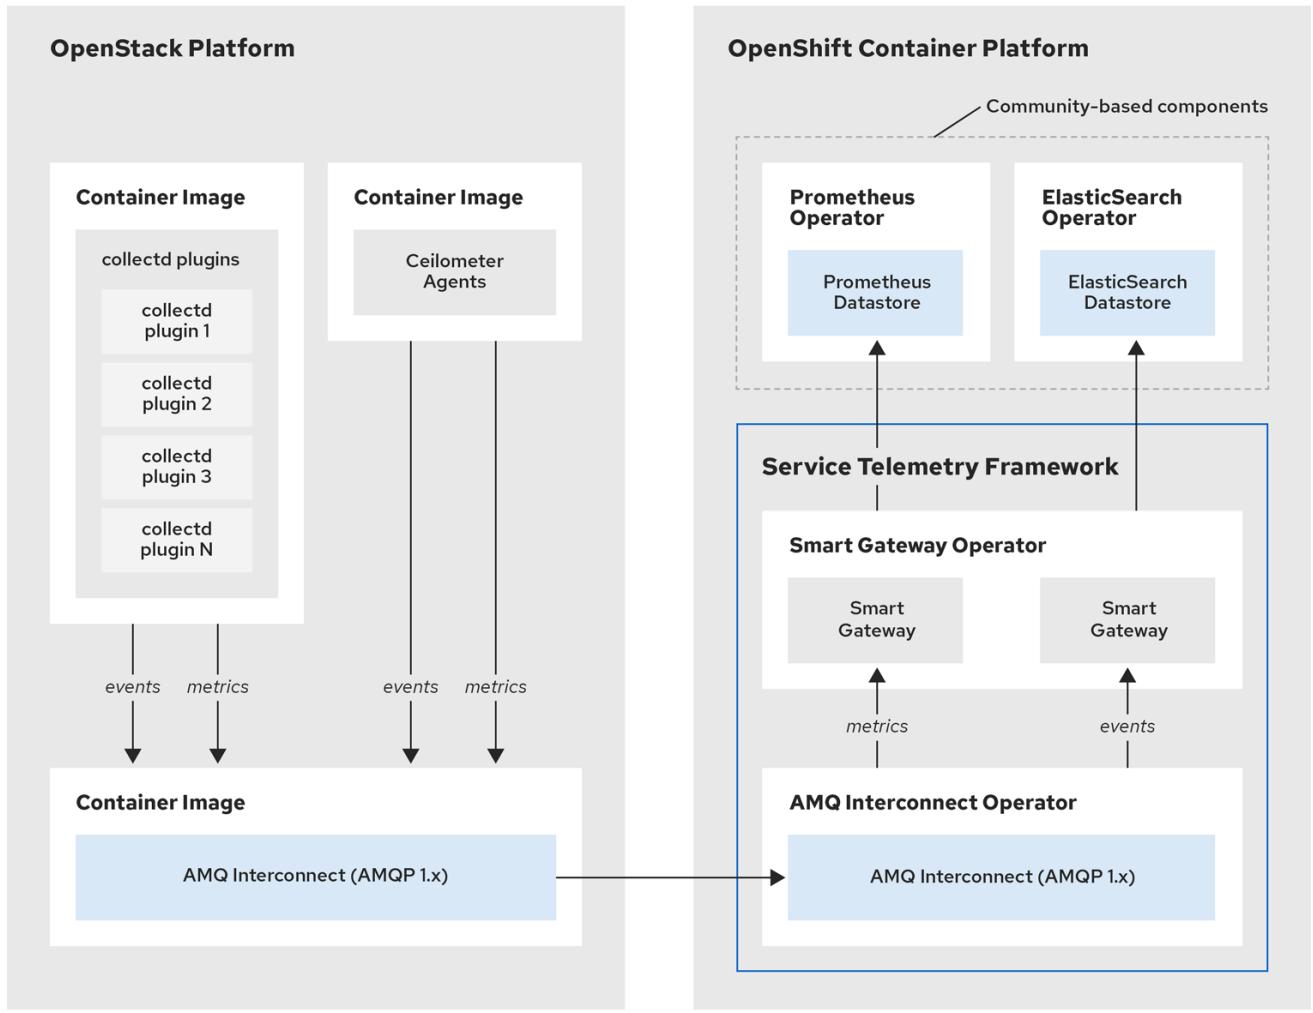

Component	Client	Server
An AMQP 1.x compatible messaging bus	yes	yes
Smart Gateway	no	yes
Prometheus	no	yes
ElasticSearch	no	yes
collectd	yes	no
Ceilometer	yes	no

### IMPORTANT

To ensure that the monitoring platform can report operational problems with your cloud, do not install STF on the same infrastructure that you are monitoring.

Figure 1.1. Service Telemetry Framework architecture overview

65\_OpenStack\_0620

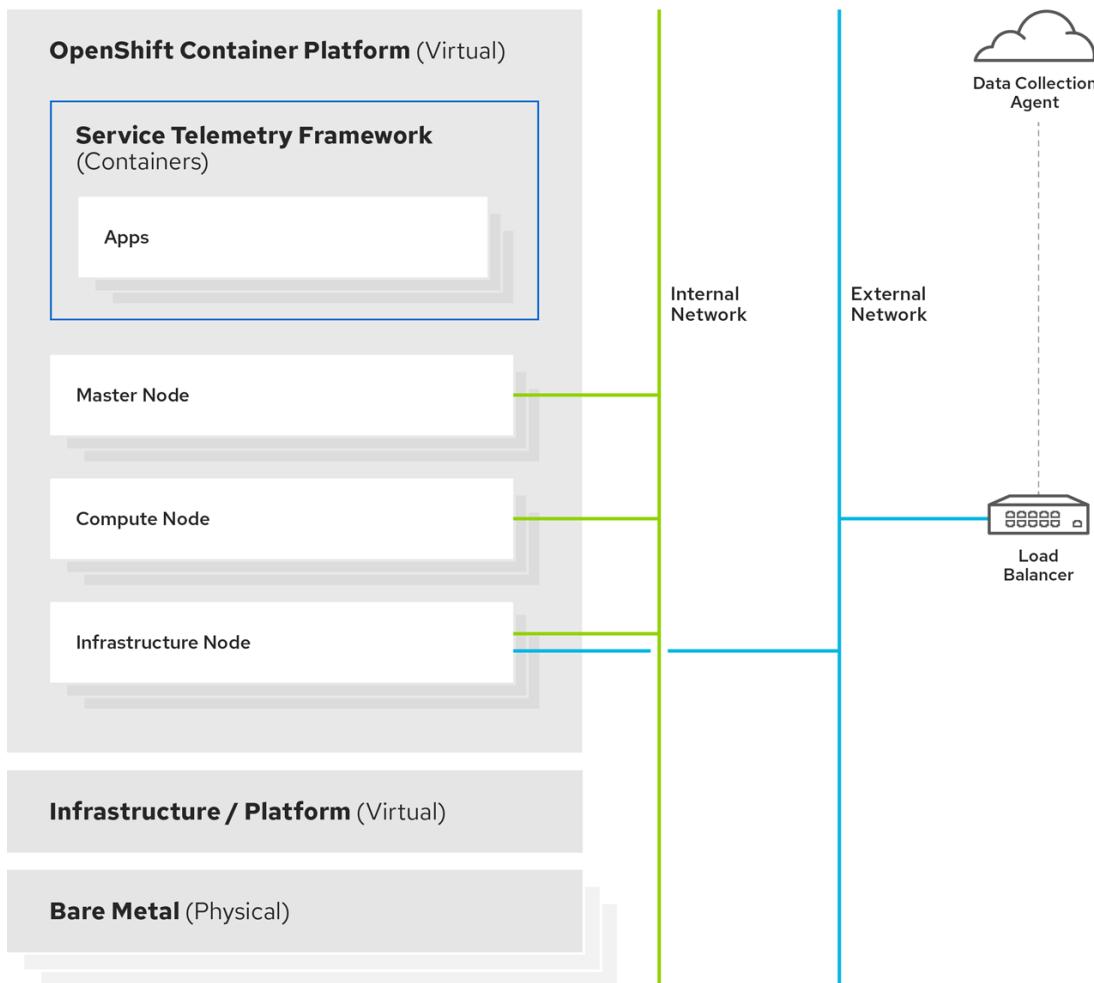

On the client side, collectd provides infrastructure metrics without project data, and Ceilometer provides Red Hat OpenStack Platform (RHOSP) platform data based on projects or user workload. Both Ceilometer and collectd deliver data to Prometheus by using the AMQ Interconnect transport, delivering the data through the message bus. On the server side, a Golang application called the Smart Gateway takes the data stream from the bus and exposes it as a local scrape endpoint for Prometheus.

If you plan to collect and store events, collectd and Ceilometer deliver event data to the server side by using the AMQ Interconnect transport. Another Smart Gateway writes the data to the ElasticSearch datastore.

Server-side STF monitoring infrastructure consists of the following layers:

- Service Telemetry Framework 1.3
- Red Hat OpenShift Container Platform 4.6 through 4.8
- Infrastructure platform

Figure 1.2. Server-side STF monitoring infrastructure

65\_OpenStack\_0120

## 1.3. INSTALLATION SIZE OF RED HAT OPENSHIFT CONTAINER PLATFORM

The size of your Red Hat OpenShift Container Platform installation depends on the following factors:

- The infrastructure that you select.
- The number of nodes that you want to monitor.
- The number of metrics that you want to collect.
- The resolution of metrics.
- The length of time that you want to store the data.

Installation of Service Telemetry Framework (STF) depends on an existing Red Hat OpenShift Container Platform environment.

For more information about minimum resources requirements when you install Red Hat OpenShift Container Platform on baremetal, see [Minimum resource requirements](#) in the *Installing a cluster on bare metal* guide. For installation requirements of the various public and private cloud platforms that you can install, see the corresponding installation documentation for your cloud platform of choice.

# CHAPTER 2. PREPARING YOUR RED HAT OPENSHIFT CONTAINER PLATFORM ENVIRONMENT FOR SERVICE TELEMETRY FRAMEWORK

To prepare your Red Hat OpenShift Container Platform environment for Service Telemetry Framework (STF), you must plan for persistent storage, adequate resources, and event storage:

- Ensure that persistent storage is available in your Red Hat OpenShift Container Platform cluster for a production grade deployment. For more information, see [Section 2.1, "Persistent volumes"](#).
- Ensure that enough resources are available to run the Operators and the application containers. For more information, see [Section 2.2, "Resource allocation"](#).

## 2.1. PERSISTENT VOLUMES

Service Telemetry Framework (STF) uses persistent storage in Red Hat OpenShift Container Platform to request persistent volumes so that Prometheus and ElasticSearch can store metrics and events.

When you enable persistent storage through the Service Telemetry Operator, the Persistent Volume Claims (PVC) requested in an STF deployment results in an access mode of RWO (ReadWriteOnce). If your environment contains pre-provisioned persistent volumes, ensure that volumes of RWO are available in the Red Hat OpenShift Container Platform default configured **storageClass**.

### Additional resources

- For more information about configuring persistent storage for Red Hat OpenShift Container Platform, see [Understanding persistent storage](#).
- For more information about recommended configurable storage technology in Red Hat OpenShift Container Platform, see [Recommended configurable storage technology](#).
- For more information about configuring persistent storage for Prometheus in STF, see [the section called "Configuring persistent storage for Prometheus"](#).
- For more information about configuring persistent storage for ElasticSearch in STF, see [the section called "Configuring persistent storage for ElasticSearch"](#).

### 2.1.1. Ephemeral storage

You can use ephemeral storage to run Service Telemetry Framework (STF) without persistently storing data in your Red Hat OpenShift Container Platform cluster.

#### WARNING

If you use ephemeral storage, you might experience data loss if a pod is restarted, updated, or rescheduled onto another node. Use ephemeral storage only for development or testing, and not production environments.

## 2.2. RESOURCE ALLOCATION

To enable the scheduling of pods within the Red Hat OpenShift Container Platform infrastructure, you need resources for the components that are running. If you do not allocate enough resources, pods remain in a **Pending** state because they cannot be scheduled.

The amount of resources that you require to run Service Telemetry Framework (STF) depends on your environment and the number of nodes and clouds that you want to monitor.

### Additional resources

- For recommendations about sizing for metrics collection, see [Service Telemetry Framework Performance and Scaling](#).
- For information about sizing requirements for ElasticSearch, see <https://www.elastic.co/guide/en/cloud-on-k8s/current/k8s-managing-compute-resources.html>.

# CHAPTER 3. INSTALLING THE CORE COMPONENTS OF SERVICE TELEMETRY FRAMEWORK

You can use Operators to load the Service Telemetry Framework (STF) components and objects. Operators manage each of the following STF core and community components:

- AMQ Interconnect
- Smart Gateway
- Prometheus and AlertManager
- ElasticSearch
- Grafana

## Prerequisites

- An Red Hat OpenShift Container Platform version inclusive of 4.6 through 4.8 is running.
- You have prepared your Red Hat OpenShift Container Platform environment and ensured that there is persistent storage and enough resources to run the STF components on top of the Red Hat OpenShift Container Platform environment. For more information, see [Service Telemetry Framework Performance and Scaling](#).

### IMPORTANT

STF is compatible with Red Hat OpenShift Container Platform version 4.6 through 4.8.

## Additional resources

- For more information about Operators, see the [Understanding Operators](#) guide.

## 3.1. DEPLOYING SERVICE TELEMETRY FRAMEWORK TO THE RED HAT OPENSHIFT CONTAINER PLATFORM ENVIRONMENT

Deploy Service Telemetry Framework (STF) to collect, store, and monitor events:

### Procedure

1. Create a namespace to contain the STF components, for example, **service-telemetry**:

```
$ oc new-project service-telemetry
```

2. Create an OperatorGroup in the namespace so that you can schedule the Operator pods:

```
$ oc create -f - <<EOF
apiVersion: operators.coreos.com/v1
kind: OperatorGroup
metadata:
  name: service-telemetry-operator-group
  namespace: service-telemetry
spec:
```

```
targetNamespaces:
- service-telemetry
EOF
```

For more information, see [OperatorGroups](#).

