8.4.1. Replace an existing Application Credential	35
8.4.1.1. For configuration files	35
8.4.1.2. For clouds.yaml files	35

# PREFACE

As a cloud administrator, you can manage projects, users, and roles. Projects are organizational units in the cloud to which you can assign users. Projects(tenants) are also known as accounts. Users can be members of one or more projects. Roles define the actions that users can perform.

Each OpenStack deployment must include at least one project, one user, and one role, linked together. As a cloud administrator, you can add, update, and delete projects and users, assign users to one or more projects, and change or remove these assignments. You can manage projects and users independently from each other.

You can also configure user authentication with the Keystone identity service to control access to services and endpoints. Keystone provides token-based authentication and can integrate with LDAP and Active Directory, so you can manage users and identities externally and synchronize the user data with Keystone.

### NOTE

Keystone v2 was deprecated in Red Hat OpenStack Platform 11 (Ocata). It was removed in Red Hat OpenStack Platform 13 (Queens), leaving only Keystone v3 available.

# **CHAPTER 1. USER MANAGEMENT**

# **1.1. USER MANAGEMENT**

As a cloud administrator, you can add, modify, and delete users in the dashboard. Users can be members of one or more projects. You can manage projects and users independently from each other.

## 1.1.1. Create a User

Use this procedure to create users in the dashboard. You can assign a primary project and role to the user. Note that users created in the dashboard are Keystone users by default. To integrate Active Directory users, you can configure the LDAP provider included in the Red Hat OpenStack Platform Identity service.

- 1. As an admin user in the dashboard, select **Identity > Users**
- 2. Click Create User.
- 3. Enter a user name, email, and preliminary password for the user.
- 4. Select a project from the Primary Project list.
- 5. Select a role for the user from the **Role** list (the default role is **\_member\_**).
- 6. Click Create User.

#### 1.1.2. Edit a User

Use this procedure to update the user's details, including the primary project.

- 1. As an admin user in the dashboard, select Identity > Users
- 2. In the User's Actions column, click Edit.
- 3. In the Update User window, you can update the User Name, Email, and Primary Project.
- 4. Click Update User.

### 1.1.3. Enable or Disable a User

Use this procedure to enable or disable a user. You can disable or enable only one user at a time. A disabled user cannot log in to the dashboard, and does not have access to any OpenStack services. Also, a disabled user's primary project cannot be set as active. A disabled user can be enabled again, unlike deleting a user where the action cannot be reversed. A disabled user must be re-enabled for any user-project action in the dashboard.

- 1. As an admin user in the dashboard, select Identity > Users
- 2. In the Actions column, click the arrow, and select Enable User or Disable User. In the Enabled column, the value then updates to either **True** or **False**.

### 1.1.4. Delete a User

As an admin user, use this procedure to delete a user using the dashboard. This action cannot be reversed, unlike disabling a user. Deleted users get delisted from a project's members' list for projects it belongs to. All roles associated with the user-project pair are also lost.

- 1. As an admin user in the dashboard, select **Identity > Users**
- 2. Select the users you want to delete.
- 3. Click **Delete Users**. The **Confirm Delete Users** window is displayed.
- 4. Click **Delete Users** to confirm the action.

# CHAPTER 2. ROLE MANAGEMENT

# 2.1. ROLE MANAGEMENT

OpenStack uses a role-based access control (RBAC) mechanism to manage access to its resources. Roles define which actions users can perform. By default, there are two predefined roles: a member role that gets attached to a project, and an administrative role to enable non-admin users to administer the environment. Note that there are abstract levels of permission, and it is possible to create the roles the administrator needs, and configure services adequately.

## 2.1.1. View Roles

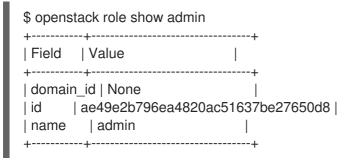

Use the following command to list the available predefined roles.

\$ openstack role list +-----+ | ID | Name | +-----+ | 4fd37c2c993a4acab8e1b5896afb8687 | SwiftOperator | | 9fe2ff9ee4384b1894a90878d3e92bab | \_member\_ | | a0f19c1381c54770ae068456c4411d82 | ResellerAdmin | | ae49e2b796ea4820ac51637be27650d8 | admin | +-----+

To get details for a specified role, run:

\$ openstack role show admin

### Example

# 2.1.2. Create and Assign a Role

As a cloud administrator, you can create and manage roles on the Keystone client using the following set of commands. Each OpenStack deployment must include at least one project, one user, and one role, linked together. However, users can be members of multiple projects. To assign users to multiple projects, create a role and assign that role to a user-project pair. Note that you can create a user and assign a primary project and default role in the dashboard.

### NOTE

Either the name or ID can be used to specify users, roles, or projects.

1. Create the **new-role** role:

\$ openstack role create [ROLE\_NAME]

#### Example

\$ openstack role create new-role
++
Field   Value
++
domain_id   None
id   880c116b6a55464b99ca8d8d8fe26743
name new-role
++

- 2. To assign a user to a project, you must assign the role to a user-project pair. To do this, obtain the user, role, and project names or IDs:
  - a. List users:

- .
- b. List roles:

c. List projects:

3. Assign a role to a user-project pair.

openstack role add --project [PROJECT\_NAME] --user [USER\_ID] [ROLE\_ID]

#### Example

In this example, you assign the **admin** role to the **admin** user in the **demo** project:

\$ openstack role add --project demo --user 895e43465b9643b9aa29df0073572bb2 ae49e2b796ea4820ac51637be27650d8

4. Verify the role assignment for the user **admin**:

\$ openstack role assignment list --user [USER\_ID] --project [PROJECT\_ID]

#### Example

<pre>\$ openstack role demo</pre>	assignment listuser	895e43465b9643b9aa29df00735	72bb2project
+		+++	
Role Inherited	User	Group   Project	Domain
+	+	+++	

# 2.2. IMPLIED ROLES AND DOMAIN-SPECIFIC ROLES

## 2.2.1. Implied roles

In OpenStack, access control is enforced by confirming that a user is assigned to a specific role. Until recently, those roles had to be explicitly assigned to either a user, or to a group in which the user was a member. Identity Service (keystone) has now added the concept of implied role assignments: If a user is explicitly assigned to a role, then the user could be implicitly assigned to additional roles as well.

