CHAPTER 1. INTRODUCTION

You can use host-based subscriptions for Red Hat Enterprise Linux virtual machines in the following virtualization platforms:

- Red Hat Virtualization
- Red Hat Enterprise Linux Virtualization (KVM)
- Red Hat OpenStack Platform
- VMware vSphere
- Microsoft Hyper-V

1.1. HOST-BASED SUBSCRIPTIONS

Virtual machines can use host-based subscriptions instead of consuming entitlements from physical subscriptions. A host-based subscription is attached to a hypervisor and entitles it to provide subscriptions to its virtual machines. Many host-based subscriptions provide entitlements for unlimited virtual machines.

To allow virtual machines to inherit subscriptions from their hypervisors, you must install and configure `virt-who`. `Virt-who` queries the virtualization platform and reports hypervisor and virtual machine information to Red Hat Satellite.

When a virtual machine is registered with an activation key that has no subscriptions attached and `auto-attach` set to **true**, and sufficient host-based subscriptions are available, one of the following behaviors occurs:

- If the virtual machine has been reported by `virt-who` and a host-based subscription is attached to the hypervisor, the virtual machine inherits a subscription from the hypervisor.
- If the virtual machine has been reported by `virt-who`, and the hypervisor is registered to Satellite but does not have a host-based subscription attached, a host-based subscription is attached to the hypervisor and inherited by the virtual machine.
- If the virtual machine, or its hypervisor, has not been reported by `virt-who`, Satellite grants the virtual machine a temporary subscription, valid for up to seven days. After `virt-who` reports updated information, Satellite can determine which hypervisor the virtual machine is running on and attach a permanent subscription to the virtual machine.

If `auto-attach` is enabled, but `virt-who` is not running or there are no host-based subscriptions available, Satellite attaches physical subscriptions to the virtual machines instead, which might consume more entitlements than intended.

If `auto-attach` is not enabled, virtual machines cannot use host-based subscriptions.

To see if a subscription requires `virt-who`, in the Satellite web UI, navigate to **Content > Subscriptions**. If there is a tick in the **Requires Virt-Who** column, you must configure `virt-who` to use that subscription.

Virtual machine subscription process

This diagram shows the subscription workflow when a virtual machine has not yet been reported by `virt-who`:

- 1 Satellite provisions a virtual machine.
- 2 The virtual machine requests a subscription from Satellite Server.
- 3 Satellite Server grants the virtual machine a temporary subscription, valid for a maximum of seven days, while it determines which hypervisor the virtual machine belongs to.
- 4 Virt-who connects to the hypervisor or virtualization manager and requests information about its virtual machines.
- 5 The hypervisor or virtualization manager returns a list of its virtual machines to virt-who, including each UUID.
- 6 Virt-who reports the list of virtual machines and their hypervisors to Satellite Server.
- 7 Satellite Server attaches a permanent subscription to the virtual machine, if sufficient entitlements are available.

Additional resources

For more information about the Red Hat subscription model, see [Introduction to Red Hat Subscription Management Workflows](#).

1.2. CONFIGURATION OVERVIEW

To allow virtual machines to inherit subscriptions from their hypervisors, complete the following steps:

Prerequisites

Prerequisites

- Import a Subscription Manifest that includes a host-based subscription into Satellite Server. For more information, see [Importing a Subscription Manifest into Satellite Server](#) in the *Content Management Guide*.
- Ensure you have sufficient entitlements for the host-based subscription to cover all of the hypervisors you plan to use.
- If you are using Microsoft Hyper-V, enable remote management on the hypervisors.
- Create a user with read-only access and a non-expiring password on each hypervisor or virtualization manager. Virt-who uses this account to retrieve the list of virtual machines to report to Satellite Server.
 - For Red Hat products and Microsoft Hyper-V, create a virt-who user on each hypervisor that runs Red Hat Enterprise Linux virtual machines.
 - For VMware vSphere, create a virt-who user on the vCenter Server. The virt-who user requires at least read-only access to all objects in the vCenter Data Center.