3. Enable the OperatorHub.io Community Catalog Source to install data storage and visualization Operators:

#### NOTE

Red Hat supports the core Operators and workloads, including AMQ Interconnect, AMQ Certificate Manager, Service Telemetry Operator, and Smart Gateway Operator.

```
$ oc create -f - <<EOF
apiVersion: operators.coreos.com/v1alpha1
kind: CatalogSource
metadata:
  name: operatorhubio-operators
  namespace: openshift-marketplace
spec:
  sourceType: grpc
  image: quay.io/operatorhubio/catalog:latest
  displayName: OperatorHub.io Operators
  publisher: OperatorHub.io
EOF
```

4. Subscribe to the AMQ Certificate Manager Operator by using the redhat-operators CatalogSource:

#### NOTE

The AMQ Certificate Manager deploys to the **openshift-operators** namespace and is then available to all namespaces across the cluster. As a result, on clusters with a large number of namespaces, it can take several minutes for the Operator to be available in the **service-telemetry** namespace. The AMQ Certificate Manager Operator is not compatible with the dependency management of Operator Lifecycle Manager when you use it with other namespace-scoped operators.

```
$ oc create -f - <<EOF
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: amq7-cert-manager-operator
  namespace: openshift-operators
spec:
  channel: 1.x
  installPlanApproval: Automatic
  name: amq7-cert-manager-operator
  source: redhat-operators
  sourceNamespace: openshift-marketplace
EOF
```

- 
- Validate your ClusterServiceVersion. Ensure that amq7-cert-manager.v1.0.1 displays a phase of **Succeeded**:

```
$ oc get --namespace openshift-operators csv

NAME          DISPLAY          VERSION  REPLACES  PHASE
amq7-cert-manager.v1.0.1  Red Hat Integration - AMQ Certificate Manager  1.0.1
Succeeded
```

- If you plan to store events in ElasticSearch, you must enable the Elastic Cloud on Kubernetes (ECK) Operator. To enable the ECK Operator, create the following manifest in your Red Hat OpenShift Container Platform environment:

```
$ oc create -f - <<EOF
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: elasticsearch-eck-operator-certified
  namespace: service-telemetry
spec:
  channel: stable
  installPlanApproval: Automatic
  name: elasticsearch-eck-operator-certified
  source: certified-operators
  sourceNamespace: openshift-marketplace
EOF
```

- Verify that the ClusterServiceVersion for Elastic Cloud on Kubernetes **Succeeded**:

```
$ oc get csv

NAME          DISPLAY          VERSION  REPLACES
PHASE

...
elasticsearch-eck-operator-certified.v1.7.1  Elasticsearch (ECK) Operator  1.7.1
elasticsearch-eck-operator-certified.v1.6.0  Succeeded
...
```

- Create the Service Telemetry Operator subscription to manage the STF instances:

```
$ oc create -f - <<EOF
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: service-telemetry-operator
  namespace: service-telemetry
spec:
  channel: stable-1.3
  installPlanApproval: Automatic
  name: service-telemetry-operator
  source: redhat-operators
  sourceNamespace: openshift-marketplace
EOF
```

- Validate the Service Telemetry Operator and the dependent operators:

```
$ oc get csv --namespace service-telemetry

amq7-cert-manager.v1.0.1           Red Hat Integration - AMQ Certificate Manager
1.0.1                               Succeeded
amq7-interconnect-operator.v1.10.1   Red Hat Integration - AMQ Interconnect
1.10.1    amq7-interconnect-operator.v1.2.4   Succeeded
elasticsearch-eck-operator-certified.v1.8.0 Elasticsearch (ECK) Operator      1.8.0
elasticsearch-eck-operator-certified.v1.7.1 Succeeded
prometheusoperator.0.47.0          Prometheus Operator                0.47.0
prometheusoperator.0.37.0          Succeeded
service-telemetry-operator.v1.3.1632925572 Service Telemetry Operator
1.3.1632925572                   Succeeded
smart-gateway-operator.v3.0.1632925565 Smart Gateway Operator
3.0.1632925565                   Succeeded
```

## 3.2. CREATING A SERVICE TELEMETRY OBJECT IN RED HAT OPENSHIFT CONTAINER PLATFORM

Create a **ServiceTelemetry** object in Red Hat OpenShift Container Platform to result in the Service Telemetry Operator creating the supporting components for a Service Telemetry Framework (STF) deployment. For more information, see [Section 3.2.1, “Primary parameters of the ServiceTelemetry object”](#).

### Procedure

- To create a **ServiceTelemetry** object that results in an STF deployment that uses the default values, create a **ServiceTelemetry** object with an empty **spec** parameter:

```
$ oc apply -f - <<EOF
apiVersion: infra.watch/v1beta1
kind: ServiceTelemetry
metadata:
  name: default
  namespace: service-telemetry
spec: {}
EOF
```

To override a default value, define the parameter that you want to override. In this example, enable ElasticSearch by setting **enabled** to **true**:

```
$ oc apply -f - <<EOF
apiVersion: infra.watch/v1beta1
kind: ServiceTelemetry
metadata:
  name: default
  namespace: service-telemetry
spec:
  backends:
    events:
      elasticsearch:
        enabled: true
EOF
```

Creating a **ServiceTelemetry** object with an empty **spec** parameter results in an STF deployment with the following default settings:

```
apiVersion: infra.watch/v1beta1
kind: ServiceTelemetry
metadata:
  name: default
spec:
  alerting:
    alertmanager:
      storage:
        persistent:
          pvcStorageRequest: 20G
          storageSelector: {}
    receivers:
      snmpTraps:
        enabled: false
        target: 192.168.24.254
      strategy: persistent
  enabled: true
  backends:
    events:
      elasticsearch:
        enabled: false
        storage:
          persistent:
            pvcStorageRequest: 20Gi
            storageSelector: {}
        strategy: persistent
    metrics:
      prometheus:
        enabled: true
        scrapeInterval: 10s
        storage:
          persistent:
            pvcStorageRequest: 20G
            storageSelector: {}
        retention: 24h
        strategy: persistent
  graphing:
    enabled: false
  grafana:
    adminPassword: secret
    adminUser: root
    disableSignoutMenu: false
    ingressEnabled: false
    baseImage: docker.io/grafana/grafana:8.1.2
  highAvailability:
    enabled: false
  transports:
    qdr:
      enabled: true
    web:
      enabled: false
  clouds:
    - name: cloud1
```

```

metrics:
  collectors:
    - collectorType: collectd
      subscriptionAddress: collectd/telemetry
      debugEnabled: false
    - collectorType: ceilometer
      subscriptionAddress: anycast/ceilometer/metering.sample
      debugEnabled: false
    - collectorType: sensubility
      subscriptionAddress: sensubility/telemetry
      debugEnabled: false
  events:
    collectors:
      - collectorType: collectd
        subscriptionAddress: collectd/notify
        debugEnabled: false
      - collectorType: ceilometer
        subscriptionAddress: anycast/ceilometer/event.sample
        debugEnabled: false

```

To override these defaults, add the configuration to the **spec** parameter.

2. View the STF deployment logs in the Service Telemetry Operator:

```

$ oc logs --selector name=service-telemetry-operator

...
----- Ansible Task Status Event StdOut -----
PLAY RECAP ****
localhost : ok=57  changed=0  unreachable=0  failed=0  skipped=20
rescued=0  ignored=0

```

## Verification

- To determine that all workloads are operating correctly, view the pods and the status of each pod.

### NOTE

If you set the **backends.events.elasticsearch.enabled** parameter to **true**, the notification Smart Gateways report **Error** and **CrashLoopBackOff** error messages for a period of time before ElasticSearch starts.

```
$ oc get pods
```

NAME	READY	STATUS	RESTARTS	AGE

### 3.2.1. Primary parameters of the ServiceTelemetry object

The **ServiceTelemetry** object comprises the following primary configuration parameters:

- **alerting**
- **backends**
- **clouds**
- **graphing**
- **highAvailability**
- **transports**

You can configure each of these configuration parameters to provide different features in an STF deployment.

#### IMPORTANT

Support for **servicetelemetry.infra.watch/v1alpha1** was removed from STF 1.3.

#### The backends parameter

Use the **backends** parameter to control which storage back ends are available for storage of metrics and events, and to control the enablement of Smart Gateways that the **clouds** parameter defines. For more information, see [the section called “The clouds parameter”](#).

Currently, you can use Prometheus as the metrics storage back end and ElasticSearch as the events storage back end.

#### Enabling Prometheus as a storage back end for metrics

To enable Prometheus as a storage back end for metrics, you must configure the **ServiceTelemetry** object.

#### Procedure

- Configure the **ServiceTelemetry** object:

```
apiVersion: infra.watch/v1beta1
kind: ServiceTelemetry
metadata:
  name: default
  namespace: service-telemetry
spec:
  backends:
    metrics:
      prometheus:
        enabled: true
```

## Configuring persistent storage for Prometheus

Use the additional parameters that are defined in `backends.metrics.prometheus.storage.persistent` to configure persistent storage options for Prometheus, such as storage class and volume size.

Use **storageClass** to define the back end storage class. If you do not set this parameter, the Service Telemetry Operator uses the default storage class for the Red Hat OpenShift Container Platform cluster.

Use the **pvcStorageRequest** parameter to define the minimum required volume size to satisfy the storage request. If volumes are statically defined, it is possible that a volume size larger than requested is used. By default, Service Telemetry Operator requests a volume size of **20G** (20 Gigabytes).

### Procedure

- List the available storage classes:

```
$ oc get storageclasses
NAME      PROVISIONER      RECLAIMPOLICY VOLUMEBINDINGMODE
ALLOWVOLUMEEXPANSION AGE
csi-manila-ceph   manila.csi.openstack.org Delete   Immediate   false
20h
standard (default) kubernetes.io/cinder   Delete   WaitForFirstConsumer true
20h
standard-csi      cinder.csi.openstack.org Delete   WaitForFirstConsumer true
20h
```

- Configure the **ServiceTelemetry** object:

```
apiVersion: infra.watch/v1beta1
kind: ServiceTelemetry
metadata:
  name: default
  namespace: service-telemetry
spec:
  backends:
    metrics:
      prometheus:
        enabled: true
      storage:
        strategy: persistent
        persistent:
          storageClass: standard-csi
          pvcStorageRequest: 50G
```

## Enabling ElasticSearch as a storage back end for events

To enable ElasticSearch as a storage back end for events, you must configure the **ServiceTelemetry** object.

### Procedure

- Configure the **ServiceTelemetry** object:

```
apiVersion: infra.watch/v1beta1
kind: ServiceTelemetry
metadata:
```

```

name: default
namespace: service-telemetry
spec:
backends:
events:
elasticsearch:
enabled: true

```

### Configuring persistent storage for ElasticSearch

Use the additional parameters defined in **backends.events.elasticsearch.storage.persistent** to configure persistent storage options for ElasticSearch, such as storage class and volume size.

Use **storageClass** to define the back end storage class. If you do not set this parameter, the Service Telemetry Operator uses the default storage class for the Red Hat OpenShift Container Platform cluster.

Use the **pvcStorageRequest** parameter to define the minimum required volume size to satisfy the storage request. If volumes are statically defined, it is possible that a volume size larger than requested is used. By default, Service Telemetry Operator requests a volume size of **20Gi** (20 Gibabytes).

### Procedure

- List the available storage classes:

```

$ oc get storageclasses
NAME      PROVISIONER      RECLAIMPOLICY VOLUMEBINDINGMODE
ALLOWVOLUMEEXPANSION AGE
csi-manila-ceph   manila.csi.openstack.org Delete    Immediate    false
20h
standard (default) kubernetes.io/cinder   Delete    WaitForFirstConsumer true
20h
standard-csi      cinder.csi.openstack.org Delete    WaitForFirstConsumer true
20h

```

- Configure the **ServiceTelemetry** object:

```

apiVersion: infra.watch/v1beta1
kind: ServiceTelemetry
metadata:
  name: default
  namespace: service-telemetry
spec:
backends:
events:
elasticsearch:
enabled: true
storage:
strategy: persistent
persistent:
  storageClass: standard-csi
  pvcStorageRequest: 50G

```

### The **clouds** parameter

Use the **clouds** parameter to define which Smart Gateway objects deploy, thereby providing the interface for multiple monitored cloud environments to connect to an instance of STF. If a supporting

back end is available, then metrics and events Smart Gateways for the default cloud configuration are created. By default, the Service Telemetry Operator creates Smart Gateways for **cloud1**.

You can create a list of cloud objects to control which Smart Gateways are created for the defined clouds. Each cloud consists of data types and collectors. Data types are **metrics** or **events**. Each data type consists of a list of collectors, the message bus subscription address, and a parameter to enable debugging. Available collectors for metrics are **collectd**, **ceilometer**, and **sensibility**. Available collectors for events are **collectd** and **ceilometer**. Ensure that the subscription address for each of these collectors is unique for every cloud, data type, and collector combination.

The default **cloud1** configuration is represented by the following **ServiceTelemetry** object, which provides subscriptions and data storage of metrics and events for collectd, Ceilometer, and Sensibility data collectors for a particular cloud instance:

```
apiVersion: infra.watch/v1beta1
kind: ServiceTelemetry
metadata:
  name: stf-default
  namespace: service-telemetry
spec:
  clouds:
    - name: cloud1
      metrics:
        collectors:
          - collectorType: collectd
            subscriptionAddress: collectd/telemetry
          - collectorType: ceilometer
            subscriptionAddress: anycast/ceilometer/metering.sample
          - collectorType: sensibility
            subscriptionAddress: sensibility/telemetry
            debugEnabled: false
      events:
        collectors:
          - collectorType: collectd
            subscriptionAddress: collectd/notify
          - collectorType: ceilometer
            subscriptionAddress: anycast/ceilometer/event.sample
```

Each item of the **clouds** parameter represents a cloud instance. A cloud instance consists of three top-level parameters: **name**, **metrics**, and **events**. The **metrics** and **events** parameters represent the corresponding back end for storage of that data type. The **collectors** parameter specifies a list of objects made up of two required parameters, **collectorType** and **subscriptionAddress**, and these represent an instance of the Smart Gateway. The **collectorType** parameter specifies data collected by either collectd, Ceilometer, or Sensibility. The **subscriptionAddress** parameter provides the AMQ Interconnect address to which a Smart Gateway subscribes.