## 2.2.2. Inference Rules

Implied assignment is managed by role inference rules. An inference rule is written in the form **superior implies subordinate**. For example, a rule might state that the **admin** role implies the **\_member\_** role. As a result, a user assigned to **admin** for a project would implicitly be assigned to the **\_member\_** role as well.

With *implied roles*, a user's role assignments are processed cumulatively, allowing the user to inherit the subordinate roles. This result is dependent on an inference rule being created that specifies this outcome.

### 2.2.2.1. Keystone Configuration

For keystone to observe implied roles, the **infer\_roles** setting must be enabled in */etc/keystone/keystone.conf*:

[token] infer\_roles = true

Implied roles are governed by a defined set of inference rules. These rules determine how a role assignment can result in the implied membership of another role. See Section 2.2.3.1, "Demonstration of Implied Roles" for an example.

## 2.2.3. Prevent Certain Roles From Being Implied

You can prevent certain roles from being implied onto a user. For example, in */etc/keystone/keystone.conf*, you can add a **ListOpt** of roles:

[assignment] prohibited\_implied\_role = admin

This will prevent a user from ever being assigned a role implicitly. Instead, the user will need to be explicitly granted access to that role.

### 2.2.3.1. Demonstration of Implied Roles

This section describes how to create an inference rule, resulting in an implied role. These rules control how one role can imply membership of another. The example rule used in the following procedure will imply that members of the **admin** role also have **\_\_member\_\_** access:

#### 2.2.3.1.1. Assign a Role to the User

1. Retrieve the ID of a user that will have the **\_member\_** role implied. For example:

\$ openstack	user show User1	
+	+   Value	+ 
+	+	+
domain_id	default	
enabled	True	
id	ce803dd127c94	489199c89ce3b68d39b4
name	User1	
options	{}	
password_e	expires_at   None	
+	+	+

2. Retrieve the ID of the **demo** project:

\$ openstack project show demo
++   Field   Value
++
description   default tenant
domain_id   default
enabled   True
id   2717ebc905e449b5975449c370edac69
is_domain   False
name   demo
parent_id   default
++

3. Retrieve the ID of the **admin** role:

•	stack role sh			
Field	Value			
domai   id	n_id   None   9b821b293   admin	20544be7a4	.d8f71fa9   	9fcd35

4. Give the **User1** user **admin** privileges to the **demo** project:

\$ openstack role add --user User1 --project demo admin

5. Confirm the **admin** role assignment:

\$ openstack role assignment list --user User1 --project demo --effective
+-----+

++	+		
Role	User	Group   Project	Domain
Inherited	·		
+	+	++++	
++	+		
9b821b292054	4be7a4d8f71fa99fcd35	5   ce803dd127c9489199c89ce3b6	68d39b4
2717ebc905e44	9b5975449c370edac6	9   False	
+	+	+++	
++	+		

#### 2.2.3.1.2. Create the Inference Rule

Now that you have granted the **admin** role to User1, run the following steps to create the inference rule:

1. First, confirm User1's current role membership:

	0	User1project demoeffective	
++   Role Inherited		Group   Project	Domain
+++   9b821b2920544	+	++++	
	+	+++	

2. Retrieve the list of role IDs:

\$ openstack ro		
+   ID	+   Name	+ 
9b821b2920   9fe2ff9ee438   ea199fe4293   fe8eba5dfd1		cd35   admin   2bab   _member_   17b95   ResellerAdmin   995e   SwiftOperator

3. Create the inference rule. These are currently created using **curl**. This example uses the IDs of the roles returned in the previous step. It also runs the command using the **admin\_token** in *keystone.conf*:

#### source overcloudrc

export OS\_TOKEN=`grep ^admin\_token /etc/keystone/keystone.conf | awk -F'=' '{print \$2}'` curl -X PUT -H "X-Auth-Token: \$OS\_TOKEN" -H "Content-type: application/json" \$OS\_AUTH\_URL/roles/9b821b2920544be7a4d8f71fa99fcd35/implies/9fe2ff9ee4384b1894a90 878d3e92bab

4. Review the results using the CLI. In this example, User1 has received implied access to the **\_\_member\_** role, as indicated by ID **9fe2ff9ee4384b1894a90878d3e92bab**:

source overcloudrc

+   Role Inherited	+   User	Group   Project	Domain
+	+	+++	
1	•	ce803dd127c9489199c89ce3b6 9           False	68d39b4
	1894a90878d3e92bab 9b5975449c370edac69	ce803dd127c9489199c89ce3b6     False	68d39b4

5. Review your inference rules using curl:

```
source overcloudrc
export OS TOKEN=`grep ^admin token /etc/keystone/keystone.conf | awk -F'=' '{print $2}'`
curl -s -H "X-Auth-Token: $OS TOKEN" $OS AUTH URL/role inferences | python -
mison.tool
{
  "role_inferences": [
     ł
       "implies": [
          {
            "id": "9fe2ff9ee4384b1894a90878d3e92bab",
            "links": {
               "self":
"https://osp.lab.local:5000/v3/roles/9fe2ff9ee4384b1894a90878d3e92bab"
            },
            "name": "_member_"
          }
       ],
       "prior_role": {
          "id": "9b821b2920544be7a4d8f71fa99fcd35",
          "links": {
            "self": "https://osp.lab.local:5000/v3/roles/9b821b2920544be7a4d8f71fa99fcd35"
          },
          "name": "admin"
       }
     }
  ]
}
```

## 2.2.4. Domain-Specific Roles

Domain-specific roles grant you more granular control when defining rules for roles, allowing the roles to act as aliases for the existing *prior* roles. Note that you cannot have a global role implying a domain-specific role. As a result, if you list the effective role assignments of a user in a project, the domain-specific roles will not be present.