Procedure Overview

1. [Section 1.3, “Virt-who Configuration for Each Virtualization Platform”](#). Use the table in this section to plan how to configure and deploy virt-who for your virtualization platform.
2. [Chapter 2, Creating an Activation Key for Virtual Machines](#). Create an activation key with auto-attach enabled and no subscriptions attached.
3. [Chapter 3, Attaching a Host-based Subscription to Hypervisors](#). Attach a host-based subscription to all of the hypervisors you plan to use.
4. [Chapter 4, Creating a virt-who Configuration](#). Create a virt-who configuration for each hypervisor or virtualization manager.
5. [Chapter 5, Deploying a virt-who Configuration](#). Deploy the virt-who configurations using the scripts generated by Satellite.
6. [Chapter 6, Registering Virtual Machines to use a Host-based Subscription](#). Register the virtual machines using the auto-attach activation key.

1.3. VIRT-WHO CONFIGURATION FOR EACH VIRTUALIZATION PLATFORM

Virt-who is configured using files that specify details such as the virtualization type and the hypervisor or virtualization manager to query. The supported configuration is different for each virtualization platform.

Example virt-who configuration file

This example shows a virt-who configuration file created using the Satellite web UI or Hammer CLI:

```
[virt-who-config-1]
type=libvirt
hypervisor_id=hostname
owner=Default_Organization
env=Library
```

```
server=hypervisor1.example.com
username=virt_who_user
encrypted_password=$cr_password
rhsm_hostname=satellite.example.com
rhsm_username=virt_who_reporter_1
rhsm_encrypted_password=$user_password
rhsm_prefix=/rhsm
```

The **type** and **server** values depend on the virtualization platform. The following table provides more detail.

The **username** refers to a read-only user on the hypervisor or virtualization manager, which you must create before configuring virt-who. The **rhsm-username** refers to an automatically generated user that only has permissions for virt-who reporting to Satellite Server.

Required configuration for each virtualization platform

Use this table to plan your virt-who configuration:

Supported virtualization platform	Type specified in the configuration file	Server specified in the configuration file	Server where the configuration file is deployed
Red Hat Virtualization RHEL Virtualization (KVM) Red Hat OpenStack Platform	libvirt	Hypervisor (one file for each hypervisor)	Each hypervisor
VMware vSphere	esx	vCenter Server	Satellite Server, Capsule Server, or a dedicated RHEL server
Microsoft Hyper-V	hyperv	Hyper-V hypervisor (one file for each hypervisor)	Satellite Server, Capsule Server, or a dedicated RHEL server

IMPORTANT

The **rhev** and **xen** hypervisor types are not supported.

The **kubvirt** hypervisor type is provided as a Technology Preview only.

CHAPTER 2. CREATING AN ACTIVATION KEY FOR VIRTUAL MACHINES

Use this procedure to create an activation key with auto-attach enabled and no subscriptions attached. When you register virtual machines using this activation key, the virtual machines inherit a subscription from their hypervisor if that hypervisor has a host-based subscription attached.

For more information about activation keys, see [Managing Activation Keys](#) in the *Content Management Guide*.

Procedure

1. In the Satellite web UI, navigate to **Content** > **Activation keys** and click **Create Activation Key**.
2. In the **Name** field, enter the name of the activation key.
3. Ensure the **Unlimited Hosts** check box is selected. Alternatively, if you want to set a limit, clear the **Unlimited hosts** check box, and in the **Limit** field, enter the maximum number of virtual machines you can register with the activation key.
4. In the **Description** field, enter a description for the activation key.
5. From the **Environment** list, select the environment to use.
6. From the **Content View** list, select a Content View to use.
7. Click **Save**.
8. When the new activation key appears in the **Activation Keys** window, click the name of the key.
9. Click the **Subscriptions** tab.
10. Ensure that **Auto-Attach** is set to **Yes**. If it is not, click the edit icon, select the check box, and click **Save**.