You can use the optional Boolean parameter **debugEnabled** within the **collectors** parameter to enable additional console debugging in the running Smart Gateway pod.

## Additional resources

- For more information about deleting default Smart Gateways, see [Section 4.4.3, "Deleting the default Smart Gateways"](#).
- For more information about how to configure multiple clouds, see [Section 4.4, "Configuring multiple clouds"](#).

### The alerting parameter

Use the **alerting** parameter to control creation of an Alertmanager instance and the configuration of the storage back end. By default, **alerting** is enabled. For more information, see [Section 5.3, "Alerts in Service Telemetry Framework"](#).

### The graphing parameter

Use the **graphing** parameter to control the creation of a Grafana instance. By default, **graphing** is disabled. For more information, see [Section 5.1, "Dashboards in Service Telemetry Framework"](#).

### The highAvailability parameter

Use the **highAvailability** parameter to control the instantiation of multiple copies of STF components to reduce recovery time of components that fail or are rescheduled. By default, **highAvailability** is disabled. For more information, see [Section 5.5, "High availability"](#).

### The transports parameter

Use the **transports** parameter to control the enablement of the message bus for a STF deployment. The only transport currently supported is AMQ Interconnect. By default, the **qdr** transport is enabled.

## 3.3. REMOVING SERVICE TELEMETRY FRAMEWORK FROM THE RED HAT OPENSHIFT CONTAINER PLATFORM ENVIRONMENT

Remove Service Telemetry Framework (STF) from an Red Hat OpenShift Container Platform environment if you no longer require the STF functionality.

### Procedure

1. [Deleting the namespace](#).
2. [Removing the catalog source](#).

#### 3.3.1. Deleting the namespace

To remove the operational resources for STF from Red Hat OpenShift Container Platform, delete the namespace.

### Procedure

1. Run the **oc delete** command:

```
$ oc delete project service-telemetry
```

2. Verify that the resources have been deleted from the namespace:

```
$ oc get all  
No resources found.
```

#### 3.3.2. Removing the CatalogSource

If you do not expect to install Service Telemetry Framework (STF) again, delete the CatalogSource. When you remove the CatalogSource, PackageManifests related to STF are automatically removed from the Operator Lifecycle Manager catalog.

### Procedure

1. If you enabled the OperatorHub.io Community Catalog Source during the installation process and you no longer need this catalog source, delete it:

```
$ oc delete --namespace=openshift-marketplace catalogsource operatorhubio-operators catalogsource.coreos.com "operatorhubio-operators" deleted
```

## Additional resources

For more information about the OperatorHub.io Community Catalog Source, see [Section 3.1, “Deploying Service Telemetry Framework to the Red Hat OpenShift Container Platform environment”](#).

# CHAPTER 4. CONFIGURING RED HAT OPENSTACK PLATFORM FOR SERVICE TELEMETRY FRAMEWORK

To collect metrics, events, or both, and to send them to the Service Telemetry Framework (STF) storage domain, you must configure the Red Hat OpenStack Platform (RHOSP) overcloud to enable data collection and transport.

STF can support both single and multiple clouds. The default configuration in RHOSP and STF set up for a single cloud installation.

- For a single RHOSP overcloud deployment with default configuration, see [Section 4.1, "Deploying Red Hat OpenStack Platform overcloud for Service Telemetry Framework"](#).
- To plan your RHOSP installation and configuration STF for multiple clouds, see [Section 4.4, "Configuring multiple clouds"](#).
- As part of an RHOSP overcloud deployment, you might need to configure additional features in your environment:
  - To deploy data collection and transport to STF on RHOSP cloud nodes that employ routed L3 domains, such as distributed compute node (DCN) or spine-leaf, see [Section 4.2, "Deploying to non-standard network topologies"](#).
  - If you synchronized container images to a local registry, you must create an environment file and include the paths to the container images. For more information, see [Section 4.3, "Adding Red Hat OpenStack Platform container images to the undercloud"](#).

## 4.1. DEPLOYING RED HAT OPENSTACK PLATFORM OVERCLOUD FOR SERVICE TELEMETRY FRAMEWORK

To configure the Red Hat OpenStack Platform (RHOSP) overcloud, you must configure the data collectors and the data transport to Service Telemetry Framework (STF), and deploy the overcloud.

### Procedure

1. [Section 4.1.1, "Getting CA certificate from Service Telemetry Framework for overcloud configuration"](#)
2. [Retrieving the AMQ Interconnect route address](#)
3. [Creating the base configuration for STF](#)
4. [Configuring the STF connection for the overcloud](#)
5. [Deploying the overcloud](#)
6. [Validating client-side installation](#)

### 4.1.1. Getting CA certificate from Service Telemetry Framework for overcloud configuration

To connect your Red Hat OpenStack Platform overcloud to Service Telemetry Framework (STF), retrieve the CA certificate of AMQ Interconnect that runs within Service Telemetry Framework and use the certificate in the Red Hat OpenStack Platform configuration.

### Procedure

- View a list of available certificates in Service Telemetry Framework:

```
$ oc get secrets
```

- Retrieve and note the content of the **default-interconnect-selfsigned** Secret:

```
$ oc get secret/default-interconnect-selfsigned -o jsonpath='{.data.ca\.crt}' | base64 -d
```

### 4.1.2. Retrieving the AMQ Interconnect route address

When you configure the Red Hat OpenStack Platform (RHOSP) overcloud for Service Telemetry Framework (STF), you must provide the AMQ Interconnect route address in the STF connection file.

### Procedure

- Log in to your Red Hat OpenShift Container Platform environment.
- In the **service-telemetry** project, retrieve the AMQ Interconnect route address:

```
$ oc get routes -ogo-template='{{ range .items }}{{printf "%s\n" .spec.host }}{{ end }}' | grep "\-5671"
default-interconnect-5671-service-telemetry.apps.infra.watch
```

### 4.1.3. Creating the base configuration for STF

To configure the base parameters to provide a compatible data collection and transport for Service Telemetry Framework (STF), you must create a file that defines the default data collection values.

### Procedure

- Log in to the Red Hat OpenStack Platform (RHOSP) undercloud as the **stack** user.
- Create a configuration file called **enable-stf.yaml** in the **/home/stack** directory.

#### IMPORTANT

Setting **EventPipelinePublishers** and **PipelinePublishers** to empty lists results in no event or metric data passing to RHOSP legacy telemetry components, such as Gnocchi or Panko. If you need to send data to additional pipelines, the Ceilometer polling interval of 30 seconds, as specified in **ExtraConfig**, might overwhelm the legacy components, and you must increase the interval to a larger value, such as **300**. Increasing the value to a longer polling interval results in less telemetry resolution in STF.

```
parameter_defaults:
```

```

# only send to STF, not other publishers
EventPipelinePublishers: []
PipelinePublishers: []

# manage the polling and pipeline configuration files for Ceilometer agents
ManagePolling: true
ManagePipeline: true

# enable Ceilometer metrics and events
CeilometerQdrPublishMetrics: true
CeilometerQdrPublishEvents: true

# set collectd overrides for higher telemetry resolution and extra plugins to load
CollectdConnectionType: amqp1
CollectdAmqpInterval: 5
CollectdDefaultPollingInterval: 5
CollectdExtraPlugins:
- vmem

# set standard prefixes for where metrics and events are published to QDR
MetricsQdrAddresses:
- prefix: 'collectd'
  distribution: multicast
- prefix: 'anycast/ceilometer'
  distribution: multicast

ExtraConfig:
  ceilometer::agent::polling::polling_interval: 30
  ceilometer::agent::polling::polling_meters:
    - cpu
    - disk.*
    - ip.*
    - image.*
    - memory
    - memory.*
    - network.*
    - perf.*
    - port
    - port.*
    - switch
    - switch.*
    - storage.*
    - volume.*

# to avoid filling the memory buffers if disconnected from the message bus
collectd::plugin::amqp1::send_queue_limit: 50

# receive extra information about virtual memory
collectd::plugin::vmem::verbose: true

# set memcached collectd plugin to report its metrics by hostname
# rather than host IP, ensuring metrics in the dashboard remain uniform
collectd::plugin::memcached::instances:
  local:
    host: "%{hiera('fqdn_canonical')}"
    port: 11211

```

```
# align defaults across OSP versions
collectd::plugin::cpu::reportbycpu: true
collectd::plugin::cpu::reportbystate: true
collectd::plugin::cpu::reportnumcpu: false
collectd::plugin::cpu::valuespercentage: true
collectd::plugin::df::ignoreselected: true
collectd::plugin::df::reportbydevice: true
collectd::plugin::df::fstypes: ['xfs']
collectd::plugin::load::reportrelative: true
collectd::plugin::virt::extra_stats: "pcpu cpu_util vcpupin vcpu memory disk disk_err
disk_allocation disk_capacity disk_physical domain_state job_stats_background perf"
```

#### 4.1.4. Configuring the STF connection for the overcloud

To configure the Service Telemetry Framework (STF) connection, you must create a file that contains the connection configuration of the AMQ Interconnect for the overcloud to the STF deployment. Enable the collection of events and storage of the events in STF and deploy the overcloud. The default configuration is for a single cloud instance with the default message bus topics. For configuration of multiple cloud deployments, see [Section 4.4, “Configuring multiple clouds”](#).

##### Prerequisites

- Retrieve the CA certificate from the AMQ Interconnect deployed by STF. For more information, see [Section 4.1.1, “Getting CA certificate from Service Telemetry Framework for overcloud configuration”](#).
- Retrieve the AMQ Interconnect route address. For more information, see [Section 4.1.2, “Retrieving the AMQ Interconnect route address”](#).

##### Procedure

1. Log in to the RHOSP undercloud as the **stack** user.
2. Create a configuration file called **stf-connectors.yaml** in the **/home/stack** directory.
3. In the **stf-connectors.yaml** file, configure the **MetricsQdrConnectors** address to connect the AMQ Interconnect on the overcloud to the STF deployment.
  - Replace the **host** parameter with the value of **HOST/PORT** that you retrieved in [Section 4.1.2, “Retrieving the AMQ Interconnect route address”](#).
  - Replace the **caCertFileContent** parameter with the contents retrieved in [Section 4.1.1, “Getting CA certificate from Service Telemetry Framework for overcloud configuration”](#).

```
parameter_defaults:
  MetricsQdrConnectors:
    - host: default-interconnect-5671-service-telemetry.apps.infra.watch
      port: 443
      role: edge
      sslProfile: sslProfile
      verifyHostname: false

  MetricsQdrSSLProfiles:
    - name: sslProfile
```

```
caCertFileContent: |
  ----BEGIN CERTIFICATE----
  <snip>
  ----END CERTIFICATE----
```

#### 4.1.5. Deploying the overcloud

Deploy or update the overcloud with the required environment files so that data is collected and transmitted to Service Telemetry Framework (STF).

##### Procedure

1. Log in to the Red Hat OpenStack Platform (RHOSP) undercloud as the **stack** user.
2. Source the authentication file:

```
[stack@undercloud-0 ~]$ source stackrc
```

```
(undercloud) [stack@undercloud-0 ~]$
```

3. Add the following files to your RHOSP director deployment to configure data collection and AMQ Interconnect:
  - The **collectd-write-qdr.yaml** file to ensure that collectd telemetry and events are sent to STF
  - The **ceilometer-write-qdr.yaml** file to ensure that Ceilometer telemetry and events are sent to STF
  - The **qdr-edge-only.yaml** file to ensure that the message bus is enabled and connected to STF message bus routers
  - The **enable-stf.yaml** environment file to ensure defaults are configured correctly
  - The **stf-connectors.yaml** environment file to define the connection to STF

```
(undercloud) [stack@undercloud-0 ~]$ openstack overcloud deploy <other_arguments>
--templates /usr/share/openstack-tripleo-heat-templates \
--environment-file <...other_environment_files...> \
--environment-file /usr/share/openstack-tripleo-heat-
templates/environments/metrics/ceilometer-write-qdr.yaml \
--environment-file /usr/share/openstack-tripleo-heat-
templates/environments/metrics/collectd-write-qdr.yaml \
--environment-file /usr/share/openstack-tripleo-heat-
templates/environments/metrics/qdr-edge-only.yaml \
--environment-file /home/stack/enable-stf.yaml \
--environment-file /home/stack/stf-connectors.yaml
```

4. Deploy the overcloud.

#### 4.1.6. Validating client-side installation

To validate data collection from the Service Telemetry Framework (STF) storage domain, query the data sources for delivered data. To validate individual nodes in the Red Hat OpenStack Platform (RHOSP) deployment, use SSH to connect to the console.

## TIP

Some telemetry data is available only when RHOSP has active workloads.

### Procedure

1. Log in to an overcloud node, for example, controller-0.
2. Ensure that the **metrics\_qdr** container is running on the node:

```
$ sudo docker container inspect --format '{{.State.Status}}' metrics_qdr
running
```

3. Return the internal network address on which AMQ Interconnect is running, for example, **172.17.1.44** listening on port **5666**:

```
$ sudo docker exec -it metrics_qdr cat /etc/qpid-dispatch/qdrouterd.conf
listener {
    host: 172.17.1.44
    port: 5666
    authenticatePeer: no
    saslMechanisms: ANONYMOUS
}
```

4. Return a list of connections to the local AMQ Interconnect:

```
$ sudo docker exec -it metrics_qdr qdstat --bus=172.17.1.44:5666 --connections
Connections
  id host                               container
  role dir security           authentication tenant

```

There are four connections:

- Outbound connection to STF
- Inbound connection from ceilometer
- Inbound connection from collectd
- Inbound connection from our **qdstat** client

The outbound STF connection is provided to the **MetricsQdrConnectors** host parameter and is the route for the STF storage domain. The other hosts are internal network addresses of the client connections to this AMQ Interconnect.