Domain-specific roles can be created by a user who administers their keystone domain; they do not have to be administrators of the OpenStack deployment. This means that a domain-specific role definition can be limited to a specific domain.

## NOTE

Domain-specific roles cannot be used to scope a token. This can only be done with global roles.

#### 2.2.4.1. Using Domain-Specific Roles

This example describes how to create a domain specific role and review its effect.

1. Create a domain:

\$ openstack domain create corp01

2. Create a role that specifies a domain (note that this parameter is distinct from --domain):

\$ openstack role create operators --role-domain domain-corp01

# **CHAPTER 3. GROUP MANAGEMENT**

# **3.1. MANAGE KEYSTONE GROUPS**

## 3.1.1. Using the Command-line

You can use Identity Service (keystone) groups to assign consistent permissions to multiple user accounts. This example creates a group and then assigns permissions to the group. As a result, members of the group will inherit the same permissions that were assigned to the group:

#### NOTE

The openstack group subcommands require keystone v3.

1. Create the group grp-Auditors:

\$ openstack group create grp-Auditors
++
Field   Value
++
description
domain_id   default
id   2a4856fc242142a4aa7c02d28edfdfff
name   grp-Auditors
++

2. View a list of keystone groups:

\$ openstack group list	long		
+		-	
ID	Name	Domain ID	Description
+	•	•	
2a4856fc242142a4a		101	
+	+	+	F+

3. Grant the **grp-Auditors** group permission to access the **demo** project, while using the **\_\_member\_** role:

\$ openstack role add \_member\_ --group grp-Auditors --project demo

4. Add the existing user **user1** to the **grp-Auditors** group:

5. Confirm that **user1** is a member of **grp-Auditors**:

\$ openstack group contains user grp-Auditors user1
user1 in group grp-Auditors

6. Review the effective permissions that have been assigned to **user1**:

\$ openstack role a	ssignment listeffec	tiveuser user1	
+	+	+++	
++	·+		
Role Inherited	User	Group   Project	Domain
+	++	+++	
++	·+		
1	894a90878d3e92bab 8983bed2a568fa832	9   3fefe5b4f6c948e6959d1feaef4822f2       False	I
+	+	+++	
++	·+		

## 3.1.2. Using Dashboard

You can use the dashboard to manage the membership of keystone groups. You will need to use the command-line to assign role permissions to a group, as covered in the previous example.

#### 3.1.2.1. Create a Group

- 1. As an admin user in the dashboard, select Identity > Groups
- 2. Click +Create Group.
- 3. Enter a name and description for the group.
- 4. Click Create Group.

#### 3.1.2.2. Manage Group Membership

You can use the dashboard to manage the membership of keystone groups.

- 1. As an admin user in the dashboard, select Identity > Groups
- 2. Click Manage Members for the group you need to edit.
- 3. Use **Add users** to add a user to the group. If you need to remove a user, mark its checkbox and click or **Remove users**.

# CHAPTER 4. QUOTA MANAGEMENT

# 4.1. QUOTA MANAGEMENT

As a cloud administrator, you can set and manage quotas for a project. Each project is allocated resources, and project users are granted access to consume these resources. This enables multiple projects to use a single cloud without interfering with each other's permissions and resources. A set of resource quotas are preconfigured when a new project is created. The quotas include the amount of VCPUs, instances, RAM, floating IPs, that can be assigned to projects. Quotas can be enforced at both the project and the project-user level. Note that you can set or modify Compute and Block Storage quotas for new and existing projects using the dashboard. See Chapter 5, *Project Management* for the procedure on how to set and update project quotas within the dashboard.

## 4.1.1. View Compute Quotas for a User

Run the following command to list the currently set quota values for a user:

\$ nova quota-show --user [USER] --tenant [TENANT]

#### Example

\$ nova quota-show --user demoUser --tenant demo

+	++
Quota	Limit
+	+
instances	10
cores	20
ram	51200
floating_ips	5
fixed_ips	-1
metadata_items	128
injected_files	5
injected_file_conte	ent_bytes   10240
injected_file_path_	_bytes   255
key_pairs	100
security_groups	10
security_group_ru	les  20
server_groups	10
server_group_mer	mbers  10
+	+

## 4.1.2. Update Compute Quotas for a User

Run the following commands to update a particular quota value:

```
$ nova quota-update --user [USER] --[QUOTA_NAME] [QUOTA_VALUE] [TENANT]
$ nova quota-show --user [USER] --tenant [TENANT]
```

#### Example

```
$ nova quota-update --user demoUser --floating-ips 10 demo
$ nova quota-show --user demoUser --tenant demo
```

+	+
Quota	Limit
+	+
instances	10
cores	20
ram	51200
floating_ips	10
+	+

## NOTE

To view a list of options for the quota-update command, run:

\$ nova help quota-update

## 4.1.3. Set Object Storage Quotas for a User

Object Storage quotas can be classified under the following categories:

- Container quotas Limits the total size (in bytes) or number of objects that can be stored in a single container.
- Account quotas Limits the total size (in bytes) that a user has available in the Object Storage service.

To set either container quotas or the account quotas, the Object Storage proxy server must have the parameters **container\_quotas** or **account\_quotas** (or both) added to the **[pipeline:main]** section of the **proxy-server.conf** file:

[pipeline:main] pipeline = catch\_errors [...] tempauth container-quotas \ account-quotas slo dlo proxy-logging proxy-server

[filter:account\_quotas] use = egg:swift#account\_quotas

[filter:container\_quotas] use = egg:swift#container\_quotas

Use the following command to view and update the Object Storage quotas. All users included in a project can view the quotas placed on the project. To update the Object Storage quotas on a project, you must have the role of a ResellerAdmin in the project.