Do not add any subscriptions to this activation key.

For CLI Users

1. Create the activation key:

```
# hammer activation-key create \
--name "VM_Activation_Key" \
--unlimited-hosts \
--description "For VMs to inherit a VDC Subscription" \
--lifecycle-environment "Environment_Name" \
--content-view "CV_Name" \
--organization "My_Organization"
```

2. Enable auto-attach on the activation key:

```
# hammer activation-key update --name "VM_Activation_Key" \
--organization "My_Organization" --auto-attach true
```

CHAPTER 3. ATTACHING A HOST-BASED SUBSCRIPTION TO HYPERVISORS

Use this procedure to attach a host-based subscription, such as **Red Hat Enterprise Linux for Virtual Datacenters**, to hypervisors that are already registered to Red Hat Satellite.

To register a new hypervisor, ensure your host activation key includes a host-based subscription, then see [Registering Hosts](#) in the *Managing Hosts* guide. You must register a hypervisor before configuring virt-who to query it.

Prerequisites

- Import a Subscription Manifest that includes a host-based subscription into Satellite Server.
- Ensure you have sufficient entitlements for the host-based subscription to cover all of the hypervisors you plan to use.

Procedure

1. In the Satellite web UI, navigate to **Hosts > Content Hosts**.
2. In the **Content Hosts** list, select the check box next to the name of each hypervisor you want to attach the subscription to.
3. From the **Select Action** list, select **Manage Subscriptions**.
4. In the Content Host Bulk Subscriptions window, select a host-based subscription, then click **Add Selected**.

For CLI Users

1. On Satellite Server, list the available subscriptions to find the host-based subscription's ID:

```
# hammer subscription list \  
--organization-id organization_id
```

2. Attach the host-based subscription to a hypervisor:

```
# hammer host subscription attach \  
--host host_name \  
--subscription-id subscription_id
```

Repeat these steps for each hypervisor you plan to use.

CHAPTER 4. CREATING A VIRT-WHO CONFIGURATION

Use this procedure to create a virt-who configuration. Red Hat products and Microsoft Hyper-V require one configuration for each hypervisor that runs Red Hat Enterprise Linux virtual machines. VMware vSphere requires one configuration for each vCenter Server.

Most values in this procedure are added to an `/etc/virt-who.d/conf_name.conf` file and apply only to the specified hypervisor or virtualization manager. **Interval**, **Enable debugging output**, **HTTP Proxy**, and **Ignore Proxy** are global values stored in the `/etc/sysconfig/virt-who` file. Global configuration values apply to all virt-who configurations on the same server, and are overwritten each time a new virt-who configuration is deployed on that server.

Every virt-who configuration creates a **virt_who_reporter_[id]** user and assigns it the **Virt-who Reporter** role, which provides minimal permissions for virt-who reporting to Satellite Server. This user cannot be manually configured or used to log in to Satellite Server.

Prerequisites

- If you are creating a virt-who configuration for a Red Hat hypervisor (Red Hat Enterprise Linux or Red Hat Virtualization Host), register the hypervisor to Red Hat Satellite.
- Create a read-only virt-who user on the hypervisor or virtualization manager:
 - For Red Hat products and Microsoft Hyper-V, create a virt-who user on each hypervisor that runs Red Hat Enterprise Linux virtual machines.
 - For VMware vSphere, create a virt-who user on the vCenter Server. The virt-who user requires at least read-only access to all objects in the vCenter Data Center.