5. To ensure that messages are delivered, list the links, and view the **\_edge** address in the **deliv** column for delivery of messages:

```
$ sudo docker exec -it metrics_qdr qdstat --bus=172.17.1.44:5666 --links
Router Links
  type   dir conn id  id  peer class  addr          phs cap pri undel unsett deliv

```

6. To list the addresses from RHOSP nodes to STF, connect to Red Hat OpenShift Container Platform to retrieve the AMQ Interconnect pod name and list the connections. List the available AMQ Interconnect pods:

```
$ oc get pods -l application=default-interconnect
NAME                  READY STATUS RESTARTS AGE
default-interconnect-7458fd4d69-bgzfb 1/1  Running 0       6d21h
```

7. Connect to the pod and list the known connections. In this example, there are three **edge** connections from the RHOSP nodes with connection **id** 22, 23, and 24:

```
$ oc exec -it default-interconnect-7458fd4d69-bgzfb -- qdstat --connections

2020-04-21 18:25:47.243852 UTC
default-interconnect-7458fd4d69-bgzfb

## 4.2. DEPLOYING TO NON-STANDARD NETWORK TOPOLOGIES

If your nodes are on a separate network from the default **InternalApi** network, you must make configuration adjustments so that AMQ Interconnect can transport data to the Service Telemetry Framework (STF) server instance. This scenario is typical in a spine-leaf or a DCN topology. For more information about DCN configuration, see the [Spine Leaf Networking](#) guide.

If you use STF with Red Hat OpenStack Platform (RHOSP) 13 and plan to monitor your Ceph, Block, or Object Storage nodes, you must make configuration changes that are similar to the configuration changes that you make to the spine-leaf and DCN network configuration. To monitor Ceph nodes, use the **CephStorageExtraConfig** parameter to define which network interface to load into the AMQ Interconnect and collectd configuration files.

### CephStorageExtraConfig:

```
tripleo::profile::base::metrics::collectd::amqp_host: "%{hiera('storage')}"
tripleo::profile::base::metrics::qdr::listener_addr: "%{hiera('storage')}"
tripleo::profile::base::ceilometer::agent::notification::notifier_host_addr: "%{hiera('storage')}"
```

Similarly, you must specify **BlockStorageExtraConfig** and **ObjectStorageExtraConfig** parameters if your environment uses Block and Object Storage roles.

To deploy a spine-leaf topology, you must create roles and networks, then assign those networks to the available roles. When you configure data collection and transport for STF for an RHOSP deployment, the default network for roles is **InternalApi**. For Ceph, Block and Object storage roles, the default network is **Storage**. Because a spine-leaf configuration can result in different networks being assigned to different Leaf groupings and those names are typically unique, additional configuration is required in the **parameter\_defaults** section of the RHOSP environment files.

### Procedure

1. Document which networks are available for each of the Leaf roles. For examples of network name definitions, see [Creating a network data file](#) in the *Spine Leaf Networking* guide. For more information about the creation of the Leaf groupings (roles) and assignment of the networks to those groupings, see [Creating a roles data file](#) in the *Spine Leaf Networking* guide.
2. Add the following configuration example to the **ExtraConfig** section for each of the leaf roles. In this example, **internal\_api0** is the value defined in the **name\_lower** parameter of your network definition, and is the network to which the **Compute0** leaf role is connected. In this case, the network identification of 0 corresponds to the Compute role for leaf 0, and represents a value that is different from the default internal API network name.  
For the **Compute0** leaf role, specify extra configuration to perform a hiera lookup to determine which network interface for a particular network to assign to the collectd AMQP host parameter. Perform the same configuration for the AMQ Interconnect listener address parameter.

### Compute0ExtraConfig:

```
tripleo::profile::base::metrics::collectd::amqp_host: "%{hiera('internal_api0')}"
tripleo::profile::base::metrics::qdr::listener_addr: "%{hiera('internal_api0')}"
```

This example configuration is on a CephStorage leaf role:

### CephStorage0ExtraConfig:

```
tripleo::profile::base::metrics::collectd::amqp_host: "%{hiera('storage0')}"
tripleo::profile::base::metrics::qdr::listener_addr: "%{hiera('storage0')}"
```

## 4.3. ADDING RED HAT OPENSTACK PLATFORM CONTAINER IMAGES TO THE UNDERCLOUD

If you synchronized container images to a local registry, you must create an environment file and include the paths to the container images.

### Procedure

1. Create a new environment file, for example, **container-images.yaml**, and insert the following container images and paths:

```
parameter_defaults:  
    DockerCollectdConfigImage: <image-registry-path>/rhosp{vernum}/openstack-  
        collectd:latest  
    DockerCollectdImage: <image-registry-path>/rhosp{vernum}/openstack-collectd:latest  
    DockerMetricsQdrConfigImage: <image-registry-path>/rhosp{vernum}/openstack-  
        qdrouterd:latest  
    DockerMetricsQdrImage: <image-registry-path>/rhosp{vernum}/openstack-qdrouterd:latest
```

Replace **<image-registry-path>** with the path to the image registry.

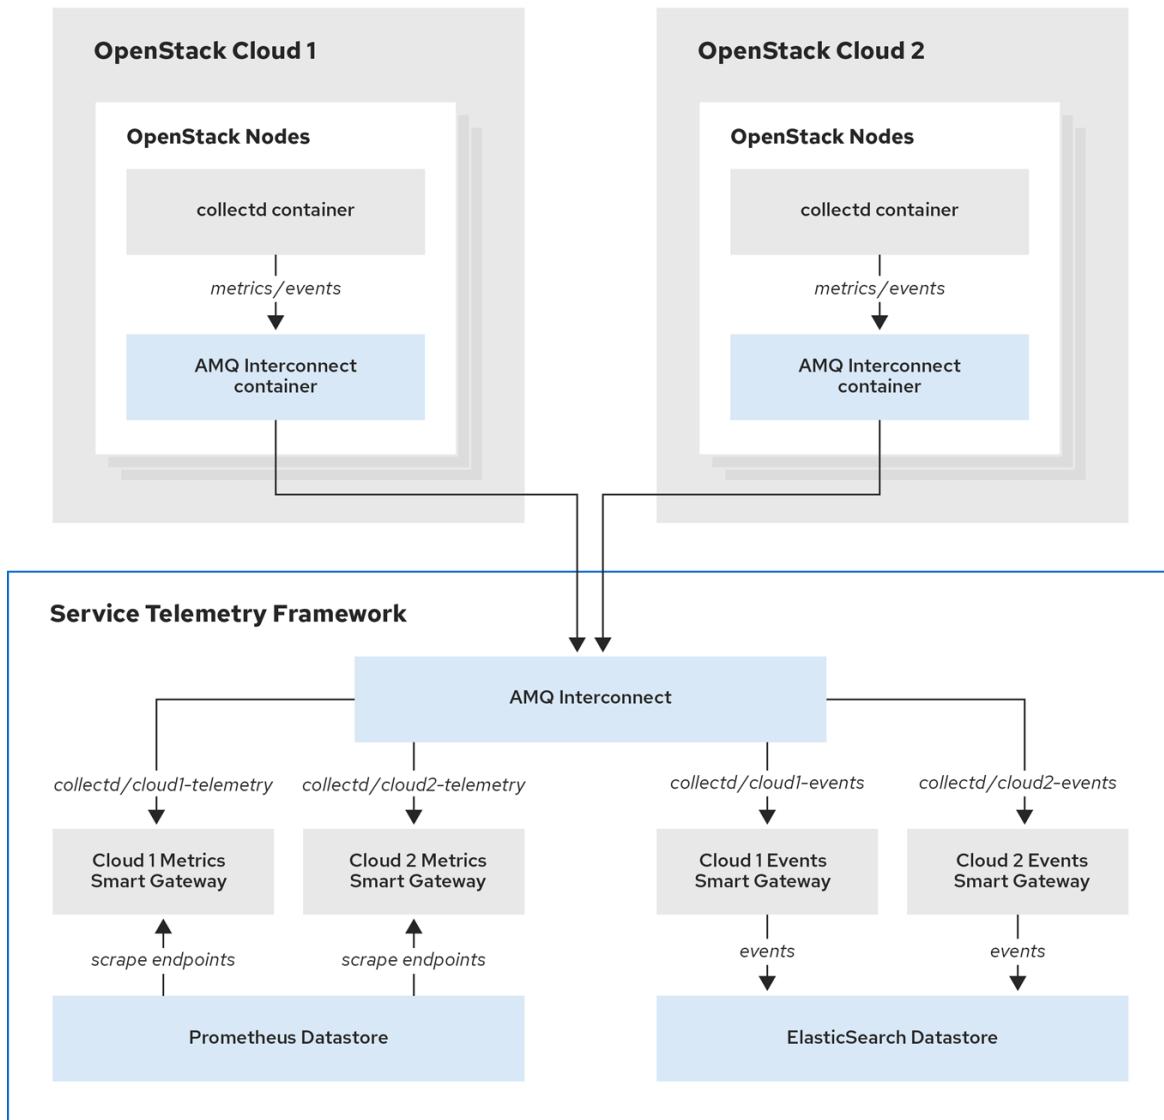

2. To deploy collectd and AMQ Interconnect to your overcloud, include the **/usr/share/local-container-images/container-images.yaml** environment file so Red Hat OpenStack Platform director can prepare the images. The following snippet is an example of how to include this environment file:

```
$ openstack overcloud container image prepare \  
...  
-e /usr/share/local-container-images/container-images.yaml \  
...
```

## 4.4. CONFIGURING MULTIPLE CLOUDS

You can configure multiple Red Hat OpenStack Platform (RHOSP) clouds to target a single instance of Service Telemetry Framework (STF). When you configure multiple clouds, every cloud must send metrics and events on their own unique message bus topic. In the STF deployment, Smart Gateway instances listen on these topics to save information to the common data store. Data that is stored by the Smart Gateway in the data storage domain is filtered by using the metadata that each of Smart Gateways creates.

Figure 4.1. Two RHOSP clouds connect to STF

65\_OpenStack\_0120

To configure the RHOSP overcloud for a multiple cloud scenario, complete the following tasks:

1. Plan the AMQP address prefixes that you want to use for each cloud. For more information, see [Section 4.4.1, "Planning AMQP address prefixes"](#).
2. Deploy metrics and events consumer Smart Gateways for each cloud to listen on the corresponding address prefixes. For more information, see [Section 4.4.2, "Deploying Smart Gateways"](#).
3. Configure each cloud with a unique domain name. For more information, see [Section 4.4.4, "Setting a unique cloud domain"](#).
4. Create the base configuration for STF. For more information, see [Section 4.1.3, "Creating the base configuration for STF"](#).
5. Configure each cloud to send its metrics and events to STF on the correct address. For more information, see [Section 4.4.5, "Creating the Red Hat OpenStack Platform environment file for multiple clouds"](#).

#### 4.4.1. Planning AMQP address prefixes

By default, Red Hat OpenStack Platform nodes receive data through two data collectors; collectd and Ceilometer. These components send telemetry data or notifications to the respective AMQP addresses, for example, collectd/telemetry. STF Smart Gateways listen on the AMQP addresses for monitoring data. To support multiple clouds and to identify which cloud generated the monitoring data, configure each cloud to send data to a unique address. Add a cloud identifier prefix to the second part of the address. The following list shows some example addresses and identifiers:

- **collectd/cloud1-telemetry**
- **collectd/cloud1-notify**
- **anycast/ceilometer/cloud1-metering.sample**
- **anycast/ceilometer/cloud1-event.sample**
- **collectd/cloud2-telemetry**
- **collectd/cloud2-notify**
- **anycast/ceilometer/cloud2-metering.sample**
- **anycast/ceilometer/cloud2-event.sample**
- **collectd/us-east-1-telemetry**
- **collectd/us-west-3-telemetry**

#### 4.4.2. Deploying Smart Gateways

You must deploy a Smart Gateway for each of the data collection types for each cloud; one for collectd metrics, one for collectd events, one for Ceilometer metrics, and one for Ceilometer events. Configure each of the Smart Gateways to listen on the AMQP address that you define for the corresponding cloud. To define Smart Gateways, configure the **clouds** parameter in the **ServiceTelemetry** manifest.

When you deploy STF for the first time, Smart Gateway manifests are created that define the initial Smart Gateways for a single cloud. When you deploy Smart Gateways for multiple cloud support, you deploy multiple Smart Gateways for each of the data collection types that handle the metrics and the events data for each cloud. The initial Smart Gateways are defined in **cloud1** with the following subscription addresses:

collector	type	default subscription address
collectd	metrics	collectd/telemetry
collectd	events	collectd/notify
Ceilometer	metrics	anycast/ceilometer/metering.sample
Ceilometer	events	anycast/ceilometer/event.sample

#### Prerequisites

- You have determined your cloud naming scheme. For more information about determining your naming scheme, see [Section 4.4.1, “Planning AMQP address prefixes”](#).
- You have created your list of clouds objects. For more information about creating the content for the **clouds** parameter, see [the section called “The clouds parameter”](#).

## Procedure

1. Log in to Red Hat OpenShift Container Platform.
2. Change to the **service-telemetry** namespace:

```
$ oc project service-telemetry
```

3. Edit the **default** ServiceTelemetry object and add a **clouds** parameter with your configuration:

### WARNING

Long cloud names might exceed the maximum pod name of 63 characters. Ensure that the combination of the **ServiceTelemetry** name **default** and the **clouds.name** does not exceed 19 characters. Cloud names cannot contain any special characters, such as -. Limit cloud names to alphanumeric (a-z, 0-9).

Topic addresses have no character limitation and can be different from the **clouds.name** value.