To view account quotas:

# swift stat Account: AUTH\_b36ed2d326034beba0a9dd1fb19b70f9 Containers: 0 Objects: 0 Bytes: 0 Meta Quota-Bytes: 214748364800

X-Timestamp: 1351050521.29419 Content-Type: text/plain; charset=utf-8 Accept-Ranges: bytes

To update quotas:

# swift post -m quota-bytes:<BYTES>

For example, to place a 5 GB quota on an account:

# swift post -m quota-bytes:5368709120

To verify the quota, run the swift stat command again:

# swift stat

Account: AUTH\_b36ed2d326034beba0a9dd1fb19b70f9 Containers: 0 Objects: 0 Bytes: 0 Meta Quota-Bytes: 5368709120 X-Timestamp: 1351541410.38328 Content-Type: text/plain; charset=utf-8 Accept-Ranges: bytes

# **CHAPTER 5. PROJECT MANAGEMENT**

# **5.1. PROJECT MANAGEMENT**

As a cloud administrator, you can create and manage projects (tenants). A tenant describes a project with an assigned number of OpenStack users and resources. It is possible to set up quotas for each tenant. This enables multiple projects to use a single cloud without interfering with each other's permissions and resources. The words project and tenant are used interchangeably. Users can be associated with more than one project. Each user-project pairing must have a role associated with it.

## 5.1.1. Create a Project

Use this procedure to create projects, add members to the project, and set resource limits for the project.

- 1. As an admin user in the dashboard, select Identity > Projects
- 2. Click Create Project.
- 3. On the **Project Information** tab, enter a name and description for the project (the **Enabled** check box is selected by default).
- 4. On the Project Members tab, add members to the project from the All Users list.
- 5. On the **Quotas** tab, specify resource limits for the project.
- 6. Click Create Project.

## 5.1.2. Edit a Project

You can edit a project to change its name or description, enable or temporarily disable it, or update its members.

- 1. As an admin user in the dashboard, select Identity > Projects
- 2. In the project's Actions column, click the arrow, and click Edit Project.
- 3. In the **Edit Project** window, you can update a project to change its name or description, and enable or temporarily disable the project.
- 4. On the **Project Members** tab, add members to the project, or remove them as needed.
- 5. Click Save.

#### NOTE

The **Enabled** check box is selected by default. To temporarily disable the project, clear the **Enabled** check box. To enable a disabled project, select the **Enabled** check box.

### 5.1.3. Delete a Project

- 1. As an admin user in the dashboard, select Identity > Projects
- 2. Select the project you want to delete.

- 3. Click Delete Projects. The Confirm Delete Projects window is displayed.
- 4. Click **Delete Projects** to confirm the action.

The project gets deleted and any user pairing will be disassociated.

### 5.1.4. Update Project Quotas

Quotas are operational limits that can be set per project to optimize cloud resources. You can set quotas to prevent project resources from being exhausted without notification. Quotas can be enforced at both the project and the project-user level.

- 1. As an admin user in the dashboard, select Identity > Projects
- 2. In the project's Actions column, click the arrow, and click Modify Quotas.
- 3. In the **Quota** tab, modify project quotas as needed.
- 4. Click Save.

### 5.1.5. Change Active Project

A user can set a project as the active project only of which they are a member. It is also necessary for the user to be a member of more than one project to have the **Set as Active Project** option be enabled. Setting a project as an active project enables you to access objects in the dashboard for the active project. Note that a disabled project cannot be set as active, unless it is re-enabled.

- 1. As an admin user in the dashboard, select **Identity > Projects**
- 2. In the project's Actions column, click the arrow, and click Set as Active Project
- 3. Alternatively, as a non-admin user, in the project's **Actions** column, click **Set as Active Project** which becomes the default action in the column.

# **5.2. PROJECT HIERARCHIES**

### 5.2.1. Hierarchical Multitenancy (HMT) in Identity Service

Projects can be nested using multitenancy in keystone. Multitenancy allows subprojects to inherit role assignments from a parent project.

#### 5.2.1.1. Create the Project and Subprojects

You can implement Hierarchical Multitenancy (HMT) using keystone domains and projects. Begin by creating a new domain and then creating a project within that domain. You can then add subprojects to that project. You can also promote a user to administrator of a subproject by adding the user to the **admin** role for that subproject.

#### NOTE

The HMT structure used by keystone is not currently represented in the dashboard.

For example:

1. Create a new keystone domain called **corp**:

\$ openst	ack domain create corp	
+   Field	+   Value	+ 
+	+	+
descrip	tion	
enabled	d  True	
id	69436408fdcb44ab9e	111691f8e9216d
name	corp	
+	+	+

2. Create the parent project (private-cloud) within the corp domain:

\$ openstack project create private-clouddomain corp
++
Field   Value
++
description
domain_id   69436408fdcb44ab9e111691f8e9216d
enabled   True
id   c50d5cf4fe2e4929b98af5abdec3fd64
is_domain   False
name   private-cloud
parent_id   69436408fdcb44ab9e111691f8e9216d
++

**3.** Create a subproject (**dev**) within the **private-cloud** parent project, while also specifying the **corp** domain:

\$ openstack project create dev --parent private-cloud --domain corp
+----+
| Field | Value |
+----+
description	
domain\_id	69436408fdcb44ab9e111691f8e9216d
enabled	True
id	11fccd8369824baa9fc87cf01023fd87
is\_domain	False
name	dev
parent\_id	c50d5cf4fe2e4929b98af5abdec3fd64
+----++

4. Create another subproject called **qa**:

\$ openstack project create qa --parent private-cloud --domain corp +----+ | Field | Value | +----+ | description | | | domain\_id | 69436408fdcb44ab9e111691f8e9216d | | enabled | True | | id | b4f1d6f59ddf413fa040f062a0234871 | | is\_domain | False | | name | qa | | parent\_id | c50d5cf4fe2e4929b98af5abdec3fd64 | +-----+

## NOTE

You can use the Identity API to view the project hierarchy. For more information, see https://developer.openstack.org/api-ref/identity/v3/index.html?expanded=show-project-details-detail

#### 5.2.1.2. Granting Access to Users

By default, a newly-created project has no assigned roles. When you assign role permissions to the parent project, you can include the **--inherited** flag to instruct the subprojects to inherit the assigned permissions from the parent project. For example, a user with **admin** role access to the parent project will also have **admin** access to the subprojects.