Procedure

1. In the Satellite web UI, navigate to **Infrastructure > Virt-who configurations**.
2. Click **Create Config**. In the New Virt-who Config window, you can click the help icons for more information about each field.
3. Enter a **Name** for the configuration.
4. From the **Hypervisor Type** list, select your virtualization platform:
 - Red Hat Enterprise Linux Virtualization (KVM), Red Hat Virtualization, or Red Hat OpenStack Platform: **libvirt**
 - VMware vSphere: **esx**
 - Microsoft Hyper-V: **hyperv**
 - Note that the **rhevm** and **xen** hypervisor types are not supported, and the **kubevirt** hypervisor type is provided as a Technology Preview only.
5. In the **Hypervisor Server** field, enter the FQDN or IP address of the server this configuration applies to. For VMware vSphere, use the vCenter Server's FQDN or IP address. For all other products, use the hypervisor's FQDN or IP address.
6. In the **Hypervisor Username** field, enter the name of the virt-who user that you created on the hypervisor or virtualization manager.

7. In the **Hypervisor Password** field, enter the password for the virt-who user. This password is encrypted when you deploy the configuration. This field is not required when using the **libvirt** type.
8. From the **Interval** list, select how often virt-who requests new or updated virtual machine information. Because the virtual machines are granted temporary subscriptions for up to seven days, frequent queries are not required; you can select an interval that suits the size of your environment. **Every 24 hours** is suitable for most environments.
9. Enter the **Satellite server FQDN**
10. From the **Hypervisor ID** list, select whether to identify the hypervisors in Satellite Server by their host name or UUID.
11. Select a **Filtering** option:
 - The default is **Unlimited**. All hypervisors covered by this configuration are queried by virt-who. Use this option if you do not have to limit which hypervisors are queried.
 - You can **Whitelist** or **Blacklist** hypervisors. For example, if some hypervisors only run Microsoft Windows Server virtual machines, those hypervisors do not need to be reported by virt-who.
12. If you selected **Whitelist** or **Blacklist**: In the **Filter hosts** or **Exclude hosts** field, enter a comma-separated list of hypervisors according to the selected **Hypervisor ID**. For example, if hypervisors are identified by their host name, they must be included or excluded by their host name. If a hypervisor's name contains special characters, enclose it in quotation marks. Wildcards and regular expressions are supported. Note that when using regular expressions, backslashes must be escaped.
13. If you selected the **esx** type and **Whitelist** or **Blacklist**: In the **Filter host parents** or **Exclude host parents** field, enter a comma-separated list of clusters. Hypervisors in a whitelisted cluster are reported by virt-who. Hypervisors in a blacklisted cluster are not reported by virt-who. If a cluster name contains special characters, enclose it in quotation marks. Wildcards and regular expressions are supported. Note that when using regular expressions, backslashes must be escaped.
14. Optional: Select the **Enable debugging output** check box if you require debugging output for troubleshooting.
15. Optional: Enter an **HTTP Proxy** to use for communication between the server where virt-who is deployed and the hypervisors or virtualization managers.
To use no proxy, leave this field blank; this has the same result as entering * in the **Ignore Proxy** field.
16. Optional: In the **Ignore Proxy** field, enter a comma-separated list of host names, IP addresses, or domains to bypass existing proxy settings.
17. Click **Submit**.

For CLI Users

- On Satellite Server, enter the **hammer virt-who-config create** command. For more information about the options, enter **hammer virt-who-config create --help**.
This example creates a virt-who configuration for a Red Hat Enterprise Linux hypervisor:

```
# hammer virt-who-config create \
--name rhel.example.com \
--organization "Example Company" \
--interval 720 \ 1
--filtering-mode none \ 2
--hypervisor-id hostname \ 3
--hypervisor-type libvirt \ 4
--hypervisor-server rhel.example.com \ 5
--hypervisor-username virt-who \ 6
--satellite-url satellite.example.com
```