```
$ oc edit stf default
```

```
apiVersion: infra.watch/v1beta1
kind: ServiceTelemetry
metadata:
...
spec:
...
clouds:
- name: cloud1
  events:
    collectors:
      - collectorType: collectd
        subscriptionAddress: collectd/cloud1-notify
      - collectorType: ceilometer
        subscriptionAddress: anycast/ceilometer/cloud1-event.sample
  metrics:
    collectors:
      - collectorType: collectd
        subscriptionAddress: collectd/cloud1-telemetry
      - collectorType: ceilometer
        subscriptionAddress: anycast/ceilometer/cloud1-metering.sample
```

```
- name: cloud2
```

```
events:
```

```
...
```

4. Save the ServiceTelemetry object.

5. Verify that each Smart Gateway is running. This can take several minutes depending on the number of Smart Gateways:

```
$ oc get po -l app=smart-gateway
```

NAME	READY	STATUS	RESTARTS	AGE
default-cloud1-ceil-event-smartgateway-6cfb65478c-g5q82	2/2	Running	0	13h
default-cloud1-ceil-meter-smartgateway-58f885c76d-xmxwn	2/2	Running	0	13h
default-cloud1-coll-event-smartgateway-58fbdbd4485-rl9bd	2/2	Running	0	13h
default-cloud1-coll-meter-smartgateway-7c6fc495c4-jn728	2/2	Running	0	13h

#### 4.4.3. Deleting the default Smart Gateways

After you configure Service Telemetry Framework (STF) for multiple clouds, you can delete the default Smart Gateways if they are no longer in use. The Service Telemetry Operator can remove

**SmartGateway** objects that were created but are no longer listed in the ServiceTelemetry **clouds** list of objects. To enable the removal of SmartGateway objects that are not defined by the **clouds** parameter, you must set the **cloudsRemoveOnMissing** parameter to **true** in the **ServiceTelemetry** manifest.

#### TIP

If you do not want to deploy any Smart Gateways, define an empty clouds list by using the **clouds: []** parameter.

#### WARNING

The **cloudsRemoveOnMissing** parameter is disabled by default. If you enable the **cloudsRemoveOnMissing** parameter, you remove any manually created **SmartGateway** objects in the current namespace without any possibility to restore.

#### Procedure

1. Define your **clouds** parameter with the list of cloud objects that you want the Service Telemetry Operator to manage. For more information, see [the section called “The clouds parameter”](#).
2. Edit the ServiceTelemetry object and add the **cloudsRemoveOnMissing** parameter:

```
apiVersion: infra.watch/v1beta1
kind: ServiceTelemetry
metadata:
...
spec:
...
```

```

cloudsRemoveOnMissing: true
clouds:
...

```

3. Save the modifications.
4. Verify that the Operator deleted the Smart Gateways. This can take several minutes while the Operators reconcile the changes:

```
$ oc get smartgateways
```

#### 4.4.4. Setting a unique cloud domain

To ensure that AMQ Interconnect router connections from Red Hat OpenStack Platform (RHOSP) to Service Telemetry Framework (STF) are unique and do not conflict, configure the **CloudDomain** parameter.

##### Procedure

1. Create a new environment file, for example, **hostnames.yaml**.
2. Set the **CloudDomain** parameter in the environment file, as shown in the following example:

```

parameter_defaults:
  CloudDomain: newyork-west-04
  CephStorageHostnameFormat: 'ceph-%index%'
  ObjectStorageHostnameFormat: 'swift-%index%'
  ComputeHostnameFormat: 'compute-%index%'

```

3. Add the new environment file to your deployment. For more information, see [Section 4.4.5, “Creating the Red Hat OpenStack Platform environment file for multiple clouds”](#) and [Core overcloud parameters](#) in the *Overcloud Parameters* guide.

#### 4.4.5. Creating the Red Hat OpenStack Platform environment file for multiple clouds

To label traffic according to the cloud of origin, you must create a configuration with cloud-specific instance names. Create an **stf-connectors.yaml** file and adjust the values of **CeilometerQdrEventsConfig**, **CeilometerQdrMetricsConfig** and **CollectdAmqpInstances** to match the AMQP address prefix scheme.

##### Prerequisites

- You have retrieved the CA certificate from the AMQ Interconnect deployed by STF. For more information, see [Section 4.1.1, “Getting CA certificate from Service Telemetry Framework for overcloud configuration”](#).
- You have created your list of clouds objects. For more information about creating the content for the clouds parameter, see the [clouds configuration parameter](#).
- You have retrieved the AMQ Interconnect route address. For more information, see [Section 4.1.2, “Retrieving the AMQ Interconnect route address”](#).

- You have created the base configuration for STF. For more information, see [Section 4.1.3, "Creating the base configuration for STF"](#).
- You have created a unique domain name environment file. For more information, see [Section 4.4.4, "Setting a unique cloud domain"](#).

## Procedure

1. Log in to the Red Hat OpenStack Platform undercloud as the **stack** user.
2. Create a configuration file called **stf-connectors.yaml** in the **/home/stack** directory.
3. In the **stf-connectors.yaml** file, configure the **MetricsQdrConnectors** address to connect to the AMQ Interconnect on the overcloud deployment. Configure the **CeilometerQdrEventsConfig**, **CeilometerQdrMetricsConfig**, and **CollectdAmqplInstances** topic values to match the AMQP address that you want for this cloud deployment.
  - Replace the **caCertFileContent** parameter with the contents retrieved in [Section 4.1.1, "Getting CA certificate from Service Telemetry Framework for overcloud configuration"](#).

### stf-connectors.yaml

```

resource_registry:
  OS::TripleO::Services::Collectd: /usr/share/openstack-tripleo-heat-
templates/deployment/metrics/collectd-container-puppet.yaml ①

parameter_defaults:
  MetricsQdrConnectors:
    - host: stf-default-interconnect-5671-service-telemetry.apps.infra.watch ②
      port: 443
      role: edge
      verifyHostname: false
      sslProfile: sslProfile

  MetricsQdrSSLProfiles:
    - name: sslProfile
      caCertFileContent: |
        ---BEGIN CERTIFICATE---
        <snip>
        ---END CERTIFICATE---

  CeilometerQdrEventsConfig:
    driver: amqp
    topic: cloud1-event ③

  CeilometerQdrMetricsConfig:
    driver: amqp
    topic: cloud1-metering ④

  CollectdAmqplInstances:
    cloud1-notify: ⑤
      notify: true
      format: JSON
      presettle: false

```

cloud1-telemetry:  
format: JSON  
presettle: false

- 1** Directly load the collectd service because you are not including the **collectd-write-qdr.yaml** environment file for multiple cloud deployments.
  - 2** Replace the **host** parameter with the value of **HOST/PORT** that you retrieved in [Section 4.1.2, “Retrieving the AMQ Interconnect route address”](#).
  - 3** Define the topic for Ceilometer events. This value is the address format of **anycast/ceilometer/cloud1-event.sample**.
  - 4** Define the topic for Ceilometer metrics. This value is the address format of **anycast/ceilometer/cloud1-metering.sample**.
  - 5** Define the topic for collectd events. This value is the format of **collectd/cloud1-notify**.
  - 6** Define the topic for collectd metrics. This value is the format of **collectd/cloud1-telemetry**.
4. Ensure that the naming convention in the **stf-connectors.yaml** file aligns with the **spec.bridge.amqpUrl** field in the Smart Gateway configuration. For example, configure the **CeilometerQdrEventsConfig.topic** field to a value of **cloud1-event**.
  5. Source the authentication file:
- ```
[stack@undercloud-0 ~]$ source stackrc
(undercloud) [stack@undercloud-0 ~]$
```
6. Include the **stf-connectors.yaml** file and unique domain name environment file **hostnames.yaml** in the **openstack overcloud deployment** command, with any other environment files relevant to your environment:

#### WARNING

If you use the **collectd-write-qdr.yaml** file with a custom **CollectdAmqplInstances** parameter, data publishes to the custom and default topics. In a multiple cloud environment, the configuration of the **resource\_registry** parameter in the **stf-connectors.yaml** file loads the collectd service.

```
(undercloud) [stack@undercloud-0 ~]$ openstack overcloud deploy <other_arguments>
--templates /usr/share/openstack-tripleo-heat-templates \
--environment-file <...other_environment_files...> \
--environment-file /usr/share/openstack-tripleo-heat-
templates/environments/metrics/ceilometer-write-qdr.yaml \
```

```
--environment-file /usr/share/openstack-tripleo-heat-templates/environments/metrics/qdr-edge-only.yaml \
--environment-file /home/stack/hostnames.yaml \
--environment-file /home/stack/enable-stf.yaml \
--environment-file /home/stack/stf-connectors.yaml
```

7. Deploy the Red Hat OpenStack Platform overcloud.

#### Additional resources

- For information about how to validate the deployment, see [Section 4.1.6, “Validating client-side installation”](#).

#### 4.4.6. Querying metrics data from multiple clouds

Data stored in Prometheus has a **service** label according to the Smart Gateway it was scraped from. You can use this label to query data from a specific cloud.

To query data from a specific cloud, use a Prometheus *promql* query that matches the associated **service** label; for example: **collectd\_uptime{service="default-cloud1-coll-meter"}**.

# CHAPTER 5. USING OPERATIONAL FEATURES OF SERVICE TELEMETRY FRAMEWORK

You can use the following operational features to provide additional functionality to the Service Telemetry Framework (STF):

- Configuring dashboards
- Configuring the metrics retention time period
- Configuring alerts
- Configuring SNMP traps
- Configuring high availability
- Configuring ephemeral storage
- Creating a route in Red Hat OpenShift Container Platform

## 5.1. DASHBOARDS IN SERVICE TELEMETRY FRAMEWORK

Use the third-party application, Grafana, to visualize system-level metrics that collectd and Ceilometer gathers for each individual host node.

For more information about configuring collectd, see [Section 4.1, “Deploying Red Hat OpenStack Platform overcloud for Service Telemetry Framework”](#).

### 5.1.1. Configuring Grafana to host the dashboard

Grafana is not included in the default Service Telemetry Framework (STF) deployment so you must deploy the Grafana Operator from OperatorHub.io. When you use the Service Telemetry Operator to deploy Grafana, it results in a Grafana instance and the configuration of the default data sources for the local STF deployment.

#### Procedure

1. Log in to Red Hat OpenShift Container Platform.
2. Change to the **service-telemetry** namespace:

```
$ oc project service-telemetry
```

3. Deploy the Grafana operator:

```
$ oc apply -f - <<EOF
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: grafana-operator
  namespace: service-telemetry
spec:
  channel: alpha
  installPlanApproval: Automatic
```

```
name: grafana-operator
source: operatorhubio-operators
sourceNamespace: openshift-marketplace
EOF
```

4. Verify that the Operator launched successfully. In the command output, if the value of the **PHASE** column is **Succeeded**, the Operator launched successfully:

```
$ oc get csv --selector operators.coreos.com/grafana-operator.service-telemetry

NAME          DISPLAY      VERSION  REPLACES      PHASE
grafana-operator.v3.10.3  Grafana Operator  3.10.3  grafana-operator.v3.10.2  Succeeded
```

5. To launch a Grafana instance, create or modify the **ServiceTelemetry** object. Set **graphing.enabled** and **graphing.grafana.ingressEnabled** to **true**:

```
$ oc edit stf default

apiVersion: infra.watch/v1beta1
kind: ServiceTelemetry
...
spec:
...
graphing:
  enabled: true
grafana:
  ingressEnabled: true
```

6. Verify that the Grafana instance deployed:

```
$ oc get pod -l app=grafana

NAME          READY  STATUS  RESTARTS  AGE
grafana-deployment-7fc7848b56-sbkhv  1/1   Running  0        1m
```

7. Verify that the Grafana data sources installed correctly:

```
$ oc get grafanadatasources

NAME      AGE
default-datasources  20h
```

8. Verify that the Grafana route exists:

```
$ oc get route grafana-route

NAME      HOST/PORT      PATH  SERVICES      PORT
TERMINATION  WILDCARD
grafana-route  grafana-route-service-telemetry.apps.infra.watch  grafana-service  3000
edge      None
```

### 5.1.2. Retrieving and setting Grafana login credentials

Service Telemetry Framework (STF) sets default login credentials when Grafana is enabled. You can override the credentials in the **ServiceTelemetry** object.

### Procedure

1. Log in to Red Hat OpenShift Container Platform.
2. Change to the **service-telemetry** namespace:

```
$ oc project service-telemetry
```

3. To retrieve the default username and password, describe the Grafana object:

```
$ oc describe grafana default
```

4. To modify the default values of the Grafana administrator username and password through the ServiceTelemetry object, use the **graphing.grafana.adminUser** and **graphing.grafana.adminPassword** parameters.

## 5.2. METRICS RETENTION TIME PERIOD IN SERVICE TELEMETRY FRAMEWORK

The default retention time for metrics stored in Service Telemetry Framework (STF) is 24 hours, which provides enough data for trends to develop for the purposes of alerting.

For long-term storage, use systems designed for long-term data retention, for example, Thanos.

### Additional resources

- To adjust STF for additional metrics retention time, see [Section 5.2.1, “Editing the metrics retention time period in Service Telemetry Framework”](#).
- For recommendations about Prometheus data storage and estimating storage space, see <https://prometheus.io/docs/prometheus/latest/storage/#operational-aspects>
- For more information about Thanos, see <https://thanos.io/>

### 5.2.1. Editing the metrics retention time period in Service Telemetry Framework

You can adjust Service Telemetry Framework (STF) for additional metrics retention time.

### Procedure

1. Log in to Red Hat OpenShift Container Platform.
2. Change to the service-telemetry namespace:

```
$ oc project service-telemetry
```

3. Edit the ServiceTelemetry object:

```
$ oc edit stf default
```

- Add **retention: 7d** to the storage section of backends.metrics.prometheus.storage to increase the retention period to seven days:

#### NOTE

If you set a long retention period, retrieving data from heavily populated Prometheus systems can result in queries returning results slowly.