1. View the existing permissions assigned to a project:

\$ openstack role assignment list --project private-cloud

2. View the existing roles:

\$ openstack role list +-----+ | ID | Name | +-----+ | 3a5137e4b620489791df1152ac013bfa | ResellerAdmin | | 9fe2ff9ee4384b1894a90878d3e92bab | \_member\_ | | cf4f87df933b455f957cf03b6d3784d2 | admin | | eef5cea6ff9549aa98cccc208c370d80 | SwiftOperator | +-----+

3. Grant the user account user1 access to the private-cloud project:

\$ openstack role add --user user1 --user-domain corp --project private-cloud \_member\_

Re-run the command above using the **--inherited** flag. As a result, **user1** also has access to the **privatecloud** subprojects, which have inherited the role assignment:

\$ openstack role add --user user1 --user-domain corp --project private-cloud \_member\_ --inherited

4. Review the result of the permissions update:

	0	tiveuser user1user-domain corp		
++			Damain	lucha suite al l
Role +	User	Group   Project	Domain   +	
++	·			
1	894a90878d3e92bab 9b98af5abdec3fd64	)   10b5b34df21d485ca044433818d   False	134be	
9fe2ff9ee4384b1	1894a90878d3e92bab	o   10b5b34df21d485ca044433818d	134be	

11fccd8369824baa9fc87cf01023fd87     True	
9fe2ff9ee4384b1894a90878d3e92bab   10b5b34df21d485ca044433818d134be	
b4f1d6f59ddf413fa040f062a0234871     True	
+++++++	+
	'

You will see in the results that **user1** has inherited access to the **qa** and **dev** projects. In addition, because the **--inherited** flag was applied to the parent project, **user1** will also automatically get access to any subprojects that are created later.

#### 5.2.2. Removing access

Explicit and inherited permissions must be separately removed. For example:

1. Remove a user from an explicitly assigned role:

\$ openstack role remove --user user1 --project private-cloud \_member\_

2. Review the result of the change. Notice that the inherited permissions are still present:

	0	tiveuser user1user-domain co	1
++   Role	User	Group   Project	Domain   Inherited
		+++	
++	·		·
9fe2ff9ee4384	4b1894a90878d3e92bab	10b5b34df21d485ca044433818	3d134be
11fccd8369824	lbaa9fc87cf01023fd87	True	
9fe2ff9ee4384	4b1894a90878d3e92bab	10b5b34df21d485ca044433818	3d134be
b4f1d6f59ddf4	13fa040f062a0234871	True	
+	+	+++	+
++			

3. Remove the inherited permissions:

\$ openstack role remove --user user1 --project private-cloud \_member\_ --inherited

**4.** Review the result of the change. The inherited permissions have been removed, and the resulting output is now empty:

\$ openstack role assignment list --effective --user user1 --user-domain corp

### 5.2.3. Nested Quotas

At present, *nested quotas* are not yet supported. As such, you will need to manage quotas individually against projects and subprojects.

#### 5.2.4. Reseller Overview

With the *Reseller* project, the goal is to have a hierarchy of domains; these domains will eventually allow you to consider reselling portions of the cloud, with a subdomain representing a fully-enabled cloud. This work has been split into phases, with phase 1 described below:

### 5.2.4.1. Phase 1 of Reseller

Reseller (phase 1) is an extension of Hierarchical Multitenancy (HMT), described here: Section 5.2.1, "Hierarchical Multitenancy (HMT) in Identity Service". Previously, keystone domains were originally intended to be containers that stored users and projects, with their own table in the database back-end. As a result, domains are now no longer stored in their own table, and have been merged into the project table:

- A domain is now a type of project, distinguished by the **is\_domain** flag.
- A domain represents a top-level project in the project hierarchy: domains are roots in the project hierarchy
- APIs have been updated to create and retrieve domains using the **projects** subpath:
  - Create a new domain by creating a project with the **is\_domain** flag set to true
  - List projects that are domains: get projects including the **is\_domain** query parameter.

## NOTE

Phase 1 does not allow you to create a hierarchy of domains, meaning that the subdomains are not yet available. In addition, this does not change the scope of tokens, neither does it include the hierarchy support necessary for projects other than keystone.

# 5.3. PROJECT SECURITY MANAGEMENT

Security groups are sets of IP filter rules that can be assigned to project instances, and which define networking access to the instance. Security groups are project specific; project members can edit the default rules for their security group and add new rule sets.

All projects have a default security group that is applied to any instance that has no other defined security group. Unless you change the default values, this security group denies all incoming traffic and allows only outgoing traffic to your instance.

### 5.3.1. Create a Security Group

- 1. In the dashboard, select Project > Compute > Access & Security
- 2. On the Security Groups tab, click Create Security Group.
- 3. Provide a name and description for the group, and click Create Security Group.

## 5.3.2. Add a Security Group Rule

By default, rules for a new group only provide outgoing access. You must add new rules to provide additional access.