- 1 Choose how often, in minutes, virt-who queries the virtualization platform. Because the virtual machines are granted temporary subscriptions for up to seven days, frequent queries are not required; you can select an interval that suits the size of your environment. Once a day (**1440**) is suitable for most environments.
- 2 Choose whether to filter hypervisors. Use **none** if you do not have to limit which hypervisors are queried. Alternatively, you can **whitelist** or **blacklist** hypervisors. For example, if some hypervisors only run Microsoft Windows Server virtual machines, those hypervisors do not need to be reported by virt-who.
- 3 Choose how to identify the hypervisor (or hypervisors) this configuration applies to. Use **hostname** to provide meaningful host names in the Satellite web UI. Alternatively, you can use **uuid** to avoid duplication if a hypervisor is renamed. **hwuuid** can be used only if this configuration applies to a virtualization manager instead of an individual hypervisor, and must not be changed to another option after virt-who starts running because this causes duplicate entries in Subscription Manager.
- 4 Specify the supported type for your virtualization platform:
 - Red Hat Enterprise Linux Virtualization (KVM), Red Hat Virtualization, or Red Hat OpenStack Platform: **libvirt**
 - VMware vSphere: **esx**
 - Microsoft Hyper-V: **hyperv**
 - Note that the **rhev** and **xen** hypervisor types are not supported, and the **kubevirt** hypervisor type is provided as a Technology Preview only.
- 5 Specify the FQDN or IP address of the server this configuration applies to. For VMware vSphere, use the vCenter Server's FQDN or IP address. For all other products, use the hypervisor's FQDN or IP address.
- 6 Specify the read-only virt-who user that you created on the hypervisor or virtualization manager. You do not need to specify a password when using the **libvirt** type. For other types, you must specify the virt-who user's password with the **--hypervisor-password** option.

CHAPTER 5. DEPLOYING A VIRT-WHO CONFIGURATION

After you create a virt-who configuration, Satellite provides a script to automate the deployment process. The script installs virt-who and creates the individual and global virt-who configuration files.

For Red Hat products, you must deploy each configuration file on the hypervisor specified in the file. For other products, you must deploy the configuration files on Satellite Server, Capsule Server, or a separate Red Hat Enterprise Linux server that is dedicated to running virt-who.

- To deploy the files on a hypervisor or Capsule Server, see [Section 5.1, “Deploying a virt-who Configuration on a Hypervisor”](#).
- To deploy the files on Satellite Server, see [Section 5.2, “Deploying a virt-who Configuration on Satellite Server”](#).
- To deploy the files on a separate Red Hat Enterprise Linux server, see [Section 5.3, “Deploying a virt-who Configuration on a Separate Red Hat Enterprise Linux Server”](#).

5.1. DEPLOYING A VIRT-WHO CONFIGURATION ON A HYPERVISOR

Use this procedure to deploy a virt-who configuration on the Red Hat hypervisor that you specified in the file. Global values apply only to this hypervisor.

You can also use this procedure to deploy a vCenter or Hyper-V virt-who configuration on Capsule Server. Global configuration values apply to all virt-who configurations on the same Capsule Server, and are overwritten each time a new virt-who configuration is deployed.

Prerequisites

- Register the hypervisor to Red Hat Satellite.
- If you are using Red Hat Virtualization Host (RHVH), update it to the latest version so that the minimum virt-who version is available. Virt-who is available by default on RHVH, but cannot be updated individually from the **rhel-7-server-rhvh-4-rpms** repository.
- Create a read-only virt-who user on the hypervisor.
- Create a virt-who configuration for your virtualization platform.

Procedure

1. In the Satellite web UI, navigate to **Infrastructure > Virt-who configurations**.
2. Click the name of the virt-who configuration.
3. Click the **Deploy** tab.
4. Under **Configuration script**, click **Download the script**
5. Copy the script to the hypervisor:

```
# scp deploy_virt_who_config_1.sh root@hypervisor.example.com:
```

6. Make the deployment script executable and run it:

```
# chmod +x deploy_virt_who_config_1.sh
# sh deploy_virt_who_config_1.sh
```

7. After the deployment is complete, delete the script:

```
# rm deploy_virt_who_config_1
```

5.2. DEPLOYING A VIRT-WHO CONFIGURATION ON SATELLITE SERVER

Use this procedure to deploy a vCenter or Hyper-V virt-who configuration on Satellite Server.