```
apiVersion: infra.watch/v1beta1
kind: ServiceTelemetry
metadata:
  name: stf-default
  namespace: service-telemetry
spec:
...
backends:
  metrics:
    prometheus:
      enabled: true
      storage:
        strategy: persistent
        retention: 7d
...

```

- Save your changes and close the object.

#### Additional resources

- For more information about the metrics retention time, see [Section 5.2, "Metrics retention time period in Service Telemetry Framework"](#).

## 5.3. ALERTS IN SERVICE TELEMETRY FRAMEWORK

You create alert rules in Prometheus and alert routes in Alertmanager. Alert rules in Prometheus servers send alerts to an Alertmanager, which manages the alerts. Alertmanager can silence, inhibit, or aggregate alerts, and send notifications by using email, on-call notification systems, or chat platforms.

To create an alert, complete the following tasks:

- Create an alert rule in Prometheus. For more information, see [Section 5.3.1, "Creating an alert rule in Prometheus"](#).
- Create an alert route in Alertmanager. For more information, see [Section 5.3.3, "Creating an alert route in Alertmanager"](#).

#### Additional resources

For more information about alerts or notifications with Prometheus and Alertmanager, see <https://prometheus.io/docs/alerting/overview/>

To view an example set of alerts that you can use with Service Telemetry Framework (STF), see <https://github.com/infrawatch/service-telemetry-operator/tree/master/deploy/alerts>

### 5.3.1. Creating an alert rule in Prometheus

Prometheus evaluates alert rules to trigger notifications. If the rule condition returns an empty result set, the condition is false. Otherwise, the rule is true and it triggers an alert.

## Procedure

1. Log in to Red Hat OpenShift Container Platform.
2. Change to the **service-telemetry** namespace:

```
$ oc project service-telemetry
```

3. Create a **PrometheusRule** object that contains the alert rule. The Prometheus Operator loads the rule into Prometheus:

```
$ oc apply -f - <<EOF
apiVersion: monitoring.coreos.com/v1
kind: PrometheusRule
metadata:
  creationTimestamp: null
  labels:
    prometheus: default
    role: alert-rules
  name: prometheus-alarm-rules
  namespace: service-telemetry
spec:
  groups:
    - name: ./openstack.rules
      rules:
        - alert: Metric Listener down
          expr: collectd_qpid_router_status < 1 1
EOF
```

- 1 To change the rule, edit the value of the **expr** parameter.
4. To verify that the Operator loaded the rules into Prometheus, create a pod with access to **curl**:

```
$ oc run curl --generator=run-pod/v1 --image=radial/busyboxplus:curl -i --tty
```

5. Run the **curl** command to access the **prometheus-operated** service to return the rules loaded into memory:

```
[ root@curl:/ ]$ curl prometheus-operated:9090/api/v1/rules
{"status":"success","data":{"groups":
[{"name": "./openstack.rules","file":"/etc/prometheus/rules/prometheus-default-rulefiles-0/service-telemetry-prometheus-alarm-rules.yaml","rules":[{"name":"Metric Listener down","query":"collectd_qpid_router_status \u003c 1","duration":0,"labels":{},"annotations":{},"alerts":[],"health":"ok","type":"alerting"}],"interval":30}]}}
```

6. To verify that the output shows the rules loaded into the **PrometheusRule** object, for example the output contains the defined **./openstack.rules**, exit the pod:

```
[ root@curl:/ ]$ exit
```

- Clean up the environment by deleting the **curl** pod:

```
$ oc delete pod curl
pod "curl" deleted
```

## Additional resources

- For more information on alerting, see <https://github.com/coreos/prometheus-operator/blob/master/Documentation/user-guides/alerting.md>

### 5.3.2. Configuring custom alerts

You can add custom alerts to the **PrometheusRule** object that you created in [Section 5.3.1, “Creating an alert rule in Prometheus”](#).

#### Procedure

- Use the **oc edit** command:

```
$ oc edit prometheusrules prometheus-alarm-rules
```

- Edit the **PrometheusRules** manifest.

- Save and close the manifest.

## Additional resources

- For more information about how to configure alerting rules, see [https://prometheus.io/docs/prometheus/latest/configuration/alerting\\_rules/](https://prometheus.io/docs/prometheus/latest/configuration/alerting_rules/).
- For more information about PrometheusRules objects, see <https://github.com/coreos/prometheus-operator/blob/master/Documentation/user-guides/alerting.md>

### 5.3.3. Creating an alert route in Alertmanager

Use Alertmanager to deliver alerts to an external system, such as email, IRC, or other notification channel. The Prometheus Operator manages the Alertmanager configuration as a Red Hat OpenShift Container Platform secret. By default, Service Telemetry Framework (STF) deploys a basic configuration that results in no receivers:

```
alertmanager.yaml: |-
global:
  resolve_timeout: 5m
route:
  group_by: ['job']
  group_wait: 30s
  group_interval: 5m
  repeat_interval: 12h
  receiver: 'null'
receivers:
- name: 'null'
```

To deploy a custom Alertmanager route with STF, you must pass an **alertmanagerConfigManifest** parameter to the Service Telemetry Operator that results in an updated secret, managed by the Prometheus Operator.

## Procedure

1. Log in to Red Hat OpenShift Container Platform.

2. Change to the **service-telemetry** namespace:

```
$ oc project service-telemetry
```

3. Edit the **ServiceTelemetry** object for your STF deployment:

```
$ oc edit stf default
```

4. Add the new parameter **alertmanagerConfigManifest** and the **Secret** object contents to define the **alertmanager.yaml** configuration for Alertmanager:

### NOTE

This step loads the default template that the Service Telemetry Operator manages. To verify that the changes are populating correctly, change a value, return the **alertmanager-default** secret, and verify that the new value is loaded into memory. For example, change the value of the parameter **global.resolve\_timeout** from **5m** to **10m**.

```
apiVersion: infra.watch/v1beta1
kind: ServiceTelemetry
metadata:
  name: default
  namespace: service-telemetry
spec:
  backends:
    metrics:
      prometheus:
        enabled: true
  alertmanagerConfigManifest: |
    apiVersion: v1
    kind: Secret
    metadata:
      name: 'alertmanager-default'
      namespace: 'service-telemetry'
    type: Opaque
    stringData:
      alertmanager.yaml: |-
```

global:  
 resolve\_timeout: 10m  
route:  
 group\_by: ['job']  
 group\_wait: 30s  
 group\_interval: 5m  
 repeat\_interval: 12h

```

    receiver: 'null'
receivers:
- name: 'null'
```

- Verify that the configuration is applied to the secret:

```

$ oc get secret alertmanager-default -o go-template='{{index .data "alertmanager.yaml" | base64decode }}'

global:
  resolve_timeout: 10m
route:
  group_by: ['job']
  group_wait: 30s
  group_interval: 5m
  repeat_interval: 12h
  receiver: 'null'
receivers:
- name: 'null'
```

- To verify the configuration is loaded into Alertmanager, create a pod with access to **curl**:

```
$ oc run curl --generator=run-pod/v1 --image=radial/busyboxplus:curl -i --tty
```

- Run **curl** against the **alertmanager-operated** service to retrieve the status and **configYAML** contents, and verify that the supplied configuration matches the configuration in Alertmanager:

```
[ root@curl:/ ]$ curl alertmanager-operated:9093/api/v1/status

{"status":"success","data":{"configYAML":"global:\\n  resolve_timeout: 10m\\n  http_config: {}\\n  smtp_hello: localhost\\n  smtp_require_tls: true\\n  pagerduty_url: https://events.pagerduty.com/v2/enqueue\\n  hipchat_api_url: https://api.hipchat.com\\n  opsgenie_api_url: https://api.opsgenie.com\\n  wechat_api_url: https://qyapi.weixin.qq.com/cgi-bin\\n  victorops_api_url: https://alert.victorops.com/integrations/generic/20131114/alert\\n  route:\\n    receiver: \"null\"\\n    group_by:\\n      - job\\n    group_wait: 30s\\n    group_interval: 5m\\n    repeat_interval: 12h\\n  receivers:\\n    - name: \"null\"\\n      templates: []\\n    ...}}
```

- Verify that the **configYAML** field contains the changes you expect.

- Exit the pod:

```
[ root@curl:/ ]$ exit
```

- To clean up the environment, delete the **curl** pod:

```

$ oc delete pod curl
pod "curl" deleted
```

## Additional resources

- For more information about the Red Hat OpenShift Container Platform secret and the Prometheus operator, see [Alerting](#).

## 5.4. CONFIGURING SNMP TRAPS

You can integrate Service Telemetry Framework (STF) with an existing infrastructure monitoring platform that receives notifications through SNMP traps. To enable SNMP traps, modify the **ServiceTelemetry** object and configure the **snmpTraps** parameters.

For more information about configuring alerts, see [Section 5.3, “Alerts in Service Telemetry Framework”](#).

### Prerequisites

- Know the IP address or hostname of the SNMP trap receiver where you want to send the alerts

### Procedure

1. To enable SNMP traps, modify the **ServiceTelemetry** object:

```
$ oc edit stf default
```

2. Set the **alerting.alertmanager.receivers.snmpTraps** parameters:

```
apiVersion: infra.watch/v1beta1
kind: ServiceTelemetry
...
spec:
...
alerting:
  alertmanager:
    receivers:
      snmpTraps:
        enabled: true
        target: 10.10.10.10
```

3. Ensure that you set the value of **target** to the IP address or hostname of the SNMP trap receiver.

## 5.5. HIGH AVAILABILITY

With high availability, Service Telemetry Framework (STF) can rapidly recover from failures in its component services. Although Red Hat OpenShift Container Platform restarts a failed pod if nodes are available to schedule the workload, this recovery process might take more than one minute, during which time events and metrics are lost. A high availability configuration includes multiple copies of STF components, which reduces recovery time to approximately 2 seconds. To protect against failure of a Red Hat OpenShift Container Platform node, deploy STF to an Red Hat OpenShift Container Platform cluster with three or more nodes.

### WARNING

STF is not yet a fully fault tolerant system. Delivery of metrics and events during the recovery period is not guaranteed.

Enabling high availability has the following effects:

- Three ElasticSearch pods run instead of the default one.
- The following components run two pods instead of the default one:
  - AMQ Interconnect
  - Alertmanager
  - Prometheus
  - Events Smart Gateway
  - Metrics Smart Gateway
- Recovery time from a lost pod in any of these services reduces to approximately 2 seconds.

### 5.5.1. Configuring high availability

To configure Service Telemetry Framework (STF) for high availability, add **highAvailability.enabled: true** to the ServiceTelemetry object in Red Hat OpenShift Container Platform. You can set this parameter at installation time or, if you already deployed STF, complete the following steps:

#### Procedure

1. Log in to Red Hat OpenShift Container Platform.
2. Change to the **service-telemetry** namespace:
 

```
$ oc project service-telemetry
```
3. Use the oc command to edit the ServiceTelemetry object:
 

```
$ oc edit stf default
```
4. Add **highAvailability.enabled: true** to the **spec** section:
 

```
apiVersion: infra.watch/v1beta1
kind: ServiceTelemetry
...
spec:
...
highAvailability:
  enabled: true
```
5. Save your changes and close the object.

## 5.6. EPHEMERAL STORAGE

You can use ephemeral storage to run Service Telemetry Framework (STF) without persistently storing data in your Red Hat OpenShift Container Platform cluster.

## WARNING

If you use ephemeral storage, you might experience data loss if a pod is restarted, updated, or rescheduled onto another node. Use ephemeral storage only for development or testing, and not production environments.

### 5.6.1. Configuring ephemeral storage

To configure STF components for ephemeral storage, add **...storage.strategy: ephemeral** to the corresponding parameter. For example, to enable ephemeral storage for the Prometheus back end, set **backends.metrics.prometheus.storage.strategy: ephemeral**. Components that support configuration of ephemeral storage include **alerting.alertmanager**, **backends.metrics.prometheus**, and **backends.events.elasticsearch**. You can add ephemeral storage configuration at installation time or, if you already deployed STF, complete the following steps:

#### Procedure

1. Log in to Red Hat OpenShift Container Platform.
2. Change to the **service-telemetry** namespace:

```
$ oc project service-telemetry
```

3. Edit the ServiceTelemetry object:

```
$ oc edit stf default
```

4. Add the **...storage.strategy: ephemeral** parameter to the **spec** section of the relevant component:

```
apiVersion: infra.watch/v1beta1
kind: ServiceTelemetry
metadata:
  name: stf-default
  namespace: service-telemetry
spec:
  alerting:
    enabled: true
  alertmanager:
    storage:
      strategy: ephemeral
  backends:
    metrics:
      prometheus:
        enabled: true
        storage:
          strategy: ephemeral
    events:
      elasticsearch:
```

```
    enabled: true
    storage:
      strategy: ephemeral
```

- Save your changes and close the object.

## 5.7. CREATING A ROUTE IN RED HAT OPENSHIFT CONTAINER PLATFORM

In Red Hat OpenShift Container Platform, you can expose applications to the external network through a route. For more information, see [Configuring ingress cluster traffic](#).

In Service Telemetry Framework (STF), routes are not exposed by default to limit the attack surface of STF deployments. To access some services deployed in STF, you must expose the services in Red Hat OpenShift Container Platform for access.

A common service to expose in STF is Prometheus, as shown in the following example:

### Procedure

- Log in to Red Hat OpenShift Container Platform.
- Change to the **service-telemetry** namespace:

```
$ oc project service-telemetry
```

- List the available services in the **service-telemetry** project:

```
$ oc get services
NAME          TYPE    CLUSTER-IP   EXTERNAL-IP PORT(S)
AGE
alertmanager-operated   ClusterIP  None        <none>
9093/TCP,9094/TCP,9094/UDP           93m
default-cloud1-ceil-meter-smartgateway ClusterIP  172.30.114.195 <none>     8081/TCP
93m
default-cloud1-coll-meter-smartgateway ClusterIP  172.30.133.180 <none>     8081/TCP
93m
default-interconnect       ClusterIP  172.30.3.241  <none>
5672/TCP,8672/TCP,55671/TCP,5671/TCP,5673/TCP 93m
ibm-auditlogging-operator-metrics   ClusterIP  172.30.216.249 <none>
8383/TCP,8686/TCP               11h
prometheus-operated         ClusterIP  None        <none>     9090/TCP
93m
service-telemetry-operator-metrics ClusterIP  172.30.11.66  <none>
8383/TCP,8686/TCP               11h
smart-gateway-operator-metrics   ClusterIP  172.30.145.199 <none>
8383/TCP,8686/TCP               11h
```

- Take note of the port and service name that you want to expose as a route, for example, service **prometheus-operated** and port **9090**.
- Expose the **prometheus-operated** service as an edge route and redirect insecure traffic to the secure endpoint of port **9090**:

```
$ oc create route edge metrics-store --service=prometheus-operated --insecure-policy="Redirect" --port=9090
route.route.openshift.io/metrics-store created
```

6. To verify and find the exposed external DNS for the route, use the **oc get route** command:

```
$ oc get route metrics-store -o go-template='{{.spec.host}}'
metrics-store-service-telemetry.apps.infra.watch
```

The **prometheus-operated** service is now available at the exposed DNS address, for example, <https://metrics-store-service-telemetry.apps.infra.watch>

#### NOTE

The address of the route must be resolvable and configuration is environment specific.

#### Additional resources

- For more information about Red Hat OpenShift Container Platform networking, see [Understanding networking](#)
- For more information about route configuration, see [Route configuration](#)
- For more information about ingress cluster traffic, see [Configuring ingress cluster traffic overview](#)

# CHAPTER 6. UPGRADING SERVICE TELEMETRY FRAMEWORK TO VERSION 1.4

To migrate from Service Telemetry Framework (STF) v1.3 to STF v1.4, you must replace the **ClusterServiceVersion** and **Subscription** objects in the **service-telemetry** namespace on your Red Hat OpenShift Container Platform environment.

## Prerequisites

- You have upgraded your Red Hat OpenShift Container Platform environment to v4.8. STF v1.4 does not run on Red Hat OpenShift Container Platform versions less than v4.8.
- You have backed up your data. Upgrading STF v1.3 to v1.4 results in a brief outage while the Smart Gateways and other components are updated. Additionally, changes to the **ServiceTelemetry** and **SmartGateway** objects do not have any effect while the Operators are being replaced.

To upgrade from STF v1.3 to v1.4, complete the following procedures:

## Procedure

1. [Remove the STF 1.3 Smart Gateway Operator](#) .
2. [Update the Service Telemetry Operator to 1.4](#) .

## 6.1. REMOVING STF 1.3 SMART GATEWAY OPERATOR

Remove the Smart Gateway Operator from STF 1.3.

## Procedure

1. Log in to Red Hat OpenShift Container Platform.
2. Change to the **service-telemetry** namespace:

```
$ oc project service-telemetry
```

3. Retrieve the **Subscription** name of the Smart Gateway Operator. Replace **service-telemetry** in the selector with the namespace that hosts your STF instance if it is different from the default namespace. Verify that only one subscription is returned:

```
$ oc get sub --selector=operators.coreos.com/smart-gateway-operator.service-telemetry
```

| NAME                                                                     | PACKAGE                | SOURCE           |
|--------------------------------------------------------------------------|------------------------|------------------|
| CHANNEL                                                                  |                        |                  |
| smart-gateway-operator-stable-1.3-redhat-operators-openshift-marketplace | smart-gateway-operator | redhat-operators |
| operator                                                                 | stable-1.3             |                  |

4. Delete the Smart Gateway Operator subscription:

```
$ oc delete sub --selector=operators.coreos.com/smart-gateway-operator.service-telemetry
```

```
subscription.operators.coreos.com "smart-gateway-operator-stable-1.3-redhat-operators-
```

**openshift-marketplace" deleted**

5. Retrieve the Smart Gateway Operator ClusterServiceVersion and verify that only one ClusterServiceVersion is returned:

```
$ oc get csv --selector=operators.coreos.com/smart-gateway-operator.service-telemetry
```

| NAME                                   | DISPLAY                | VERSION        | REPLACES | PHASE |
|----------------------------------------|------------------------|----------------|----------|-------|
| smart-gateway-operator.v3.0.1635451893 | Smart Gateway Operator | 3.0.1635451893 |          |       |
|                                        | Succeeded              |                |          |       |

6. Delete the Smart Gateway Operator ClusterServiceVersion:

```
$ oc delete csv --selector=operators.coreos.com/smart-gateway-operator.service-telemetry
```

```
clusterserviceversion.operators.coreos.com "smart-gateway-operator.v3.0.1635451893"
deleted
```

7. Delete the SmartGateway Custom Resource Definition (CRD). After removal of the CRD, no data flows to STF until the upgrade is completed and the Smart Gateway instances are reinstated:

```
$ oc delete crd smartgateways.smartgateway.infra.watch
```

```
customresourcedefinition.apiextensions.k8s.io "smartgateways.smartgateway.infra.watch"
deleted
```

## 6.2. UPDATING THE SERVICE TELEMETRY OPERATOR TO 1.4

You must change the subscription channel of the Service Telemetry Operator which manages the STF instances to the **stable-1.4** channel.

### Procedure

1. Log in to Red Hat OpenShift Container Platform.

2. Change to the **service-telemetry** namespace:

```
$ oc project service-telemetry
```

3. Patch the Service Telemetry Operator Subscription to use the stable-1.4 channel. Replace the **service-telemetry** in the selector with the namespace that hosts your STF instance if it is different from the default namespace:

```
$ oc patch $(oc get sub --selector=operators.coreos.com/service-telemetry-operator.service-telemetry -o name) --patch '$spec:\n  channel: stable-1.4' --type=merge
```

```
subscription.operators.coreos.com/service-telemetry-operator patched
```

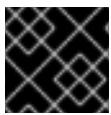

4. Monitor the output of the **oc get csv** command until the Smart Gateway Operator is installed and Service Telemetry Operator moves through the update phases. When the phase changes to **Succeeded**, the Service Telemetry Operator has completed the update:

| NAME<br>REPLACES                                             | DISPLAY<br>PHASE                                           | VERSION |
|--------------------------------------------------------------|------------------------------------------------------------|---------|
| amq7-cert-manager.v1.0.3<br>amq7-cert-manager.v1.0.2         | Red Hat Integration - AMQ Certificate Manager<br>Succeeded | 1.0.3   |
| amq7-interconnect-operator.v1.10.5<br>1.10.5                 | Red Hat Integration - AMQ Interconnect<br>Succeeded        | 1.10.5  |
| elasticsearch-eck-operator-certified.1.9.1                   | Elasticsearch (ECK) Operator<br>Succeeded                  | 1.9.1   |
| prometheusoperator.0.47.0                                    | Prometheus Operator                                        | 0.47.0  |
| prometheusoperator.0.37.0                                    | Succeeded                                                  |         |
| service-telemetry-operator.v1.4.1641504218<br>1.4.1641504218 | Service Telemetry Operator<br>Succeeded                    |         |
| smart-gateway-operator.v4.0.1641504216<br>4.0.1641504216     | Smart Gateway Operator<br>Succeeded                        |         |

5. Validate that all pods are ready and running. Your environment might differ from the following example output:

| NAME                                                    | READY | STATUS  | RESTARTS | AGE   |
|---------------------------------------------------------|-------|---------|----------|-------|
| alertmanager-default-0                                  | 3/3   | Running | 0        | 162m  |
| default-cloud1-ceil-event-smartgateway-5599bcfc9d-wp48n | 2/2   | Running | 1        | 160m  |
| default-cloud1-ceil-meter-smartgateway-c8fdf579c-955kt  | 3/3   | Running | 0        | 160m  |
| default-cloud1-coll-event-smartgateway-97b54b7dc-5zz2v  | 2/2   | Running | 0        | 159m  |
| default-cloud1-coll-meter-smartgateway-774b9988b8-wb5vd | 3/3   | Running | 0        | 160m  |
| default-cloud1-sens-meter-smartgateway-b98966fbf-rnqwf  | 3/3   | Running | 0        | 159m  |
| default-interconnect-675dd97bc4-dcrzk                   | 1/1   | Running | 0        | 171m  |
| default-snmp-webhook-7854d4889d-wgmgg                   | 1/1   | Running | 0        | 171m  |
| elastic-operator-c54ff8cc-jcg8d                         | 1/1   | Running | 6        | 3h55m |
| elasticsearch-es-default-0                              | 1/1   | Running | 0        | 160m  |
| interconnect-operator-6bf74c4ffb-hkmbq                  | 1/1   | Running | 0        | 3h54m |
| prometheus-default-0                                    | 3/3   | Running | 1        | 160m  |
| prometheus-operator-fc64987d-f7gx4                      | 1/1   | Running | 0        | 3h54m |
| service-telemetry-operator-68d888f767-s5kzh             | 1/1   | Running | 0        | 163m  |
| smart-gateway-operator-584df7959-llxgl                  | 1/1   | Running | 0        | 163m  |

## CHAPTER 7. COLLECTD PLUGINS

### IMPORTANT

Red Hat is currently updating the plugin information in this guide for this release.

You can configure multiple collectd plugins depending on your Red Hat OpenStack Platform (RHOSP) 13 environment.

The following list of plugins shows the available heat template **ExtraConfig** parameters that you can set to override the defaults. Each section provides the general configuration name for the **ExtraConfig** option. For example, if there is a collectd plugin called **example\_plugin**, the format of the plugin title is **collectd::plugin::example\_plugin**.

Reference the tables of available parameters for specific plugins, such as in the following example:

**ExtraConfig:**  
collectd::plugin::example\_plugin::<parameter>: <value>

Reference the metrics tables of specific plugins for Prometheus or Grafana queries.

### collectd::plugin::aggregation

You can aggregate several values into one with the **aggregation** plugin. Use the aggregation functions such as **sum**, **average**, **min**, and **max** to calculate metrics, for example average and total CPU statistics.

- collectd::plugin::aggregation::aggregators
- collectd::plugin::aggregation::interval

### collectd::plugin::amqp

#### collectd::plugin::amqp1

Use the **amqp1** plugin to write values to an amqp1 message bus, for example, AMQ Interconnect.

**Table 7.1. amqp1 parameters**

| Parameter      | Type    |
|----------------|---------|
| manage_package | Boolean |
| transport      | String  |
| host           | string  |
| port           | integer |
| user           | String  |
| password       | String  |
| address        | String  |

| Parameter        | Type    |
|------------------|---------|
| instances        | Hash    |
| retry_delay      | Integer |
| send_queue_limit | Integer |
| interval         | Integer |

**Example configuration:**

```

Parameter_defaults:
CollectdExtraPlugins:
- amqp1
ExtraConfig:
collectd::plugin::amqp1::send_queue_limit: 50

```

**collectd::plugin::apache**

Use the **apache** plugin to collect Apache data.

**Table 7.2. apache parameters**

| Parameter               | Type    |
|-------------------------|---------|
| instances               | Hash    |
| interval                | Integer |
| manage-package          | Boolean |
| package_install_options | List    |

**Example configuration:**

```

parameter_defaults:
ExtraConfig:
collectd::plugin::apache:
localhost:
url: "http://10.0.0.111/status?auto"

```

**Additional resources**

For more information about configuring the **apache** plugin, see [apache](#).

**collectd::plugin::battery**

Use the **battery** plugin to report the remaining capacity, power, or voltage of laptop batteries.

**Table 7.3. battery parameters**

| Parameter         | Type    |
|-------------------|---------|
| values_percentage | Boolean |
| report_degraded   | Boolean |
| query_state_fs    | Boolean |
| interval          | Integer |

## Additional resources

For more information about configuring the **battery** plugin, see [battery](#).

### collectd::plugin::bind

Use the **bind** plugin to retrieve encoded statistics about queries and responses from a DNS server. The plugin submits the values to collectd.

### collectd::plugin::ceph

Use the **ceph** plugin to gather data from ceph daemons.

**Table 7.4. ceph parameters**

| Parameter                  | Type    |
|----------------------------|---------|
| daemons                    | Array   |
| longrunavglatency          | Boolean |
| convertspecialmetricatypes | Boolean |
| manage_package             | Boolean |
| package_name               | String  |

## Example configuration:

```
parameter_defaults:
  ExtraConfig:
    collectd::plugin::ceph::daemons:
      - ceph-osd.0
      - ceph-osd.1
      - ceph-osd.2
      - ceph-osd.3
      - ceph-osd.4
```

### NOTE

If an Object Storage Daemon (OSD) is not on every node, you must list the OSDs.

**NOTE**

When you deploy collectd, the **ceph** plugin is added to the Ceph nodes. Do not add the **ceph** plugin on Ceph nodes to **CollectdExtraPlugins**, because this results in a deployment failure.

**Additional resources**

For more information about configuring the **ceph** plugin, see [ceph](#).

**collectd::plugins::cgroups**

Use the **cgroups** plugin to collect information for processes in a cgroup.

**Table 7.5. cgroups parameters**

| Parameter       | Type    |
|-----------------|---------|
| ignore_selected | Boolean |
| interval        | Integer |
| cgroups         | List    |

**Additional resources**

For more information about configuring the **cgroups** plugin, see [cgroups](#).

**collectd::plugin::connectivity**

Use the connectivity plugin to monitor the state of network interfaces.

**NOTE**

If no interfaces are listed, all interfaces are monitored by default.

**Table 7.6. connectivity parameters**

| Parameter  | Type  |
|------------|-------|
| interfaces | Array |

**Example configuration:**

```
parameter_defaults:
  ExtraConfig:
    collectd::plugin::connectivity::interfaces:
      - eth0
      - eth1
```

**Additional resources**

For more information about configuring the **connectivity** plugin, see [connectivity](#).

## collectd::plugin::conntrack

Use the **conntrack** plugin to track the number of entries in the Linux connection-tracking table. There are no parameters for this plugin.

## collectd::plugin::contextswitch

Use the **ContextSwitch** plugin to collect the number of context switches that the system handles.

### Additional resources

For more information about configuring the **contextswitch** plugin, see [contextswitch](#).

## collectd::plugin::cpu

Use the **cpu** plugin to monitor the time that the CPU spends in various states, for example, idle, executing user code, executing system code, waiting for IO-operations, and other states.

The **cpu** plugin collects **\_jiffies**, not percentage values. The value of a jiffy depends on the clock frequency of your hardware platform, and therefore is not an absolute time interval unit.

To report a percentage value, set the Boolean parameters **reportbycpu** and **reportbystate** to **true**, and then set the Boolean parameter **valuespercentage** to true.

**Table 7.7. cpu metrics**

| Name      | Description                                                                                                           | Query                                           |
|-----------|-----------------------------------------------------------------------------------------------------------------------|-------------------------------------------------|
| idle      | Amount of idle time                                                                                                   | collectd_cpu_total{...,type_instance=idle}      |
| interrupt | CPU blocked by interrupts                                                                                             | collectd_cpu_total{...,type_instance=interrupt} |
| nice      | Amount of time running low priority processes                                                                         | collectd_cpu_total{...,type_instance=nice}      |
| softirq   | Amount of cycles spent in servicing interrupt requests                                                                | collectd_cpu_total{...,type_instance=waitirq}   |
| steal     | The percentage of time a virtual CPU waits for a real CPU while the hypervisor is servicing another virtual processor | collectd_cpu_total{...,type_instance=steal}     |
| system    | Amount of time spent on system level (kernel)                                                                         | collectd_cpu_total{...,type_instance=system}    |
| user      | Jiffies that user processes use                                                                                       | collectd_cpu_total{...,type_instance=user}      |
| wait      | CPU waiting on outstanding I/O request                                                                                | collectd_cpu_total{...,type_instance=wait}      |

**Table 7.8. cpu parameters**

| Parameter          | Type    |
|--------------------|---------|
| reportbystate      | Boolean |
| valuespercentage   | Boolean |
| reportbycpu        | Boolean |
| reportnumcpu       | Boolean |
| reportgueststate   | Boolean |
| subtractgueststate | Boolean |
| interval           | Integer |

### Example configuration:

```

parameter_defaults:
  CollectdExtraPlugins:
    - cpu
  ExtraConfig:
    collectd::plugin::cpu::reportbystate: true

```

### Additional resources

For more information about configuring the **cpu** plugin, see [cpu](#).

### collectd::plugin::cpufreq

- None

### collectd::plugin::cpusleep

### collectd::plugin::csv

- collectd::plugin::csv::datadir
- collectd::plugin::csv::storerates
- collectd::plugin::csv::interval

### collectd::plugin::curl\_json

### collectd::plugin::curl

### collectd::plugin::curl\_xml

### collectd::plugin::dbi

### collectd::plugin::df

Use the **df** plugin to collect disk space usage information for file systems.

Table 7.9. df metrics

| Name     | Description                   | Query                                                 |
|----------|-------------------------------|-------------------------------------------------------|
| free     | Amount of free disk space     | collectd_df_df_complex{..., type_instance="free"}     |
| reserved | Amount of reserved disk space | collectd_df_df_complex{..., type_instance="reserved"} |
| used     | Amount of used disk space     | collectd_df_df_complex{..., type_instance="used"}     |

**Table 7.10. df parameters**

| Parameter        | Type    |
|------------------|---------|
| devices          | Array   |
| fstypes          | Array   |
| ignoreselected   | Boolean |
| mountpoints      | Array   |
| reportbydevice   | Boolean |
| reportinodes     | Boolean |
| reportreserved   | Boolean |
| valuesabsolute   | Boolean |
| valuespercentage | Boolean |

**Example configuration:**

```

parameter_defaults:
  CollectdExtraPlugins:
    - df
  ExtraConfig:
    collectd::plugin::df::FStype: "ext4"

```

**Additional resources**

For more information about configuring the **df** plugin, see [df](#).

**collectd::plugin::disk**

Use the **disk** plugin to collect performance statistics of hard disks and, if supported, partitions. This plugin is enabled by default.

**Table 7.11. disk parameters**

| Parameter      | Type    |
|----------------|---------|
| disks          | Array   |
| ignoreselected | Boolean |
| udevnameattr   | String  |

**Table 7.12. disk metrics**

| Name               | Description                                                                                                                                                   |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| merged             | The number of operations that can be merged together, already queued operations, for example, one physical disk access served two or more logical operations. |
| time               | The average time an I/O-operation takes to complete. The values might not be fully accurate.                                                                  |
| io_time            | Time spent doing I/Os (ms). You can use this metric as a device load percentage. A value of 1 second matches 100% of load.                                    |
| weighted_io_time   | Measure of both I/O completion time and the backlog that might be accumulating.                                                                               |
| pending_operations | Shows queue size of pending I/O operations.                                                                                                                   |

**Example configuration:**

```

parameter_defaults:
  ExtraConfig:
    collectd::plugin::disk::disk: "sda"
    collectd::plugin::disk::ignoreselected: false
  
```

**Additional resources**

For more information about configuring the **disk** plugin, see [disk](#).

- collectd::plugin::hddtemp::port
- collectd::plugin::hddtemp::interval

### **collectd::plugin::hugepages**

Use the hugepages plugin to collect hugepages information. This plugin is enabled by default.

**Table 7.13. hugepages parameters**

| Parameter          | Type    | Defaults |
|--------------------|---------|----------|
| report_per_node_hp | Boolean | true     |
| report_root_hp     | Boolean | true     |
| values_pages       | Boolean | true     |
| values_bytes       | Boolean | false    |

| Parameter         | Type    | Defaults |
|-------------------|---------|----------|
| values_percentage | Boolean | false    |

### Example configuration:

```
parameter_defaults:
  ExtraConfig:
    collectd::plugin::hugepages::values_percentage: true
```

### Additional resources

- For more information about configuring the **hugepages** plugin, see [hugepages](#).

### collectd::plugin::intel\_rdt

### collectd::plugin::interface

Use the **interface** plugin to measure interface traffic in octets, packets per second, and error rate per second. This plugin is enabled by default.

Table 7.14. interface parameters

| Parameter      | Type           |
|----------------|----------------|
| Default        | interfaces     |
| Array          | []             |
| ignoreselected | Boolean        |
| false          | reportinactive |
| Boolean        | true           |

### Example configuration:

```
parameter_defaults:
  ExtraConfig:
    collectd::plugin::interface::interfaces:
      - lo
    collectd::plugin::interface::ignoreselected: true
```

### Additional resources

- For more information about configuring the **interfaces** plugin, see [interfaces](#).

### collectd::plugin::ipc

- None

## collectd::plugin::ipmi

- collectd::plugin::ipmi::ignore\_selected
- collectd::plugin::ipmi::notify\_sensor\_add
- collectd::plugin::ipmi::notify\_sensor\_remove
- collectd::plugin::ipmi::notify\_sensor\_not\_present
- collectd::plugin::ipmi::sensors
- collectd::plugin::ipmi::interval

## collectd::plugin::iptables

### collectd::plugin::irq

- collectd::plugin::irq::irqs
- collectd::plugin::irq::ignoreselected
- collectd::plugin::irq::interval

## collectd::plugin::load

Use the **load** plugin to collect the system load and an overview of the system use. This plugin is enabled by default.

**Table 7.15. plugin parameters**

| Parameter       | Type    |
|-----------------|---------|
| report_relative | Boolean |

### Example configuration:

```
parameter_defaults:
  ExtraConfig:
    collectd::plugin::load::report_relative: false
```

### Additional resources

- For more information about configuring the **load** plugin, see [load](#).

## collectd::plugin::logfile

- collectd::plugin::logfile::log\_level
- collectd::plugin::logfile::log\_file
- collectd::plugin::logfile::log\_timestamp
- collectd::plugin::logfile::print\_severity
- collectd::plugin::logfile::interval

**collectd::plugin::log\_logstash**  
**collectd::plugin::madwifi**  
**collectd::plugin::match\_empty\_counter**  
**collectd::plugin::match\_hashed**  
**collectd::plugin::match\_regex**  
**collectd::plugin::match\_timediff**  
**collectd::plugin::match\_value**  
**collectd::plugin::mbmon**  
**collectd::plugin::mcelog**

Use the **mcelog** plugin to send notifications and statistics that are relevant to Machine Check Exceptions when they occur. Configure **mcelog** to run in daemon mode and enable logging capabilities.

Table 7.16. mcelog parameters

| Parameter  | Type                                                                 |
|------------|----------------------------------------------------------------------|
| Mcelogfile | String                                                               |
| Memory     | Hash { mcelogclientsocket[string], persistentnotification[boolean] } |

#### Example configuration:

```

parameter_defaults:
  CollectdExtraPlugins: mcelog
  CollectdEnableMcelog: true

```

#### Additional resources

- For more information about configuring the **mcelog** plugin, see [mcelog](#).

- collectd::plugin::openvpn::collectusercount
- collectd::plugin::openvpn::interval

### **collectd::plugin::ovs\_stats**

Use the **ovs\_stats** plugin to collect statistics of OVS-connected interfaces. The **ovs\_stats** plugin uses the OVSDB management protocol (RFC7047) monitor mechanism to get statistics from OVSDB.

**Table 7.18. ovs\_stats parameters**

| Parameter | Type    |
|-----------|---------|
| address   | String  |
| bridges   | List    |
| port      | Integer |
| socket    | String  |

#### **Example configuration:**

The following example shows how to enable the **ovs\_stats** plugin. If you deploy your overcloud with OVS, you do not need to enable the **ovs\_stats** plugin.

```
parameter_defaults:
  CollectedExtraPlugins:
    - ovs_stats
  ExtraConfig:
    collectd::plugin::ovs_stats::socket: '/run/openvswitch/db.sock'
```

## Additional resources

- For more information about configuring the **ovs\_stats** plugin, see [ovs\\_stats](#).

### collectd::plugin::pcie\_errors

Use the **pcie\_errors** plugin to poll PCI config space for baseline and Advanced Error Reporting (AER) errors, and to parse syslog for AER events. Errors are reported through notifications.

**Table 7.19. pcie\_errors parameters**

| Parameter                | Type               |
|--------------------------|--------------------|
| source                   | Enum (sysfs, proc) |
| access                   | String             |
| reportmasked             | Boolean            |
| persistent_notifications | Boolean            |

#### Example configuration:

```
parameter_defaults:
  CollectdExtraPlugins:
    - pcie_errors
```

## Additional resources

- For more information about configuring the **pcie\_errors** plugin, see [pcie\\_errors](#).

### collectd::plugin::ping

- collectd::plugin::ping::hosts
- collectd::plugin::ping::timeout
- collectd::plugin::ping::ttl
- collectd::plugin::ping::source\_address
- collectd::plugin::ping::device
- collectd::plugin::ping::max\_missed
- collectd::plugin::ping::size
- collectd::plugin::ping::interval

### collectd::plugin::powerdns

- collectd::plugin::powerdns::interval
- collectd::plugin::powerdns::servers

- collectd::plugin::powerdns::recursors
- collectd::plugin::powerdns::local\_socket
- collectd::plugin::powerdns::interval

## collectd::plugin::processes

The **processes** plugin provides information about system processes. This plugin is enabled by default.

**Table 7.20. plugin parameters**

| Parameter               | Type    |
|-------------------------|---------|
| processes               | Array   |
| process_matches         | Array   |
| collect_context_switch  | Boolean |
| collect_file_descriptor | Boolean |
| collect_memory_maps     | Boolean |

### Additional resources

- For more information about configuring the **processes** plugin, see [processes](#).

## collectd::plugin::protocols

- collectd::plugin::protocols::ignoreselected
- collectd::plugin::protocols::values

## collectd::plugin::python

## collectd::plugin::sensors

## collectd::plugin::serial

## collectd::plugin::smart

- collectd::plugin::smart::disks
- collectd::plugin::smart::ignoreselected
- collectd::plugin::smart::interval

## collectd::plugin::snmp

## collectd::plugin::snmp\_agent

Use the **snmp\_agent** plugin as an SNMP subagent to map collectd metrics to relevant OIDs. The snmp agent also requires a running snmpd service.

### Example configuration:

```
parameter_defaults:
  CollectdExtraPlugins:
```

```
snmp_agent
resource_registry:
  OS::TripleO::Services::Snmp: /usr/share/openstack-tripleo-heat-
  templates/deployment/snmp/snmp-baremetal-puppet.yaml
```

## Additional resources:

For more information about how to configure **snmp\_agent**, see [snmp\\_agent](#).

### collectd::plugin::statsd

- collectd::plugin::statsd::host
- collectd::plugin::statsd::port
- collectd::plugin::statsd::deletecounters
- collectd::plugin::statsd::deletetimers
- collectd::plugin::statsd::deletegauges

- collectd::plugin::uuid::interval

**collectd::plugin::virt**

Use the **virt** plugin to collect CPU, disk, network load, and other metrics through the **libvirt** API for virtual machines on the host.

**Table 7.21. virt parameters**

| Parameter              | Type    |
|------------------------|---------|
| connection             | String  |
| refresh_interval       | Hash    |
| domain                 | String  |
| block_device           | String  |
| interface_device       | String  |
| ignore_selected        | Boolean |
| plugin_instance_format | String  |
| hostname_format        | String  |

| Parameter        | Type   |
|------------------|--------|
| interface_format | String |
| extra_stats      | String |

### Example configuration:

```
ExtraConfig:
  collectd::plugin::virt::plugin_instance_format: name
```

### Additional resources

For more information about configuring the **virt** plugin, see [virt](#).

## collectd::plugin::vmem

## collectd::plugin::vserver

## collectd::plugin::wireless

## collectd::plugin::write\_graphite

- `collectd::plugin::write_graphite::carbons`
- `collectd::plugin::write_graphite::carbon_defaults`
- `collectd::plugin::write_graphite::globals`

## collectd::plugin::write\_http

Use the **write\_http** output plugin to submit values to an HTTP server by using POST requests and encoding metrics with JSON, or by using the **PUTVAL** command.

Table 7.22. `write_http` parameters

| Parameter                   | Type                               |
|-----------------------------|------------------------------------|
| <code>ensure</code>         | Enum[ <i>present, absent</i> ]     |
| <code>nodes</code>          | Hash[String, Hash[String, Scalar]] |
| <code>urls</code>           | Hash[String, Hash[String, Scalar]] |
| <code>manage_package</code> | Boolean                            |

### Example configuration:

```
parameter_defaults:
  CollectdExtraPlugins:
```

```

- write_http
ExtraConfig:
  collectd::plugin::write_http::nodes:
    collectd:
      url: "http://collectd.tld.org/collectd"
      metrics: true
      header: "X-Custom-Header: custom_value"

```

## Additional resources

- For more information about configuring the **write\_http** plugin, see [write\\_http](#).

## collectd::plugin::write\_kafka

Use the **write\_kafka** plugin to send values to a Kafka topic. Configure the **write\_kafka** plugin with one or more topic blocks. For each topic block, you must specify a unique name and one Kafka producer. You can use the following per-topic parameters inside the topic block:

**Table 7.23. write\_kafka parameters**

| Parameter   | Type          |
|-------------|---------------|
| kafka_hosts | Array[String] |
| kafka_port  | Integer       |
| topics      | Hash          |
| properties  | Hash          |
| meta        | Hash          |

## Example configuration:

```

parameter_defaults:
  CollectdExtraPlugins:
    - write_kafka
  ExtraConfig:
    collectd::plugin::write_kafka::kafka_hosts:
      - nodeA
      - nodeB
    collectd::plugin::write_kafka::topics:
      some_events:
        format: JSON

```

## Additional resources:

For more information about how to configure the **write\_kafka** plugin, see [write\\_kafka](#).