- 1. In the dashboard, select Project > Compute > Access & Security
- 2. On the Security Groups tab, click Manage Rules for the security group that you want to edit.
- 3. Click Add Rule to add a new rule.
- 4. Specify the rule values, and click **Add**. The following rule fields are required:

#### Rule

Rule type. If you specify a rule template (for example, *SSH*), its fields are automatically filled in:

- TCP: Typically used to exchange data between systems, and for end-user communication.
- UDP: Typically used to exchange data between systems, particularly at the application level.
- ICMP: Typically used by network devices, such as routers, to send error or monitoring messages.

#### Direction

Ingress (inbound) or Egress (outbound).

#### **Open Port**

For TCP or UDP rules, the **Port** or **Port Range** (single port or range of ports) to open:

- For a range of ports, enter port values in the **From Port** and **To Port** fields.
- For a single port, enter the port value in the **Port** field.

#### Туре

The type for ICMP rules; must be in the range -1:255.

#### Code

The code for ICMP rules; must be in the range -1:255.

#### Remote

The traffic source for this rule:

- CIDR (Classless Inter-Domain Routing): IP address block, which limits access to IPs within the block. Enter the CIDR in the Source field.
- Security Group: Source group that enables any instance in the group to access any other group instance.

#### 5.3.3. Delete a Security Group Rule

- 1. In the dashboard, select Project > Compute > Access & Security
- 2. On the Security Groups tab, click Manage Rules for the security group.
- 3. Select the security group rule, and click Delete Rule.
- 4. Click Delete Rule again.

#### NOTE

You cannot undo the delete action.

### 5.3.4. Delete a Security Group

- 1. In the dashboard, select **Project > Compute > Access & Security**
- 2. On the Security Groups tab, select the group, and click Delete Security Groups
- 3. Click Delete Security Groups

## NOTE

You cannot undo the delete action.

# **CHAPTER 6. DOMAIN MANAGEMENT**

Identity Service (keystone) domains are additional namespaces you can create in keystone. You would use keystone domains to partition users, groups, and projects. These separate domains can also be configured to authenticate users in different LDAP or Active Directory environments. For more information see Integrate with Identity Service.

## NOTE

Identity Service includes a built-in domain called **Default**. It is suggested you reserve this domain only for service accounts, and create a separate domain for user accounts.

# **6.1. VIEW A LIST OF DOMAINS**

You can view a list of domains using **openstack domain list**. For example:

++       ++           ID         Name         Enabled   Description         ++       ++           3abefa6f32c14db9a9703bf5ce6863e1   TestDomain         True           69436408fdcb44ab9e111691f8e9216d   corp         True           a4f61a8feb8d4253b260054c6aa41adb   federated_domain   True                   default         Default         True	\$ openstack doma			
3abefa6f32c14db9a9703bf5ce6863e1   TestDomain   True                   69436408fdcb44ab9e111691f8e9216d   corp   True                   a4f61a8feb8d4253b260054c6aa41adb   federated_domain   True                   default	ID	Name	Enabled   Description	
+++	3abefa6f32c14d   69436408fdcb44   a4f61a8feb8d42   default	b9a9703bf5ce68 lab9e111691f8e9 53b260054c6aa4   Default	63e1   TestDomain   True   9216d   corp   True   41adb   federated_domain   True     True   The default domain	 

#### NOTE

If this command is not available, check you have enabled keystone v3 for your command line session.

# 6.2. CREATE A NEW DOMAIN

You can create a new domain using **openstack domain create**. For example:

\$ openstack domain create TestDomain
++
Field   Value
++
description
enabled   True
id   3abefa6f32c14db9a9703bf5ce6863e1
name   TestDomain
LL

# 6.3. VIEW THE DETAILS OF A DOMAIN

You can view the details of a domain using **openstack domain show**. For example:

\$ openstack domain show TestDomain		
+	+	+
Field	Value	

+----+ | description | | | enabled | True | | id | 3abefa6f32c14db9a9703bf5ce6863e1 | | name | TestDomain | +----+

# 6.4. DISABLE A DOMAIN

1. You can disable a domain using --disable. For example:

\$ openstack domain set TestDomain --disable

2. Confirm the domain has been disabled:

\$ openstack domain show TestDomain +-----+ | Field | Value | +----+ | description | | | enabled | False | | id | 3abefa6f32c14db9a9703bf5ce6863e1 | | name | TestDomain | +----+

3. You can then re-enable the domain, if required:

\$ openstack domain set TestDomain --enable

# CHAPTER 7. IDENTITY MANAGEMENT

# 7.1. SECURE LDAP COMMUNICATION

If you have configured the Identity service (keystone) to authenticate against or to retrieve identity information from an LDAP server, you can secure LDAP communication for the Identity service using a CA certificate.

This section outlines how to obtain the CA certificate from Active Directory, how to convert the CA certificate file into Privacy Enhanced Mail (PEM) file format, and the three methods for configuring secure LDAP communication for the Identity service. The procedure in each method must be performed depending on where and how the CA trust is configured.

## 7.1.1. Obtaining the CA Certificate from Active Directory

The following code shows an example of how to query Active Directory to obtain the CA certificate. The CA\_NAME is the name of the certificate (you can see it in mmc.exe) and the rest of the parameters can be changed according to your setup:

CA\_NAME="WIN2012DOM-WIN2012-CA" AD\_SUFFIX="dc=win2012dom,dc=com" LDAPURL="ldap://win2012.win2012dom.com" ADMIN\_DN="cn=Administrator,cn=Users,\$AD\_SUFFIX" ADMINPASSWORD="MyPassword"

CA\_CERT\_DN="cn=latexmath:[\$CA\_NAME,cn=certification authorities,cn=public key services,cn=services,cn=configuration,\$]AD\_SUFFIX"

TMP\_CACERT=/tmp/cacert.`date +'%Y%m%d%H%M%S'`.\$\$.pem

Idapsearch -xLLL -H Iatexmath:[\$LDAPURL -D `echo \"\$]ADMIN\_DN"`-W -s base -b`echo "\$CA\_CERT\_DN"` objectclass=\* cACertificate

## 7.1.2. Converting the CA Certificate into PEM file format

Create a file called /path/cacert.pem and include the contents of the LDAP query – that obtained the CA certificate from Active Directory, within the header and footer, as shown in the example below:

-----BEGIN CERTIFICATE-----MIIDbzCCAlegAwIBAgIQQD14hh1Yz7tPFLXCkKUOszANB... -----END CERTIFICATE-----

For troubleshooting, you can execute the following query to check if LDAP is working, and to ensure the PEM certificate file was created correctly.