Global configuration values apply to all virt-who configurations on Satellite Server, and are overwritten each time a new virt-who configuration is deployed.

Prerequisites

- Create a read-only virt-who user on the hypervisor or virtualization manager.
- If you are deploying a Hyper-V virt-who configuration, enable remote management on the Hyper-V hypervisor.
- Create a virt-who configuration for your virtualization platform.

Procedure

1. In the Satellite web UI, navigate to **Infrastructure > Virt-who configurations**.
2. Click the name of the virt-who configuration.
3. Under **Hammer command**, click **Copy to clipboard**
4. On Satellite Server, paste the Hammer command into your terminal.

5.3. DEPLOYING A VIRT-WHO CONFIGURATION ON A SEPARATE RED HAT ENTERPRISE LINUX SERVER

Use this procedure to deploy a vCenter or Hyper-V virt-who configuration on a dedicated Red Hat Enterprise Linux 7 server. The server can be physical or virtual.

Global configuration values apply to all virt-who configurations on this server, and are overwritten each time a new virt-who configuration is deployed.

Prerequisites

- Create a read-only virt-who user on the hypervisor or virtualization manager.
- If you are deploying a Hyper-V virt-who configuration, enable remote management on the Hyper-V hypervisor.
- Create a virt-who configuration for your virtualization platform.

Procedure

1. On the Red Hat Enterprise Linux server, install Satellite Server's CA certificate:

```
# rpm -ivh http://satellite.example.com/pub/katello-ca-consumer-latest.noarch.rpm
```

2. Register the Red Hat Enterprise Linux server to Satellite Server:

```
# subscription-manager register \  
--org=organization_label \  
--auto-attach
```

3. Open a network port for communication between virt-who and Satellite Server:

```
# firewall-cmd --add-port="443/tcp" \  
# firewall-cmd --add-port="443/tcp" --permanent
```

4. Open a network port for communication between virt-who and each hypervisor or virtualization manager:

- VMware vCenter: TCP port 443
- Microsoft Hyper-V: TCP port 5985

5. In the Satellite web UI, navigate to **Infrastructure** > **Virt-who configurations**.

6. Click the name of the virt-who configuration file.

7. Click the **Deploy** tab.

8. Under **Configuration script**, click **Download the script**

9. Copy the script to the Red Hat Enterprise Linux server:

```
# scp deploy_virt_who_config_1.sh root@rhel.example.com:
```

10. Make the deployment script executable and run it:

```
# chmod +x deploy_virt_who_config_1.sh \  
# sh deploy_virt_who_config_1.sh
```

11. After the deployment is complete, delete the script:

```
# rm deploy_virt_who_config_1
```

CHAPTER 6. REGISTERING VIRTUAL MACHINES TO USE A HOST-BASED SUBSCRIPTION

Use an auto-attach activation key to register virtual machines so that they inherit a subscription from their hypervisor.

For more information about activation keys, see [Managing Activation Keys](#) in the *Content Management Guide*.

Prerequisites

- Create an activation key with auto-attach enabled and no subscriptions attached.
- Attach a host-based subscription to the virtual machine's hypervisor.
- Create and deploy a virt-who configuration that queries the virtual machine's hypervisor.

Procedure

1. Configure the virtual machine to register with Satellite Server:

```
# yum install http://satellite.example.com/pub/katello-ca-consumer-latest.noarch.rpm
```

2. Register the virtual machine using the auto-attach activation key:

```
# subscription-manager register --org=organization_label \  
--activationkey=activation_key_name
```

The virtual machine receives a temporary subscription while Satellite Server waits for virt-who to provide information about which hypervisor the virtual machine is running on. After virt-who provides this information, Satellite Server attaches a permanent subscription to the virtual machine.

If the virtual machine migrates to another hypervisor that reports to virt-who and has a host-based subscription attached, the virtual machine inherits a subscription from that hypervisor. If the hypervisor does not have a host-based subscription attached, Satellite Server automatically attaches a host-based subscription to the hypervisor, and the virtual machine inherits that subscription.

If the virtual machine migrates to another hypervisor that does not report to virt-who, or there are insufficient subscriptions available to attach to the hypervisor, the virtual machine cannot inherit a subscription. To avoid this, either ensure that all hypervisors the virtual machine can migrate to have host-based subscriptions attached and report to virt-who, or limit the virtual machine's migration to specific hypervisors.

APPENDIX A. TROUBLESHOOTING VIRT-WHO

A.1. MODIFYING A VIRT-WHO CONFIGURATION

You can modify an existing virt-who configuration using either the Satellite web UI or the Hammer CLI. For example, if you need to change how frequently virt-who runs, the virt-who configuration must be updated and deployed again.

Procedure

1. In the Satellite web UI, navigate to **Infrastructure > Virt-who configurations**.
2. Locate the virt-who configuration you want to modify, and click **Edit** in the **Actions** column.
3. Edit the fields you want to change.
4. Click **Submit**.
5. Redeploy the modified virt-who configuration.

For CLI users

1. On Satellite Server, enter the **hammer virt-who-config update** command, specifying the name of the configuration you want to modify, and new values for the options you want to change. If you want to change the name of the configuration, you must use the option **--new-name**.

```
# hammer virt-who-config update \  
--name current_name \  
--new-name new_name \  
--interval 1440
```

2. Redeploy the modified virt-who configuration.

A.2. REMOVING AN EXISTING VIRT-WHO CONFIGURATION

To remove an existing virt-who configuration, you must first remove the configuration entry in the Satellite web UI and then remove the configuration file from the file system of the host that the configuration was deployed on.

Procedure

1. In the Satellite web UI, navigate to **Infrastructure > Virt-who configurations**.
2. From the **Actions** list for the configuration you want to remove, select **Delete**.
3. On the host that you want to remove the virt-who configuration from, remove the configuration file:

```
# rm /etc/virt-who.d/conf_name.conf
```

A.3. VIRT-WHO TROUBLESHOOTING METHODS

Verifying virt-who status

To verify virt-who's status in the Satellite web UI, navigate to **Infrastructure > Virt-who configurations** and check the **Status** column for each virt-who instance. A status of **OK** indicates that virt-who is successfully connecting to Satellite Server and reporting the virtual machines managed by each hypervisor.

To list the status of all virt-who instances using the CLI, enter the following command on Satellite Server:

```
# hammer virt-who-config list
```

The command's output includes the date and time at which each virt-who instance reported to Satellite Server.

Debug logging

Check the `/var/log/rhsm/rhsm.log` file, where virt-who logs all its activity by default.

To enable more detailed logging, modify the virt-who configuration:

- In the Satellite web UI, select the **Enable debugging output** check box.
- In the Hammer CLI, add the **--debug true** option.

Redeploy the configuration for the change to take effect.

When the underlying issue is resolved, modify the virt-who configuration to disable debugging, then redeploy the configuration again.

Testing configuration options

Make a change and test the result, repeating as needed. Virt-who provides two options to help test the configuration files, credentials, and connectivity to the virtualization platform:

- The **virt-who --one-shot** command reads the configuration files, retrieves the list of virtual machines and sends it to Satellite Server, then exits immediately.
- The **virt-who --print** command reads the configuration files and prints the list of virtual machines, but does not send it to Satellite Server.

The expected output is a list of hypervisors and their virtual machines, in JSON format. The following is an extract from a VMware vSphere instance. The output from all hypervisors follows the same structure.

```
{
  "guestId": "422f24ed-71f1-8ddf-de53-86da7900df12",
  "state": 5,
  "attributes": {
    "active": 0,
    "virtWhoType": "esx",
    "hypervisorType": "vmware"
  }
},
```

Identifying issues when using multiple virt-who configuration files

If you have multiple virt-who configuration files on one server, move one file at a time to a different

directory while testing after each file move. If the issue no longer occurs, the cause is associated with the most recently moved file. After you have resolved the issue, return the virt-who configuration files to their original location.