LDAPTLS\_CACERT=/path/cacert.pem ldapsearch -xLLL -ZZ -H \$LDAPURL -s base -b "" "objectclass=\*" currenttime

The query should return a result similar to:

dn: currentTime: 20141022050611.0Z

You can run the following command to get a CA certificate if it was hosted by a web server.

#### Example

- \$HOST=redhat.com
- \$PORT=443

# echo Q | openssl s\_client -connect \$HOST:\$PORT | sed -n -e
'/BEGIN CERTIFICATE/,/END CERTIFICATE/ p'

## 7.1.3. Methods for Configuring Secure LDAP Communication for the Identity Service

#### 7.1.3.1. Method 1

Use this method if the CA trust is configured at the LDAP level using a PEM file. Manually specify the location of a CA certificate file. The following procedure secures LDAP communication not only for the Identity service, but for all applications that use the OpenLDAP libraries.

- 1. Copy the file containing your CA certificate chain in PEM format to the /etc/openIdap/certs directory.
- 2. Edit /etc/openIdap/Idap.conf and add the following directive, replacing [CA\_FILE] with the location and name of the CA certificate file:

TLS\_CACERT /etc/openIdap/certs/[CA\_FILE]

3. Restart the *httpd* service:

#### 7.1.3.2. Method 2

Use this method if the CA trust is configured at the LDAP library level using a Network Security Services (NSS) database. Use the **certutil** command to import and trust a CA certificate into the NSS certificate database used by the OpenLDAP libraries. The following procedure secures LDAP communication not only for the Identity service, but for all applications that use the OpenLDAP libraries.

1. Import and trust the certificate, replacing [CA\_FILE] with the location and name of the CA certificate file:

# certutil -d /etc/openIdap/certs -A -n "My CA" -t CT,, -a -i [CA\_FILE] # certutil -d /etc/openIdap/certs -A -n "My CA" -t CT,, -a -i [CA\_FILE]

2. Confirm the CA certificate was imported correctly:

# certutil -d /etc/openIdap/certs -L

Your CA certificate is listed, and the trust attributes are set to CT,,.

3. Restart the *httpd* service:

# systemctl restart httpd.service

#### 7.1.3.3. Method 3

Use this method if the CA trust is configured at the Keystone level using a PEM file. The final method of securing communication between the Identity service and an LDAP server is to configure TLS for the Identity service.

However, unlike the two methods above, this method only secures LDAP communication for the Identity service and does not secure LDAP communication for other applications that use the OpenLDAP libraries.

The following procedure uses the **openstack-config** command to edit values in the /etc/keystone/keystone.conf file.

1. Enable TLS:

# openstack-config --set /etc/keystone/keystone.conf ldap use\_tls True

2. Specify the location of the certificate, replacing [CA\_FILE] with the name of the CA certificate:

# openstack-config --set /etc/keystone/keystone.conf ldap tls\_cacertfile [CA\_FILE]

3. Specify the client certificate checks performed on incoming TLS sessions from the LDAP server, replacing [CERT\_BEHAVIOR] with one of the behaviors listed below:

#### demand

a certificate will always be requested from the LDAP server. The session will be terminated if no certificate is provided, or if the certificate provided cannot be verified against the existing certificate authorities file.

#### allow

a certificate will always be requested from the LDAP server. The session will proceed as normal even if a certificate is not provided. If a certificate is provided but it cannot be verified against the existing certificate authorities file, the certificate will be ignored and the session will proceed as normal.

#### never

a certificate will never be requested.

# openstack-config --set /etc/keystone/keystone.conf ldap tls\_req\_cert [CERT\_BEHAVIOR]

4. Restart the *httpd* service:

# systemctl restart httpd.service

# **CHAPTER 8. APPLICATION CREDENTIALS**

Application Credentials help you to avoid the practice of embedding user account credentials in configuration files. Instead, the user creates an Application Credential that receives delegated access to a single project and has its own distinct secret. The user can also limit the delegated privileges to a single role in that project. This allows you to adopt the principle of least privilege, where the authenticated service only gains access to the one project and role that it needs to function, rather than all of them.

This approach allows you to consume an API with revealing your user credentials, and lets applications authenticate to Keystone without requiring embedded user credentials.

You can use Application Credentials to generate tokens and configure **keystone\_authtoken** settings for applications. These use cases are described in the following sections.

## NOTE

The Application Credential is dependent on the user account that created it, so it will terminate if that account is ever deleted, or loses access to the relevant role.

# 8.1. USE APPLICATION CREDENTIALS TO GENERATE TOKENS

Application Credentials are available to users as a self-service function in the dashboard. This example demonstrates how a user can create an Application Credential and then use it to generate a token.

- 1. Create a test project, and test user accounts:
  - a. Create a project called **AppCreds**. For example:

\$ openstack project create AppCreds

b. Create a user called **AppCredsUser**. For example:

\$ openstack user create --project AppCreds --password-prompt AppCredsUser

c. Grant AppCredsUser access to the \_member\_ role for the AppCreds project. For example:

\$ openstack role add --user AppCredsUser --project AppCreds \_member\_

Login to the dashboard as AppCredsUser and create an Application Credential:
 Overview → Identity → Application Credentials → +Create Application Credential.

#### NOTE

Be sure to download the **clouds.yaml** file contents, as you will not be able to access it again once you close the pop-up window titled **Your Application Credential**.