Alternatively, you can test an individual file after moving it by using the **--config** option to specify its location. For example:

```
# virt-who --debug --one-shot --config /tmp/conf_name.conf
```

Identifying duplicate hypervisors

Duplicate hypervisors can cause subscription and entitlement errors. Enter the following commands to check for duplicate hypervisors:

```
# systemctl stop virt-who
# virt-who -op >/tmp/virt-who.json
# systemctl start virt-who
# cat /tmp/virt-who.json | json_reformat | grep name | sort | uniq -c | sort -nr | head -n10
3  "name": "localhost"
1  "name": "rhel1.example.com"
1  "name": "rhel2.example.com"
1  "name": "rhel3.example.com"
1  "name": "rhel4.example.com"
1  "name": "rhvh1.example.com"
1  "name": "rhvh2.example.com"
1  "name": "rhvh3.example.com"
1  "name": "rhvh4.example.com"
1  "name": "rhvh5.example.com"
```

In this example, three hypervisors have the same FQDN (**localhost**), and must be corrected to use unique FQDNs.

Identifying duplicate virtual machines

Enter the following commands to check for duplicate virtual machines:

```
# systemctl stop virt-who
# virt-who -op >/tmp/virt-who.json
# systemctl start virt-who
# cat /tmp/virt-who.json | json_reformat | grep "guestId" | sort | uniq -c | sort -nr | head -n10
```

Checking the number of hypervisors

Enter the following commands to check the number of hypervisors virt-who currently reports:

```
# systemctl stop virt-who
# virt-who -op >/tmp/virt-who.json
# systemctl start virt-who
# cat /tmp/virt-who.json | json_reformat | grep name | sort | uniq -c | wc -l
```

Checking the number of virtual machines

Enter the following commands to check the number of virtual machines that virt-who currently reports:

```
# systemctl stop virt-who
```

```
# virt-who -op >/tmp/virt-who.json  
# systemctl start virt-who  
# cat /tmp/virt-who.json | json_reformat | grep "guestId" | sort | uniq -c | wc -l
```

A.4. VIRT-WHO TROUBLESHOOTING SCENARIOS

Virt-who fails to connect to the virtualization platform

If virt-who fails to connect to the hypervisor or virtualization manager, check the Red Hat Subscription Manager log file `/var/log/rhsm/rhsm.log`. If you find the message **No route to host**, the hypervisor might be listening on the wrong port. In this case, modify the virt-who configuration and append the correct port number to the **Hypervisor Server** value.

You must redeploy the virt-who configuration after modifying it.

Virt-who fails to connect to the virtualization platform through an HTTP proxy on the local network

If virt-who cannot connect to the hypervisor or virtualization manager through an HTTP proxy, either configure the proxy to allow local traffic to pass through, or modify the virt-who configuration to use no proxy.

You must redeploy the virt-who configuration after modifying it.

Virt-who fails to report back the host-guest mapping to Red Hat Satellite server

Virt-who fails to report back the host-guest mapping to Red Hat Satellite server in the following circumstances.

1. virt-who is configured and deployed on Red Hat Satellite server.
2. The **rhsm.conf** file of Red Hat Satellite server is configured to use a proxy server to talk to `subscription.rhsm.redhat.com` and `cdn.redhat.com`.
3. The **no_proxy=*** setting in `/etc/sysconfig/virt-who` is present but being ignored by subscription-manager, and virt-who attempts to connect back to Satellite server through a proxy server but fails.

In this case, add the following parameter to the `/etc/rhsm/rhsm.conf` file.

```
no_proxy = satellite.example.com
```