3. Create a file named /home/stack/.config/openstack/clouds.yaml using the CLI and paste the contents of the clouds.yaml file. For example:

# This is a clouds.yaml file, which can be used by OpenStack tools as a source

# of configuration on how to connect to a cloud. If this is your only cloud, # just put this file in ~/.config/openstack/clouds.yaml and tools like # python-openstackclient will just work with no further config. (You will need # to add your password to the auth section) # If you have more than one cloud account, add the cloud entry to the clouds # section of your existing file and you can refer to them by name with # OS CLOUD=openstack or --os-cloud=openstack clouds: openstack: auth: auth url: http://10.0.0.10:5000/v3 application\_credential\_id: "6d141f23732b498e99db8186136c611b" application\_credential\_secret: "<example secret value>" region name: "regionOne" interface: "public" identity api version: 3 auth\_type: "v3applicationcredential"

### NOTE

These exact values will be different for your deployment.

4. Use the Application Credential to generate a token. You must not be sourced as any specific user when using the following command, and you must be in the same directory as your **clouds.yaml** file.

[stack@undercloud-0 openstack]\$ openstack --os-cloud=openstack token issue -----+ | Field | Value -----+ | expires | 2018-08-29T05:37:29+0000 | gAAAAABbhiMJ4TxxFITMdsYJpfStsGotPrns0InpvJq9ILtdi-| id NKqisWBeNiJIUXwmnoGQDh2CMyK9OeTsuEXnJNmFfKjxiHWmcQVYzAhMKo6 QMUtu Qm 6mtpzYYHBrUGboa Ay0LBuFDtsjtgtvJ-r8G3TsJMowbKF-yo--O XLhERU QQVI3hl8zmMRdmLh P9Cbhuolt | | project\_id | 1a74eabbf05c41baadd716179bb9e1da user id | ef679eeddfd14f8b86becfd7e1dc84f2 +-----+ 

# NOTE

If you receive an error similar to \_\_init\_\_() got an unexpected keyword argument 'application\_credential\_secret', then you might still be sourced to the previous credentials. For a fresh environment, run sudo su - stack.

# 8.2. INTEGRATE APPLICATION CREDENTIALS WITH APPLICATIONS

Application Credentials can be used to authenticate applications to keystone. When using Application Credentials, the **keystone\_authtoken** settings use **v3applicationcredential** as the authentication type and will contain the credentials you received during the credential creation process. You will need to enter the following values:

- **application\_credential\_secret**: The Application Credential secret.
- **application\_credential\_id**: The Application Credential id.
- **application\_credential\_name**: (Optional) You might use this if using a named application credential, rather than an ID.

For example:

```
[keystone_authtoken]
auth_url = http://10.0.0.10:5000/v3
auth_type = v3applicationcredential
application_credential_id = "6cb5fa6a13184e6fab65ba2108adf50c"
application_credential_secret = "<example password>"
```

# 8.3. USE THE COMMAND LINE TO MANAGE APPLICATION CREDENTIALS

You can use the command line to create and delete Application Credentials.

The **create** subcommand will create an application credential based on the currently sourced account. For example, creating the credential when sourced as an **admin** user will grant the same roles to the Application Credential:

\$ openstack application credential createdescription "App C	reds - All roles" AppCredsUse
Field   Value	+ 
+++	+   
name   AppCredsUser   project_id   507663d0cfe244f8bc0694e6ed54d886	
roles   member reader admin   secret   fVnqa6I_XeRDDkmQnB5lx361W1jHtOtw3ci_mf_ by8ykEhEa1QLPFJLNV4cS2Roo9lOg     unrestricted   False	 tOID-09MrPAzkU7mv- 
L	L

By default, the resulting role membership includes all the roles assigned to the account that created the credentials. You can limit the role membership by only delegating access to a specific role. For example:

\$ openstack application credential create --description "App Creds - Member" --role member
AppCredsUser
+-----+
| Field | Value |
+-----+
| description | App Creds - Member |
| expires\_at | None |

id   e21e7f4b578240f79814085a169c9a44   name   AppCredsUser	I	I
	I	
project_id   507663d0cfe244f8bc0694e6ed54d886		
roles   member		
secret		
XCLVUTYIreFhpMqLVB5XXovs_z9JdoZWpdwrkaG1qi5GQcmBMUF0	G7cN2htzM	IIFe5T5mdPsnf5JMNb
u0lh-4aCg		
unrestricted   False		
+++	+	

To delete an Application Credential:

\$ openstack application credential delete AppCredsUser

# 8.4. OPERATIONAL TASKS

#### 8.4.1. Replace an existing Application Credential

Application Credentials are bound to the user account that created them and will become invalid if the user account is ever deleted, or if the user loses access to the delegated role. As a result, you should be prepared to generate a new Application Credential as needed.

#### 8.4.1.1. For configuration files

To update the Application Credentials assigned to an application (using a configuration file):

- 1. Create a new set of Application Credentials.
- 2. Add the new credentials to the application's configuration file, replacing the existing credentials. This is described in Section 8.2, "Integrate Application Credentials with applications".
- 3. Restart the application's service to apply the change.
- 4. Delete the old Application Credential, if appropriate. For more information on the command line options, see Section 8.3, "Use the command line to manage Application Credentials" .

#### 8.4.1.2. For clouds.yaml files

To replace an existing Application Credential used by **clouds.yaml**:

For example, if your **clouds.yaml** contains an Application Credential called **AppCred1**, and it is due to expire:

- 1. Create an Application Credential called *AppCred2*.
- 2. Add the new AppCred2 to the clouds.yaml file, while removing the AppCred1 configuration.
- 3. Generate a token with **clouds.yaml** to confirm that the credentials are working as expected. See step 4 of Section 8.1, "Use Application Credentials to generate tokens" for more information.
